Metagenome of a versatile chemolithoautotroph from expanding oceanic dead zones

Summary: Time-resolved metagenomic approaches are used to describe carbon and energy metabolism of an ecologically relevant microbe from expanding oceanic dead zones mediating carbon sequestration, sulfur-detoxification and biological nitrogen loss.

Running Title:

Versatile energy metabolism in a ubiquitous oxygen minimum zone microbe

Abstract

Oxygen minimum zones (OMZs), also known as oceanic “dead zones”, are widespread oceanographic features currently expanding due to global warming and coastal eutrophication. Although inhospitable to metazoan life, OMZs support a thriving but cryptic microbiota whose combined metabolic activity is intimately connected to nutrient and trace gas cycling within the global ocean. Here we report time-resolved metagenomic analyses of a ubiquitous and abundant but uncultivated OMZ microbe (SUP05) closely related to chemoautotrophic gill symbionts of deep-sea clams and mussels. The SUP05 metagenome harbors a versatile repertoire of genes mediating autotrophic carbon assimilation, sulfur-oxidation and nitrate respiration responsive to a wide range of water column redox states. Thus, SUP05 plays integral roles in shaping nutrient and energy flow within oxygen-deficient oceanic waters via carbon sequestration, sulfide detoxification and biological nitrogen loss with important implications for marine productivity and atmospheric greenhouse control.

1 Dissolved oxygen (O_2) concentration is a critical determinant of marine ecosystem
2 function and food web structure. Water column O_2 deficit results in habitat compression
3 and reduced productivity for aerobic respiring organisms with concomitant expansion of
4 chemolithoautotrophic metabolism (1) manifested by biological nitrogen loss and the
5 production of climate active trace gases (2, 3). Therefore, OMZ expansion and
6 intensification (3-5) represents a global ecological phenomenon with potentially
7 deleterious feedback and forcing effects (1, 6). In order to understand, respond to, or
8 mitigate these transitions, studies monitoring and modeling dynamics and systems
9 metabolism of OMZ microbiota in relation to physical and chemical oceanographic
10 parameters are imperative.

11 Extensive OMZs are found throughout the Eastern North Pacific (ENP), Eastern
12 South Pacific (ESP), Northern Indian Ocean, and Southwest African shelf waters (*i.e.*
13 Namibian upwelling system) (3). Although the extent of oxygen-deficiency varies within
14 and between oceanographic provinces, taxonomic surveys have revealed conserved
15 patterns of microbial community composition (7-11). In all sites thus far examined, small
16 subunit ribosomal RNA (SSU rRNA) gene libraries are enriched with sequences
17 affiliated with chemoautotrophic gill symbionts of deep-sea clams and mussels (EOSA-1
18 in the ESP and GSO in African shelf waters) (9-11). Phylogenetic analyses indicate that
19 the GSO/EOSA-1 complex consists of two closely related, co-occurring and uncultivated
20 lineages, ARCTIC96BD-19 (12) and SUP05 (13) with the latter encompassing the
21 symbionts (Fig. 1A-B). From an ecophysiological perspective, blooming SUP05
22 populations have recently been implicated in chemolithotrophic sulfide (H_2S) oxidation
23 coupled to nitrate (NO_3^-) reduction in the Namibian upwelling system (10). Both,

1 ARCTIC96BD-19 and SUP05 populations are also prevalent in non-sulfidic waters of the
2 ENP and ESP, suggesting alternative or amended modes of energy metabolism. Given the
3 likely importance of ARCTIC96BD-19 and SUP05 to carbon, nitrogen and sulfur cycling
4 in marine OMZs, and their largely unexplored metabolic capabilities, a deeper
5 understanding of both lineages is needed to constrain their respective ecological and
6 biogeochemical roles.

7 Saanich Inlet, British Columbia is a seasonally anoxic fjord characterized by an
8 annual cycle of stratification and deep water renewal (14) that is associated with large
9 water column redox gradients and high rates of trace gas production and consumption
10 (Fig. S1A-C). Time resolved studies identified pelagic SUP05 as a dynamic and
11 numerically abundant denizen of the Saanich Inlet water column, representing up to 37%
12 of total bacteria (Table S2) (11). Closer examination of SUP05 SSU rRNA gene copy
13 number during onset and progression of seasonal stratification revealed blooming
14 populations below the oxycline, reaching up to 4.75×10^5 copies ml⁻¹ in regions of H₂S and
15 NO₃⁻ depletion (Fig. S2). Further high-resolution SSU rRNA gene surveys revealed two
16 SUP05 phylotypes, SI-1 and SI-2 (Fig. 1A and 2A), differing by ~4% nucleotide identity.
17 While SI-1 dominated suboxic waters throughout the year, SI-2 was less common, and
18 transiently increased during deep water renewal events, alluding to the presence of
19 ecologically differentiated populations (Fig. 2A). Given these observations we reasoned
20 that Saanich Inlet would provide a natural enrichment amenable to environmental
21 genomic (*i.e.* metagenomic) assembly and metabolic pathway reconstruction of pelagic
22 SUP05 populations. To this end, we analyzed sixteen bi-directionally end sequenced

1 fosmid libraries constructed from environmental DNA samples spanning oxic to anoxic
2 waters over the seasonal stratification and deep water renewal cycle (Fig. S1D).

3 Fosmid end sequences were initially screened for putative SUP05 genotypes by
4 fragment recruitment to closely related symbiont reference genomes (*15, 16*) revealing
5 extensive coverage within oxygen-deficient sampling intervals (Fig. S3). To reconstruct
6 and identify SUP05-specific scaffolds, paired-end sequences were assembled and binned
7 based on shared sequence similarity to symbiont reference genomes and analysis of
8 intrinsic oligonucleotide composition patterns (Fig. S4A-B). Nineteen scaffolds
9 encompassing 1.16 million base pairs of SUP05 DNA, herein referred to as the SUP05
10 metagenome, were identified and taxonomically verified (Table S3). See Table S1 for
11 additional breakdown of important assembly features. Although derived from a
12 heterogeneous population, average polymorphism within the SUP05 metagenome was
13 0.4%, indicating assembly of closely related sympatric donor genotypes. Consistent with
14 this observation, a single SSU-LSU rRNA operon affiliated with the SI-I phylotype was
15 identified (Fig. S4). Closer examination of individual fosmid library contributions to the
16 assembly revealed a majority of paired-end sequences within SUP05 scaffolds were
17 derived from samples exhibiting elevated SI-1 phylotype abundance, further supporting
18 scaffold assignments (Fig. 2B). Overall coverage efficiency was assessed based on
19 recovery of 83 of 93 information processing genes, including 31 of 32 canonically
20 conserved single copy genes (*17*) (Table S3) suggesting near complete recovery of the
21 core genome, in turn facilitating downstream efforts to reconstruct and interpret
22 metabolic pathways.

1 The comparative architecture of SUP05 and symbiont reference genomes revealed
2 patterns of genetic relatedness consistent with derivation from a common free-living
3 ancestor. At the same time, differences in gene content and organization provided insight
4 into the process of genome divergence and niche partitioning. Approximately 20% of
5 predicted gene content shared between symbiont reference genomes was absent from the
6 SUP05 metagenome. Genes from this set typically clustered together (Fig. 3), and could
7 represent genomic features mediating symbiont-host interactions or adaptations to
8 hydrothermal vent or cold seep settings (18). Of the 861 genes shared between symbiont
9 reference genomes, 80% were also conserved in the SUP05 metagenome (Fig. 3 and S5-
10 6), indicating significant metabolic overlap. Many of these genes are predicted to mediate
11 informational processing steps, particularly translation, although a significant fraction
12 function in carbon, sulfur, amino acid, and coenzyme metabolism (Fig. S6).
13 Approximately 35% of the gene content predicted in the SUP05 metagenome was unique,
14 reflecting characteristic differences between pelagic and symbiotic modes of existence
15 (Fig. 3 and S5-6). These included genes implicated in DNA uptake and repair,
16 denitrification and adaptive or stress responses (See supporting online material for more
17 details).

18 Given the potential importance of pelagic SUP05 populations on the ecology and
19 biogeochemistry of oxygen-deficient oceanic waters, examination of carbon and energy
20 metabolism within the SUP05 metagenome is of particular interest. Similar to symbiotic
21 counterparts, the SUP05 metagenome harbors genes mediating the Calvin-Benson-
22 Bassham (CBB) cycle for autotrophic carbon assimilation, including a single form II
23 ribulose 1,5-bisphosphate carboxylase-oxygenase (RubisCO) gene, implicating SUP05 in

1 chemosynthetic carbon fixation within OMZs (19). In addition, a gene encoding β -class
2 carbonic anhydrase, encoding a potential CO₂ concentrating mechanism, was also
3 identified. A complete repertoire of genes mediating the conversion of fixed carbon to
4 hexose and ribose sugars via gluconeogenesis and the non-oxidative branch of the
5 pentose phosphate pathway was identified along with the majority of tricarboxylic acid
6 (TCA) cycle components (Fig. S6). However, genes mediating the interconversion of
7 succinyl-CoA and 2-oxoglutarate were not recovered (Fig. S6), indicating the potential
8 for obligate autotrophy as posited earlier for clam symbionts (15, 16).

9 From the standpoint of energy metabolism, the SUP05 metagenome harbors a
10 diverse repertoire of genes mediating chemolithotrophic oxidation of reduced sulfur
11 compounds. Genes encoding flavocytochrome c/sulfide dehydrogenase (*fccAB*) unique to
12 the SUP05 metagenome, and sulfide quinone oxidoreductase (*sqr*) conserved between
13 pelagic SUP05 and symbiont reference genomes mediating the oxidation of H₂S to
14 elemental sulfur (S⁰) were identified (Fig. S6). The presence of two enzymatic complexes
15 may facilitate sulfur-based energy metabolism under variable sulfide regimes. For
16 instance, FccAB is thought to be functionally significant at low sulfide concentrations
17 (20). In addition, sirohaem dissimilatory sulfite reductase subunits (*dsrAB*), APS
18 reductase (*apr*), ATP sulfurylase (*sat*) mediating the complete oxidation of S⁰ to sulfate,
19 and the Sox pathway (*soxABXYZ*) for thiosulfate (S₂O₃²⁻) oxidation (Fig. S6) (21) were
20 also conserved between pelagic SUP05 and symbiont reference genomes. The capacity to
21 obtain electrons from S₂O₃²⁻ may be of considerable ecological relevance given that
22 mixing of sulfidic and oxygenated water masses results in S₂O₃²⁻ accumulation due to the
23 chemical oxidation of H₂S (22, 23). Moreover, the apparent absence of *soxCD* sulfur

1 dehydrogenase genes suggests the capacity to store S^0 , which can be subsequently
2 oxidized via the reverse DSR pathway thereby provisioning SUP05 in the absence of
3 ambient reductant (24). Indeed, *soxCD* homologues are also absent from symbiont
4 reference genomes, and sulfur globule formation has been associated with a subset of
5 clam symbionts (25).

6 Although symbiont reference genomes harbor multiple aerobic respiratory
7 complexes (15, 16), none were recovered in the SUP05 metagenome consistent with a
8 facultative or strictly anaerobic lifestyle. Indeed, all the enzymatic machinery needed to
9 reduce NO_3^- to the greenhouse gas nitrous oxide (N_2O) including membrane-bound
10 (*narKK₂GHJI*) and periplasmic (*napFBAHGD*) dissimilatory nitrate reductases
11 potentially operating under high and low NO_3^- conditions, respectively (26, 27), copper-
12 containing nitrite reductase (*nirK*), and N_2O forming nitric oxide reductase (*norCB*) (Fig.
13 4 and S6) were identified, mechanistically implicating pelagic SUP05 in biological
14 nitrogen loss from oxygen-deficient oceanic waters. Moreover, the genomic co-
15 localization of sulfur oxidation and denitrification genes suggests a highly integrated and
16 redox-sensitive energy metabolism (Fig. 4). For example, the genomic proximity of
17 Crp/Fnr transcriptional regulators with *fcc* and *nap* gene clusters (Fig. 4) may indicate
18 coordinated gene expression in response to changing redox status (20, 26, 28). In both the
19 Namibian upwelling system and Saanich Inlet, blooming SUP05 populations occur in
20 regions of H_2S and NO_3^- depletion (Fig. S2) where coexpression of *nap* and *fcc* genes
21 clusters may become critical for survival as energetic substrates become limiting.

22 Curiously, we identified more than ten putative toxin-antitoxin (TA) modules
23 unique to the SUP05 metagenome, indicating a highly regulated stress response (Table

1 S4). TA modules consist of a stable toxin and a labile antitoxin and are commonly
2 associated with environmental bacteria where they control induction of reversible cellular
3 stasis (29). Of specific interest is a TA module of the RelE superfamily identified within
4 an operon encoding molybdopterin-guanine dinucleotide synthase (*mobA*) (Fig. 4). The
5 product of MobA, molybdopterin-guanine dinucleotide (MGD), is an essential cofactor
6 for all described classes of nitrate reductase (30) and therefore *mobA* expression is
7 integral to denitrification in pelagic SUP05 populations. Severe NO_3^- limitation could
8 limit *mobA* expression leading to co-repression of the embedded TA module. This would
9 result in activation of the RelE toxin, through degradation of the labile antitoxin, and
10 induction of cellular stasis (31). In this regard, the integration of a TA system into a
11 denitrification regulon may allow SUP05 to persist during periods of extreme NO_3^-
12 limitation, analogous to other forms of nutritional stress response (e.g. amino acid
13 starvation in *E. coli*).

14 As the number of studies surveying OMZ community structure increases, the
15 ubiquity and abundance of the SUP05 lineage becomes ever more apparent. Analysis of
16 the SUP05 metagenome, and the water column disposition of pelagic SUP05 with respect
17 to H_2S and NO_3^- gradients, resolves a chemolithoautotrophic metabolism based on
18 oxidation of reduced sulfur compounds with NO_3^- through multiple and highly regulated
19 bioenergetic routes. Paradoxically, as “dark” primary producers, blooming SUP05
20 populations have the potential to sequester large amounts of CO_2 while simultaneously
21 producing N_2O via NO_3^- respiration. Therefore the SUP05 metagenome provides a
22 functional template for analysis of gene expression in relation to climatologically relevant
23 biogeochemical transformations within oxygen-deficient oceanic waters. We anticipate

1 that this information will become an essential resource for comparative analysis of
2 ecotype diversification within the SUP05 and ARCTIC96BD-19 lineages aiding in the
3 development of monitoring tools to assess and model microbial community responses to
4 OMZ expansion and intensification.

14 **Sample collection and processing.** Sample collection, O₂ and NO₃⁻ measurements, microbial
15 biomass concentration, environmental DNA extraction, and quantitative PCR analysis of bacteria
16 and SUP05 SSU rRNA gene sequences were performed as previously described (1). Samples for
17 H₂S measurement were fixed with 2% (final concentration) zinc acetate and analyzed by
18 spectrophotometer as described in (2).
19

20 **Saanich Inlet SSU rRNA gene library construction and analysis.** For each of sixteen Saanich
21 Inlet environmental DNA samples (see Fig S1), clone libraries were constructed and sequenced
22 from pooled PCR products amplified using the bacterial-specific forward primer 27F (5'-
23 AGAGTTTGATCCTGGCTCAG-3') and reverse primer 1391R (5'-
24 GACGGGCGGTGWGTRCA-3') as described at <http://jgi.doe.gov>. Chimeric sequences,
25 identified using Bellerophon (3) and Mallard (4), were excluded from the sequence dataset. A

total of 5,753 partial bacterial SSU rRNA clones passed the quality and chimera check. SSU rRNA gene sequences were aligned using the SILVA aligner (5), imported into an ARB database (6) with the same alignment, and 1,067 SUP05 sequences were identified based on their position in the SILVA reference tree. The 1,067 SUP05 sequences were extracted from ARB, realigned with MUSCLE (7) and two sequence clusters (i.e. the SI-1 and SI-2 phylotypes) were defined after assignment of sequences to operational taxonomic units (OTUs) by applying DOTUR (8) analysis to an uncorrected distance matrix generated with dnadist (9). The frequency distribution of SI-1 and SI-2 phylotypes across libraries was calculated by dividing phylotype abundance by the total number of library clones. ARCTIC96-BD-19 clones were identified in a similar manner. The phylogenetic tree (Figure 1a) was inferred from a manually refined MUSCLE alignment of partial sequences by PHYML, using an HKY + 4 Γ + I model of evolution and estimated values for the α parameter of the Γ distribution, the proportion of invariable sites, and the transition/transversion (10). The confidence of each node was determined by assembling a consensus tree of 100 bootstrap replicates.

Eastern North Pacific SSU rRNA gene analysis. An environmental DNA sample extracted from microbial biomass collected from within the OMZ (1000 m) at Station P4 (48° 39.0' N, 126° 40.0' W) of the Line P oceanographic time series (http://www.pac.dfo-mpo.gc.ca/sci/osap/projects/linepdata/default_e.htm) was used to construct a bacterial SSU rRNA gene clone library that was then sequenced as previously described (1). In total, 170 nonchimeric sequences were generated and analyzed as describe above.

Fosmid library construction and sequencing. Sixteen fosmid libraries (7,680 clones/libraries) were constructed from DNA samples collected from four depths during four cruises over the 2006-07 seasonal stratification cycle (see Fig. S1). Prior to cloning, ~5 µg of environmental DNA was further purified on a CsCl density gradient as previously described (11). Fosmid libraries were prepared using the CopyControl Fosmid Library Production Kit (Epicentre). Briefly, ~1 µg of CsCl-purified DNA was blunt end repaired and separated on a 1% low melt agarose pulse-field gel O/N at 6 V/cm. The 40-50 kb fragment range was excised and gel purified using agarase, followed by concentration using an Amicon Ultracel 10K filter device. DNA was ligated into the pCC1fos vector, packaged using the MaxPlax lambda packaging extract, and used to transfect TransforMax EPI300 *E. coli* cells. Transfected cells were plated on selective agar and fosmid clones picked using the Q-Pix robotic colony picker and grown in selective media for DNA sequencing. Bidirectional end sequencing of fosmids was performed with standard M13 -28 or -40 primers and the BigDye sequencing kit (Applied Biosystems). The reactions were purified by a magnetic bead protocol and run on an ABI PRISM 3730 (Applied Biosystems) capillary DNA sequencer (for research protocols, see <http://jgi.doe.gov>).

SUP05-focused assembly of fosmid end sequence data. All 243,264 fosmid end sequences (see Table S1) were initially assembled with Phrap using parameters (minmatch 30 maxmatch 55 minscore 55 max_subclone_size 50000 revise_greedy vector_bound 20) reported in (12). Phrap-generated contigs were linked into “ambiguous” scaffolds (*i.e.* allowed contig overlap) with Bambus (13), using the default settings, based on fosmid paired-end information. The initial assembly was comprised of 31,766 scaffolds with a total length (excluding gaps) and span of 35.6 Mb and 85.2 Mb respectively, and included 192 scaffolds $\geq$ 5 kb in length. Of the 192

scaffolds, those that exhibited highest similarity to the genomes of either of two symbiont reference species, *Candidatus* ‘*Ruthia magnifica*’ or *Candidatus* ‘*Vesicomysocius okutanii*’, upon a BLASTN search of the NCBI refseq database were flagged as potential SUP05 scaffolds and targeted for further assembly as follows. Overlapping contigs within these ambiguous scaffolds were identified in Sequencher using a 90% identity cut-off and 100 bp minimum overlap. Those contigs that cross-assembled in the same order and orientation described by Bambus were then reassembled using the miniassembly tool in consed (14) with the following parameters: minscore 55 minmatch 30 forcelevel 10. Addition of the forcelevel parameter decreases assembly stringency and permits assembly between polymorphic reads, leading to the collapse of short non-polymorphic contigs into longer polymorphic scaffold. These next generation contigs were then re-ordered and oriented into ambiguous scaffolds with Bambus and the whole process was repeated until contig extension no longer occurred. Upon final scaffolding of contigs, the untangle script included with Bambus was used to break ambiguous scaffold into single linear scaffolds (*i.e.* disallowed contig overlap). In addition, the stringency of the final assembly was increased by requiring a minimum of four read pairs to link contig into scaffolds. The final assembly was comprised of 33,630 scaffolds with a total length (excluding gaps) and span of 34.9 Mb and 38.8 Mb respectively, and included 86 scaffolds ≥ 5 kb in length (Figure S4a). Within the assembly, 5,703 polymorphic sites, defined by ≥ 2 reads exhibiting high quality discrepancies with the scaffold consensus sequence, were identified.

Identification of putative SUP05 scaffolds. Predicted protein-encoding genes from all scaffolds ≥ 5 kb were searched against the two clam symbiont genomes using BLASTP. A subset of scaffold enriched in SUP05 was identified using the following criterion: ≥ 3 syntenic open

1 reading frames (ORFs) of high sequence similarity (blast score ratio ≥ 0.6) with either symbiont
2 reference genome. The initial bin was comprised of 38 scaffolds (total length and span of 1.36
3 Mb and 2.54 Mb, respectively), contained two rRNA operons, and the corresponding SSU rRNA
4 genes were SI-1 and SI-2 phylotypes, respectively (Figure 1a). Principal component analysis
5 (PCA) of intrinsic DNA signatures was then used to explore the oligonucleotide frequencies of
6 the 38 scaffolds. The frequencies of all tri-, tetra-, and penta-nucleotides were summed for each
7 scaffold and their over- and under- representations were evaluated against their expected
8 frequencies using a maximal-order Markov model as previously described (15). In addition to
9 scaffolds, four full length overlapping fosmids (~40 kb in length each) known to originate from
10 SUP05 based on an SI-1 SSU rRNA gene sequence were included in order to identify the
11 expected oligonucleotide patterns of SUP05 sequences. The resulting Z scores (15) were
12 normalized by length, imported into the statistical package PC-ORD 5.10 (16) and subjected to
13 PCA using a Correlation Cross-products matrix. Visualization of the first two axes of the PCA
14 analysis revealed many scaffolds that were uniquely positioned in the ordination space, but also
15 revealed a single cluster consisting of 19 scaffolds that exhibited very similar nucleotide pattern
16 compositions (Figure S4b, red circles). We interpret this subset of related scaffolds as arising
17 from the same closely related population of SUP05 cells in Saanich. In support of this
18 interpretation, the SI-I phylotype was observed in this scaffold subset (Figure 1a). Nucleotide
19 composition patterns for the four fully sequenced and overlapping fosmids (spanning ~140 Kb)
20 affiliated with SI-1 on the basis of SSU rRNA gene linkage were indistinguishable from these
21 scaffolds further reinforcing the accuracy and resolution of our binning method (Figure S4b,
22 green circles). The remaining scaffolds (Figure S4b, blue circles), may represent less abundant
23 SUP05 genotypes, as evident from the presence of an SI-2 SSU rRNA gene sequence, or

unrelated bacterial taxa sharing genomic similarity with clam symbionts. As their taxonomic identity is questionable, they were removed prior to further analysis and the remaining scaffolds are herein referred to as the SUP05 metagenome (Table 1). An automated phylogenetic approach using Phylogenie (17) was used on a set of 76 typically conserved genes, to assess allelic variation and to verify the absence of non-SUP05 scaffolds in the SUP05 metagenome (see Table S2).

SUP05 metagenome annotation and comparative genome analysis. Scaffolds were annotated using the FGENESB gene calling pipeline from Softberry (www.softberry.com/berry.phtml, Mount Kisco, NY). Ribosomal RNA and tRNA genes were identified using BLASTN and tRNA-Scan (18). Functional annotation and classification of the predicted proteome was performed by using BLASTP homology searches against COG, KEGG, and NCBI nr public database, and domain analysis with InterProScan (<http://www.ebi.ac.uk/Tools/InterProScan>) (19). Metabolic pathways were constructed based on KEGG and MetaCyc (20). Comparison of gene content between the SUP05 metagenome and the reference symbiont genomes was performed by BLAST Score Ratio (BSR) analysis with a BSR cut off = 0.4 (21). Mapping of shared gene content and COG categories onto the *R. magnifica* reference genome was performed with GenomeViz (www.uniklinikum-giessen.de/genome)(22). Multi genome alignment of SUP05 scaffolds and symbiont genomes was performed with Mauve (<http://asap.ahabs.wisc.edu/mauve/>) (23).

Supplementary Text

Quantification of total bacterial and SUP05 SSU rRNA gene sequences during the 2008

seasonal stratification cycle in Saanich Inlet. To assess SUP05 distribution with respect to vertical profiles of oxygen (O_2), nitrate (NO_3^-), and sulfide (H_2S), we quantified SUP05 SSU rRNA gene sequences at three time intervals representing the main stages of the 2008 seasonal stratification cycle (Fig. S2). On April 9th, an extensive suboxic zone, defined by the absence of detectable O_2 or H_2S , was observed between ~135 and 185 m, NO_3^- was depleted below 185 m and H_2S was detected at 200 m. SUP05 was detected at $\geq 1.4 \times 10^5$ copies ml^{-1} below 150 m and peaked sharply at the base of the suboxic zone, coinciding with the point of NO_3^- depletion. By August 11th, the suboxic zone had narrowed to within ~150 and 165 m and sulfidic water was detected at 185 m. SUP05 increased in abundance from a depth of 100 to 150 m and then remained at $\sim 2.5 \times 10^5$ copies ml^{-1} through the suboxic zone and into the sulfidic waters below. Although the absolute abundance of SUP05 decreased at 185 m from April 9th to August 11th, as a proportion of the bacterial community SUP05 abundance increased from 20 to 30% of total bacteria. On October 15th, deep water renewal was underway and a large suboxic zone between 90 and 135 m was observed that was bracketed by oxygenated water above and below. H_2S was not detected at any depths, while NO_3^- was between 20-30 μM above and below the suboxic zone and decreased rapidly within the suboxic zone, reaching the detection limit at 135 m. Overall, SUP05 abundance was lower during deepwater renewal than during the earlier stages of stratification however the SUP05 SSU rRNA gene sequences were still detected at all depths below 100 m and ranged between $\sim 3.0 \times 10^4$ and 1.5×10^5 copies ml^{-1} . The highest bacterial

1 abundance was observed within the suboxic zone during renewal (4×10^6 copies ml^{-1}), but SUP05
2 was only a minor component of this deep water fall bloom as it was consistently below 10% of
3 total detected bacteria. The abundance of SUP05 within water characterized by very little to no
4 O_2 situated above sulfidic water suggests reliance on reduced sulfur compounds for energy
5 conservation and also suggests the ability to do so anaerobically, most likely through the
6 reduction of NO_3^- , in support of previous findings (24).

7
8 **Alignment of unassembled fosmid end reads to symbiont reference genomes.** We
9 investigated the overall genome sequence conservation amongst the Saanich Inlet SUP05
10 populations and the symbiont reference genomes using fragment recruitment plots generated
11 using nucmer (25). Nucmer plots comparing Saanich Inlet metagenomic data to the *R. magnifica*
12 genome were constructed with the following parameters and cut-offs: breaklength = 1000,
13 maximum gap length = 200, and minimum match length = 10. Alignment of all the unassembled
14 fosmid end reads to the *R. magnifica* genome resulted in greater than 6000 reads (3% of total),
15 averaging 79% nucleotide identity, aligning to the reference genome (Fig. S3). Similar results
16 were obtained for *V. okutanii* as the reference, as the two symbionts have highly conserved
17 genome architecture (26). The distribution of aligned reads over the length of the reference
18 genome varied considerably between different Saanich Inlet samples, yet a similar pattern to the
19 SUP05 SSU rRNA gene distribution was observed. Coverage was greatest in samples from 200
20 m collected in the winter and spring, however significant coverage was detected below 100 m
21 depth throughout the year. Such high coverage is striking and suggests significant conservation
22 of gene content between the symbiont genomes and pelagic SUP05. Moreover, only 28% of the
23 aligning sequences were derived from fosmid mate pairs, suggesting a large proportion of genes

1 present in the Saanich Inlet SUP05 population are either absent or poorly conserved within the
2 reference genome.

3
4 **Insights into symbiosis.** Until now, the closest genome-sequenced relative of the clam
5 symbionts was the sulfur-oxidizing chemoautotroph *Thiomicrospira crunogena* (27). Although
6 *T. crunogena* has proved useful in comparative investigation of symbiont gene content (28), the
7 availability of metagenomic data from a pelagic member of the symbiont lineage allows for
8 further study of the differences between symbiont and pelagic members of SUP05. The largest
9 category of genes specific to the SUP05 metagenome were those involved in DNA replication
10 recombination and repair, and have likely been lost from symbionts as is typical for obligate
11 intracellular bacteria (29). Moreover, ribonucleotide biosynthesis in pelagic SUP05 can proceed
12 via the alpha and beta subunits of ribonucleotide reductase (*nrdAB*) that is conserved with the
13 symbionts. However, the SUP05 metagenome specifically encodes a second, oxygen sensitive
14 reductase (*nrdD*), further supporting the facultative or strict anaerobic lifestyle of the pelagic
15 SUP05 population in Saanich Inlet. Other genes involved in DNA metabolism specific to the
16 SUP05 metagenome include DNA internalization and competence genes as well as a Type II
17 secretion/type IV pilus system that may be involved in DNA uptake or perhaps protein secretion
18 or twitching motility (30). The SUP05 metagenome also has many genes involved in inorganic
19 ion transport and metabolism, reflecting the variable external environment of pelagic SUP05.
20 These include high and low affinity sulfate transporter, nitrate/nitrite transporters, TonB
21 dependent receptors, ferrous iron transport proteins, bacterioferritin, and alkylphosphonate
22 uptake proteins.

1 Recently, a comparative analysis of two symbiont genomes lead to the hypothetical
2 reconstruction of the last common symbiotic ancestor's (LCSA's) carbon and energy metabolism
3 (28). By in large, our analysis of the SUP05 metagenome supports the findings that LCSA had a
4 complex sulfur metabolism including both the Sox system and reverse DSR pathways of sulfur
5 compound oxidation, fixed CO₂ via the CBB cycle, and had the ability to respire nitrate
6 anaerobically via a membrane bound dissimilatory nitrate reductase. In addition, it was
7 previously determined that the larger *R. magnifica* genome had many genes involved in the
8 biosynthesis of polysaccharides and peptidoglycan that were not present in the slightly smaller *V.*
9 *okutanii* genome. Many of these genes were also absent from the SUP05 metagenome (Figure
10 S5) and hence appear specific to the *R magnifica* symbiont genome where they may play an
11 interactive role with the clam host. A complete functional breakdown of genes shared among and
12 between symbionts and the SUP05 metagenome is available from the authors upon request.

Fig. S1 The seasonal stratification cycle in Saanich Inlet. (A) Oxygen (O_2) (B) nitrate (NO_3^-) and (C) sulfide (H_2S) concentrations plotted from February 2006 to December 2008. H_2S data collection began in April 07. The inset at the bottom left of the Fig. (D) outlines the depths and dates of samples employed in environmental genomic analysis

Fig. S2 Quantification of SUP05 and bacterial SSU rRNA genes during the main stages of the 2008 seasonal stratification and renewal cycle. The grey box denotes the non-sulfidic suboxic zone.

Fig. S3 Identification of metagenomic reads originating from SUP05 in Saanich Inlet. For each water sample, fosmid end reads were aligned to the *R. magnifica* symbiont reference genome using nucmer (25).

Fig. S4 Overview of scaffolds identified during the SUP05 assembly and binning process (A) Net scaffold length versus sequence depth of the assembled Saanich Inlet scaffolds, highlighting the set of scaffolds enriched with SUP05. The complete scaffold set comprises 13,628 scaffolds ≥ 1 kb comprised two or more reads, with a combined net length of 21.6 Mb. (B) Visualization of the first two components of a principal component analysis of the SUP05-enriched scaffolds and known fully-sequenced SUP05 fosmids, in which Z-scores for all possible 64 tri-mers, 256 tetramers, and 1024 penta-mers were calculated with TETRA (31) and normalized by length. Scaffolds binned to SUP05 are in red while scaffolds that were included in the enriched scaffold

set but were not binned to SUP05 are in blue. The complete scaffold set is in grey. Fully sequenced SUP05 fosmids are in green. Scaffolds and fosmids containing SSU rRNA genes are indicated.

Fig. S5 Functional analysis of the genes shared between the SUP05 members based on (A) COG and (B) KEGG categories. Column colors correspond to the same sectors of the Venn diagram in Fig. 3. The number of genes is normalized to the nonredundant size of each sector of the Venn diagram, which is included in the column headers in brackets. Therefore, one can compare the functional distribution of genes within any one sector (across columns) but not between sectors (across rows).

Fig. S6 Pathways of central carbon, nitrogen, and sulfur metabolism in the SUP05 metagenome. Genes are color coded by their distribution amongst the three SUP05 representatives as revealed in the Venn diagram presented in Fig. 3.

Fig. S7 Color coding system for COG categories used in Fig. 3.

¹ Genes outlined in bold are the 32 universally conserved single copy genes reported in Ciccarelli et al 2006. Genes missing from the SUP05 metagenome, but present in the *R. magnifica* reference genome are highlighted in green.

² For those genes present in multiple copies, the pairwise amino acid sequence similarity is presented in brackets.

³ NA refers to genes that were present in the SUP05 metagenome but not automatically annotated by fgenesb gene-calling software.

⁴ + refers to genes that formed a phylogenetically coherent cluster with the symbiont reference genomes upon automated phylogenetic reconstruction.

Table S4. Toxin-antitoxin systems identified in the SUP05 metagenome.

Toxin family ¹	Locus tag	Putative antidote locus tag	Genes in operon with TA system
<i>relE/parE</i>	Sup05_0405	Sup05_0404	MGD synthase
	Sup05_0483	Sup05_0482	-
	Sup05_0538	-	-
	Sup05_0866	-	-
	Sup05_0615	-	-
	Sup05_0057	Sup05_0056	-
	Sup05_0104	Sup05_0103	PRPP synthetase
	Sup05_0829	Sup05_0830	-
	Sup05_0293	-	-
	Sup05_1093	Sup05_1092	Selenophosphate synthase
			OmpA-like protein, PIN domain proteins
<i>hicB</i>	Sup05_1327	Sup05_1326	
	Sup05_0962	Sup05_0961	Integrases, transposases
