APPENDIX A - MILL SITE POPULATION TABLES	A.1

INTRODUCTION

The U.S. Environmental Protection Agency (EPA) was directed by Congress to promulgate health and environmental standards for uranium mill tailings under the Uranium Mill Tailings Radiation Control Act of 1978. This Act established two programs to protect public health, safety and the environment from uranium mill tailings. One program was aimed at sites designated inactive--sites at which all milling had stopped and which are no longer under license. The second program was directed at active sites--sites that are licensed by the Nuclear Regulatory Commission (NRC) or the state in which the site is located. EPA issued such standards during 1983.

Estimates of the health risks from radon emitted from tailings sites were a most important consideration in developing these standards. Because radon emitted from tailings piles disperses rapidly in the atmosphere, risk estimates are greatly dependent on the total number of people living nearby and on their proximity to the tailings areas. Thus, it is necessary to have accurate population data at tailings sites to make reasonably accurate estimates of the health risk.

The only population data available to EPA were those contained in environmental impact statements for active sites and in technical reports prepared throughout 1981 by Ford, Bacon and Davis Utah, Inc. for inactive sites. However, the information in these reports was sparse, inconsistent, and lacked sufficient detail for use in assessing health risks. Therefore, EPA concluded that better population estimates were needed to assure reasonably accurate health risk estimates. This led to the Pacific Northwest Laboratory (PNL) surveys described in this report.

The 27 active and 25 inactive mill sites that were to be investigated by PNL are shown in Table 1 and Table 2, respectively. As can be seen in Table 1, those sites considered active may be either operating or shut-down. Eight PNL personnel performed the population studies, which took place during the months of April, May, and June in 1983. For each mill site, a table showing population by radius (1/2, 1, 2, 3, 4, and 5 kilometers) in 16 compass directions was generated. These tables appear in Appendix A.

Canonsburg, Pennsylvania
Falls City, Texas (Susquehanna Western)
Green River, Utah
Mexican Hat, Utah
Salt Lake City, Utah
Converse County, Wyoming
Riverton, Wyoming

PRE-TRIP PREPARATION

The first step undertaken was to gather information on the 52 uranium mill sites through available literature sources. The primary objective was to find tailings layout diagrams and coordinates, but data concerning mill operation, any previous population surveys, and other background information were also gathered.

In general, much more information was available for inactive uranium mills than for operating or shut-down mills. Perhaps the most valuable source identified was a series of engineering assessments of tailings piles at inactive mill sites prepared throughout 1981 by Ford, Bacon and Davis Utah, Inc.⁽¹⁻²⁰⁾ Another useful source was a report having gamma radiation surveys at inactive uranium mill sites that was prepared in August 1975 by EPA.⁽²¹⁾

Information for operating and shut-down sites was found in a report prepared in April 1982 by Pacific Northwest Laboratory for NRC.⁽²²⁾ This report discusses the environmental factors affecting stabilization of radon suppression covers for uranium mill tailings and also provides location maps. Also of use for these types of mill sites were various environmental impact statements filed by the operating companies.

After these literature sources were reviewed, each mill location was plotted on a general U.S. road map. Mill sites were then grouped and assigned to team members as efficiently as possible, making every effort to minimize traveling distances between sites, hence minimizing travel costs. Ten such groups were formed with a range of 3 to 7 mill sites per group. Eight PNL personnel performed the site visits, since 2 people were assigned 2 groups each.

U.S.G.S. topographic quadrangle maps were used as base plotting maps for the population field surveys. Researchers referred to a topographic index for their particular state to identify the 7 1/2 minute topographic quadrangles necessary to cover the area around their assigned mills. However, many of the mills were located in areas where only 15 minute topographic maps were available. Maps were ordered if their receipt could be guaranteed prior to the researcher's departure; otherwise, they were purchased when the researcher arrived at his destination.

If maps were received prior to departure, the tailings layout, the tailings centroid, and the corresponding 5 kilometer radius circle around the centroid were penciled in. In many cases, however, no adequate tailings layout diagrams could be found in the literature. This was especially true for the operating mill sites.

Some individuals contacted state, county, and city planning offices before they left to obtain information over the phone or to arrange meetings upon their arrival. Others waited until they arrived before establishing these contacts.

ON-SITE DATA COLLECTION

After the preliminary collection of maps and site information, team members began on-site data collection. Once in the field, appropriate visits were made to the various planning agencies to secure any additional maps, aerial photos, or statistical population data to be used during the site surveys. Topographic maps with plotted mill tailings disposal areas were the basis for beginning the on-site population surveys.

For most mills, enough detailed information was available to accurately locate and plot the tailings disposal areas for the mill site before beginning the field surveys. For some mills, however, site coordinates and detailed mill tailings layouts were unavailable. In these cases, the information was obtained from on-site inspections of the mill facilities. This visual siting technique was difficult in some instances due to the large extent of company-owned area around the mills. In these instances, tailings disposal areas were sighted at a distance and sketched as best as possible on the topographic maps.

Multiple tailings areas existed on many sites. To facilitate a speedy population density count, an approximate center of tailings was selected and a 5 kilometer radius circle was penciled on the maps. To insure adequate ground coverage due to the approximated centers, an additional 1/2 to 1 kilometer area peripheral to the 5 kilometer radius was surveyed.

The actual field surveys involved counting occupied dwellings and plotting their locations on the topographic maps described earlier. Dwelling counts were made by visual inspection via automobile. Only public roads were traversed, so as not to trespass on private lands. Some difficulty arose in navigating and plotting when using older topographic maps that did not show new road changes. In some cases, especially in the sparsely populated and isolated areas, occupied dwellings were difficult to sight due to lengthy private access roads marked no trespassing or to inclement weather causing impassable roads. In other areas, it was difficult to determine if dwellings were occupied due to a seasonal-type appearance or if a "for sale" sign appeared. Under these circumstances, possible clues as to habitation that were used included: a car in front of the dwelling, toys or tools in the yard, clothes hanging on an outside

line, a usable looking mailbox, a recently traveled access road, or smoke coming from the dwelling's chimney.

Densely populated areas posed greater difficulties in estimating occupied dwellings. In these areas, such as near Salt Lake City, Utah, Grand Junction, Colorado, and Canonsburg, Pennsylvania, statistical sampling techniques were used. Areas within the 5 km study radius were selected at random for detailed on-site field surveys. These results were later combined with other detailed census tract and block data to derive the estimated population numbers.

ANALYSIS OF FIELD DATA

Each team member analyzed their plotted field maps and their recorded field data to derive a population distribution around each mill site. The same techniques and standards were followed for each site to insure consistency of results.

First, the centroid of the tailings area was accurately determined for each mill site. In the case of multiple tailings areas, each individual area was assigned a centroid. In conjunction with a coordinate system, each individual centroid was weighted according to its area to derive the appropriate "overall" centroid. A transparent template with inscribed radii at 1/2, 1, 2, 3, 4 and 5 kilometers and divisions at 16 compass directions was used to accurately and uniformly divide the site into sectors. Plotted occupied dwellings were summed in each sector and tabulated.

Overlapping sites occurred in some cases. When this happened, area was apportioned to each site to avoid double counting of population. Straight line divisions were drawn through the points of intersection of the radii around each site center. In the final tabulated population results, asterisks were used to indicate when such site areas fell within other site boundaries. No double counting occurs at any adjacent mill sites.

In determining the population figures for each mill site, the number of occupied dwellings in each sector was multiplied by the average number of persons per household for each particular county. These county statistics for 1980 were obtained from the U.S. Bureau of Census and are shown in Table 3. In a few cases, the average number of persons per household for each city was used because it was considered more representative and often more recent than 1980 county averages. City averages that were used are shown in Table 4.

Because it was not feasible to count every occupied dwelling at the Canonsburg, Pennsylvania, Grand Junction, Colorado, and Salt Lake City, Utah mill sites, the above method of population determination could not be used. For these densely populated sites, estimation techniques using detailed 1980 U.S. Bureau of Census tract and block data were employed. The sectors formed

by the radii and divisions at 16 compass directions were drawn on census tract or census block maps. Population within each census tract or census block was apportioned to each sector on an area basis if the distribution of population appeared relatively uniform. If information gathered in the field or through aerial photographs showed the distribution of population within each census tract or census block to be non-uniform, the population was apportioned according to these observations.

RESULTS

Estimated total population within a 5 kilometer radius of the centroid of the tailings area is shown for active mill sites in Table 5, and for inactive mill sites in Table 6. As evidenced by the tables, total population observed varied significantly, ranging from 7 sites having zero population to the Salt Lake City, Utah site having an estimated total population of 91,498 within the defined 5 kilometer radius.

The distribution of these total population numbers for each of the 52 sites can be found in the tables in Appendix A. Each table gives precise longitudinal and latitudinal coordinates of the centroid of the tailings area, as well as the number of people in each sector formed by transposing 16 compass point directions upon concentric rings of 1/2, 1, 2, 3, 4 and 5 kilometers around the tailing centroid. These tables appear in the order shown in Tables 5 and 6.
