ENVIRONMENTAL DATA
FOR
SITES IN THE NATIONAL SOLAR DATA NETWORK

INTRODUCTION

The Department of Energy's National Solar Data Network monitors solar energy systems in residential and commercial buildings. Instrumented solar research and development installations employing on-site microcomputers are linked via telephone lines to a Central Data Processing System (CDPS) located at Vitro Laboratories, Silver Spring, Maryland. Vitro collects, archives, analyzes, and reports upon data from this Network to determine the thermal performance of the solar systems.

The Network consists of: (1) sensors which measure key performance parameters at each site; (2) the microprocessor-based Site Data Acquisition Subsystem (SDAS); (3) a modem and telephone transmission interface; (4) the Central Data Processing System (CDPS). The collected data is transferred via telephone communications. At the Central Data Processing Facility, the collected data is processed, analyzed, evaluated and documented. Sensor data are collected and stored on a cassette tape in the SDAS.

Most on-site sensors are interrogated every five minutes and twenty seconds. Solar radiation and other parameters, which are subject to rapid variance, are sampled every 32 seconds and averaged over 320 seconds by the microprocessor. The CDPS communicates with each SDAS on a daily basis and retrieves the stored data. At the conclusion of data retrieval, the SDAS cassette is reset by command from the CDPS to continue data collection.

This report presents environmental information collected at the sites for the reporting month. Certain data are flagged or indicated to be invalid by the use of an asterisk (*). Only those sites for which a significant amount of the data are found to be valid are reported.

ORGANIZATION OF THE DATA

The environmental data for the NSDN are presented in the form of tables for each solar site. The solar sites are grouped into 12 zones, each of which consists of several adjacent states (as shown in Figure 1). The solar energy sites are listed in alphabetical sequence within each zone.

The tables provide available microclimate data for each reporting location in the NSDN as follows:

- Insolation. The insolation table presents total solar radiation in the plane of the collector (Figure 3). The total insolation represents the measured value of direct plus diffuse radiation at that orientation. Extraterrestrial radiation is calculated for the same plane of orientation outside the atmosphere. A simple ratio of these two values represents an atmospheric transmission index similar to a cloudiness index. The maximum insolation value occurring in the time-frame of sensor interrogation (320 seconds) and its time of occurrence are also shown for each day.

Figure 1. National Solar Data Program Zones

KEY

- Aw** Tropical savanna. Hot; seasonally dry (usually winter)
- BS** Tropical steppe. Semiarid; hot
- BSk** Mid-latitude steppe. Semiarid; cool or cold
- BWh** Tropical desert. Arid; hot
- Caf** Humid subtropical. Mild winter; moist all seasons; long hot summer
- Cb** Marine. Mild winter; moist all seasons; warm summer
- Cs** Coastal Mediterranean. Mild winter; dry summer; short warm summer
- Daf** Humid continental. Severe winter; moist all seasons; long, hot summer
- Dbf** Humid continental. Severe winter; moist all seasons; short warm summer
- H** Undifferentiated highland climates

Trewartha, G.T. The Earth's Problem Climates. University Wisconsin Press, Madison, WI, 1961.

Figure 2. Climate Zones

At selected NSDN sites, a shadowband apparatus is deployed with an EPPLEY PSP sensor to measure the diffuse component of incoming solar radiation. The table also shows a daily value for direct beam insolation based on subtraction of the diffuse values from the direct values. These values must be corrected for the amount of sky occluded by the shadowband.

- Temperature. The temperature tables give the average daytime, nighttime, maximum, and inlet-water temperatures at sites with DHW solar systems. Outdoor ambient temperature sensors are mounted near the collectors in appropriate radiation shields. The inlet-water temperatures are mass flow weighted to read values only when flow occurred. Additional tables are presented for some of these NSDN sites at which wind and/or relative humidity data are monitored.
- Wind. All of the passive and some of the active solar sites are equipped with wind sensors. These provide information for two wind tables. The first furnishes wind speed and direction. The second table correlates wind speed with time for each day.
- Humidity. The humidity table provides relative humidity values for day and night. It also gives values for the maximum and minimum humidity for each day and times of occurrence.

A technical discussion of the instruments used for measurement to obtain NSDN data on site environmental conditions follows.

A map illustrating the climate zones is provided in Figure 2 for comparison to NSDN zones and site location.

INSTRUMENTATION

Insolation

EPPLEY PSP pyranometers are used to measure the total solar radiant energy in the plane of the collection subsystem (Figure 3). A pyranometer measures the total amount of solar energy available. Also included are both the direct beam component and the diffuse component if a shadowband instrument is employed at the site to measure the diffuse component. Measurements are given in BTU/ft²-day.

The addition of a shadowband to a pyranometer enables the instrument to detect only the diffuse portion of the sunlight by shielding the sensor from the direct rays of the sun (the beam component). The amount of beam radiation available is readily calculated by subtracting the diffuse radiation measurement from the total radiation measured by the unshaded standard pyranometer. This beam radiation measurement is useful when working with focusing solar collectors but must be corrected in user software for the amount of sky occluded by the band apparatus. When using the shadowband pyranometer, the accuracy of measurement depends on the correct adjustment of the shadowband to be certain that the sensor is shielded from the direct rays of the sun. The data reported in these

summaries have been carefully screened to eliminate publication of invalid data. Thus, this publication may be employed to screen environmental data taken directly from NSDN magnetic tapes.

The EPPLEY PSP pyranometer used includes a circular multijunction wirewound thermopile. The receiver is circular, and coated with Parsons' black lacquer. The instrument has a pair of precision ground and polished hemispheres of Schott optical glass. The sensor head contains a desiccant which can be readily serviced. The clear glass employed transmits wavelengths of 285 to 2,800 nanometers. The temperature dependence is $\pm 1\%$ over the range of -40°F to 140°F . The PSP has a response time of one second and a linearity of $\pm 5\%$ over the range of the instrument. Field checking of instruments against calibrated standards indicates very good accuracy and drift resistance under normal deployment conditions.

Figure 3. Measurement of Incoming Solar Radiation

Temperature

Ambient temperature sensors, (Minco Products S53) platinum Resistance Temperature Detector (RTD), housed in a WeatherMeasure Radiation Shield, (Figure 4) are used to monitor ambient dry bulb temperatures. Sensors are located away from extraneous heat sources. The sensors are sited to be close to the structure and collector array but beyond obvious radiative and convective influences.

The RTD's are connected to a bridge microboard in the SDAS and yield an output signal of 0-100 millivolts proportional to calibrated temperature ranges.

The RTD's are individually calibrated to National Bureau of Standards traceable standards at the factory. In addition, an electrical five-point check is done at the site in an attempt to take into account any deviation of the measurement system from nominal values due to sensor wire resistance.

The data processing software at the CDPS takes these checks and calibrations into account, using a third-order polynomial curve fit to convert digital data to temperature engineering units (°F).

Figure 4. Temperature Sensor

Wind

Where monitored, wind speed and direction are detected by a Model W101-P-DC/360 (or W102-P-DC/360) sensor by the WeatherMeasure Corporation, Sacramento, California (Figure 5).

Wind speed is measured by a four-bladed propeller coupled to a DC generator. The balanced propeller is fabricated from a special low-density, fiberglass-reinforced plastic to yield maximum sensitivity and strength. Wind speeds below one mile per hour are not reported because these values are below the sensitivity of the instrument.

Dual-wiper, precious-metal slip rings are used to bring the wind speed analog output (15 volts DC at 100 miles per hour) to the base of the sensor from the 0-360° pivoting Skyvane, which doubles as a direction detector.

Wind direction is measured by means of a dual-wiper 1000-ohm potentiometer housed in the base of the sensor. It is attached to a stainless steel shaft which supports, and rotates with, the upper body assembly.

Figure 5. Typical Wind Speed-Direction Sensor

Relative Humidity

Relative humidity is measured by a WeatherMeasure Corporation Model HM111-P/HM14-P sensor (Figure 6). This measurement is of interest in monitoring atmospheric corrosion at active solar sites, and comfort levels at passive solar sites.

This solid-state sensor measures relative humidity over the full range of 0-100%. Response of the sensing element is linear within approximately 1%, from 0-80% relative humidity.

Sensor analog output is dependent on the capacitance change of a polymer thin-film capacitor under varying ambient water vapor conditions. The sensor element internally compensates for temperature. A one-micron-thick dielectric polymer layer absorbs water molecules through a thin

metal electrode and causes a capacitance change proportional to water vapor pressure deficit. The thin polymer layer reacts with a time constant of one second to 90% humidity change at 68°F. Probe electronics generate linear analog output to the SDAS.

For use outdoors, a sintered filter is used over the probe to reduce the sulphur dioxide absorbed and eliminate small particles. The small pore size of the filter gives good protection to the sensor from acid or particulate degradation. The time constant of the sensor, however, is increased to several seconds.

Figure 6. Relative Humidity Probe

OTHER PUBLICATIONS

These environmental data reports will be issued monthly and will include all sites which are transmitting valid data at the time of publication.
