INFLUENCE OF SITE FACTORS ON VEGETATION PRODUCTIVITY:
A REVIEW AND SUMMARIZATION OF MODELS, DATA, AND REFERENCES

G. M. Van Dyne, R. G. Wright, and J. F. Dollar

INTRODUCTION

Among the uncertainties that exist regarding the biological and environmental consequences of thermonuclear war are the short-term and long-term effects of such war on the different plant communities that cover the North American continent and which constitute the bulk of our renewable biological resources. Post-attack recovery is a problem of major concern to civil defense workers and the situation is succinctly summarized as follows (Panel D group of Project Harbor, Miller et al. 1964:

"There is still uncertainty about the immediate and long-term ecological impact of a nuclear attack. Limited knowledge suggests that degradation of the landscape would be in part a function of the size and nature of attack, and in part due to the resulting interaction between organisms. That vast areas might be involved is a distinct possibility. However, at the present time there are insufficient data on this problem, making it difficult to predict events except in the most general qualitative fashion."

Some attention has been given to predicting the effect of such an attack on our economic structure and its recovery (Winter 1963) or to some biological problems related to man's food supply and intensive agriculture (Nicholson 1964). Some physical factors of the environment have been studied intensively to evaluate their relationship to man's environment, for example the fallout threat (Callahan et al. 1960), the probability of and conditions necessary for widespread fire (Chandler et al. 1963), possible weather and climatic modification (Ayres 1964c), and some interrelations of physical factors (Lord 1964b).

Mitchell (1960) surveyed many of the expected ecological problems influencing postwar recuperation and Ayres (1963) has reviewed special aspects of environment following nuclear war, especially those directly affecting human health and food supply. Most of these studies have

been concerned, however, with immediate, or, at most, short-term effects. The influence of environmental insults on natural and seminatural plant and animal communities has received less attention, especially the delayed and long continuing effects.

Life history data have been used by Lord (1963b) in considering possible postattack problems with nondomestic animals. Historical examples of animal outbreaks, such as the rabbit problem in Australia, have been considered by Ingersoll (1964). Although attempts have been made to consider the entire ecosystem's response to insults (e.g., Lord 1964a), it has been possible to consider only a limited number of hypothetical situations, and only by such methods as the use of scenarios (Ayres 1964a) in illustrating some possible consequences of environmental insults. These approaches have been valuable in helping to obtain a general perspective of the problem even though they were often only synthetic examples. The trend toward a more quantitative analysis of these environmental problems has been suggested by the initial development of mathematical models for estimating cycles in animal populations (see Vincent in Lord 1963a) and the application of input-output analysis to a homeostatic system (Ayres 1964b).

The above references are indicative of our state of knowledge concerning the expected response of ecosystems to environmental insults. They provide a wealth of ideas and insights into the problem and suggest much can now be accomplished by utilizing our knowledge of ecosystems and ecosystem processes (incomplete as it may be) in developing models to predict the consequences of environmental insults on ecosystems. Our current state of knowledge and tools will allow exploration of a wider variety of situations and will allow us to obtain some idea of the average and extreme responses of ecosystems to environmental insults.

The philosophy underlying the current research, which builds upon the preceding studies, is (1) that existing data on, and our knowledge of natural, and seminatural ecosystems can be successfully utilized with recently developed tools and techniques to develop realistic models to describe ecosystems on a landscape scale, (2) that these data, knowledge, tools, and techniques can be used in making realistic predictions of

ecosystem responses to environmental insults, and (3) that with knowledge of the average and extreme predicted responses we can evaluate alternative repair strategies for optimizing the recovery rate or stability of ecosystems.

OBJECTIVES

The major long-term objective of this research is to develop accurate simulation models and to use these models to explore the consequences of various types of insults due to thermonuclear war to grassland, shrub, and forest ecosystems on a regional scale and to evaluate the influences of various strategies employed to minimize ecological imbalances. The development of accurate simulation models requires, however, the study of many subproblems which must be combined eventually in explaining variations in ecosystems in space and time.

The purpose of the work reported herein was to begin a thorough study of the influence of site factors on vegetation productivity, that is, to determine in an analytical sense the spatial variation in vegetation productivity.

Specific objectives were (1) to review and examine types of mathematical models which have been used in predicting vegetation productivity as a function of edaphic, climatic, and physiographic parameters; (2) to summarize in a tabular manner information from the literature, or from unpublished research, on the types of site variables and the types of estimates of vegetation productivity that have been reported for individual species productivity; (3) to locate, collect, and prepare for computer analysis individual plot data on dependent productivity measurements and independent site factors; and (4) to provide a preliminary bibliography of site factor studies.

The work reported herein must be considered only an initial step in the development of complex but realistic simulation models. Further phases of study will be reported in succeeding reports and will include the study of and incorporation of responses of communities to radiation, fire damage, and remedial treatments such as fertilization, mechanical renovation, reseeding, and plant control measures.

MATHEMATICAL MODELS IN SOIL-SITE RELATIONSHIP STUDIES

Direct measurement of annual productivity of a community generally is not undertaken for forested communities, but gross productivity often is measured in herbaceous communities. Net productivity measurements are sufficient for most practical purposes, but for theoretical considerations it is necessary also to estimate respiration in order to determine gross productivity. Most of the productivity-soil relationship literature is concerned with forest communities. Forest harvest productivity may be obtained by determining gross volume of wood produced per acre per year over a normal "rotation" or life span of these species involved. Gross productivity data are especially scarce for forests, and estimates are contingent upon several variables in addition to site factors such as genetic traits, age or rotation, history of the stand, and stand density. Height of free-growing trees of a given species and age often are used as a measure of productivity of the site. Height of free-growing trees corrected to a specified standard age commonly is termed site index and is used as a measure of site quality. Generally, the standard age for site index measurements is 50 years for most eastern and southern species and 100 years for many western or longer-lived species. A more complete discussion of the applicability of site index as a measure of productivity is given by Spurr (1964).

The most common procedure for analyzing site productivity relations in recent years has been by multiple regression analysis. For many of the older studies, and for some of the recent ones, however, computer facilities were not available to examine productivity and site relations by this useful but laborious technique. In some instances it is evident there was a lack of communication between the biometrician advising on the analyses, the computer technologists conducting the analyses, and the biologist originating the problem, collecting the data, and interpreting the results.

In almost all studies the dependent variable has been some measure of plant growth such as height growth, site index, basal diameter growth,

basal area growth rate, density or frequency of species, summer wood percentage, annual production, and so forth. The independent variables are numerous and varied and will be discussed further below.

With few exceptions, the literature pertaining to the study of the relationships between site index and soil, climatic, and topographic properties includes one basic model, the standard multiple regression equation:

$$Y_i = b_0 + \sum_j b_j X_{ij} + e_i$$

In this equation Y_i is the dependent variable for the i th plot, b_j is the partial regression coefficient, and X_{ij} is an independent variable. A variety of forms of this general equation have been used in the studies reported in the literature.

Eight different forms of dependent variables have been utilized in the literature investigated. These included six basic measurements plus two logarithmic forms. Site index or logarithm of site index was utilized in 50 equations, height or logarithm of height of tree species in 52 equations, and the remainder of 116 equations reported included, in order of decreasing importance, cubic foot growth, basal area, diameter at breast height, and periodic growth as dependent variables (Table 1).

No interaction or curvilinearity was evaluated in 53 of the 116 equations. Curvilinearity was included in at least one independent variable in 61 of the equation. By far and large the most frequently encountered curvilinear effect was the reciprocal of age. Interaction terms were included in only 2 of the 116 equations evaluated.

A summary of equations reporting site index (S_i) or logarithm of site index ($\log S_i$) as the dependent variable are given in Table 1. In many studies included in Table 1 a larger number of independent variables were measured than are reported. Many variables were eliminated by the authors of the articles due to difficulty to measure or inappropriateness of the particular parameter. More frequently, however, the variable was eliminated because it did not appear to have a significant relationship to the dependent variable based upon a preliminary inspection of a scatter diagram.

Height as dependent variable is summarized in Table 2, and other dependent variables are listed in Table 3.

Inspection of these summaries of models and of the variables analyzed in each particular study suggest that, for predictive purposes, a more thorough examination of models should be undertaken. Most investigators have relied upon examination of scatter diagrams to determine whether or not to include the particular variable in the analysis. However, it is well known that the effects of any given variable may not be shown clearly in a simple scatter diagram because of interacting or conflicting influences of the other independent variables. Furthermore, it is logical that many site variables have interacting influences on plant growth. The data summarized in Tables 1 through 3 show that most published models do not include interacting effects.

TABULAR SUMMARY OF SITE FACTOR STUDIES

Literature concerning site factor studies is summarized in Table 4 in which the author, number of plots investigated, species concerned, and dependent variable evaluated are given with a listing of independent variables which have been investigated in each particular study. The independent variables are grouped as soil factors, climatic or climatic-related factors, biotic factors, and physiographic or topographic factors. In some instances a single author has grouped a variety of species together in the analyses, but where possible, we have separated individual species and summarized site variables independently. This gives a better estimate of the actual number of plots involved in different studies. The numbers of plots involved have varied from less than 10 in several studies to several hundred in other studies. Areas involved in the sampling may be a given experiment station or portion thereof in some instances to locations in several states in other cases. The majority of the data in Table 4 are for individual tree species productivity-soil relationships. In a few instances data are given on shrub productivity (e.g., Medin) or in a few instances the dependent variable was some measure of vegetation pattern (e.g., Patten).

Table 2. Height (H) and Logarithm of Height (Log H) As a Dependent Variable

		Number of Curvilinear Variables	Dependent Variable	Number of Independent Variables										Tctal
				1	2	3	4	5	6	7	8	9	10	
No Interaction			H	1	1	-	-	-	-	-	-	-	-	2
No Curvilinearity			log H	2	1	2	1	1	-	1	-	-	1	9
With Curvilinearity	1		H	-	-	-	-	2	-	-	1	-	-	3

With Two-Variable Interaction		5 YR	-	-	1	-	-	-	-	-	-	-	1
													14

The ten most frequently utilized variables found in Table 4, are listed as the following in descending order:

Variable	Percentage of Total
Age	34
Distance to ridge or stream	30
Calcium (ppm)	29
Thickness A, B, or C horizon	26
Percent clay	23
Depth of surface soil	23
Elevation	21
Position on slope	20
Precipitation average year or month	19
Organic matter in A and B horizons	19

The number of independent variables used by a single author varies widely with as few as one, and a maximum of 22, utilized in the studies presented in Table 4. The average number of independent variables used in all studies is slightly more than eight.

A summary of the footnotes found in Table 4 follows:

A-----A horizon
 B-----B horizon
 C-----C horizon
 D-----A + B + C horizon
 E-----A2 and B horizon
 F-----A2 horizon
 G-----B2 horizon
 H-----A2 + B2 horizon
 I-----A + B2 horizon
 J-----B1 horizon
 K-----A1 horizon

TABLE 4. TABULAR SUMMARY OF DATA SHOWING RELATIONSHIPS OF SITE FACTORS TO VEGETATION PRODUCTIVITY. DATA ARE GIVEN IN APPENDIX A. AN "X" IN THE BODY OF THE TABLE SPECIFIES THAT DATA ARE AVAILABLE CONCERNING THAT VARIABLE; OTHER LETTERS ARE DESCRIBED IN THE TEXT AND REFER TO SOIL HORIZON(S) FOR WHICH THE DATA APPLY. COLUMNS, FROM LEFT TO RIGHT, REFER TO AUTHOR, NUMBER OF PLOTS, SPECIES OR VEGETATION TYPE, DEPENDENT VARIABLE, AND INDEPENDENT VARIABLES.

DATA SUMMARIZATION

Individual plot data were sought from agencies, investigators, and universities for relating site factors to various indirect measures of vegetation productivity. In many instances the original data are no longer available. Many data were discarded after analyses. In other instances the original data are not available because the investigator is still planning on making analyses or is using the data in his professional work. Data which were available and which were decodable have been summarized and tabulated for subsequent analyses.

These data are appended and referenced by published papers, and in some instances, by different tree species. Preliminary summarization is made of these data to give the mean, maximum, minimum, and coefficient of variation for each of the variables. In some instances we have tabulated more data than was utilized or reported in the final analyses by the individual investigators. For description of the method of measurement or presentation of the different variables one should refer to the original articles noted herein.

The data are presented at this stage for preliminary checking and examination by the contributors, for subsequent analyses, and for preliminary coding prior to summarizing the data on a dimensionless basis for subsequent analyses.

LITERATURE ON SITE FACTOR STUDIES

For purposes of this report, literature concerning site factor studies is divided into two categories--primary references and secondary references. Primary references are those relating to the citations in Table 4. Secondary references include studies not summarized in Table 4, but those studies related in entirety or in part to the problem of the site factor relationships to vegetation productivity.

Especially for the second category, the listing appended herein can only be considered a preliminary bibliography. There is a diverse literature concerning relationships of site factors to productivity and this literature is scattered through a wide variety of experiment station reports and bulletins, scientific journal articles, and, in some instances, unpublished files of investigators.

The literature cited section refers only to specific references mentioned in the text of this report.

SUMMARY

This report summarizes models, data, and references concerning the influence of site factors on indirect measures of vegetation productivity. The information presented herein is a necessary first step in a comprehensive modeling and analysis of the subject. Study of the data and models as reported herein has suggested several interesting lines of investigation upon which to proceed.

A first step in examining mathematical models will be to re-analyze the data as presented by the individual investigators as a check on accuracy of our summarization of data. Furthermore, it will now be possible in many instances to include a greater variety of independent variables in the analyses due to the availability of large, high-speed digital computers. Additionally, many realistically important interaction terms now may be included in the analyses. Stepwise regression, with logical choice of the independent variables, will be utilized as a means of screening independent variables for analyses.

A second major step in the analyses will be to convert the data to a dimensionless or relative scale within each study. For example, it will be possible to represent the data for each individual plot for each variable as a percentage of the mean value for that variable. By this manner, we can eliminate the wide extremes of actual values of such independent variables as elevation, soil depths, and so forth and organize the data in a manner for comparative analyses.

Different sets of data can be grouped for comparative analyses to determine the relative importance of different site factors on the measures of vegetation productivity. Subdivision will be made by species or by regional areas where there are large amounts of data available. The original plot data are being placed on magnetic tape for subsequent recall and analyses.

Further search is being made of the literature concerning site factor influences on productivity with emphasis on coding references according to various subtopics or independent and dependent variables, species, and regional localities.

ALLEN, J.C.
SHORTLEAF PINE
1960 NORTHWEST ALABAMA

SI = SITE INDEX

AGE = AVERAGE AGE

HT = AVERAGE HEIGHT

SDA = SOIL DEPTH OF A HORIZON

SDS = SOIL DEPTH, SURFACE

SAS = PERCENT SAND OF SURFACE

SIS = PERCENT SILT OF SURFACE

CLS = PERCENT CLAY OF SURFACE

SAB = PERCENT SAND OF SUBSOIL

SIB = PERCENT SILT OF SUBSOIL

CLR = PERCENT CLAY OF SUBSOIL

SL = PERCENT SLOPE

BA = BASAL AREA

DAG = DATA GROUP

SMALLEY, G.W.
UPLAND HARDWOODS.
1963 NORTH ALABAMA

MIA = PERCENT MICRO PORES OF A HORIZON

STA = PERCENT STONE CONTENT OF A HORIZON

TAB = THICKNESS, A AND B HORIZONS

BDB = BULK DENSITY OF B HORIZON THB = THICKNESS OF B HORIZON

SAB = PERCENT SAND IN B HORIZON SIB = PERCENT SILT IN B HORIZON

CLB = PERCENT CLAY IN B HORIZON PSB = PERCENT PORE SPACE IN B HORIZON

MPB = PERCENT MACRO PORE SPACE IN B HORIZON

MIB = PERCENT MICRO PORE SPACE IN B HORIZON

STB = PERCENT STONE CONTENT OF B HORIZON

N = PERCENT NITROGEN

LT = NO. OF LIVE TREES

GP = NO. OF GAPS

HT = WEIGHTED AVG HEIGHT (FT)

DI = WEIGHTED AVG DIAMETER (IN)
