ABSTRACT

High-speed switching properties of the emitter-coupled transistor-pair are analyzed by means of a digital computer. Waveforms and risetimes are computed for a wide range of parameters. The resulting risetimes are interpreted in terms of the gain-bandwidth products of the transistors, external capacitances, and the risetime of the input signal.

LEGAL NOTICE

This report was prepared as an account of Government sponsored work. Neither the United States, nor the Commission, nor any person acting on behalf of the Commission:

A. Makes any warranty or representation, expressed or implied, with respect to the accuracy, completeness, or usefulness of the information contained in this report, or that the use of any information, apparatus, method, or process disclosed in this report may not infringe privately owned rights; or

B. Assumes any liabilities with respect to the use of, or for damages resulting from the use of any information, apparatus, method, or process disclosed in this report.

As used in the above, "person acting on behalf of the Commission" includes any employee or contractor of the Commission, or employee of such contractor, to the extent that such employee or contractor of the Commission, or employee of such contractor prepares, disseminates, or provides access to, any information pursuant to his employment or contract with the Commission, or his employment with such contractor.

III. Results	4

I. INTRODUCTION

The emitter-coupled transistor pair of Fig. 1 has found many uses in high-speed switching circuits. When components are suitably chosen, the transistors do not saturate and switching times in the nanosecond region are readily attainable. There are many variations of the circuit: Both bases may be driven, one of the two collector resistors, R_{C1} or R_{C2} , may be omitted, current source Q_3 may be replaced by a resistor.

In the following it will be assumed that the circuit of Fig. 2 provides a reasonable approximation to the actual circuit. Transistors Q_1 and Q_2 are characterized by a single fixed parameter $\tau_0 \triangleq 1/(2\pi f_\tau)$ where f_τ is the gain-bandwidth product of both transistors, ohmic base resistances are included in R_g , and all capacitances are lumped into C_{ext} . This approximation is reasonably good if one has the circuit of Fig. 1 with $R_{C1} = 0$: In this case R_{C1} of Fig. 2 is chosen zero and the stray capacitance on the base of Q_1 and its collector-to-base capacitance are included in C_{ext} .

II. COMPUTATION OF THE TRANSIENT

The collector current $i_{C1}(t)$ will be computed for the generator voltage signal $v_g(t)$ of Fig. 3. The hybrid equivalent circuit of Fig. 4 will be used for each transistor with $\alpha \approx 1$, i. e., $\beta \rightarrow \infty$. With these assumptions the circuit shown in Fig. 5 results. It can be seen that the circuit enclosed in the box of broken lines is grounded only via R_B , hence the value and location of R_B is arbitrary; in the following an $R_B = \infty$ will be taken. Also, observing the nodes at B_1 and B_2 it is apparent that all of i_{B1} flows into C_{e1} and all of i_{B2} into C_{e2} . Thus, Fig. 5 can be redrawn as Fig. 6 where C_{ext} has been included in C_{e1} and C_{e2} .

Now, the transient of the circuit can be computed solely from the loop of v_g , R_g , C_{e1} and C_{e2} .

Defining

$$v_{B1E} \triangleq v_{B1} - v_E \quad (1)$$

and

$$v_{B2E} \triangleq v_{B2} - v_E \quad (2)$$

the collector currents are given by the diode equations as

$$i_{C1} = I_0(e^{v_{B1E}/V_T} - 1) \quad (3)$$

and

$$i_{C2} = I_0(e^{v_{B2E}/V_T} - 1), \quad (4)$$

where

$$i_{C1} + i_{C2} = I_{DC}. \quad (5)$$

Here I_0 is the saturation current (in the vicinity of nanoamperes); $V_T = n \frac{kT}{q}$,

where k is the Boltzmann constant $k = 1.38 \times 10^{-23}$ Ws/ $^{\circ}$ K, T is the absolute temperature in $^{\circ}$ K, and q is the charge of the electron $q = 1.6 \times 10^{-19}$ As.

Constant n is dimensionless, $n \approx 1$ to 1.5 for germanium, $n \approx 1.5$ to 2 for silicon diodes.

The value of kT/q at room temperature is ≈ 25 mV, thus V_T is typically between 25 mV and 50 mV.

Capacitances C_{e1} and C_{e2} are given by

$$C_{e1} \triangleq \frac{dq_{B1E}}{dv_{B1E}} = \frac{d(i_{C1}\tau_0)}{dv_{B1E}} = \frac{\tau_0}{V_T} I_0 e^{v_{B1E}/V_T} \quad (6)$$

and

$$C_{e2} \triangleq \frac{dq_{B2E}}{dv_{B2E}} = \frac{d(i_{C2}\tau_0)}{dv_{B2E}} = \frac{\tau_0}{V_T} I_0 e^{v_{B2E}/V_T}. \quad (7)$$

Also

$$C_{e1}' = C_{e1} + C_{ext} \frac{C_{e1} + C_{e2}}{C_{e2}}, \quad (8)$$

$$C_{e2}' = C_{e2} + C_{ext} \frac{C_{e1} + C_{e2}}{C_{e1}}, \quad (9)$$

and

$$i_{B1} = \frac{v_g + v_{B2E} - v_{B1E}}{R_g}. \quad (10)$$

The base-emitter voltages are given by the integrals

$$v_{B1E} = \int \frac{i_{B1}}{C_{e1}} dt \quad (11)$$

and

$$v_{B2E} = \int \frac{i_{B2}}{C_{e2}} dt = - \int \frac{i_{B1}}{C_{e2}} dt. \quad (12)$$

Unfortunately i_{B1} , C_{e1} , and C_{e2} vary with time and the integrals have to be evaluated numerically. Equation (11) can be approximated as

$$v_{B1E} = \int \frac{i_{B1}}{C_{e1}} dt \approx \sum \frac{i_{B1}}{C_{e1}} \Delta t,$$

which can be also written as

$$v_{B1E}(t + \Delta t) \approx v_{B1E}(t) + \Delta v_1, \quad (13)$$

where

$$\Delta v_1 \triangleq \frac{i_{B1}(t)}{C_{e1}(t)} \Delta t. \quad (14)$$

Similarly (12) becomes

$$v_{B2E}(t + \Delta t) \approx v_{B2E}(t) + \Delta v_2, \quad (15)$$

with

$$\Delta v_2 \triangleq \frac{-i_{B1}(t)}{C_{e2}(t)} \Delta t. \quad (16)$$

The initial values of v_{B1E} and v_{B2E} can be computed from (3), (4), and (5) as

$$v_{B1E}(t = 0) = v_g(t < 0) + V_T \ln \frac{2 + I_{DC}/I_0}{1 + e^{v_g(t < 0)/V_T}} \quad (17)$$

$$v_{B2E}(t = 0) = V_T \ln \frac{2 + I_{DC}/I_0}{1 + e^{v_g(t < 0)/V_T}} \quad (18)$$

and i_{C1} can be computed by substituting (17) into (3).

Equations (3), (8), (9), (10), (13) and (15) are solved by a digital computer using the flow chart of Fig. 7 with $\Delta t_{\max} = 0.01 \tau_0$, $\Delta t_{\min} = 10^{-5} \tau_0$, and $\Delta v_{\max} = 0.01 V_T$. The Fortran IV computer programs are shown in Fig. 10, 11, and 12.

III. RESULTS

Representative waveforms of $i_{C1}(t)$ are shown in Fig. 8 and Fig. 9. The risetimes between the 10% and 90% points of i_{C1}/I_{DC} are summarized in Table 1, together with those obtained from the approximation

$$t_r \approx \sqrt{(t_{rT} + t_{rc})^2 + t_{rg}^2}, \quad (19)$$

where

$$t_{rT} \triangleq 0.8 \frac{R_g I_{DC}}{v_{g1} - 0.4 V_T} \tau_0, \quad (20)$$

$$t_{rc} \triangleq \frac{V_T^2 \ln 9}{v_{g1} - 0.8 V_T} R_g C_{\text{ext}}, \quad (21)$$

and

$$t_{rg} \triangleq \frac{V_T^2 \ln 9}{v_{g1} - v_{g0}} t_g. \quad (22)$$

There are three contributions to the risetime: 1), t_{rT} of (20) results from a finite τ_0 (finite gain - bandwidth product), 2), t_{rc} of (21) results from the finite C_{ext} , and 3), t_{rg} of (22) from the finite risetime t_g of the input signal.

1), t_{rt} . In the limiting case when C_{ext} and t_g are zero, the risetime is given by (20). For $v_{g1} \gg V_T$ this is the current gain $R_g I_{DC} / v_{g1}$ multiplied by τ_0 and by a factor of 0.8 for a risetime computed between 10% and 90%. The term $0.4 V_T \approx 20 \text{ mV}$ in the denominator of (20) represents a voltage "used up" for dc switching, which has to be taken account if $v_{g1} \gg V_T$.

2), t_{rc} . In addition to the charge $I_{DC} \tau_0$ in the base emitter junction, the source has to provide a charge into capacitor C_{ext} which results in the risetime t_{rc} of (21). The dc voltage swing on the bases between the 10% and 90% points of i_{C1} (from (3), (4), and (5) with $i_{C1} \gg I_0$ and $i_{C2} \gg I_0$) is $\approx V_T 2 \ln 9$. Assuming a voltage of $0.8 V_T$ "lost" from v_{g1} for dc current transfer, t_{rc} represents the charge supplied to C_{ext} during a voltage swing of $V_T 2 \ln 9$.

3), t_{rg} . Equation (22) represents the risetime of the input waveform during the voltage swing of $V_T 2 \ln 9$. Since this risetime t_{rg} is independent of that of the circuit, $t_{rt} + t_{rc}$, the squares of the two risetimes are added in (19).

As can be seen in Table 1, Eq. (19) provides a rather good approximation, therefore it can be utilized to obtain risetimes for parameter values not listed in the table.

TABLE 1

10% to 90% risetime of i_{C1} for various values of v_{g0} , v_{g1} , R_g , C_{ext} , and t_g , using the flow-chart of Fig. 7 ("EXACT"), and the approximation of Eq. (19) ("APPROX"). Legend: $R = R_g I_{DC} / V_T$, $C = C_{ext} V_T / \tau_0 I_{DC}$.

$\frac{-v_{go}}{v_T}$	$\frac{v_{gl}}{v_T}$	R	C	$t_g/\tau_o = 0$		$t_g/\tau_o = 0.5$		$t_g/\tau_o = 1$		$t_g/\tau_o = 2$		$t_g/\tau_o = 5$		$t_g/\tau_o = 10$		$t_g/\tau_o = 20$		$t_g/\tau_o = 50$		$t_g/\tau_o = 100$
