Summary

Canadian pipeline company TransCanada has filed an application with the U.S. Department of State to build the Keystone XL pipeline, which would transport crude oil from the oil sands region of Alberta, Canada, to refineries in the U.S. Gulf Coast and Midwest region. Keystone XL would have the capacity to transport 700,000 barrels a day (bpd) and can deliver crude to the oil market hub at Cushing, OK, and further to points in Texas. The project is expected to cost approximately $7.0 billion, of which an estimated $5.4 billion would be spent on the U.S. portion of the pipeline. TransCanada is also planning to build a short additional pipeline so that oil from the Bakken formation in Montana and North Dakota can be carried on the Keystone XL pipeline.

Facilities such as the Keystone XL pipeline which are intended to import oil from a foreign country need a Presidential Permit from the State Department. Such a permit requires that the State Department assess potential environmental consequences, through an Environmental Impact Statement (EIS), weighing them against potential benefits of the project. The U.S. Environmental Protection Agency (EPA) found the State Department’s draft EIS on the Keystone XL project to be inadequate. The State Department is still reviewing comments by the EPA, other agencies, and the public. The project may not proceed until the State Department publishes a final EIS and issues a Record of Decision on whether or not to grant a Presidential Permit. Regardless of the State Department’s decision, legal challenges appear likely.

Opponents to the pipeline, primarily environmental groups and affected communities along the route, object to the project principally on the grounds that it supports “dirty” Canadian oil sands development, that it could pose an environmental risk to groundwater, and that it promotes continued U.S. dependency on fossil fuels. Arguments criticizing the greenhouse gas emissions of oil sands production are based to some degree on the belief that limiting pipeline capacity to U.S. markets may limit output from Canada’s oil sands.

Proponents of the Keystone XL pipeline, including Canadian agencies and petroleum industry stakeholders, point to energy security and economic benefits, such as job creation. Some contend that the Keystone XL project secures growing Canadian oil supplies for the U.S. market, which could offset imports from other, less dependable foreign sources. They also claim that if oil sands output cannot flow to the United States, infrastructure to export it to Asia will develop. Further, having recently permitted the original Keystone pipeline, the State Department could face a consistency challenge if it were to come to a different conclusion on similar environmental issues for the Keystone XL permit.

International pipeline projects like Keystone XL are not subject to the direct authority of Congress, but numerous Members of Congress have expressed support for, or opposition to, the pipeline proposal because of its potential environmental, energy security, and economic impacts. Congress may have an oversight role to play stemming from federal environmental statutes that govern the pipeline’s application review process.

Keystone XL Pipeline Project: Key Issues

Introduction

In September 2008, TransCanada (a Canadian company) applied to the U.S. Department of State for a permit to cross the U.S.-Canada international border with the Keystone XL pipeline project. If constructed, the pipeline would carry crude oil produced from the oil sands region of Alberta, Canada, to U.S. Gulf Coast refineries. Some Members of Congress have expressed support for the proposed pipeline’s energy security and economic benefits while others have expressed reservations about environmental impacts. Though Congress has no direct role in permitting its construction,1 it may have an oversight role to play stemming from federal environmental statutes that govern the pipeline’s application review process.

This report describes the Keystone XL pipeline proposal and the process required for federal approval. It summarizes key arguments for and against the pipeline put forth by the pipeline’s developers, federal agencies, environmental groups, and other stakeholders. The report discusses potential consistency challenges faced by the State Department in reviewing the pipeline application given its recent prior approvals of similar pipeline projects. Finally, the report reviews the constitutional basis for the State Department’s authority to issue a Presidential Permit, and opponents’ possible challenges to this authority.

Keystone XL would have the capacity to transport 700,000 barrels a day (bpd) and will deliver crude to the oil market hub at Cushing, Oklahoma and further to points in Texas. The project is expected to cost approximately $7.0 billion, of which $5.4 billion would be spent on the U.S. component of the pipeline. The project would be an expansion of TransCanada’s existing Keystone pipeline, which delivers oil from the oil sands region to the U.S. Midwest. Keystone received approval from the U.S. Department of State in March 2008 and began operation in June 2010.

Ordinarily, the U.S. federal government does not have permitting authority for oil pipelines, but the Keystone and Keystone XL pipeline cross the U.S. border, and thus require a Presidential Permit issued through the State Department. Under the National Environmental Policy Act (discussed below) federal agencies must assess the environmental impacts of their proposed actions, in this case permitting a pipeline border crossing, which can require the preparation of an Environmental Impact Statement (EIS). The State Department’s EIS is subject to review by the Environmental Protection Agency (EPA). The EPA found the State Department’s draft EIS on Keystone XL to be inadequate. The State Department is still reviewing comments submitted by the EPA, other agencies, and the public. The project may not proceed until the State Department publishes a final EIS and issues a Record of Decision denying or recommending the Presidential Permit. After that point, legal challenges against the State Department’s permit approval may move forward, a move that opposition groups appear likely to make if Keystone XL receives its permit. Apart from obtaining the border crossing permit, TransCanada must also satisfy several state permitting authorities. State approvals are at various stages of progress for Keystone XL.

Pipeline Description and Status

The U.S. portion of the Keystone XL pipeline project would pass through Montana, South Dakota, Nebraska, Oklahoma, and Texas (Figure 1). The pipeline would consist of approximately 1,380 miles of 36-inch-diameter pipe and have the capacity to transport 700,000 barrels per day (bpd) of crude oil to the United States, delivering crude to an existing oil terminal in Oklahoma and further to points in Texas. By increasing its pumping capacity in the future, the pipeline could ultimately transport up to 900,000 bpd.2

Figure 1. TransCanada Keystone Pipeline System Routes

Note: Figure 1 shows the preferred alternative for the Keystone XL pipeline route according to Presidential Permit application documents. For discussion of alternative routes, see the State Department EIS discussed below.

The Keystone XL project is expected to cost approximately $7.0 billion, with the U.S. portion accounting for approximately $5.4 billion of that total.3 The Keystone XL pipeline would be an extension of TransCanada’s existing Keystone pipeline, which links the Alberta oil sands to

---

refineries in Illinois and Oklahoma (Figure 1). The Keystone pipeline received State Department approval on March 17, 2008, and began commercial operation in June 2010.

Keystone XL Extension to Bakken Oil Production

The Bakken formation is an unconventional oil resource in the Williston Basin, which underlies parts of North Dakota, eastern Montana, and northwestern South Dakota. Current Bakken production is around 350,000 bpd, much of which is currently taken away by rail and truck. In part, this is because infrastructure has not kept up with rapid production growth in the Bakken region in recent years. Output is expected to increase significantly in the future.

TransCanada has signed contracts with Bakken oil producers to carry 65,000 bpd from the region via the Keystone XL pipeline. While not the full 100,000 bpd TransCanada had offered, this was enough to justify the Bakken Marketlink Project, a pipeline running from Baker, MT, to the Keystone XL pipeline, which can then carry crude to the oil hub at Cushing, OK, and on to the Gulf Coast. The Bakken Marketlink would have a 100,000 bpd capacity and is estimated to cost $140 million. It could start operating in 2013 if it and the Keystone XL pipeline receive regulatory approvals.

These new Bakken contracts also improve the economics for Keystone XL, raising its committed capacity from 75% to near 90%. Lower transportation costs and access to new markets may support investment in the Bakken. And TransCanada is not the only company adding pipeline capacity. Notably, Enbridge, another Canadian pipeline company, is building a 145,000 b/d pipeline in the same time frame. According to Enbridge, sufficient pipeline capacity has been slow to emerge in the region because “they’re smaller players in the Bakken. They are not able to make the 20-year commitments and it’s been a lot of work to get them to commit to the level that [is] required to underwrite a major project out of the Bakken.”

Required Federal Permit Approval

Ordinarily, the U.S. government does not have permit authority for oil pipelines, even interstate pipelines. This is in contrast to interstate natural gas pipelines, which, under Section 7(c) of the Natural Gas Act, must obtain a “certificate of public convenience and necessity” from the Federal Energy Regulatory Commission (FERC). However, because the Keystone and proposed

---

9 Vanderklippe, 2011.
11 15 USC § 717(f(c).
Keystone XL pipelines both are designed for the importation of oil from another country, their facilities at the border require a Presidential Permit from the Department of State under Executive Order 13337 (69 Fed. Reg. 25299) as amended, and Department of State Delegation of Authority No. 118-2 of January 26, 2006. The source of Permitting Authority for E.O. 13337 is discussed further in the Appendix.

Environmental Impact Statement

Among other requirements, State Department review of an application for a Presidential Permit requires the completion of an Environmental Impact Statement (EIS) in accordance with the National Environmental Policy Act of 1969 (NEPA, 42 U.S.C. §§ 4321-4370f),12 Section 7 of the Endangered Species Act (16 U.S.C. 1536), and other federal environmental statutes. In complying with NEPA, the State Department must meet two aims—it must consider the environmental impacts of the project before proceeding with it; and it must inform the public both that it has considered environmental concerns in its decision-making process and that it has decided upon a final action. The State Department, as the “lead agency” under NEPA, is required to get input from any local, state, tribal or federal agency that has jurisdiction by law or special expertise regarding any environmental impact involved in the project (referred to as “cooperating agencies”).13

To document the decision-making process, the EIS must include a statement of the purpose and need for action by the agency (i.e., application for a Presidential Permit), a description of all reasonable alternatives to meet that purpose and need, a description of the environment to be affected by the alternatives under consideration, and an analysis of the impacts to each environment identified. The EIS must also take into consideration the cumulative impacts of the project. Preparation of the EIS is done in two stages, resulting in a draft and a final EIS.14 The final EIS should respond to any cooperating agency comments and address any inadequacies in the draft EIS. A supplemental draft EIS may be required if the draft EIS is determined to need substantial changes.

In issuing the final EIS, the State Department is not required to elevate environmental concerns above others, such as energy supply security or economic impacts. Instead, NEPA requires only that the agency assess the environmental consequences of an action and its alternatives before proceeding. If the adverse environmental effects of the proposed action are adequately identified and evaluated, the State Department is not constrained by NEPA from deciding that other benefits outweigh the environmental costs and moving forward with the action.

The State Department released for public comment a draft EIS for the proposed Keystone XL Pipeline Project on April 16, 2010 (75 Fed. Reg. 75). The public comment period for the draft EIS officially closed on July 2, 2010. Executive Order 13337 also directs the Secretary of State to refer an application for a Presidential Permit to other specifically identified federal departments and agencies on whether granting the application would be in the national interest. The State

---

12 The requirement to obtain a Presidential Permit makes the pipeline project a “federal action” subject to NEPA. The federal agency taking that action is required to determine the environmental impacts of the project pursuant to NEPA’s requirements.

13 40 C.F.R. § 1508.5.

14 40 C.F.R. § 1502.9.
Department formally solicited the views of those agencies on June 16, 2010, requesting a response by September 15, 2010.\(^{15}\)

**Environmental Protection Agency Rating**

In addition to its potential role as a cooperating agency in the EIS process, the Environmental Protection Agency (EPA) is required to review the EIS itself to rate its adequacy and to rate a project’s environmental impacts—from “lack of objections” to “environmentally unsatisfactory.”\(^{16}\) The State Department would be required to respond to EPA’s rating of the EIS and its assessment of the environmental impacts of the project. Generally, if the EIS or the environmental impacts of a project need additional attention, EPA will provide the lead agency with detailed guidance on how to address the concerns. The lead agency would then be required to respond to those concerns.

On July 16, 2010, EPA issued its rating of the draft EIS for the pipeline project. It determined that the EIS was “inadequate” and identified a host of potential environmental impacts that had not been sufficiently addressed.\(^{17}\) Among other concerns, EPA determined that the purpose and need of the project had been too narrowly crafted, that impacts to air and water quality were not fully analyzed, and that pipeline safety procedures were inadequate. Given the extent of EPA’s concerns, the State Department may issue a revised draft EIS or a supplemental draft EIS, instead of a final EIS. In addition to EPA and other cooperating agency comments, the State Department is currently reviewing public comments on the draft EIS and has not yet decided whether it will issue a supplemental draft EIS or a final EIS.\(^{18}\)

When a final EIS is issued and all related public and agency comments are considered, the State Department will render its decision regarding the permit application. That decision will be documented in a public Record of Decision (ROD). Under NEPA, once the State Department issues the ROD, it may issue the Presidential Permit and the pipeline project may proceed, as long as approvals from relevant states are received and other statutory requirements are met. It is also after the ROD is issued that any legal challenges to the NEPA process may occur. Any element of the State Department’s NEPA compliance may be challenged. Statements made by stakeholders opposed to the project indicate that challenges to the department’s NEPA compliance may include charges that State Department officials did not consider all reasonable alternatives to meet their stated goals; that environmental impacts, including cumulative impacts, of the pipeline were not fully considered; or that the public was not provided sufficient opportunity for input. Another possible NEPA challenge relates to public statements made by Secretary Clinton in October 2010 that she was “inclined to” approve the pipeline. At the time, environmental groups charged that this statement indicated that a final decision had been made, before the NEPA process was complete.\(^{19}\)

\(^{16}\) For more information on EPA’s role in the NEPA process, see EPA’s “Environmental Impact Statement (EIS) Rating System Criteria” at [http://www.epa.gov/compliance/nepa/comments/ratings.html](http://www.epa.gov/compliance/nepa/comments/ratings.html).

State Siting and Environmental Approvals

In the absence of federal government siting authority (apart from the border crossing), state laws establish the primary siting authority for the Keystone XL pipeline. These laws vary from state to state. South Dakota, for example, required TransCanada to apply for a permit for the Keystone XL pipeline from the state public utility commission, which issued the permit on April 25, 2010.20 Montana requires a certificate from the state’s Department of Environmental Quality, but has not yet granted one for the Keystone XL project. Nebraska does not appear to have any permitting requirements that apply specifically to the construction and operation of oil pipelines, although a state statute does include an “eminent domain” provision, which grants eminent domain authority to oil pipeline companies that are unable to obtain the necessary property rights from the relevant property owners.21 A number of additional state and environmental approvals and permits required by the states along the proposed route are summarized in TransCanada’s Presidential Permit application.22 All of the aforementioned state approvals are in various stages of review along the proposed Keystone XL pipeline route.

Arguments For and Against the Pipeline

Proponents of the Keystone XL pipeline, including Canadian agencies and U.S. and Canadian petroleum industry stakeholders, base their positions primarily on increasing the diversity of the U.S. petroleum supply and economic benefits to the United States, including job creation. Opponents, primarily environmental groups and affected communities along the route, object to the project principally on the grounds that Canadian oil sands development has negative environmental impacts and that it promotes continued U.S. dependency on fossil fuels. These issues are further discussed below.

Impact on U.S. Energy Security

In its Presidential Permit application, TransCanada asserts that constructing the proposed Keystone XL pipeline is in the U.S national interest to maintain adequate crude oil supplies for U.S. refineries. The application argues that the pipeline will allow U.S. refiners to substitute Canadian supply for other foreign crude supply and to obtain direct pipeline access to secure and growing Canadian crude output. In particular, the application asserts that the pipeline would allow the United States to decrease its dependence on foreign crude oil supplies from Mexico and Venezuela, the two largest oil importers into the U.S. Gulf Coast.23 In its draft EIS for the project,
the State Department similarly finds that the Keystone XL pipeline “would counteract insufficient domestic crude oil supply while reducing U.S. dependence on less reliable foreign oil sources.” These arguments have taken on additional weight in light of the ongoing political unrest in the Middle East, which has disrupted oil production in Libya, a significant oil exporter, and has caused a spike in global crude oil prices.

**Canadian Oil Imports in the Overall U.S. Supply Context**

Gross U.S. imports of crude oil and petroleum products have averaged 11.7 million barrels a day (Mb/d) over the last 12 months. Exports averaged 2.2 Mb/d, leaving net imports at 9.5 Mb/d. U.S. imports declined each year between 2005 and 2010 as a result of lower total oil demand and higher domestic supply. Domestic demand has decreased by about 1.7 Mb/d versus 2005 levels due largely to the economic recession. Meanwhile, U.S. production of oil and oil alternatives (including crude oil, natural gas liquids, and biofuels) has increased by 1.4 Mb/d since 2005. As a result, net imports fell by roughly 3.1 Mb/d since 2005. This decline could be mitigated in the near term as oil demand recovers from the recession or if domestic supply were to fall. However, there is increasing consensus among forecasters that U.S. net oil imports have passed their high water mark already and may remain relatively flat in the long run after the economic recovery.

Among the largest sources of U.S. gross oil imports are Canada (2.5 Mb/d), Mexico (1.2 Mb/d), and Venezuela (1.0 Mb/d). Imports from the last two have decreased in recent years (Figure 2). Mexican production peaked in 2004 and has fallen by about 0.9 Mb/d since then because new projects have not been able to offset depletion at Mexico’s giant Cantarell field. Venezuelan production never fully recovered after a strike at its national oil company, Petróleos de Venezuela, in 2002-2003. Venezuelan production today is nearly 1 Mb/d less than that achieved in 2001. In both countries, policies on private investment and a broad set of priorities—some of which are non-commercial—for national oil companies have made sustaining or increasing output difficult. In addition, Venezuela has been trying to diversify its export markets away from the United States, for example, by increasing exports to China. Oil imports to the United States from the Persian Gulf have also decreased since 2008-2009. All major Persian Gulf exporters to the United States are members of the Organization of the Petroleum Exporting Countries (OPEC), which cut production in 2009. Venezuela is also an OPEC member, but according to U.S. Energy Information Administration (EIA) data, it did not join other members in voluntarily reducing output.

---

25 All data in this section are from the U.S. Energy Information Administration’s (EIA’s) Petroleum Navigator (http://www.eia.gov/dnav/pet/pet_move_implicit_a2_nus_ep00_im0_mmbi_m.htm) and International Energy Statistics (http://tonto.eia.doe.gov/cfapps/ipdbproject/IEDIndex3.cfm).
26 For context, the United States consumes roughly 19 Mb/d, more than 20% of the world’s oil market. Net imports are gross or total imports less total exports. This section will focus on gross imports, though it should be noted that among U.S. petroleum exports about 0.2 Mb/d of petroleum products go to Canada and 0.4 Mb/d to Mexico.
27 These data are based on full year 2010 estimates provided by the EIA’s Short Term Energy Outlook (STEO), http://www.eia.doe.gov/emeu/steo/pub/contents.html. The STEO provides a balance of U.S. supply and demand.
While Mexican and Venezuelan oil production has decreased, Canadian production has increased, primarily due to growing production from the Alberta oil sands region. Because production from Canada’s oil sands currently lacks the infrastructure to be exported from Canada’s west coast, increased oil sands output is necessarily directed south into the United States through existing and planned pipeline infrastructure, including the Keystone pipeline. Canadian production has increased about 0.2 Mb/d since 2005, and exports to the United States increased by 0.4 Mb/d (Figure 3).  

29 As in the United States, Canadian consumption fell due to economic downturn. This allowed the increment in exports to be higher than the increment in production.
Impact of Increased Oil Sands Crude Supply to the United States

Oil sands (also referred to as tar sands) are a mixture of clay, sand, water, and heavy black viscous oil known as bitumen. Oil sands are processed to extract the bitumen, which can then be upgraded into “syncrude” that is suitable for pipeline transport. Canada’s oil sands production is expected to be exported as either a light, upgraded synthetic crude or a heavy crude oil that is a blend of bitumen diluted with lighter hydrocarbons to ease transport. The bulk of oil sands supply growth is expected to be in the form of the latter. Oil sands imports into the United States currently go to the Midwest, where some refineries are investing in complex refining capacity to process growing volumes of heavy Canadian crude. The U.S. Gulf Coast region already has a large amount of complex refining capacity and is considered to be potentially well suited for processing Canadian heavy crude oil. Gulf Coast refineries currently process heavy crudes from Venezuela, Mexico, and elsewhere. Complex refineries in the Gulf Coast may be best equipped to handle a large increase of heavy oil sands crude, though they will still need to adjust processes and make new capital investments in equipment to accommodate particular crudes’ characteristics, especially if the new Canadian crudes will be used in large amounts.

---

31 CAPP, 2010, p. 13. According to CAPP, refineries adding capacity to process heavy oil in the Midwest include those in Roxana, IL; Whiting, IN, and Detroit, MI.
34 For a description of which units refineries may need to add (or have added) to be able to process more Canadian oil sands supply, see Praveen Gunaseelan and Christopher Buehler, “Changing US Crude Imports Are Driving Refinery Upgrades,” Oil and Gas Journal, August 10, 2009.
With expanded pipeline capacity, Canadian supplies are expected to compete with other heavy crudes such as those from Mexico, Venezuela, and elsewhere. It is difficult to predict precisely how this competition will play out, but it may take place through shifting discounts or premiums on crude oils from various sources. Because oil sands output can be transported only to Canadian and U.S. refiners currently, it could be possible for Canadian oil supplies to effectively “push out” waterborne shipments from other countries, although this depends on a wide range of market conditions. Waterborne crudes may more easily go to other destinations than Canadian crudes, though like Canadian crudes they can be tied to specialized refining capacity, as is true for Venezuelan heavy crudes.

Although Canada currently lacks pipeline capacity to transport oil sands production to the Pacific coast, there has been some interest in building such capacity. If this were to occur, Canadian crudes could access other markets by sea, especially in Asia, and would no longer be as tied to the United States. The commercial viability of such pipelines is unclear, but some have claimed a western pipeline could be economic if greater U.S. shipments were not possible. Indeed, a study commissioned by the Department of Energy concluded that

> if pipeline projects to the BC [British Columbia] coast are built, they are likely to be utilized. This is because of the relatively short marine distances to major northeast Asia markets, future expected growth there in refining capacity and increasing ownership interests by Chinese companies especially in oil sands production. Such increased capacity would alter global crude trade patterns. Western Canadian Sedimentary Basin (WCSB) crudes would be “lost” from the USA, going instead to Asia. There they would displace the world’s balancing crude oils, Middle Eastern and African predominantly OPEC grades, which would in turn move to the USA. The net effect would be substantially higher U.S. dependency on crude oils from those sources versus scenarios where capacity to move WCSB crudes to Asia was limited.

Crude oil prices are generally set in a global market. Increased supply from anywhere can, therefore, contribute to keeping oil prices lower than they would otherwise be, all other things being equal. Accordingly, building any new pipeline can lower the cost of oil and oil products in associated markets if (1) it enables lower transport or refining costs and (2) not building the pipeline would reduce global supply. The latter assumes that without the pipeline, resources would be left stranded. Some have argued that Canadian oil sands production would be the same regardless of whether the Keystone XL pipeline is built. Then, the pipeline itself may not make a significant contribution to increasing global oil supply. However, if an alternative transport route to market—for instance, via a west coast pipeline and then tanker to Asia—raises transport costs above an economic threshold, it could prevent certain marginal oil sands projects from being built. The validity of these alternative scenarios, as in most debates about proposed energy infrastructure projects, depends largely on complex assumptions about oil market structure and

---

economics about which fair-minded analysts may disagree. Consequently, stakeholders evaluating the oil supply and price impacts of the proposed Keystone XL Pipeline may need to rely on their own judgment based on the best facts available at the time.

**Economic Impact of the Pipeline**

In addition to supply diversity arguments, some Keystone XL pipeline proponents support the project based on economic benefits associated with expanding U.S. pipeline infrastructure. A recent study by the Energy Policy Research Foundation, for example, concludes that “the Keystone expansion would provide net economic benefits from improved efficiencies in both the transportation and processing of crude oil of $100 million-$600 million annually, in addition to an immediate boost in construction employment.”40 A 2009 report from the Canadian Energy Research Institute (CERI) commissioned by the American Petroleum Institute similarly concludes that

> As investment and production in oil sands ramps up in Canada, the pace of economic activity quickens and demand for US goods and services increase rapidly, resulting in an estimated 343 thousand new US jobs between 2011 and 2015. Demand for US goods and services continues to climb throughout the period, adding an estimated $34 billion to US GDP in 2015, $40.4 billion in 2020, and $42.2 billion in 2025.41

These CERI estimates apply to the entire oil sands industry, however, not only the Keystone XL project, and they are derived from a proprietary economic analysis which has not been subject to external review. Some stakeholders point to State Department and other studies reporting much lower anticipated economic benefits.42 Consequently, it is difficult to determine what specific economic and employment impacts may ultimately be attributable to the Keystone XL pipeline. Nonetheless, given the physical scale of the project, it could be expected to increase employment and investment at least during construction.

**Canadian Oil Sands Environmental Impacts**

Oil production from oil sands is controversial because it has significant environmental impacts, including emissions of greenhouse gases during extraction and processing, disturbance of mined land, and impacts on wildlife and water quality. Because bitumen in oil sands cannot be pumped from a conventional well, it must be mined, usually using strip mining or open pit techniques, or the oil can be extracted with underground heating methods.43 Large amounts of water and natural gas are also required (for heating) during the extraction process.44 The magnitude of the environmental impacts of oil sands production, in absolute terms and compared to conventional

---

Keystone XL Pipeline Project: Key Issues

Oil production, has been the subject of numerous, and sometimes conflicting, studies and policy papers. Some stakeholders who object to oil sands projects oppose the Keystone XL pipeline because it expands access to new markets for the oil produced by those projects, thereby encouraging what they consider to be further environmentally destructive oil sands development. As discussed earlier, however, if oil sands production can be diverted to other markets (e.g., Asia), preventing the Keystone XL project may not necessarily limit oil sands development.

Possible Risks to the Ogallala Aquifer

The proposed route of the Keystone XL pipeline passes across significant portions of the Ogallala Aquifer (Figure 4), one of the world’s largest known aquifers and the primary source of groundwater for approximately 20% of U.S. agricultural production. Because the aquifer is relatively close to the surface, some stakeholders are concerned that a release from the pipeline could potentially contaminate the aquifer with oil, jeopardizing its use for farming and drinking water and causing significant ecosystem damage. These concerns have been heightened in the wake of the 2010 spill from an Enbridge oil pipeline in Marshall, MI, which released 819,000 gallons of crude into a tributary of the Kalamazoo River. Furthermore, a recent report by the Natural Resources Defense Council (NRDC) argues that the Keystone XL pipeline could be more likely to fail and cause environment damage than other crude oil pipelines because the bitumen mixture it would carry is “significantly more corrosive to pipeline systems than conventional crude,” among other reasons. Canadian officials and other stakeholders have rejected these arguments, however, citing factual inaccuracies and a flawed methodology in the analysis, which compares pipeline spill rates in Canada to those in the United States.

In its draft EIS for the Keystone XL pipeline project, the State Department states that “there is the possibility that a release could migrate through the overlying surface materials and enter a groundwater system.” Nonetheless, the department concludes that “the probability of a large spill occurring is very low, and, consequently, risk of environmental impacts is minimal.” Because the probability of a pipeline spill and subsequent groundwater contamination cannot be known with certainty, however, debate as to the groundwater risk potentially posed by the Keystone XL pipeline will likely continue.

51 Ibid. p. 6-1.
Fossil Fuels Dependence

Some stakeholders object to the Keystone XL pipeline because it would increase U.S. supplies of oil, and thereby perpetuate the nation’s dependence on imported fossil fuels and increase carbon emissions from the transportation sector.\footnote{See, for example: Natural Resources Defense Council, \textit{Tar Sands Invasion: How Dirty and Expensive Oil from Canada Threatens America’s New Energy Economy}, May 2010.} Acknowledging this concern, in a public forum on October 20, 2010, Secretary of State Clinton reportedly remarked that “we’re either going to be dependent on dirty oil from the [Persian] Gulf or dirty oil from Canada … until we can get our act together as a country and figure out that clean, renewable energy is in both our economic interests and the interests of our planet.”\footnote{Darren Goode, “Clinton Seems Poised to Approve TransCanada Pipeline,” \textit{The Hill}, October 20, 2010.} Critics of the State Department’s draft EIS assert that the environmental review overlooks the pipeline project’s overall impact on greenhouse gas emissions, for example, from the extraction and refining processes. However, others have argued that whether the Keystone XL Pipeline is constructed would have little bearing on greenhouse gas emissions as there are likely to be other export routes available for Canadian oil sands crude, and therefore, the same crude oils would still be transported and refined, albeit in different geographies (e.g., China).\footnote{EnSys Energy & Systems 2010, p. 116.}
Consistency of State Department Review

In addition to the specific arguments surrounding the Keystone XL pipeline project summarized above, the State Department faces a consistency issue in reviewing the Presidential Permit application. As Figure 1 and Figure 4 show, the Keystone XL pipeline follows a similar route, starting in the Alberta oil sands and crossing the Ogallala aquifer, as the earlier Keystone pipeline, which the State Department approved. In 2009, the State Department also approved the Alberta Clipper pipeline, designed to carry crude oil from the Alberta tar sands region to Wisconsin. Because of its prior approvals of the Keystone and Alberta Clipper pipelines, it might be difficult for the State Department to reach different conclusions on certain environmental issues in its review of the Keystone XL pipeline, and reject the permit application on that basis. Doing so could create political, and potentially legal, challenges to either its earlier environmental review, or the current one. Some observers maintain that, in its ultimate decision whether to grant the Keystone XL pipeline a Presidential Permit, the State Department may, to some extent, be constrained by its recent precedents approving similar projects.
Appendix. Presidential Permitting Authority

The Executive Branch has exercised permitting authority over the construction and operation of “pipelines, conveyor belts, and similar facilities for the exportation or importation of petroleum, petroleum products” and other products at least since the promulgation of Executive Order 11423 in 1968. Executive Order 13337 amended this authority and the procedures associated with the review, but did not substantially alter the exercise of authority or the delegation to the Secretary of State in E.O. 11423. However, the source of the Executive Branch’s permitting authority is not entirely clear from the text of these Executive Orders. Generally, powers exercised by the Executive Branch are authorized by legislation or are inherent presidential powers based in the Constitution. E.O. 11423 makes no mention of any authority, and E.O. 13337 refers only to the “Constitution and the Laws of the United States of America, including Section 301 of title 3, United States Code.” 3 U.S.C. Section 301 simply provides that the President is empowered to delegate authority to the head of any department or agency of the executive branch.

The legitimacy of this permitting authority has been addressed by federal courts. In Sierra Club v. Clinton, the plaintiff Sierra Club challenged the Secretary of State’s decision to issue a Presidential Permit authorizing the Alberta Clipper pipeline. Among the plaintiff’s claims was an allegation that issuance of the permit was unconstitutional because the President had no authority to issue the permits referenced in E.O. 13337 (in this case, for the importation of crude oil from Canada via pipeline). The defendant responded that the authority to issue Presidential Permits for these border-crossing facilities “does not derive from a delegation of congressional authority ... but rather from the President’s constitutional authority over foreign affairs and his authority as Commander in Chief.” The U.S. District Court for the District of Minnesota agreed, noting that the defendant’s assertion regarding the source of the President’s authority has been “well recognized” in a series of Attorney General opinions, as well as a 2009 judicial opinion. The court also noted that these permits had been issued many times before and that “Congress has not attempted to exercise any exclusive authority over the permitting process. Congress’s inaction suggests that Congress has accepted the authority of the President to issue cross-border permits.” Based on the historical recognition of the President’s authority to issue these permits and Congress’s implied approval through inaction, the court found the Presidential Permit requirement for border facilities constitutional.

---

55 Providing for the performance of certain functions heretofore performed by the President with respect to certain facilities constructed and maintained on the borders of the United States, 33 Fed. Reg. 11741 (August 16, 1968).

58 689 F.Supp.2d 1147 (D. Minn. 2010).
59 Ibid. at 1162.
60 Ibid.
61 Ibid. at 1163 (citing 38 U.S. Atty Gen. 162 (1935); 30 U.S. Op. Atty. Gen. 217 (1913); 24 U.S. Op. Atty. Gen. 100; and Natural Resources Defense Council (NRDC) v. U.S. Department of State, 658 F.Supp.2d 105, 109 (D.D.C. 2009)). The court in NRDC held that the State Department’s issuance of a presidential permit under Executive Order 13337 was not subject to judicial review under the Administrative Procedure Act for abuse of discretion because “the issuance of presidential permits is ultimately a presidential action.” 658 F. Supp. 2d at 109, 111-12. The court said that to allow judicial review of such decisions would raise separation of powers concerns. Ibid. at 111.
