THEORETICAL STUDY ON THE TRANSFER FUNCTION OF BORAX-V WITH CENTRAL SUPERHEATER

by

Jiro Wakabayashi

ABSTRACT

An analytical, overall, reactor transfer function was derived to examine the stability problems of the BORAX-V boiling water reactor having an integral central superheater.

Special consideration was given to local pressure and time delay of void formation caused by superheating of the water. For this analysis, the boiling core was divided into inner and outer parts to introduce the effects of the radial flux distribution. Where appropriate, the analyses were individually done for these two boiler regions and the central superheater region, and the feedback effects were combined.

Basic assumptions introduced into the analyses are that (1) the flux deviation is proportional to the initial flux; (2) the power generation in the boiler (UO₂ pellets) and the superheater (UO₂ stainless steel cermet) is proportional to the overall reactor flux distribution; i.e., no spatial kinetic effects are considered; and (3) the individual reactivity phenomena (i.e., local temperature and void changes) are first-power flux-weighted to obtain the effective reactivity changes.

I. ZERO-POWER REACTOR KINETICS

The spatially-independent kinetic characteristics of a thermal reactor system are obtained by solving the following equations:

$$\frac{dN}{dt} = \left(\frac{\Delta K - \beta}{\ell^*}\right) N + \Sigma \lambda_i C_i; \tag{1.1}$$

$$\frac{dC_i}{dt} = \frac{\beta_i}{\ell *} N - \lambda_i C_i, \quad i = 1, 2, \dots, 6.$$
 (1.2)

If the above equations are combined and Laplace transformed, the zeropower transfer function is determined to be

$$\frac{\Delta N(s)/N_0}{\Delta K(s)} = \frac{1}{\ell^* s \left\{1 + \sum_{i=1}^6 \frac{\beta_i}{\ell^* (s + \lambda_i)}\right\}};$$
(1.3)

and

$$\Delta K = \Delta K_{ex} + \Delta K_{v} + \Delta K_{p} + \Delta K_{D}, \qquad (1.4)$$

where ΔK_{ex} is the externally inserted reactivity (of the control rods), and ΔK_{v} , ΔK_{θ} , and ΔK_{D} are, respectively, the reactivities due to void, water temperature, and fuel temperature (including the Doppler effect).

The values of constants λ_i , β_i , and ℓ^* are given on p. 32.

II. HEAT FLUX OF BOILING CORE

In the analyses of the heat flux from fuel rod to water coolant, it is assumed that the heat capacity of the cladding material is negligible with respect to that of the UO₂ pellets. The thermal conductivity of the cladding and the heat transfer coefficient from cladding to water are grouped as a single, overall, heat transfer coefficient, H.

The temperature in a power-generating medium of thermal conductivity, λ , and diffusivity, κ , is described as follows: (1)

$$\nabla^{2}\Theta_{f} + \frac{Q_{g}}{\pi R^{2}\lambda} = \frac{1}{\kappa} \cdot \frac{d\Theta_{f}}{dt}, \qquad (2.1)$$

where Θ_f is the fuel temperature.

Since the fuel rod is essentially a cylinder of radius R, the boundary conditions are

$$\frac{-\mathrm{d}\,\Theta_{\mathrm{f}}}{\mathrm{d}\,\mathrm{r}}\bigg|_{\mathrm{R}} = \frac{\mathrm{H}}{\lambda}\bigg\{\Theta_{\mathrm{f}}(\mathrm{R}) - \Theta_{\mathrm{w}}\bigg\},\tag{2.2}$$

$$\Theta_f \neq \infty \text{ at } r = 0,$$
 (2.3)

where $\theta_{\mathbf{w}}$ is the water or boiling water temperature.

The temperature difference between the inlet water and the boiling water is negligible compared to that between the fuel surface and the boiling water. In the subcooling region, nucleate boiling also occurs on the surface of the cladding. Θ_{uv} and H are assumed constant in all boiling regions.

Combining and Laplace transforming Eqs. (2.1) to (2.3) result in the following equations:

$$\Theta_{\mathbf{f}}^{\prime}(\mathbf{R},\mathbf{s}) = \Theta_{\mathbf{f}}^{\prime}(\mathbf{R},\mathbf{s}) - \Theta_{\mathbf{W}}, \tag{2.4}$$

$$Q_{b}(s) = \Theta_{f}(R,s) 2 \pi RH, \qquad (2.5)$$

$$N_b = RH/\lambda,$$
 (2.6)

$$T \equiv R^3/\kappa, \tag{2.7}$$

and

$$Q_{b}(s) = Q_{g}(s) \left[\frac{2J_{1}\sqrt{-Ts}/\sqrt{-Ts}}{J_{0}\sqrt{-Ts} - \frac{\sqrt{-Ts}}{N_{b}} \cdot J_{1}\sqrt{-Ts}} \right].$$
 (2.8)

Equation (2.8) may be expanded into the following series of partial fractions:

$$\frac{Q_b(s)}{Q_g(s)} = \sum_{i=1}^{\infty} \frac{F_i}{1 + \tau_i s}, \qquad (2.9)$$

where boiler fuel heat, \mathbf{F}_{i} and $\boldsymbol{\tau}_{i},$ are found from the simultaneous solution of

$$F_{i} = \frac{4\tau_{i}/T}{1 + T/\tau_{i}N_{b}^{2}},$$
 (2.10)

and

$$N_{b} = \sqrt{T/\tau_{i}} \left[\frac{J_{1} \sqrt{T/\tau_{i}}}{J_{0} \sqrt{T/\tau_{i}}} \right], \qquad (2.11)$$

where J_0 and J_1 are Bessel functions.

As an approximation Eq. (2.9) may be rewritten as

$$\frac{Q_{b}}{Q_{g}} = \sum_{i=1}^{3} \frac{F_{i}}{1 + \tau_{i}s} + \frac{1 - \sum_{i=1}^{3} F_{i}}{1 + \tilde{\tau}_{4}s}, \qquad (2.12)$$

where

$$\widetilde{\tau}_{4} = \frac{\sum_{i=4}^{\infty} F_{i} \tau_{i} / T}{\sum_{i=4}^{\infty} F_{i} / T}.$$
(2.13)

Figure 2.1 gives the solution of Eqs. (2.10), (2.11), and (2.13) as a function of $N_{\rm b}.\,$

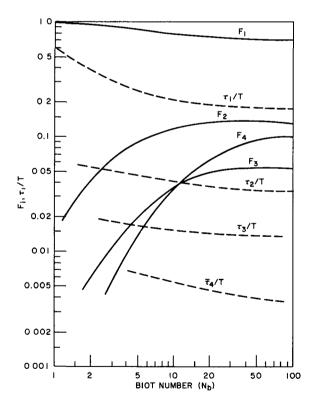

Fig. 2.1
Boiler-fuel Heat-transfer Parameters vs. Biot Number for Cylindrical Geometry

If it is assumed that the gamma energy release from the central superheater core is negligible, the power dissipated to the coolant (including γ , the gamma emission from the boiling core) is given by

$$\frac{Q_{b}(s)}{Q_{g}(s)} = \frac{q_{b}(s)}{q_{g}(s)} = (1 - \gamma) \left[\sum_{i=1}^{3} \frac{F_{i}}{1 + \tau_{i}s} + \frac{1 - \sum_{i=1}^{3} F_{i}}{1 + \widetilde{\tau}_{4}s} \right] + \gamma.$$
 (2.14)

III. FUNDAMENTAL EQUATION OF MODERATOR DYNAMICS

The equations for conservation of mass and energy at the channel of a boiling core are

$$\frac{\partial (A_s \rho_s U + A_w \rho_w W)}{\partial x} + \frac{\partial (A_s \rho_s + A_w \rho_w)}{\partial t} = 0;$$
 (3.1)

and

$$\frac{\partial (A_s H_s \rho_s U + A_w \rho_w H_w W)}{\partial x} + \frac{\partial (A_s H_s \rho_s + A_w H_w \rho_w)}{\partial t} = Q_b.$$
 (3.2)

Since the values of $\partial H_s/\partial x$, $\partial H_w/\partial x$, and $\partial \rho_s/\partial x$ may be assumed to be zero, Eqs. (3.1) and (3.2) give

$$\frac{\partial A_{s}U}{\partial x} + \frac{\partial A_{s}}{\partial t} = \frac{Q_{b}}{(H_{s} - H_{w}) \rho_{s}} - \left[\frac{\rho_{s}A_{s} \frac{dH_{s}}{dp} + \rho_{w}A_{w} \frac{dH_{w}}{dp}}{(H_{s} - H_{w}) \rho_{s}} + \frac{A_{s}}{\rho_{s}} \cdot \frac{d\rho_{s}}{dp} \right] \frac{dP}{dt}.$$
(3.3)

If the deviations from the steady-state value are small compared to the steady-state value, Eq. (3.3) may be rewritten as

$$\frac{\partial}{\partial \mathbf{x}} \left(\mathbf{a}_{\mathbf{S}} \mathbf{U}_{\mathbf{0}} + \mathbf{u} \mathbf{A}_{\mathbf{S}\mathbf{0}} \right) + \frac{\partial \mathbf{a}_{\mathbf{S}}}{\partial \mathbf{A}} = \frac{\mathbf{q}_{\mathbf{b}}}{\mathbf{H}_{\mathbf{V}}} - \left[\frac{1}{\mathbf{H}_{\mathbf{V}}} \left(\rho_{\mathbf{S}} \mathbf{A}_{\mathbf{S}\mathbf{0}} \frac{\mathrm{d}\mathbf{H}_{\mathbf{S}}}{\mathrm{d}\mathbf{p}} + \rho_{\mathbf{W}} \mathbf{A}_{\mathbf{W}\mathbf{0}} \frac{\mathrm{d}\mathbf{H}_{\mathbf{W}}}{\mathrm{d}\mathbf{p}} \right) + \frac{\mathbf{A}_{\mathbf{S}\mathbf{0}}}{\rho_{\mathbf{S}}} \cdot \frac{\mathrm{d}\rho_{\mathbf{S}}}{\mathrm{d}\mathbf{p}} \right] \frac{\mathrm{d}\mathbf{P}}{\mathrm{d}\mathbf{t}},$$

$$(3.4)$$

where

$$H_{v} \equiv \rho_{s}(H_{s} - H_{w}), \tag{3.5}$$

and it is postulated that

$$a_{s}(\mathbf{x},t)U_{0}(\mathbf{x}) + u(\mathbf{x},t)A_{s0}(\mathbf{x}) \equiv U_{p}(\mathbf{x})a_{s}(\mathbf{x},t); \tag{3.6}$$

and

$$U_{p}(x) \equiv \zeta(x)U_{0}(x). \tag{3.7}$$

Since it was found that $\zeta(x)$ approximates unity, (2) Eq. (3.4) can be further simplified as

$$\frac{\partial U_0 a_s}{\partial x} + \frac{\partial a_s}{\partial t} = \frac{q_b}{H_v} - \left[\frac{1}{H_v} \left(\rho_s A_{s0} \frac{dH_s}{dp} + \rho_w A_{w0} \frac{dH_w}{dp} \right) + \frac{A_{s0}}{\rho_s} \cdot \frac{d\rho_s}{dp} \right] \frac{dP}{dt} . \quad (3.8)$$

IV. EFFECTS OF POWER VARIATIONS

The analysis of power-to-void transfer function is presented first in Section IVA, where the pressure and the boiling boundary are assumed constant. The power-to-boiling-boundary transfer function is derived in Section IVB.

If the transfer functions derived in Sections IV and VII are combined, the total effect of power changes on void is obtained.

A. Power-to-void Transfer Function

The following equation is obtained from Eq. (3.8) and includes the effect of the void transport across the core:

$$\frac{\partial U_0 a_S}{\partial x} + \frac{\partial a_S}{\partial t} = \frac{q_b(x,t)}{H_v}.$$
 (4.1)

The initial and boundary conditions for solving Eq. (4.1) are

$$a_{s}(x,t) = 0$$
 at $t = 0$;

and

$$a_s(x,t) = 0$$
 at $x = L_b$.

In addition to the void transport effect described above, the void formation is delayed with respect to the heat flux deviation for several reasons. Because of the surface tension of the liquid, the pressure inside a bubble must be greater than the pressure of the water outside the bubble. Accordingly, energy must be spent for bubble formation. During bubble growth, the local water pressure rises and this pressure disturbance increases the saturation temperature of the water. The pressure again decreases with the transmission of the pressure wave into the void and water mixture. The void formation delayed is denoted as τ_0 , and the heat flux expended for the formation of steam is denoted as $q_b^i(x,t)$. If the bubble lag effect is included, the result is

$$\frac{\partial U_0 a_S}{\partial x} + s a_S = \frac{q_b'(x,s)}{H_V}. \tag{4.2}$$

Equation (4.1) may be rewritten as follows:

$$q_b^i(x,s) \equiv q_b(x,s)/(1+\tau_0 s).$$
 (4.3)

The velocity of the pressure wave in the mixture of steam and water is

$$\omega = \frac{\sqrt{g \rho_{SW} K'}}{\sqrt{1 + (K'/E)d/e}}.$$
 (4.4)

Since the value of (K'/E)d/e is small compared to 1, Eq. (4.2) may be approximated as

$$\omega \cong \sqrt{g \, \rho_{\rm SW} \, K'}. \tag{4.5}$$

The value of τ_0 may be estimated as

$$\tau_0 = H_e/\omega + 0.02.$$
 (4.6)

The bubble formation lag is estimated to be between 10 and 30 msec. A value of 20 msec is used in this analysis.

If it is assumed that the position of the boiling boundary is not changed with time, q'(x,s) may be denoted as

$$q_b'(\mathbf{x}, \mathbf{s}) \equiv \overline{q}_b'(\mathbf{s})D(\mathbf{x}),$$
 (4.7)

where D(x) is the normalized, steady-state, axial flux distribution; i.e.,

$$\frac{1}{L} \int_0^L D(\mathbf{x}) d\mathbf{x} = 1. \tag{4.8}$$

Combining Eqs. (4.2) and (4.7) produces

$$\frac{dU_0a_s(x,s)}{dx} + sa_s(x,s) = \frac{q_b'(s)}{H_v} D(x). \tag{4.9}$$

If the weighting function of void to reactivity, F(x), is assumed equal to D(x)/L, the effective void cross-section deviation is

$$\vec{v}(s) = \int_{L_b}^{L} a(x,s)F(x)dx = \frac{1}{L} \int_{L_b}^{L} a(x,s)D(x)dx.$$
 (4.10)

If Eq. (4.9) is solved for $a_s(x,s)$ and the result is substituted into Eq. (4.10), the following transfer function is obtained:

$$\frac{\overline{\mathbf{v}}(\mathbf{s})}{\overline{\mathbf{q}}_{\mathbf{b}}^{\prime}(\mathbf{s})} = \frac{1}{LH_{\mathbf{v}}} \int_{L_{\mathbf{b}}}^{L} D(\mathbf{x}) d\mathbf{x} \int_{L_{\mathbf{b}}}^{\mathbf{x}} D(\mathbf{x}^{\prime}) e^{\mathbf{s} \{t(\mathbf{x}^{\prime}) - t(\mathbf{x})\}} d\mathbf{x}^{\prime}, \qquad (4.11)$$

and

$$\frac{\overline{\mathbf{v}}(\mathbf{s})}{\overline{\mathbf{q}}_{\mathbf{b}}(\mathbf{s})} = \frac{1}{1 + \tau_{\mathbf{0}}\mathbf{s}} \cdot \frac{\overline{\mathbf{v}}(\mathbf{s})}{\overline{\mathbf{q}}_{\mathbf{b}}^{\dagger}(\mathbf{s})}, \tag{4.12}$$

where

$$t(\mathbf{x}) = \int_{L_b}^{\mathbf{x}} \frac{1}{U_0(\mathbf{x})} d\mathbf{x}. \tag{4.13}$$

Equation (4.12) is the general form of the power-to-effective-void, cross-section transfer function.

If the steam velocity, $U_0(x)$, is assumed to be a constant, \overline{U}_0 , and the normalized, axial flux distribution is denoted as

$$D(x) = a \sin(bx + c), \qquad (4.14)$$

then Eq. (4.12) may be solved as follows:

$$\frac{\overline{v}(s)}{q_b'(s)} = \frac{1}{1 + \tau_0 s} \cdot \frac{a^2}{H_v \overline{U}_0} \int_{L_b}^{L} \sin(bx + c) dx \int_{L_b}^{x} \sin(bx' + c) e^{(s/\overline{U}_0)(x' - x)} dx$$

$$= \frac{1}{1+\tau_0 s} A_1 \left[\frac{B_1 + C_1 s + D_1 e^{-\tau_6 s}}{1+\tau_{5s}^2 s^2} + \frac{1+e^{-\tau_6 s} (E_1 + F_1 s)}{(1+\tau_{5s}^2 s^2)^2} \right]; \tag{4.15}$$

$$\frac{\left[\overline{v}(s)/A\right] \times 100}{\overline{q}_{b}(s)} = \frac{100/A}{1 + \tau_{0}s} \cdot A_{1} \left[\frac{B_{1} + C_{1}s + D_{1}e^{-\tau_{6}s}}{1 + \tau_{5}^{2}s^{2}} + \frac{1 + e^{-\tau_{6}s}(E_{1} + F_{1}s)}{(1 + \tau_{5}^{2}s^{2})^{2}} \right], \tag{4.16}$$

where

$$A_1 = a^2 \tau_5 / (L_b H_v),$$

$$B_1 = \frac{1}{2} \left\{ \sin^2(bL + c) + \sin^2(bL_b + c) \right\},$$

$$C_1 = \tau_6/2 - (\tau_5/4) \{ \sin 2(bL + c) - \sin 2(bL_b + c) \},$$

$$D_1 = \sin(bL + c) \sin(bL_b + c),$$

$$E_1 = -\cos(\tau_6/\tau_5)$$

$$F_1 = -\tau_5 \sin(\tau_6/\tau_5)$$

$$\tau_5 = 1/(\overline{U}_0 b),$$

and

$$\tau_6 = b(L - L_b)/(\overline{U}_0 b) = b(L - L_b) \tau_5.$$

For simplicity, Eq. (4.16) is written as

$$(\bar{\mathbf{v}}(\mathbf{s})/\mathbf{A}) \cdot 100/\bar{\mathbf{q}}_{\mathbf{b}}(\mathbf{s}) \cong [1/(1+\tau_{\mathbf{0}}\mathbf{s})] \cdot [\mathbf{A}_{\mathbf{v}}/(1+\tau_{\mathbf{v}}\mathbf{s})],$$
 (4.17)

where

$$A_{v} = (100/A) \cdot A_{1}(B_{1} + D_{1} + E_{1} + 1),$$

and $\tau_{v} = (B_1 + D_1 + E_1 + 1) \tau_{5}^{2}/C_1$.

B. Power-to-boiling-boundary Transfer Function

This section discusses the effect of power variations in the subcooled region of the core.

From Eq. (3.2), the following equation is valid for the subcooled region:

$$\frac{\partial (\rho_{\mathbf{w}} A_{\mathbf{w}} H_0 W_0)}{\partial \mathbf{x}} + \frac{\partial (\rho_{\mathbf{w}} A_{\mathbf{w}} H_0)}{\partial \mathbf{t}} = Q_{\mathbf{b}}, \tag{4.18}$$

where $\rho_{\rm W}A_{\rm W}W_0$ is equal to the inlet water mass flow rate and $\rho_{\rm W}$, $A_{\rm W}$, and W_0 are assumed constant. Thus Eq. (4.18) can be rewritten as

$$\frac{\partial H_0}{\partial x} + \frac{1}{W_0} \frac{\partial H_0}{\partial t} = \frac{Q_b}{\dot{M}_f}.$$
 (4.19)

Again, if only the transient parts are used (the steady-state values are subtracted), Eq. (4.19) becomes:

$$\frac{\partial h_0(\mathbf{x},t)}{\partial \mathbf{x}} + \frac{1}{W_0} \frac{\partial h_0(\mathbf{x},t)}{\partial t} = \frac{q_b(\mathbf{x},t)}{M_f}.$$
 (4.20)

Initial and boundary conditions for solving Eq. (4.20) are

$$h_0(xt) = 0 \quad \text{at } t = 0;$$

and

$$h_0(xt) = 0 \quad \text{at } x = 0.$$

Using the Laplace transform method results in

$$\frac{dh_0(x,s)}{dx} + \frac{s}{W_0} h_0(x,s) = \frac{q_b(x,s)}{\dot{M}_f}.$$
 (4.21)

Then the solution of Eq. (4.21) is

$$\dot{M}_{fh_0(x,s)} = \bar{q}_b(s) \int_0^x D(x') e^{(s/W_0)(x'-x)} dx'.$$
 (4.22)

If the boiling boundary is denoted by δ , the following relation will be satisfied at any time (if h_0 is negative):

$$H_0(L_b + \delta) + h_0(L_b + \delta, t) = H_w = H_0(L_b).$$
 (4.23)

If δ is small compared with $L_b,$ the value of $h_0(L_b+\delta\,,t)$ can be replaced by $h_0(L_b,t).$

From Eq. (4.19), the following equation is satisfied under steadystate conditions:

$$\dot{M}_{f} \frac{dH_{0}(x)}{dx} = Q_{b}(x). \tag{4.24}$$

Now,

$$H_0(L_b + \delta) - H_0(L_b) = \frac{Q_b(L_b)}{M_f} \delta(t),$$
 (4.25)

and in Eqs. (4.23) and (4.25), $\delta(t)$ is denoted as

$$\delta(t) = - [\dot{M}_f/Q_b(L_b)]h_0(L_b,t). \tag{4.26}$$

Equations (4.22) and (4.26) yield the following power-to-boiling-boundary transfer function:

$$\frac{\delta(s)}{\overline{q}_{b}(s)} = -\frac{1}{Q_{b}(L_{b})} \int_{0}^{L_{b}} D(x)e^{-(s/W_{0})(L_{b}-x)} dx$$

$$= -\frac{a}{Q_{b}(L_{b})b} \frac{\tau_{7}s \sin(bL_{b}+c) - \cos(bL_{b}+c) - e^{-(L_{b}/W_{0})s} \{\tau_{7}s \sin c - \cos c\}}{1 + \tau_{7}^{2}s^{2}}$$

$$= A_{2} \left[\frac{B_{2} + C_{2}s - e^{-\tau_{7}s}(D_{2} + E_{2}S)}{1 + \tau_{7}^{2}s^{2}}\right], \qquad (4.27)$$

$$A_2 = -a/[Q_0(L_b)b],$$
 $B_2 = -\cos(bL_b + c),$
 $C_2 = \tau_7 \sin(bL_b + c),$
 $D_2 = -\cos c,$
 $E_2 = \tau_7 \sin c,$

and

$$\tau_7 = L_b/W_0$$
.

For simplicity, Eq. (4.27) is written as

$$\frac{\delta(s)}{\bar{q}_b(s)} = \frac{A_{\delta}}{1 + \tau_{\delta} s}, \qquad (4.28)$$

where

$$A_{\delta} = A_{w}(B_2 - D_2),$$

and

$$\tau_{\delta} = (B_2 - D_2) \tau_7^2 / C_2$$
.

V. PRESSURE-TO-VOID TRANSFER FUNCTION

In the analysis of the pressure-to-void transfer function, the power is assumed to remain constant. The following equation is obtained from Eq. (3.8):

$$\frac{\partial U_0 a_s}{\partial x} + \frac{\partial a_s}{\partial t} = -\left[\frac{1}{H_V} \left(\rho_s A_{s0} \frac{dH_s}{dp} + \rho_w A_{w0} \frac{dH_w}{dp}\right) + \frac{A_{s0}}{\rho_s} \frac{d\rho_s}{dp}\right] \frac{dp}{dt}$$

$$= -K(x) \frac{dp}{dt}.$$
(5.1)

If the procedure used in solving Eq. (4.1) is followed, the solution of Eq. (5.1) is

$$\frac{\overline{v}(s)}{sp} = \frac{1}{1 + \tau_0 s} \int_{L_b}^{L} \frac{D(x)}{L U_0(x)} dx \int_{L_b}^{x} -K(x') e^{s\{t(x')-t(x)\}} dx'.$$
 (5.2)

In Eq. (5.2), H_V , ρ_W , ρ_S , dH_S/dp , dH_W/dp , and $d\rho_S/dp$ are assumed constant. Since $A_{S0}+A_{W0}=A$ (the total channel cross section), a determination of A_{S0} is sufficient. $A_{S0}(x)$ is obtained by solving Eq. (3.3) at steady state. Thus,

$$\frac{\mathrm{d}(A_{s0}U_0)}{\mathrm{dx}} = \frac{Q_b(x)}{H_{tr}},\tag{5.3}$$

and

$$A_{s0}(x) = \frac{1}{H_v U_0(x)} \int_{L_b}^{x} Q_b(x') dx' = \frac{\overline{Q}_b}{H_v U_0(x)} \int_{L_b}^{x} D(x') dx'.$$
 (5.4)

If $U_0(x)$ is again assumed constant, $A_{s0}(x)$ may be rewritten as

$$A_{s0}(x) = \frac{\overline{Q}_{ba}}{H_{v}\overline{U}_{0b}} \{\cos(bL_{b}+c) - \cos(bx+c)\}.$$
 (5.5)

Substituting Eq. (5.5) into Eq. (5.1) results in

$$K(x) = \frac{A\rho_{w}\left(\frac{dH_{w}}{dp}\right)}{H_{v}}\left[1 + \frac{Q_{b}a}{A\left(\frac{dH_{w}}{dp}\right)H_{v}\overline{U}_{0}b} \cdot \left(\frac{dH_{s}}{dp} \cdot \frac{\rho_{s}}{\rho_{w}} - \frac{dH_{w}}{dp} + \frac{H_{v}}{\rho_{s}\rho_{w}} \cdot \frac{d\rho_{s}}{dp}\right)\right]$$

$$\left\{\cos(bL_{b} + c) - \cos(bx + c)\right\} = \frac{\overline{U}_{0}}{a}K_{1} - \frac{\overline{U}_{0}}{a}K_{2}\cos(bx + c), \tag{5.6}$$

$$K_{1} = \frac{aA\rho_{w}\left(\frac{dH_{w}}{dp}\right)}{H_{v}\overline{U}_{0}} \left\{1 + \frac{\overline{Q}_{b}a}{A\left(\frac{dH_{w}}{dp}\right)H_{v}\overline{U}_{0}b}\left(\frac{dH_{s}}{dp} \frac{\rho_{s}}{\rho_{w}} - \frac{dH_{w}}{dp} + \frac{H_{v}}{\rho_{s}\rho_{w}} \cdot \frac{d\rho_{s}}{dp}\right) + \cos(bL_{b} + c)\right\},$$

$$(5.7)$$

and

$$K_{2} = \frac{aA\rho_{w}\left(\frac{dH_{w}}{dp}\right)}{H_{v}\overline{U}_{0}} \left\{1 + \frac{\overline{Q}_{b}a}{A\left(\frac{dH_{w}}{dp}\right)H_{v}\overline{U}_{0}b}\left(\frac{dH_{s}}{dp} \cdot \frac{\rho_{s}}{\rho_{w}} - \frac{dH_{w}}{dp} + \frac{H_{v}}{\rho_{s}\rho_{w}} \cdot \frac{d\rho_{s}}{dp}\right)\right\}.$$

$$(5.8)$$

If Eq. (5.6) is substituted into Eq. (5.2), the pressure-to-void transfer function is

$$\frac{\left[\overline{v}(s)/A\right]100}{sp(s)} = \frac{100/A}{1+\tau_0 s} \cdot \frac{1}{L} \int_{L_b}^{L} \sin(bx+c) dx \int_{L_b}^{x} \left\{-K_1 + K_2 \cos(bx'+c)\right\} e^{\left(S/\overline{U}_0\right)(x'-x)} dx'$$

$$= \frac{1}{1+\tau_0 s} \cdot \frac{100}{A} \left[\frac{A_3}{S} + \left\{\frac{B_3 + C_3 s - e^{-\tau_6 s}(D_3 + E_3 s)}{1+\tau_5^2 s^2}\right\}\right]$$

$$\cdot \left\{\frac{1}{s} - \frac{F_3 + G_3 s}{1+\tau_5^2 s^2}\right\} + \frac{H_3 + I_3 s}{1+\tau_5^2 s^2}, \tag{5.9}$$

where:

$$\begin{array}{l} A_{3} = \left[K_{1} / (b^{2} \tau_{5}) \right] \left\{ \cos(bL + c) - \cos(bL_{b} + c) \right\}, \\ B_{3} = \left[K_{1} / (b^{2} \tau_{5}) \right] \cos(bL_{b} + c), \\ C_{3} = \left(K_{1} / b^{2} \right) \sin(bL_{b} + c), \\ D_{3} = \left[K_{1} / (b^{2} \tau_{5}) \right] \cos(bL + c), \\ E_{3} = \left(K_{1} / b^{2} \right) \sin(bL + c), \\ F_{3} = \left(K_{2} / K_{1} \right) \tau_{5} \cdot \sin(bL_{b} + c), \\ G_{3} = \left(K_{2} / K_{1} \right) \tau_{5}^{2} \cdot \cos(bL_{b} + c), \\ H_{3} = \left[K_{2} / (4b^{2}) \right] \left\{ 2b(L - L_{b}) - \sin 2(bL + c) + \sin 2(bL_{b} + c) \right\}, \end{array}$$

and

and

$$I_3 = [K_2/4b^2] \tau_5 \{\cos 2(bL_b + c) - \cos 2(bL + c)\}.$$

For simplicity, Eq. (5.9) is written as

$$\frac{[\overline{v}(s)/A]100}{sp(s)} = \frac{1}{1+\tau_0 s} \cdot \frac{A_{Vp}}{1+\tau_{Vp} s},$$
where
$$A_{Vp} = \{F_3(D_3 - B_3) + H_3 + C_3 - E_3 + \tau_6 D_3\} \ 100/A,$$
and
$$\tau_{Vp} = \{F_3(D_3 - B_3) + H_3 + C_3 - E_3 + \tau_6 D_3\} / (I_3/\tau_5^2 + A_3).$$
(5.10)

VI. PRESSURE-TO-BOILING-BOUNDARY TRANSFER FUNCTION

Changes of pressure produce differences in the enthalpy of saturated water and consequently change the position of the boiling boundary.

From Eq. (4.24),

$$\dot{M}_{f}(H_{w} - H_{wf}) = \int_{0}^{L_{b}} Q_{b}(x) dx,$$
 (6.1)

and the relation between the enthalpy of the water and the boiling boundary variation is as follows:

$$\dot{M}_{f}(H_{W} + h_{W} - H_{Wf}) = \int_{0}^{L_{b} + \delta} Q_{b}(x) dx,$$
 (6.2)

or

$$\dot{M}_{f}h_{W} = Q_{b}(L_{b}) \delta. \tag{6.3}$$

If the feedwater mass flowrate is negligible in comparison to that of the recirculation water, then the inlet water enthalpy will rise to $H_{
m wf}$ + $\mathbf{h}_{\mathbf{W}}$ after recirculation time $T_{\mathbf{r}}$. The pressure-to-boiling-boundary transfer function is therefore

$$\frac{\delta(s)}{sp(s)} = \frac{dH_{w}}{dp} \cdot \frac{\dot{M}_{f}}{Q_{b}(L_{b})} \cdot \frac{1 - e^{-sT_{r}}}{s}$$

$$\stackrel{\cong}{=} \frac{dH_{w}}{dp} \cdot \frac{\dot{M}_{f}}{Q_{b}(L_{b})} \cdot \frac{T_{r}}{1 + sT_{r}} = \frac{A_{\delta p}}{1 + sT_{r}},$$
(6.4)

$$A_{\delta p} = \frac{dH_W}{dp} \cdot \frac{\dot{M}_f}{Q_b(L_b)} \cdot T_r.$$

VII. BOILING-BOUNDARY-TO-VOID TRANSFER FUNCTION

The variation of the boiling boundary will cause variations in the volume of steam. The effect of the variation of steam production at the boiling boundary will appear at position x after transit time t(x).

Including the bubble lag effect as derived in Section IV, the void formation variation of the boiling boundary can be denoted by

$$U_0(L_b) a_s(L_b, s) = -[Q_b(L_b) \delta(s)]/[H_v(1 + \tau_0 s)].$$
 (7.1)

Then the relation at any position x is

$$U_0(x) a_S(x,s) = -[Q_b(L_b)/H_v] \cdot [\delta(s)/(1+\tau_0 s)] e^{-st(x)}.$$
 (7.2)

From Eq. (4.7), the mean value of the effective void cross-section area deviation is given as

$$\overline{\mathbf{v}}(\mathbf{s}) = \frac{1}{L} \int_{\mathbf{L}_{\mathbf{b}}}^{\mathbf{L}} \mathbf{a}_{\mathbf{s}}(\mathbf{x}, \mathbf{s}) \, \mathbf{D}(\mathbf{x}) \, d\mathbf{x}. \tag{7.3}$$

If Eqs. (7.2) and (7.3) are combined, the boiling-boundary-to-void transfer function is

$$\frac{\overline{\mathbf{v}}(\mathbf{s})}{\delta(\mathbf{s})} = -\frac{Q_{\mathbf{b}}(\mathbf{L}_{\mathbf{b}})}{H_{\mathbf{v}}\mathbf{L}} \cdot \frac{1}{1 + \tau_{\mathbf{0}}\mathbf{s}} \int_{\mathbf{L}_{\mathbf{b}}}^{\mathbf{L}} \frac{D(\mathbf{x})}{U_{\mathbf{0}}(\mathbf{x})} e^{-\mathbf{s}\mathbf{t}(\mathbf{x})} d\mathbf{x}$$
(7.4)

$$= -\frac{Q_{b}(L_{b})}{H_{v}L} \cdot \frac{1}{1 + \tau_{0}s} \int_{0}^{T_{s}} D[x(t)] e^{-st} dt, \qquad (7.5)$$

$$T_s = \int_{L_b}^{L} \frac{1}{U_0(x)} dx$$

and

$$t = \int_{L_b}^{x(t)} \frac{1}{U_0(x')} dx'.$$
 (7.6)

If the steam velocity is assumed constant, Eq. (7.5) becomes

$$\frac{\overline{\mathbf{v}}(\mathbf{s})}{\delta(\mathbf{s})} = -\frac{Q_{\mathbf{b}}(\mathbf{L}_{\mathbf{b}})\mathbf{a}}{\mathbf{H}_{\mathbf{v}}\mathbf{L}} \cdot \frac{1}{1 + \tau_{\mathbf{0}}\mathbf{s}} \int_{0}^{\mathbf{T}\mathbf{s}} \sin(\mathbf{b}\mathbf{U}_{\mathbf{0}}\mathbf{t} + \mathbf{b}\mathbf{L}_{\mathbf{b}} + \mathbf{c}) e^{-\mathbf{s}\mathbf{t}} d\mathbf{t}; \qquad (7.7)$$

and

$$\frac{\left[\overline{v}(s)/A\right]100}{\delta(s)} = \frac{1}{1+\tau_0 s} \cdot \frac{100}{A} \cdot A_4 \cdot \frac{B_4 + C_4 s - e^{-\tau_6 s} (D_4 + E_4 s)}{1+\tau_5^2 s^2}; \quad (7.8)$$

where:

$$A_4 = - [Q_b(L_b)a\tau_1]/(H_vL),$$
 $B_4 = \cos(bL_b + c),$
 $C_4 = \tau_5 \sin(bL_b + c),$
 $D_4 = \cos(bL + c),$

and

$$E_4 = \tau_5 \sin(bL + c)$$
.

For simplicity, Eq. (7.8) can be rewritten as

$$[\overline{\mathbf{v}}(\mathbf{s})/\mathbf{A}]100/\delta(\mathbf{s}) = [1/(1+\tau_0\mathbf{s})] \cdot [\mathbf{A}_{\mathbf{v}\delta}/(1+\tau_{\mathbf{v}\delta}\mathbf{s})], \tag{7.9}$$

where

$$A_{V\delta} = A_4(B_4 - D_4),$$

and

$$\tau_{V\delta} = \tau_5^2 (B_4 - D_4) / C_4$$
.

VIII. HEAT-FLUX-TO-STEAM-MASS TRANSFER FUNCTION

As mentioned in Section IV, $q_b'(x,t)$ is the expenditure of energy for the formation of steam. The deviation of the steam formation rate $\delta \dot{m}_s(x,t)$ can be expressed as follows:

$$\delta \dot{m}_{s}(x,t) = q_{b}'(x,t) / (H_{s} - H_{w}),$$
 (8.1)

or

$$\delta \dot{m}_{s}(x,s) = q_{b}(x,s) \cdot 1/(1+\tau_{0}s) \cdot 1/(H_{s}-H_{w}),$$
 (8.2)

and

$$\delta \overline{\dot{m}}(s) = \frac{\overline{q}_b(s)}{H_s - H_w} \cdot \frac{1}{1 + \tau_0 s} \int_{L_b}^{L} D(x) dx$$

$$= \frac{\overline{q}_b(s)}{H_s - H_w} \cdot \frac{1}{1 + \tau_0 s} \cdot \frac{a}{b} \left[\cos(bL_b + c) - \cos(bL + c) \right], \qquad (8.3)$$

where $\delta \dot{\vec{m}}_s(s)$ is the rate of steam-mass variation for one fuel rod. The total rate of steam-mass variation, $\dot{m}_s(s)$, in the vessel is thus

$$\dot{m}_{s}(s) = \frac{1}{1 + \tau_{0}s} \cdot \frac{a}{(H_{s} - H_{w})b} \left[n_{bi} \overline{q}_{bi}(s) \{ \cos(bL_{bi} + c) - \cos(bL + c) \} + n_{b0} \overline{q}_{b0}(s) \{ \cos(bL_{b0} + c) - \cos(bL + c) \} \right].$$
(8.4)

IX. STEAM-MASS-TO-PRESSURE TRANSFER FUNCTION

From Reference (3), the steam-mass-to-pressure transfer function is simplified to

$$\frac{\mathrm{sp}(\mathrm{s})}{\dot{\mathrm{m}}_{\mathrm{s}}(\mathrm{s})} = \frac{1 + \mathrm{sT}_{\mathrm{r}}}{\eta \left(1 + \mathrm{s} \cdot \frac{\gamma}{\eta} \cdot \mathrm{T}_{\mathrm{r}}\right)} = \mathrm{A}_{\mathrm{pm}} \cdot \frac{1 + \mathrm{T}_{\mathrm{r}}\mathrm{s}}{1 + \tau_{\mathrm{pm}}\mathrm{s}},\tag{9.1}$$

where

$$\gamma = \frac{M_{s}}{p} + \frac{M_{s}}{\theta_{s}} \cdot \frac{\partial \theta_{s}}{\partial p} + \frac{M_{s} \cdot \frac{\partial H_{w}}{\partial p}}{H_{s} - H_{w}},$$

$$\eta = \frac{M_{s}}{p} + \frac{M_{s}}{\theta_{s}} \cdot \frac{\partial \theta_{s}}{\partial p} + \frac{M_{s} \cdot \frac{\partial H_{w}}{\partial p}}{H_{s} - H_{w}} + \frac{M_{w} \cdot \frac{\partial H_{w}}{\partial p}}{H_{s} - H_{w}},$$

$$(9.2)$$

and

$$A_{pm} = 1/\eta,$$

$$\tau_{pm} = (\gamma/\eta) T_{r}.$$
(9.3)

X. PRESSURE-TO-WATER-TEMPERATURE TRANSFER FUNCTION

The saturation temperature of the water in the boiling region is also changed by pressure variations. After the pressure deviation occurs, the core-inlet water temperature will change. This effect will appear in the nonboiling region after $T_{\tt r}$ seconds.

The effective water temperature variation is given by

$$\theta_{\mathbf{w}}(\mathbf{s}) = \frac{\partial \theta_{\mathbf{w}}}{\partial \mathbf{p}} \cdot \frac{\mathbf{p}(\mathbf{s})}{\mathbf{L}} \left[\int_{\mathbf{L}_{\mathbf{b}}}^{\mathbf{L}} \mathbf{D}(\mathbf{x}) \, d\mathbf{x} + e^{-\mathbf{s} T_{\mathbf{r}}} \cdot \int_{\mathbf{0}}^{\mathbf{L}_{\mathbf{b}}} \mathbf{D}(\mathbf{x}) \, d\mathbf{x} \right], \quad (10.1)$$

and the pressure-to-water-temperature transfer function becomes

$$\frac{\theta_{\mathbf{w}}(\mathbf{s})}{\mathbf{p}(\mathbf{s})} = \frac{\partial \theta_{\mathbf{w}}}{\partial \mathbf{p}} \cdot \frac{\mathbf{a}}{\mathbf{L}\mathbf{b}} \left[\left\{ \cos(\mathbf{b}\mathbf{L}_{\mathbf{b}} + \mathbf{c}) - \cos(\mathbf{b}\mathbf{L} + \mathbf{c}) \right\} + e^{-\mathbf{s}T_{\mathbf{r}}} \left\{ \cos(\mathbf{c} - \cos(\mathbf{b}\mathbf{L}_{\mathbf{b}} + \mathbf{c})) \right\} \right]$$

$$\approx \frac{\partial \theta_{\mathbf{w}}}{\partial \mathbf{p}} \left[\frac{1 + \mathbf{s}T_{\mathbf{r}} \left\{ \cos(\mathbf{b}\mathbf{L}_{\mathbf{b}} + \mathbf{c}) - \cos(\mathbf{b}\mathbf{L} + \mathbf{c}) \right\} \left(\mathbf{a}/\mathbf{b}\mathbf{L} \right)}{1 + T_{\mathbf{r}}\mathbf{s}} \right]. \tag{10.2}$$

XI. POWER-TO-WATER-TEMPERATURE TRANSFER FUNCTION FOR BOILER CORE

As discussed in Section IV, some portion of the heat energy fluctuation in the boiling region is spent in superheating the water. From this it must be assumed that the water enthalpy in the boiling region can rise above the saturation enthalpy. In the nonboiling region, the effects of variation in heat flux on the temperature fluctuation do not include the effect of superheating of water.

If Eqs. (3.1), (3.2), (3.3), (3.4), and (4.4) are combined, the following equation for the boiling region results:

$$A_{\mathbf{w}} \rho_{\mathbf{w}} \mathbf{W} = \frac{\partial h_{\mathbf{w}}}{\partial \mathbf{x}} + A_{\mathbf{w}} \rho_{\mathbf{w}} \mathbf{W} = \frac{\partial h_{\mathbf{w}}}{\partial t} = q_{\mathbf{b}} - q_{\mathbf{b}}'. \tag{11.1}$$

The steam mass is negligible compared to the water mass; therefore, A_W , ρ_W and W are assumed constant. The enthalpy fluctuation, h_W , is proportional to the temperature fluctuation, θ_W . In this section, an average constant value of W is used (represented as \overline{W}). In addition, the subscript 1 refers to the boiling zone, and the subscript 2 refers to the subcooled zone. Thus, after Eq. (11.1) is Laplace transformed, the following equation can be written for the boiling zone:

$$\frac{\partial \theta_{w_1}}{\partial x} + \frac{1}{\overline{w}} \cdot \frac{\partial \theta_{w_1}}{\partial t} = K' q_b \cdot \frac{\tau_0 s}{1 + \tau_0 s}, \qquad (11.2)$$

where

$$K' = K''/(A_W \rho_W \overline{W}),$$

and

$$K'' = \theta_{w_1}/h_{w_1}$$

If the same procedure as the one in Section IV is used, the following transfer function is obtained:

$$\frac{\theta_{\mathbf{w_1}(s)}}{\overline{q}_b(s)} = \frac{K'}{L\overline{W}} \cdot \frac{\tau_{0s}}{1 + \tau_{0s}} \int_{L_b}^{L} D(\mathbf{x}) d\mathbf{x} \int_{L_b}^{\mathbf{x}} D(\mathbf{x}') e^{(s/\overline{W})(\mathbf{x}' - \mathbf{x})} d\mathbf{x}'$$

$$= \frac{\tau_{0s}}{1 + \tau_{0s}} \cdot A_5 \left[\frac{B_5 + C_5 s + D_5 e^{-\tau_{9} s}}{1 + \tau_{8s}^2 s^2} + \frac{1 + e^{-\tau_{9} s} (E_5 + F_5 s)}{(1 + \tau_{8s}^2 s^2)^2} \right], \tag{11.3}$$

$$A_{5} = K'a^{2}\tau_{8}/L_{b}^{2},$$

$$B_{5} = -\frac{1}{2} \{ \sin^{2}(bL+c) + \sin^{2}(bL_{b}+c) \},$$

$$C_{5} = \tau_{8}/2 - (\tau_{8}/4) \{ \sin 2(bL+c) - \sin 2(bL_{b}+c) \},$$

$$D_{5} = \sin(bL+c) \sin(bL_{b}+c),$$

$$E_{5} = -\cos(\tau_{9}/\tau_{8})$$

$$F_{5} = -\tau_{8} \sin(\tau_{9}/\tau_{8})$$

$$\tau_{8} = 1/\overline{W}b,$$

and

$$\tau_9 = b(L - L_b)/\overline{W}b = b(L - L_b) \tau_8.$$

For simplicity, Eq. (11.3) is stated as

$$\frac{\theta_{W1}(s)}{q_b(s)} \simeq \frac{\tau_0 s}{1 + \tau_0 s} \cdot \frac{A \theta q_1}{1 + \tau_{\theta q_1} s}, \qquad (11.4)$$

where

$$A_{\theta_{Q1}} = A_s(B_5 + D_5 + E_5 + 1),$$

and

$$\tau_{\theta q 1} = (B_5 + D_5 + E_5 + 1) \tau_8^2 / C_5.$$

At the nonboiling region, Eq. (11.2) becomes

$$\frac{\partial \theta_{w_2}}{\partial x} + \frac{1}{W_0} \cdot \frac{\partial \theta_{w_2}}{\partial t} = K'q_b. \tag{11.5}$$

If the same procedure as the one above is used, the following transfer function is obtained:

$$\frac{\theta_{W_2}(s)}{\overline{q}_b(s)} = \frac{K'}{LW_0} \int_0^{Lb} D(x) dx \int_0^x D(x') e^{(s/W_0)(x'-x)} dx'$$

$$= A_6 \left[\frac{B_6 + C_6 s + D_6 e^{-\tau_{11} s}}{1 + \tau_{10}^2 s^2} + \frac{1 + e^{-\tau_{11} s} (E_6 + F_6 s)}{(1 + \tau_{10}^2 s^2)^2} \right], \quad (11.6)$$

$$A_{6} = K'a^{2} \tau_{6}/(L_{b}^{2}),$$

$$B_{6} = -\frac{1}{2} \{ \sin^{2}(bL_{b} + c) + \sin^{2} c \},$$

$$C_{6} = \tau_{11}/2 - (\tau_{10}/4) \{ \sin 2(bL_{b} + c) - \sin 2c \},$$

$$D_{6} = \sin(bL_{b} + c) \sin c,$$

$$E_{6} = -\cos(\tau_{11}/\tau_{10})$$

$$F_{6} = -\tau_{10} \sin(\tau_{11}/\tau_{10})$$

$$\tau_{10} = 1/W_{0}b,$$

and

$$\tau_{11} = bL_b/W_0b = bL_b\tau_{10}$$
.

For simplicity, Eq. (11.6) is written as

$$\frac{\theta_{\text{W2}}(s)}{\overline{q}_{\text{b}}(s)} \cong \frac{A_{\theta q2}}{1 + \tau_{\theta q2}s}, \tag{11.7}$$

where

$$A_{\theta_{q2}} = A_6(B_6 + D_6 + E_6 + 1),$$

and

$$\tau_{\theta q2} = (B_6 + D_6 + E_6 + 1) \tau_{10}^2 / C_6$$

XII. POWER-TO-FUEL-TEMPERATURE TRANSFER FUNCTION FOR BOILING CORE

The difference between heat generation and heat energy transferred to water accounts for the temperature deviation, $\theta_{\rm f}$, of a fuel rod, as follows:

$$C_{f} \frac{d \theta_{f}(\mathbf{x}, t)}{dt} = \left[\overline{q}_{g}(t) - \overline{q}_{b}(t)\right] D(\mathbf{x}). \tag{12.1}$$

If the Laplace transform method is used, the effective average fuel temperature deviation, θ_f , is determined as follows:

$$s \overline{\theta}_{f}(s) = \frac{\overline{q}_{g}(s) - \overline{q}_{b}(s)}{C_{f}L} \int_{0}^{L} \{D(x)\}^{2} dx.$$
 (12.2)

From Eq. (12.2),

$$\frac{\overline{\theta}_{f}(s)}{\overline{q}_{g}(s)} = \frac{\{1 - \overline{q}_{b}(s)/\overline{q}_{g}(s)\}a^{2}}{C_{f}Ls} \left\{ \frac{L}{2} - \frac{\sin 2(bL+c) - \sin 2L}{4b} \right\}. \tag{12.3}$$

XIII. POWER-TO-FUEL-TEMPERATURE TRANSFER FUNCTION FOR SUPERHEATER CORE

Temperatures in the superheater core are analyzed in two regions: steam flow up and steam flow down (i.e., first pass and second pass). The transfer function is calculated by using average values of these two passes.

In the superheater core, the fuel temperature only has an effect on the reactivity. If the thermal resistance of the stainless steel cladding is neglected, fuel temperatures may be calculated from the following relations:

$$C_{sf} \frac{d \theta_{sfj}}{dt} = q_{sfj} - h(\theta_{sfj} - \theta_{ssj}), \qquad (13.1)$$

$$A_{ss}C_{ssj}\rho_{ssj} = \frac{\partial \theta_{ssj}}{\partial t} + A_{ss}C_{ssj}\rho_{ssj}U_{ssj} = h(\theta_{sfj} - \theta_{ssj}),$$
(13.2)

where j(=1 or 2) corresponds to the first and second passes.

The pressure drop in the superheater core is negligible and the mass flow rate of the superheated steam is assumed constant. Thus,

$$\overline{\theta}_{sf1}(s) = \frac{1}{L} \int_{0}^{L} \frac{\overline{q}_{sf}(s)D'(x)/h + \theta_{ss1}}{1 + \tau_{12}s} D'(x) dx, \qquad (13.3)$$

and

$$\overline{\theta}_{sf_2(s)} = \frac{1}{L} \int_0^L \frac{\overline{q}_{sf}(s)D(x)/h + \theta_{ss_2}}{1 + \tau_{12}s} D(x) dx, \qquad (13.4)$$

$$D'(x) = a \sin(bL + C - bx),$$

and

$$\tau_{12} = C_{sf}/h$$
.

If the Laplace transform method is used, Eq. (13.2) is replaced by

$$\frac{d\theta_{SS1}(\mathbf{x},s)}{d\mathbf{x}} + \left\{ \frac{s}{U_{SS1}} + \frac{(h\tau_{12}/K_{S1})s}{1 + \tau_{12}s} \right\} \theta_{SS1} = \frac{1}{1 + \tau_{12}s} \cdot \frac{\overline{q}_{Sf1}(s)}{K_{S1}} D^{*}(\mathbf{x}),$$
(13.5)

and

$$\frac{d\theta_{SS2}(x,s)}{dx} + \left\{ \frac{s}{U_{SS2}} + \frac{(h\tau_{12}/K_{S2})s}{1 + \tau_{12}s} \right\} \theta_{SS2} = \frac{1}{1 + \tau_{12}s} \cdot \frac{\overline{q}_{Sf2}(s)}{K_{S2}} D(x),$$
(13.6)

where

$$K_{s1} = A_{ss}C_{ss1}P_{ss1}U_{ss1}$$

and

$$K_{s2} = A_{ss}C_{ss2}\rho_{ss1}U_{ss2}.$$

The solutions for $\theta_{SS1}(x,s)$ and $\theta_{SS2}(x,s)$ are as follows:

$$\theta_{SS1}(x,s) = \frac{\overline{q}_{Sf}(s)}{(1+\tau_{12}s)K_{S1}} \int_{0}^{x} D'(x')e^{\{t'(x')-t'(x)\}} dx' + \theta_{SSin}, \quad (13.7)$$

and

$$\theta_{SS2}(\mathbf{x}, \mathbf{s}) = \frac{\overline{q}_{Sf}(\mathbf{s})}{(1 + \tau_{12}\mathbf{s})K_{S2}} \int_{0}^{\mathbf{x}} D(\mathbf{x}') e^{\{t''(\mathbf{x}') - t''(\mathbf{x})\}} d\mathbf{x}' + \theta_{SS1}(\mathbf{L}, \mathbf{s}),$$
(13.8)

where

$$t'(x) = \int_0^x \left\{ \frac{s}{U_{SS1}} + \frac{(h \tau_{12}/K_{S1})s}{1 + \tau_{12}s} \right\} dx,$$

and

$$t''(x) = \int_0^x \left\{ \frac{s}{U_{SS2}} + \frac{(h \tau_{12}/K_{S2})s}{1 + \tau_{12}s} \right\} dx.$$

The temperature deviation of saturated steam, $\theta_{\rm SS\,in}$ (at the first pass inlet), is negligible. If the superheated steam velocities, $U_{\rm SS\,I}$ and $U_{\rm SS\,I}$, are assumed constants, the transfer functions are

$$\frac{\overline{\theta}_{sf1}(s)}{\overline{q}_{sf}(s)} = \frac{1}{L} \int_{0}^{L} \left[\frac{1/h}{1 + \tau_{12}s} D'(x)^{2} + \frac{D'(x)}{K_{s1}(1 + \tau_{12}s)^{2}} \int_{0}^{x} D'(x') \right] dx,$$

$$\cdot e^{\{t'(x') - t'(x)\}} dx' dx, \qquad (13.9)$$

and

$$\frac{\overline{\theta}_{sf_2(s)}}{\overline{q}_{sf}(s)} = \frac{1}{L} \int_0^L \left[\frac{1/h}{1 + \tau_{12}s} D(x)^2 + \frac{D(x)}{K_{s_2}(1 + \tau_{12}s)^2} \int_0^x D(x') e^{\{t''(x') - t''(x)\}} dx' + \frac{D(x)}{(1 + \tau_{12}s) q_{sf}(s)} dx, \right] dx,$$
(13.10)

where

$$t'(x) = \alpha_{1}sx = \left\{ \frac{1/U_{SS1} + \tau_{12}h/K_{S1} + (\tau_{12}/\overline{U}_{SS1})s}{1 + \tau_{12}s} \right\} sx$$

$$= (\beta_{1} + \gamma_{1}s) sx/(1 + \tau_{12}s), \qquad (13.11)$$

$$t''(x) = \alpha_{2}sx = \left\{ \frac{1/U_{SS2} + \tau_{12}h/K_{S1} + (\tau_{12}/\overline{U}_{SS2})s}{1 + \tau_{12}s} \right\} sx$$

$$= (\beta_{2} + \gamma_{2}s) sx/(1 + \tau_{12}s), \qquad (13.12)$$

and

$$\frac{D(x)\theta_{SSI}(L,s)}{(1+\tau_{12}s)\overline{q}_{Sf}(s)} = \frac{D(x)}{(1+\tau_{12}s)^2K_{SI}} \int_0^L D'(x) e^{\{t'(x)-t'(L)\}} dx. \quad (13.13)$$

If $K_{\rm S1} \simeq K_{\rm S2}$, the transfer function for power generation rate to average superheater fuel temperature is

$$\frac{\overline{\theta}_{sf}(s)}{\overline{q}_{fs}} = \frac{\{\overline{\theta}_{sf_{1}}(s) + \overline{\theta}_{sf_{2}}(s)\}/2}{\overline{q}_{sf}(s)}$$

$$= \frac{A_{7}}{1 + \tau_{12}s} + B_{7} \left\{ \frac{C_{7} + D_{7}s + e^{-\alpha_{1}Ls} (E_{7} + F_{7}s)}{(1 + \tau_{12}s)^{2} \left(1 + \frac{\alpha_{1}}{b^{2}}s^{2}\right)} + \frac{G_{7} + H_{7}s^{2} + e^{-\alpha_{1}Ls} (I_{7} + J_{7}s + K_{7}s^{2})}{(1 + \tau_{12}s)^{2} \left(1 + \frac{\alpha_{1}}{b^{2}}s^{2}\right)^{2}}, (13.14)$$

$$\begin{split} A_7 &= \frac{a^2}{H_s L} \left\{ \frac{L}{2} + \frac{\sin 2c - \sin 2(bL + c)}{4b} \right\}, \\ B_7 &= a^2 / (K_{s_1} L b^2), \\ C_7 &= \left[\cos^2 c - \cos c \cos(bL + c) \right] / 2, \\ D_7 &= (\alpha_1 / b) \left\{ L b / 2 + \left[2 \sin 2 c - \sin 2(bL + c) - 2 \sin c \cos(bL + c) \right] / 4 \right\}, \\ E_7 &= \left[\cos^2 (bL + c) - \cos c \cos(bL + c) \right] / 2, \\ F_7 &= (\alpha_1 / b) \left\{ \cos(bL + c) \sin(bL + c) - \cos c \sin(bL + c) \right\} / 2, \\ G_7 &= \left\{ \cos^2 c + \cos^2 (bL + c) \right\} / 2, \\ H_7 &= -(\alpha_1^2 / 2b^2) \left\{ \sin^2 c + \sin^2 (bL + c) \right\}, \\ I_7 &= -\cos c \cos(bL + c), \end{split}$$

and

$$K_7 = (\alpha_1^2/b^2) \sin c \sin(bL+c)$$
.

For simplicity, Eq. (13.14) is written

 $J_7 = -(\alpha_1/b) \sin b J_A$

$$\frac{\theta_{sf}(s)}{q_{sf}(s)} = \frac{A_s}{1 + \tau_s s}, \qquad (13.15)$$

where

$${\rm A_{\,S}} \ = \ {\rm A_{7}} \, + \, {\rm B_{7}} \big({\rm C_{7}} + {\rm E_{7}} + {\rm G_{7}} + {\rm I_{7}} \big) \, , \label{eq:A_S}$$

and

$$\tau_{\rm S} = \tau_{12} \{ A_7 + B_7 (C_7 + E_7 + G_7 + I_7) \} / A_7.$$

XIV. NUMERICAL CONSTANTS, BLOCK DIAGRAM, AND ANALYTICAL RESULTS

In the analysis presented here, the prompt neutron lifetime, l^* , and the effective delayed neutron fraction, β , were assumed to be 2.7 x 10^{-5} and 0.0071, respectively. The remaining delayed neutron parameters are presented in Table 14.1.

Table 14.1

DELAYED NEUTRON PARAMETERS

i	$\lambda_{\mathbf{i}}$	$eta_{ extbf{i}}$
		
1	0.0129	0.000270
2	0.0317	0.001512
3	0.115	0.001335
4	0.311	0.002889
5	1.4	0.000909
6	3.88	0.000185

Experimentally, three cases of reactor operating modes were considered: 1) natural convection at various mean power levels; 2) forced convection (10,000 gpm) at various mean power levels; and 3) 20-MW mean power level with various forced-convection flow rates. The vessel pressure was assumed constant at 600 psi. For calculation of the forced-convection cases, a constant value of 1.5 was used for the slip ratio in the boiling channel. The flow rate of both water and steam versus boiler heat flux for the natural-convection core was calculated with the RECHOP Code (4) as shown in Fig. 14.1. The core geometry is taken from ANL-6302 (5).

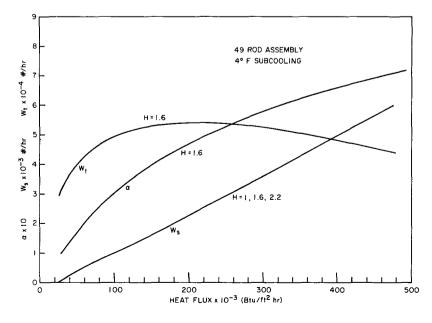

Fig. 14.1. Calculated Results for Various Natural-convection Flow Rates

Figure 14.2 is the resulting block diagram for the reactor system analyzed in this report, where α_1 , α_2 , and α_3 are the local-to-average power generation ratios in the inner boiler core, the outer boiler core, and the superheater core, respectively. Table 14.2 lists the physical constants used in the transfer functions derived above.

CONCLUSIONS

From Figs. 14.3 to 14.8, the analytical results show that BORAX-V, with a central superheater core, has the following characteristics:

- 1. In natural-convection cooling, the resonance frequency is highly dependent on the power level; for forced-convection cooling, the resonant frequency varies less with power than with flow rate. Usually the resonance frequency of a boiling reactor depends on the void transit time, so that the above result should be expected.
- 2. Increases in void coefficient tend to decrease stability. Since the resonance is caused by bubble formation lags in the feedback, this result was also expected before analysis.
- 3. For forced-convection cooling, the values of peak gain increase with mean power level at constant circulation rate. However, for natural circulation, the peak gain does not increase monotonically with power as it does in forced convection. The results show, for example, that the 5-MW peak is higher than that at 10 MW, while for power levels greater than 10 MW, the peak gain for the natural-convection case increases with power. The latter can be explained by the following effects:
- (a) Figure 14.1 shows that the steady-state water-circulation rate decreases very rapidly as the steady-state power is decreased below 10 MW. The assumed extrapolation shows that slip ratio also decreases with decreasing power level. For example, the water circulation rate at 5 MW is less than half the value at 10 MW. Similarly, the values of slip ratio at 5 and 10 MW are calculated (extrapolated) to be 1.4 and 2.0, respectively. For the above reasons, the power-void, power-boiling boundary, and the boiling boundary-void transfer functions are nearly identical in the range from 5 to 10 MW.
- (b) The part of the feedback loop that is affected, however, as power is increased from 5 to 10 MW is composed of the following two parts: (1) the pressure-boiling boundary transfer function, and (2) the boiling boundary-void transfer function. The product of the above two transfer functions was found to have a much larger gain and somewhat higher phase lag at 5 MW than at 10 MW. Thus, the indicated effects of power level on peak gain of the overall transfer function at the lower power levels for the natural convection case can be summarized as follows: The dynamic results depend heavily on the steady-state model assumed. It is admitted that the calculated steady-state results had to be extrapolated at the lower power levels (below 10 MW), which gave rise to the effects described above.

- 4. In forced-convection cooling, the coolant flow rate is one of the important factors for stability. A decrease in coolant flow rate tends to decrease stability.
- 5. The values of peak gain at high-power operation are not too different from the cases of natural-convection cooling and 10,000 gpm forced-convection cooling at equal power levels. The reason for this can be explained as follows:

For the analysis of forced-convection cooling, the calculated slip ratio is assumed to be smaller than the calculated slip ratio for natural convection at high power levels. Hence, in this analysis, the void volume inside the core is not too different from natural-convection cooling and 10,000-gpm, forced-convection cooling. The water-flow velocity for 10,000-gpm, forced convection is thus larger than that for natural convection

In the analysis, the effects due to the small differences in the void volume in the core and the large difference in the water temperature in the core cancel each other for the case of natural-convection cooling and 10,000-gpm, forced-convection cooling.

In actuality, the slip ratio is not constant for forced convection, but may increase with operating power. The resonance peak value would thus decrease, and resonance frequency would increase when compared with the analytical results for the case of 10,000-gpm, forced convection presented herein.

The object of this analysis was to estimate the stability of BORAX-V with a central superheater core before actual operation. Analytical results show that BORAX-V with a central superheater core will have stable characteristics under the designed operating conditions of power, pressure, and flow.
