1.1. Program Abstract

1.1.1. Program: DOS: The Discrete Ordinates System

1.1.2. Problem Solved: The Discrete Ordinates System determines the flux of neutrons or photons due either to fixed sources specified by the user or to sources generated by particle interaction with the problem materials. It also determines numerous secondary results which depend upon flux. Criticality searches can be performed. Numerous input, output, and file manipulation facilities are provided.

1.1.3. Method of Solution: The DOS driver program reads the problem specification from an input file and calls various program modules into execution as specified by the input file.

1.1.4. Related Codes and Materials: DOS includes a control driver and numerous subsystems which can be executed from it:

1. DRIVER Subsystems - Controls execution of member programs
2. DOT Subsystem - 1-D or 2-D transport calculations
3. ANISN Subsystem - 1-D transport calculations
4. DOPES Subsystem - Transport perturbation calculations
5. DOGS Subsystem - Results summaries and plotting

1.1.5. Restrictions: The order of module execution must be completely determined by the input stream in the present configuration. No run-time decision-making or user intervention is provided. The program modules must reside as executable load modules in a PDS.

1.1.6. Computers: While many of the modules are individually operable on various types of computers, the system is operable as a whole only on IBM 370/3033 or compatible computers.

1.1.7. Running Time: DOS problems require from 1 second to many hours on conventional computers, depending upon the problems solved.

1.1.8. Programming Languages: DOS members are programmed in standard FORTRAN, insofar as possible. In several instances, optional assembler-language routines enhance program capability or convenience.

1.1.9. Operating System: No special requirements for these codes except for the DOS driver. The driver presently operates only under IBM MVS/JES2 or compatible systems.

1.1.10. Machine Requirements: Useful problems can be solved in 270 K-bytes of memory on a machine having at least the capability of the IBM 370/3033.

1.1.11. Authors or major contributors: Noted by subsection.

1.1.12. References:

1. W. A. Rhoades and M. B. Emmett, "DOS: The Discrete Ordinates System," ORNL/TM-8362 (August 1982).

1.1.13. Material Available: User's document and source programs are available through RSIC, Box X, Oak Ridge, TN, 37830.

1.1.14. Abstract Prepared By: W. A. Rhoades

1.2. Background

The range and complexity of tasks performed by modern nuclear codes have lead to the adoption of the "code system" concept. To avoid the construction of a single mammoth code to perform such a range of tasks, semi-independent codes are linked together in one way or another. Since these can be developed and tested independently, programming costs are minimized. New "modules," as the system components are called, can be added to the system even though they have not been developed specifically for that use.

The DOS system consists of a family of interrelated codes which solve radiation transport problems, and which can be executed under control of a single driver. Redundant input data specifications are reduced. Interface files which transmit data from code to code are standardized and compatible, insofar as funding and personnel availability permit.

1.3. User Information

1.3.1. Subsystems and Modules

The various modules comprising DOS are grouped into subsystems. In general, each subsystem is operable separately, is distributed independently, and is under separate configuration management. All can be operated as a single unit under the DOS DRIVER. The subsystems are:

1. DRIVER Subsystem - Controls reading and parceling of input data; directs execution of other modules.

2. DOT Subsystem - Includes the DOT 4 1-D and 2-D neutron/photon transport code and several peripheral modules which process input and output for it.
3. ANISN Subsystem - 1-D neutron photon calculations, like DOT 4, but, perhaps, simpler to use.
4. DOPES Subsystem - Performs detailed perturbation calculations based upon DOT output.
5. DOGS Subsystem - Performs summaries and plots of DOT output.

The modules are listed in Table 1.1.

1.3.2. Method of Operation

The general operation of the system is illustrated in Fig. 1.1. The user prepares an input stream as illustrated in Figs. 1.2 and 1.3. The DOS procedure illustrated may be stored in the system procedure library. The data stream consists of control cards containing the symbol "=" and the program module name. The data for each module follows the control card for that module. An "=END" card terminates the input stream. The DOS driver executes the modules in the order indicated.

1.4. Programmer Information

1.4.1. Requirements for Program Module Compatibility

Extensive interface standardization and redundancy avoidance is obviously helpful, but a minimum set of requirements is sufficient to allow modules to be executed together:

1. The program modules must be stored as executable load modules in the data set containing the driver or in a PDS which can be concatenated to the driver PDS.

2. The program modules must finish with a condition code of 0 unless an error has been encountered.

3. Any main storage allocation must be deallocated.

4. Any direct-access data sets must be closed.

5. The following logical unit requirements must be met:

1-4,8 sequential scratch, defined by the procedure

5 card-image input for individual program modules

6,90 printed output stream

7 card-image output

9-80 user-defined (optional)

81-89,91-97 scratch files¹

98-99 scratch for driver program

6. When a module uses two printout files, it is intended that 6 be the small-scale file and that 90 be a large-scale file for microfiche processing, etc.

1.4.2. Other Capability and Limitations

In the present system, the execution procedure is explicitly determined by the input stream. Since all of the control logic is contained in a FORTRAN subroutine, DOS could easily be extended to allow the execution

Table 1.1. DOS Member Modules

Notes*	Subsystem	Module	Description
1	DRIVER	DRIVER	Initiates execution of modules as directed by CONTROL module.
		CONTROL	Reads input data, parcels problem descriptions for the various modules, signals DRIVER module to initiate execution of each member module as required.
1,2	DOT	DOT 4	Solves radiation transport problems in 1-D or 2-D using discrete ordinates or diffusion theory.
		GIP	Pre-processes cross section input for use by DOT or GIP.
		RTFLUM	Converts between various flux file formats, especially VARFLUM and ISOTXS. Lists or expands flux files.
		BNDRYS	Reformats internal boundary flux files for use as internal boundary sources.
3	ANISN	ANISN	Solves 1-D transport problems using discrete ordinates or diffusion theory.
1,4	DOPES	VIP	Performs spatial forward-adjoint folding. Allows grouping of intervals into regions.
		TPERT	Evaluates reactivity changes based on VIP results.
		DGRAD	Calculates currents required by VIP using DOT scalar diffusion-theory fluxes as input.
5	DOGS	EGAD	Geometry display.
		ISOFL0T4	Contour plots of 2-D fluxes.
		FORM	Surface plots of 2-D fluxes.
		ACTUAL	Activity calculations.
		TOOTH	Contribution calculation and plotting.
		ASPECT	Energy spectrum plotting.

*Notes:

1. Modules are described in later sections of this document.
2. A fuller treatment of DOT 4 is given in Reference 1.
3. A fuller treatment of ANISN is given in Reference 2.
4. A fuller treatment of DOPES is given in Reference 3.
5. A fuller treatment of DOGS is given in Reference 4.

path to be decided based upon previous module results. This would, for example, allow iteration between modules. Funds for such an application have not been identified, however.

The driver subsystem is inherently machine-dependent. The existing driver is operable only on IBM computers. A similar driver could probably be constructed for CDC systems.

1.4.3. Relationship to Other Systems

Subsequent to the development of the DOS driver program, a similar driver was developed for use with the SCALE system,⁵ and the modules of the DOS system are operable under the SCALE driver, providing compatible JCL is provided.

1.1. Program Abstract

1.1.1. Program: The DOS Driver Program

1.1.2. Problem Solved: The DOS driver program initiates the execution of one or more program modules in a sequence specified in the user-prepared input stream.

1.1.3. Method of Solution: The resident driver initially calls a control module, passing a resident block of control information. The control module scans the input stream to identify the first module to be executed, and to isolate the input data for that module. The resident driver then initiates execution of the indicated program module. The control module is recalled after each program module for determination of the next execution segment.

1.1.4. Related Codes and Materials: A separate document describes the DOS system and its program modules.

1.1.5. Restrictions: A few restrictions on the JCL available to members are listed in the DOS documentation.

1.1.6. Computer: An IBM-compatible system is required for the driver.

1.1.7. Running Time: The driver program, itself, requires much less than a second of CPU time.

1.1.8. Programming Languages: IBM FORTRAN IV and 360/370 assembler language are used.

1.1.9. Operating System: DOS driver presently operates under a standard IBM MVS system.

1.1.10. Machine Requirements: No special requirements are applicable.

1.1.11. Authors or Major Contributors:

D. B. Simpson, TVA, Knoxville, TN

W. A. Rhoades, ORNL, Oak Ridge, TN

L. M. Petrie, Union Carbide Nuclear Division, Oak Ridge, TN

P. K. Erickson

1.1.12. References:

1. W. A. Rhoades and M. B. Emmett, "DOS: The Discrete Ordinates System," ORNL/TM-8362 (August 1982).

1.1.13. Abstract Prepared By: W. A. Rhoades

1.2. Background

The DOS driver program allows several program modules to be executed within a single job step. Data are communicated between a resident "DRIVER" module and the subordinate modules through data files defined in DD statements, and through a small array of control data resident in the driver. Only the driver and this control array are in memory at all times.

1.3. User Information

The execution sequence is controlled by cards containing the symbol "=" and the name of the desired modules. A module called "CONTROL" is executed at the beginning of each DOS job. CONTROL moves data from the input stream (FT99F001) to a scratch file (FT98F001) and edits it. The first program module is determined from the first card, the proper data cards for that module are copied to FT05F001, and the execution is returned to the driver.

The driver initiates the desired program module and, upon completion of the program, recalls the control module. The condition code is checked after each module execution. A non-zero code results in termination of the processing. Upon recall, CONTROL identifies the next program module from the input stream and repeats the process until an "=END" card is encountered. The control module then signals the driver to end the execution.

1.4. Programmer Information

1.4.1. Driver Loading

The driver program consists of two load modules:

1. A resident "DRIVER" program, a single main program written in assembler language, initiates the subordinate modules and terminates execution.

2. A non-resident "CONTROL" program consisting of a main program named "BRAIN" plus a subroutine named "CONTRL" processes all decision making and preparation of input segments for the program modules. The sole function of BRAIN is to link the resident block of control information to CONTROL. BRAIN must be marked as the entry point.

1.4.2. Program Module Loading

Program modules may be loaded as executable load modules into the PDS containing the driver load modules, or they may be contained in a PDS concatenated to the DRIVER PDS in the STEPLIB DD statement.

1.4.3. Use of the Control Array by Other Programs

Other programs may access and use portions of the resident control array not reserved for the driver. Such programs must have BRAIN as their main program. BRAIN will then call a subroutine named CONTRL with the resident array as an argument. The user may construct a subroutine named CONTRL for his program to control subsequent execution. The contents of the resident array are specified in Appendix 1.A.

APPENDIX 1.A. Contents of the Resident Control Array

A(1) = 1st Word of Name of Next Module to Call (Preset to '\$\$\$\$')
A(2) = 2nd Word of Name of Next Module to Call (Preset to Length of
an Array)
A(3) = Number of Entries to CONTRL

Section 2. BNDYRS: Boundary Source File Manipulation Program

M. B. Emmett*

*Computer Sciences Division.

THIS PAGE
WAS INTENTIONALLY
LEFT BLANK

2.1. Program Abstract

2.1.1. Program: BNDRYS - Internal Boundary Source Code

2.1.2. Problem Solved: BNDRYS reformats an internal boundary flux file provided in the BNDRYS format,¹ producing an internal boundary source file, also in the BNDRYS format, for use in a subsequent calculation.

2.1.3. Method of Solution: BNDRYS selects the appropriate flux sets from a potentially larger collection in the input file. In the case of I-boundary sets, either rightward or leftward fluxes are retained, with the others set to 0. For J-boundary sets, either upward or downward fluxes are retained. The fluxes are multiplied by user-supplied rescaling factors and padded with 0's at both ends as specified. A set of fluxes can also be reflected to make a mirror image. The resulting fluxes are then moved to an output file in BNDRYS format.

BNDRYS allows flux emerging from a reactor core to be determined in an initial eigenvalue problem, and then to be used as a fixed source in a subsequent reflector, vessel, and shield problem. The core can be completely internal to the second problem. For accuracy, the core material is replaced with a highly absorbent material in such a problem.

2.1.4. Related Codes and Materials: The DOT code¹ prepares input files for BNDRYS, and uses the output files.

2.1.5. Restrictions: None.

2.1.6. Computers: Although the BNDRYS codes should be adaptable to many types of computers, only IBM 360/370 and CRAY operation have been demonstrated.

2.1.7. Running Time: BNDRYS problems require only a few seconds of CPU time.

2.1.8. Programming Languages: BNDRYS is programmed in standard FORTRAN, insofar as possible. Certain optional IBM assembler-language routines which enhance program capability or convenience are provided.

2.1.9. Operating System: BNDRYS presently operates under IBM MVS/JES2 or CRAY CTSS.

2.1.10. Machine Requirements: Useful problems can be solved in 270 K-bytes of memory on a machine having at least the capability of the IBM 360/75.

2.1.11. Authors or major contributors:

M. B. Emmett, Union Carbide Nuclear Division, Oak Ridge, TN.

2.1.12. References:

1. W. A. Rhoades et al., "The DOT IV Two-Dimensional Discrete-Ordinates Transport Code with Space-Dependent Mesh and Quadrature," ORNL/TM-6529 (January 1979).
2. W. A. Rhoades and M. B. Emmett, "DOS: The Discrete Ordinates System," ORNL/TM-8362 (August 1982).

2.2. Background

BNDRYS is a computer code which restructures and reformats data for use as an internal boundary condition. Its typical use is in coupling a core eigenvalue solution to a large shield problem.

2.3. User Information

2.3.1. Card-Image Input Specifications

Following the title card, all data are read using the FIDO Input system,¹ and familiarity with that system is assumed. Data arrays are entered in blocks, each terminated by a "T." Unused data arrays are not entered, but a T must be entered to signal the termination of each block, in any case. The data ordering is illustrated in Fig. 2.1.

2.3.2. Input File Specification

The input file is an external boundary flux file in the BNDRYS format.¹

2.3.3. Output File Specification

The output file is an internal boundary source file that has been reformatted so that the I-directional source array contains MMA*JM *NINTFX values and the J-directional source array contains MMA*IM *NJNTEFX values.

2.3.4. Logical Unit Requirements

Logical unit 71 - default - Input BNDRYS file

Logical unit 72 - default - output file

Logical unit 5 - card input

Logical unit 6 - printed output

The first two unit numbers are overridden if NTIB1 and NTIB0 are defined in the 1\$ array.

2.4. Programmer Information

See Section 5.

3.1. Program Abstract

3.1.1. Program: GIP: Group-Organized Cross Section Input Program

3.1.2. Problem Solved: GIP accepts nuclide-organized microscopic cross section data either from the input stream in card-image format or from a data library prepared by the ALC1 program.¹ GIP prepares a group-organized file of microscopic and/or macroscopic cross sections for use by DOT,² ANISN,³ or related codes. Adjoint cross sections can be prepared. The total upscatter cross section can be inserted into the data format as required by DOT and ANISN.

3.1.3. Method of Solution: A simple sequential file sorting technique is used. Macroscopic data are specified by a "mixing table" similar to that of DOT.

3.1.4. Related Codes and Materials: See references.

Reference 2 gives a complete definition of the output file format.

3.1.5. Restrictions: The sorting procedure is well suited to problems where the total volume of cross section data to be processed is, for example, 3 or 4 times the available data storage space. If very large problems must be solved on small computers, a random-access program may be more efficient.

Complex library formats such as ISOTXS⁴ are beyond the scope of GIP.

3.1.6. Computers: GIP has performed well on many types of IBM, Amdahl CDC, CRAY, and UNIVAC computers.

3.1.7. Running Time: Most GIP problems require much less than a minute of IBM 360/91 CPU time.

3.1.8. Programming Languages: GIP can be operated entirely in standard FORTRAN. On IBM computers, optional assembler-language programs provide enhanced convenience.

3.1.9. Operating System: No special requirements.

3.1.10. Machine Requirements: Provisions must be made for:

- standard input and output files on 5 and 6
- sequential scratch files on logical units 1-4
- output file on logical unit 8
- input library file, if any, on logical unit 9

3.1.13. Abstract Prepared By: W. A. Rhoades

3.2. General Description

3.2.1. Background

GIP accepts nuclide-organized microscopic cross-section data either from the input stream in card-image format or from a data library prepared by the ALC1 program.¹ Macroscopic cross-section mixtures can be prepared as specified by a mixing table similar to that of DOT.² The total upscatter cross section can be calculated and inserted into the set. The result is a "GIP" cross section file as defined in Reference 2. Microscopic and/or macroscopic data can be output to the file and/or printed.

The chief virtues of GIP are its extreme simplicity and its high compatibility with DOT, ANISN,³ and related codes. It is operable on virtually any type of computer which provides sequential scratch files. It uses the FIDO card-image input processor, and shares many subroutines with DOT. Its major disadvantages are the inability to translate complex input files such as ISOTXS⁴ and its inefficiency for very large problems.

GIP treats each component of a Legendre expansion as a separate nuclide. This was seen as a requirement in the 1960's, when the code originated. Although certain features of the mixing table expedite the mixing of PL sets, there is little doubt that the code would be more convenient for present-day problems if all of the components were treated as a unit.

3.2.2. Method Used

The cross sections specified by the input stream are selected, and the number of energy groups which can be processed at one time is decided. The

groups for one corefull are selected as each nuclide is read, and dumped onto a source file. The remaining groups, if any, are written to a holding file. When all nuclides have been located, the data are read from the source file into core and written in group-ordered format onto a sorting file. A new corefull of data are then moved from the holding file to the source file, and then to the sorting file as before. Unprocessed groups, if any, are spilled to a second holding file, which is processed as was the first holding file. This sequence continues until all groups have been processed. It happens that one group of data can be written directly to the sorting file each time that the source file is loaded, and this improves efficiency somewhat. In the final step, the group-organized data are read, mixed, edited, and moved to the output file.

The advantages of this system are that it can process a cross section volume of several corefulls with inconsequential cost, using only sequential files, and that it is easily adapted to new computing environments. Unfortunately, if the cross section volume increases to, for example, 10 or more corefulls, the sorting process becomes inefficient.

This method originated with W. W. Engle, Jr., in a program called TAPEMAKER, which was operated on the IBM 7090 before the days of random access files. The basic procedure has changed little since then.

3.3. User Information

3.3.1. Card-Image Input Specifications

Following the title card, all data are read using the FIDO input system,² and familiarity with that system is assumed. Data arrays are entered

In blocks, each terminated by a "T." Unused data arrays (e.g. 10\$ if MS=0) are not entered, but a T must be entered to signal the termination of each block, in any case. The data ordering is illustrated in Fig. 3.1.

The input of the 14* array is performed by subroutines which have certain restrictions in addition to those of normal FIDO input:

- a. The nuclide spaces are preset to 0.0, so that "E" or "F0" will have the effect of filling the remaining space with 0.0, but "E" and "F" must not be used in the input for the last nuclide.
- b. The 14* or 14** designation may precede each nuclide block, but is not required except in the first block.
- c. Entries, including operators such as "T," following the last data item for nuclides other than the last, and on the same card as the last item, will be ignored.
- d. The T which terminates this block must appear alone in column 3 of a separate card.

The mixing table is prepared as described for the DOT code,² and the meaning of items 1-8 of the 1\$ array are compatible with DOT. NBUF must allow buffer space for the data sets which are listed below. As with DOT, the integers in the mixing table refer to a continuous array of MTM cross section sets, of which the first MCR+MTP are nuclide data read from card-image input and library file, respectively. All of the sets beyond MCR+MTP are preset to 0 before the mixing table is executed. Reference to eigenvalue modification in the DOT description has no application to GIP mixing.

For most DOT problems, I/O manipulation can be reduced by asking for output of only the mixtures from GIP. They are then referred to in DOT such that material 1 is the first GIP mixture, etc. Any microscopic data to be used in DOT activity edits must be included as a mixture, as must nuclides whose concentrations are to be modified in a search.

Multiple problems can be stacked in succession with a blank card between cases. No input data are saved between cases.

3.3.2. Special Diffusion Theory Option

If the cross section set contains a transport cross section in position N, then setting ISCT=-N causes the total cross section to be replaced by the transport cross section and the self-scatter cross section (position IHS) to be reduced such as to maintain a constant absorption cross section. The resulting cross section set is suitable for use in a P0 DOT calculation, especially one using the diffusion package. Negative entries in the 10\$ array must not be used with this option.

3.3.3. Upscatter

If $IHS > IHT + 1$, the upscatter processor calculates the total upscattering cross section from each group and places it in the appropriate table position. No user action is required.

3.3.4. Adjoint

If ITH=1, two major reordering steps are accomplished:

1. The Inscatter matrix is transposed, i.e. the table position associated with group g describing scattering from g' to g is changed to describe scattering from g to g' .
2. The ordering of the groups is reversed, i.e. data for group IGM appear first in the output file, followed by IGM-1, etc.

Figure 3.2 shows the results of this reordering.

3.3.5. Input Library Format

The input library format from which MTP nuclides are taken is defined in Appendix 3.A.

3.3.6. Output File

The output file is in GIP format.² If IOUT=0, the output includes MCR+MTP microscopic cross sections, plus (MTM-MCR-MTP) mixtures. If IOUT=2, only the mixtures will be output. Printed cross section edits are similarly controlled by IPRT.

3.3.7. Logical Unit Requirements

Logical Unit 1 -	}	Scratch, should be blocked for efficiency
Logical Unit 2 -		
Logical Unit 3 -		
Logical Unit 4 -		
Logical Unit 9 -		Tape Input
Logical Unit 8 -		Tape Output
Logical Unit 6 -		Printed Output
Logical Unit 5 -		Card Input

Logical unit assignments for the first 6 data files can be modified by altering locations 15-20 of the 1\$ array to the new logical unit numbers.

The new values will not be listed in the input edit, however.

3.4. Programmer Information

See Section 5.

Section 4. RTFLUM: A Module for Converting, Expanding, and Editing
Standard Data Files

W. A. Rhoades

THIS PAGE
WAS INTENTIONALLY
LEFT BLANK

4.1. Program Abstract

4.1.1. Program: RTFLUM: A Module for Converting, Expanding, and Editing Standard Data Files.

4.1.2. Problem Solved: RTFLUM provides conversion between flux moment files in the DOTIII,¹ VARFLM,² or RTFLUX³ formats. Scalar flux, flux moments, and/or boundary fluxes can be edited by user option.

4.1.3. Method of Solution: Reformatting is done in-core. Essential data required by the output file but absent from the input file must be supplied in the input stream by the user. Default values of unessential data are supplied by the code.

4.1.4. Related Codes and Materials: See references.

4.1.5. Restrictions: None.

4.1.6. Computers: RTFLUM has performed well on many types of IBM, Amdahl, CDC, and CRAY computers.

4.1.7. Running Time: Most RTFLUM problems require much less than a minute of IBM 360/91 CPU time.

4.1.8. Programming Languages: RTFLUM can be operated entirely in standard FORTRAN. On IBM computers, optional assembler-language programs provide enhanced convenience.

4.1.9. Operating System: No special requirements.

4.1.10. Machine Requirements: Provisions must be made for:
standard input and output files on 5 and 6
Input and output files on units specified by the user

4.1.11. Authors or Major Contributors:

4.1.13. Abstract Prepared By: W. A. Rhoades.

4.2. General Description

4.2.1. Background

The ERDA/RDD Physics Branch Committee on Computer Code Coordination (CCCC) has specified the RTFLUX file format for expressing double-precision scalar, fixed-mesh flux data (LA-5486-MS). This file is produced by VENTURE and certain other codes. The file contains certain identification information, followed by scalar flux for each group, with the first two space dimensions blocked together.

This file was not suitable for DOT IV application. A new single-precision file format, VARFLM, includes flux moments, accommodates an irregular mesh, and includes boundary directional fluxes required for an accurate restart. It also has enough identification to relate the file uniquely to the job which produced it, and has provision for enough mesh information to allow automatic plotting and processing without reference to geometry files. It is blocked as required by row-oriented codes.

A third format in wide use is the "scalar flux tape" produced by DOT III and used by many related plotting, perturbation, and processing codes (ORNL/TM-4280).

The RTFLUM program offers a simple means of editing these various files and of converting from one format to another. This allows VENTURE data to be used as a DOT IV starting guess, or to be plotted with a DOT III plotting code, for example. In addition, provision is made to expand the number of moments or directions implied, so that a low-order output can be used to

start a high-order input. In solving large, deep-penetration problems, a file may often be left incomplete, due to premature problem termination. RTFLUM can repair such output, also.

4.2.2. Application

RTFLUM requires only input and output file definition. If no output file is desired, a dummy is to be supplied. The input data are supplied in FIDO format as used by DOT IV. Two blocks of data are required. The first contains control arrays 1\$\$ and 2** as listed in the sample problem output, followed by "T." The second block requires only "T" for present applications.

Certain defaults minimize the input requirements, as indicated in the output listing. If a VARFLM file is used as input, the default values of MM, ISCAT, IGM, IM, JM, ISCAI, MMI, and IGMI will be replaced by data from the file. Default values for data beyond IGMI will suffice for many applications.

If RTFLUX is used, MM and ISCAT are assumed to be 6 and 0.

If a DOT III scalar flux tape is used as input, MM, ISCAT, IGM, IM, and JM must be supplied as input. The default values of ISCAI, MMI, and IGMI will cause the values of ISCAT, MM, and IGM to be used.

If the input and output direction numbers are to be different, enter MM and MMI explicitly. If the moment orders are to differ, enter ISCAT and ISCAI explicitly. If the input file does not contain IGM groups of good data, enter a value for IGMI equal to the number of good groups.

The IEDIT parameter is used as follows:

IEDIT = 0	no edit of output
1	edit scalar output only
2	edit full moment expansion
10, 11, or 12	as 0, 1, or 2, but also edit boundary flux.

4.2.3. Output

The output from a job converting a VARFLM file to DOT III format is illustrated in Fig. 4.1. A set of self-explanatory input sets in Fig. 4.2 help to illustrate the use of the defaults. The output in Fig. 4.1 results from using the first input set in Fig. 4.2.

Section 5. Programmer Information for DOT Subsystem

W. A. Rhoades

THIS PAGE
WAS INTENTIONALLY
LEFT BLANK

5.1. Inter-machine Adaptability

The DOT subsystem codes are intended to be easily adaptable to any type of sophisticated computer, and yet to take advantage of certain localized structural features which may be machine-dependent.

In general, the guidelines of ANS-STD.3-1971¹ are followed. This requires general adherence to a simple, standard FORTRAN language except where deviations provide important improvements in capability and can be documented. In addition, machine-dependent features have been kept localized and have been kept away from the subroutines which perform actual computation.

The recommended procedures of the Committee on Computer Code Coordination (CCCC)^{2,3} have been followed where practical. Compliance with these standards has been incomplete where cost was prohibitive, the nature of the codes did not allow it, or the expected level of performance could not be obtained in that fashion.

Where minor machine-dependent features are required, alternate features are enclosed in pairs of 3-character "language flags." The alternative statements remain in the source program, with inappropriate sections transformed into comment statements. If the code is set up for IBM operation, for example, it might contain:

```

CIB
      ENTRY IBCDC(H,E,L,P)
CIB
CDC
C      ENTRY IBCDC
CDC

```

The corresponding CDC configuration would be:

```

CIB
C      ENTRY IBCDC(H,E,L,P)
CIB
CDC
      ENTRY IBCDC
CDC

```

All versions of a given procedure are thus available for inspection by all users. The selection of options is made by a computer program at distribution time. A listing of machine-dependent sections can also be prepared in that process.

The language flags achieve the major objective of having a single, unified source for each program which is maintained for all users. With these provisions, the basic FORTRAN programs are operable on IBM, CDC, UNIVAC, CRAY, Amdahl, and other computers, except that system-dependent service routines as specified by CCCC must be provided.

Optional packages and procedures which provide enhanced convenience are also available. The optional run-time storage allocation requires system-dependent routines. Instructions for installing these options are distributed with the source programs. All known users at this time use all of the optional enhancements available to them. Even so, the basic operation with FORTRAN routines plus the CCCC package remains available if needed.

5.2. Service Subroutines

Certain standard service subroutines are specified by the CCCC for use in reactor physics codes. The service routines used in these codes include:

TIMER	Provides timing and job identification data
REED]	Provide sequential access to data files
RITE]	
DRED]	Provide random access to data files
DRIT]	
DOPC	Provides initiating, closing, and certain repositioning of data files
CRED]	Provide block transfer of data between fast and slow memory.
CRIT]	

Many of these subroutines also call other subroutines. Many are entirely system dependent. Each configuration to be distributed contains an appropriate set of service subroutines, insofar as possible. The realities of computing environments may require local modification or substitution. The specifications given in Reference 3, together with extensive in-stream comments, provide guides for such modification.

An Updated Version of the DOT 4 One- and Two-Dimensional
Neutron/Photon Transport Code

Published as ORNL-5851 (1982)

1.1. Program: DOT 4

1.2. Problem Solved: DOT 4 determines the flux or fluence of particles throughout a one- or two-dimensional geometric system due to sources either generated as a result of particle interaction with the medium or incident upon the system from extraneous sources. The principal application is to the deep-penetration transport of neutrons and photons. Criticality (k -type and search) problems can also be solved. Numerous printed edits of the results are available, and results can be transferred to output files for subsequent analysis.

1.3. Method of Solution: The Boltzmann transport equation is solved, using either the method of discrete ordinates or the diffusion theory approximation. In the discrete ordinates method, the primary mode of operation, balance equations are solved for the flow of particles moving in a set of discrete directions in each cell of a space mesh, and in each group of a multigroup energy structure. Iterations are performed until all implicitness in the coupling of cells, directions, groups, and source regeneration has been resolved. Several methods are available to accelerate convergence. Anisotropic cross sections can be expressed in a Legendre expansion of arbitrary order. Output data sets can be used to provide an accurate restart of a previous problem or to deliver information to other codes.

Several techniques are available to remove the effects of negative fluxes caused by the finite difference approximation, and of negative scattering sources due to truncation of the cross-section expansion. The space mesh can be described such that the number of first-dimensional (1)

Intervals varies with the second dimension (j). The number of discrete directions can vary across the space mesh and with energy. Direction sets can be biased, with discrete directions concentrated such as to give fine detail to streaming phenomena.

1.4. Related Material:

Data Files

Microscopic cross-section input file

Independent source file (optional)

Flux guess input file (optional)

Flux result output files (optional)

Total source output file (optional)

Related Programs

DOS - a driver program which coordinates problem execution
(IBM only)

BNDRYS - selects boundary fluxes for subsequent use as internal
boundary sources

GIP - prepares cross-section input from card or tape input

GRTUNCL - prepares first-collision source due to a point source
in RZ geometry (on or off axis)

RTFLUM - edits flux files and converts between various file
formats

1.5. Restrictions: External force fields or non linear effects cannot be treated. Flexible dimensioning is used throughout, so that no restrictions

are imposed on individual problem parameters. Certain options, especially diffusion theory, are not compatible with variable mesh and quadrature problems.

1.6. Computers: DOT 4 is designed to be applicable to most sophisticated computers which support direct (random) access disk storage or the equivalent. It has special provisions for efficient use of a large, slow memory from which data are moved to fast memory in strings. Certain directly-addressed arrays of low usage can also be kept in slow memory, and slow memory is also used as a buffer between fast memory and certain disk files. Features which may be troublesome on new machines are restricted to replaceable packages. Proper operation has been demonstrated on many types of IBM, CDC, UNIVAC, and CRAY computers.

1.7. Running Time: Running time is roughly proportional to:

Flux work units (FWU) = number of space mesh cells x number of directions x number of energy groups x number of iterations per group.

Depending on the options chosen, a rate of one million FWU per minute on the IBM 370/3033 is typical. Thus, a very large problem with 5,000 space cells, 48 directions, 50 energy groups, 10 iterations per group, and P_3 scattering would require roughly 1 to 1.5 hours of CPU time. Execution on CDC or CRAY computers is usually faster.

1.8. Programming Languages: The standard FORTRAN described in ANS STD.3-1971 is used. The program can be operated with 100% FORTRAN, except for the subroutines necessary to implement I/O. On CRAY, CDC, and UNIVAC systems, these subroutines are obtained from the system library at load time.

On IBM systems, they are supplied with the code. On all systems, optional use of non-FORTRAN routines is provided in order to enhance convenience and speed.

1.9. Operating System: No special requirements are made of the operating system. IBM or UNIVAC overlay, CDC overlay, or CDC segmentation facilities may be used if available. The system must support direct (random) access data files.

1.10. Machine Requirements: Memory must be approximately 50,000 words for small problems. The requirement expands with problem size. External data storage must be provided for 9 scratch files, of which 5 must be direct (random) access. User-supplied input and output data files must be supplied on sequential-access devices, i.e., tapes or the equivalent.

1.11. Authors: Many persons have contributed to DOT development since 1965. Major contributors to this version are:

W. A. Rhoades

R. L. Childs

Major contributors to previous versions include:

W. W. Engle, Jr.

M. L. Gritzner

F. R. Mynatt

R. J. Rodgers

D. B. Simpson

E. T. Tomlinson

Questions concerning this code should be referred to the Radiation Shielding Information Center (RSIC), Oak Ridge National Laboratory, P. O. Box X, Oak Ridge, Tennessee 37830.

1.1. Name: ANISN

Title: A One-Dimensional Discrete Ordinates Transport Code with
Anisotropic Scattering

Auxiliary Programs: GIP - prepares cross section input

DOGS - provides graphical output

1.2. Contributors: W. W. Engle, Jr.

Oak Ridge National Laboratory

P.O. Box X

Oak Ridge, TN 37830

1.3. Language: FORTRAN IV

1.4. Nature of Problem: ANISN determines the flux of particles throughout a one-dimensional geometric system due either to sources generated by particle interactions with the medium or to sources which are independent of the system.

1.5. Method of Solution: The Boltzman transport equation is solved using the method of discrete ordinates. Space dependent rebalance using an automatic coarse mesh calculation is used to accelerate the convergence of the flux iterations.

1.6. Restrictions: External force fields and non-linear effects cannot be treated. Variable dimensioning is used in all routines so that there are no restrictions on individual problem parameters.

1.7. Typical Running Time: Running time is proportional to the number of space, angle and energy dependent fluxes which are calculated and can vary from less than a second to more than an hour on the IBM 3033 System.

1.8. Hardware Requirements: Memory must be approximately 50,000 words for a reasonable problem, expanding or contracting with problem size. Sequential scratch storage is required and input and output files must be supplied on sequential devices.

1.9. Software Requirements: The program is operable with 100% FORTRAN but the standard ORNL version uses the machine language routine ALOCAT to achieve run-time allocation of memory.

1.1. Program: DOPES: Discrete Ordinates Perturbation System

1.2. Problem Solved: The Discrete Ordinates Perturbation System can be used to perform perturbation-theory calculations using either diffusion or transport theory, and first order or exact method. It can also be used in other applications where the inner product of two fluxes is necessary, i.e., sensitivity calculations.

1.3. Method of Solution: The DGRAD module calculates cell averaged partial currents or partial flux gradients for both forward and adjoint fluxes based on the geometry, cross sections and diffusion theory flux files. The VIP module calculates zone-dependent ϕ, ϕ^* tables for use in perturbation analyses for either regular and uncollided flux files using either transport-theory fluxes (with flux moments included) or diffusion-theory fluxes from DGRAD. The TPERT module can be used to calculate perturbations to systems using transport or diffusion-perturbation theory. Either first order or exact perturbation theory can be used to obtain k_{eff} , dose rate, etc. perturbations. Each component of the perturbation is edited separately, i.e., leakage, fission, removal, etc.

1.4. Related Codes and Materials: The GIP, DOT, and RTFLUM programs may be used in preparing input files for DOPES.

1.5. Restrictions: The variable-mesh features of DOT are not presently available in DOPES.

1.6. Computers: Although the DOPES codes should be adaptable to many types of computers, only IBM 360/370 operation has been demonstrated.

1.7. Running Time: DOPES problems require from 1 second to a few minutes on conventional computers, depending upon the problems solved.

1.8. Programming Languages: DOPES members are programmed in standard FORTRAN, insofar as possible. In several instances, optional IBM assembler-language routines which enhance program capability or convenience are provided.

1.9. Operating System: The DOPES modules presently operate under MVS/JES2.

1.10. Machine Requirements: Useful problems can be solved in 270 K-bytes of memory on a machine having at least the capability of the IBM 360/75.

DOGS - A Collection of Graphics for Support of Discrete Ordinates Codes

Published as ORNL/TM-7188 (1980)

D. T. Ingersoll
C. O. Slater

THIS PAGE
WAS INTENTIONALLY
LEFT BLANK

1.1. Name: DOGS

Title: A collection of routines for the graphical display of calculated data generated by discrete-ordinates codes.

Individual Routines: EGAD - Plot 2-dimensional geometries

ISOPLOT4 - Plot 2D flux contours

FORM - Plot 2D surface maps

ACTUAL - Calculate activities

TOOTH - Plot 1D contribution surfaces

ASPECT - Plot energy/space distributions

Auxiliary Routines: DOGS routines read flux files written by:

ANISN - 1 D transport code

XSDRNPM - 1D transport code

DOT - 2D transport code

1.2. Contributors: D. T. Ingersoll and C. O. Slater

Oak Ridge National Laboratory

P.O. Box X

Oak Ridge, TN 37830

1.3. Language: FORTRAN IV and Assembler

1.4. Nature of Problem: To produce graphical display of flux data calculated by common discrete-ordinates radiation transport codes.

1.5. Method of Solution: DOGS uses the DISSPLA proprietary graphics software package to provide flexible plot construction and manipulation.

1.6. Restrictions: All of the DOGS routines use flexible dimensioning, and therefore, no restrictions are placed on problem size. All of the routines except ACTUAL require the availability of DISSPLA software.

1.7. Typical Running Time: The execution time depends on the number of plots being generated. The time required for each plot is on the order of a few seconds.

1.8. Hardware Requirements: The DOGS routines are operational on IBM 360/91, 370/195, and 3033 systems. Most of the routines require a sequential scratch storage device and T00TH requires a random access device. All routines except ACTUAL require a plotting device.

1.9. Software Requirements: All routines except ACTUAL requires the DISS-PLA graphics package sold by Integrated Systems Software Corp. Also, all routines use the assembly language subroutine ALUCAT to achieve run-time allocation of memory space. This can be avoided by compiling a fixed dimension for the main container array. T00TH additionally requires the assembly language routines DEFILE and CLOSDA to manipulate random access storage device.
