GLOSSARY

GWd	Gigawatt-days = 10^9 watt-days
MWd	Megawatt-days = 10^6 watt-days
MTIHM	Metric tons (10^6 g) of initial heavy metal
Depletion calculation	Calculation of the fresh reactor fuel irradiation that predicts the discharged fuel composition
Fuel element	The smallest structurally discrete part of a fuel assembly that has nuclear fuel as the principal constituent; also called a fuel pin or a fuel rod
Fuel assembly	A grouping of fuel elements that remains intact during the charging and discharging of a reactor core
Pin cell	A cylindrical model of a fuel element used in a reactor physics calculation
Assembly cell	A cylindrical model of a fuel assembly used in a reactor physics calculation
Fuel channel	Hexagonal, sheet-metal can surrounding each fuel assembly to prevent cross-flow of coolant between assemblies
LMFBR	Liquid metal (cooled), fast-breeder reactor. "Fast" refers to the fact that the neutron spectrum is high-energy, i.e., not thermal.
FFTF	Fast-Flux Test Facility in Richland, Washington

PREFACE

This revision is being issued to correct a significant error that occurred in generating the cross sections for the ORIGEN2 LMFBR reactor models described in the original report. Specifically, the weighting of the multigroup cross section library with a multigroup neutron energy spectrum to yield a one-group cross-section library was done improperly because the nuclide concentrations were not correct. This error was propagated throughout much of the data presented in the appendixes, thus necessitating a completely new version of this portion of the report. In addition, some minor changes have been made based on information obtained after the original report had been issued. The most notable of these are: (1) the FFTF irradiation parameters have been updated; (2) Table B.1, in which the values in the first column were shifted, has been corrected; and (3) an error in the specific power for the radial blanket in the AMORUUUX and EMOPUUUX reactor models has been eliminated.

The impact of these changes on the principal actinide nuclides (e.g., uranium, plutonium) is negligible since they are dependent on variable cross sections which were not affected by the multigroup cross-section processing errors. However, the changes in the one-group cross sections will affect virtually all other nuclides to varying degrees. It should be noted that the cross-section processing errors described above do not affect the FFTF model in this report or the CRBRP model described in NUREG/CR-2762.

LMFBR MODELS FOR THE ORIGEN2 COMPUTER CODE

A. G. Croff
J. W. McAdoo
M. A. Bjerke

ABSTRACT

Reactor physics calculations have led to the development of nine liquid-metal fast breeder reactor (LMFBR) models for the ORIGEN2 computer code. Four of the models are based on the U-Pu fuel cycle, two are based on the Th-U-Pu fuel cycle, and three are based on the Th-²³³U fuel cycle. The reactor models are based on cross sections taken directly from the reactor physics codes. Descriptions of the reactor models as well as values for the ORIGEN2 flux parameters THERM, RES, and FAST are given.

1. INTRODUCTION AND SUMMARY

1.1 Introduction

1.1.1 Background

The ORIGEN¹ computer code is a versatile tool used for calculating the buildup and depletion of isotopes in nuclear materials. This computer code was written in the late 1960s and early 1970s by the ORNL Chemical Technology Division. At that time, the required nuclear data libraries (half-lives, cross sections, fission product yields, etc.) and reactor models (PWR-U, PWR-Pu, LMFBR, HTGR, and MSBR) were also developed. The code was principally intended for use in generating spent fuel and waste characteristics (composition, thermal power, etc.) that would form the basis for the study and design of fuel reprocessing plants, spent fuel shipping casks, waste treatment and disposal facilities, and waste shipping casks. Since fuel cycle operations were being examined generically in order to accommodate a wide range of fuel

characteristics, it was only necessary that the ORIGEN results be representative of this range. A satisfactory result was obtained by simply adjusting the resonance integrals of the major fissile and fertile species to obtain agreement with a spent fuel composition from an exogenous source.

Soon after the ORIGEN computer code was documented, it was made available to other users through the Radiation Shielding Information Center at ORNL. Because of the relative simplicity of ORIGEN and its convenient and detailed output, many organizations acquired it; some began using ORIGEN for applications that were more specific and that required greater precision in the calculated results than the generic fuel cycle studies for which the code was originally developed. (For example, environmental impact studies required relatively precise calculations of minor isotopes such as ^3H , ^{14}C , ^{232}U , and $^{242,244}\text{Cm}$.) In response to these requirements, attempts were made to update specific aspects of ORIGEN and its data bases;^{2,3} however, inconsistencies and numerous data bases resulted from these efforts.

To remedy these problems, a concerted program was initiated in 1975 to update the ORIGEN computer code and its associated data bases and reactor models. This is one of several reports describing the various aspects of the ORIGEN update effort. Previously issued reports describe (1) a revised version of the ORIGEN computer code,^{4,5} designated ORIGEN2, (2) updated decay and photon data libraries,⁶ (3) updated U-Pu cycle PWR and BWR models,⁷ and (4) alternative-fuel-cycle (thorium cycles and extended burnup) PWR models,⁸ and CANDU reactor models.⁹

1.1.2 Scope

This report describes nine model LMFBRs. Eight of these are commercial designs based on the Prototype Large Breeder Reactor study¹⁰ and the ninth is based on the currently operating FFTF reactor¹¹ in the Richland, Washington area. A characteristic description of the fuel cycles considered in these reactor models is given in Table 1.

40% denatured ²³³ UO ₂	ThO ₂	ThO ₂	ThO ₂	100	AMO2TTTX
High-grade Pu	UO ₂			45	FFTF

The fundamental objective of this work was to develop LMFBFR models based on existing cross section data^{12,13} rather than the arbitrary adjustment of cross sections that typified previous ORIGEN reactor models. The generation of the information required for these reactor models began with the gathering and initial processing of the existing cross section data into a library of 126 neutron energy groups that could be used by a modular system of reactor physics codes (AMPX)¹⁴ at ORNL (Sect. 2). Two separate libraries were created: (1) a smaller one containing nuclides whose presence in the reactor would have the greatest effects on the neutron spectrum and depletion characteristics, and (2) a larger library containing many nuclides of interest in ORIGEN2 with negligible effects on the neutron spectrum and depletion. Only the smaller library was considered in the subsequent multigroup fuel-depletion calculations.

Following these initial steps, composition-dependent cross sections that accounted for spatial and energy self-shielding effects were generated for each of the commercial reactors (Sect. 3). The libraries resulting from this procedure contained nine neutron energy groups, which were then used in a diffusion-theory depletion code to predict the spent fuel composition and to supply some of the cross sections required by ORIGEN2. The 126-group cross sections were then collapsed to 1-group cross sections, using a typical neutron spectrum that was derived from the depletion calculation. Fission product yields were obtained by spectrum-weighting energy-dependent yields, using this same neutron spectrum. Additional calculations were then performed that yielded new values of the ORIGEN2 flux parameters — THERM, RES, AND FAST.

Finally, an investigation was undertaken to determine appropriate input parameters for the reactor models. The parameters investigated included the actinide and impurity composition of the fresh fuel and the structural material type and composition of a fuel assembly.

2. THE GENERATION OF THE MASTER, MULTIGROUP CROSS-SECTION DATA BASE

This section describes the sources of the unprocessed cross-section data used to develop the LMFBR models and the initial processing of these cross sections into an AMPX master cross-section library. The 126-energy-group library structure (of which two groups were in the thermal energy range) is shown in Appendix A.

Cross sections that were used for the ORIGEN2 LMFBR models were collected into two groups. Group 1 contains all fission product isotopes having cross-section data available for processing. Data for the group 1 nuclides (listed in Table 2) were obtained from ENDF/B-IV and are documented in ref. 15. These data were processed with the AMPX modules NPTXS and XLACS2.

Nuclides in group 2, initially divided into subgroups 2A and 2B, include the activation products, actinides, coolant, and structural materials considered in this work. Subgroup 2A consists of nuclides that are important in the reactor physics calculations. Most of the cross-section data for subgroup 2A was derived from ENDF/B-IV¹² and its processing^{16,17} was accomplished with the MINX¹⁸ computer code. Data for a few of the nuclides in this subgroup were obtained from a preliminary version of ENDF/B-V¹³ and were processed into the master, multigroup format using the AMPX modules NPTXS and XLACS2 (or, in the case of ²³³U, the NJOY¹⁹ computer code). Data for the nuclides in subgroup 2A, which are summarized in Table 3, were used through the entire sequence of fuel depletion calculations.

Subgroup 2B contains nuclides for which data were obtained from ENDF/B-IV, through the processing sequence defined in refs. 16 and 17. Data for these nuclides (which include the light nuclides, such as ¹H, and the minor actinides, such as ²³³Pa) were not used in the physics calculations for the LMFBR models, but were intended for subsequent weighting with a representative spectrum. However, during the course of this study the more complete cross-section data from ENDF/B-V became available, superseding the ENDF/B-IV data. As a result, multigroup cross-section data were calculated for all of the individual nuclides

in group 2, and for some additional actinides, using ENDF/B-V as the data source. Cross sections for this new grouping of nuclides (designated as group 3 and listed in Table 4) were introduced into the sequence of reactor physics codes after the depletion calculation had been performed using the ENDF/B-IV cross sections. The collapse of these cross sections to 1-group values is discussed further in Sect. 3.1.4.

3. MULTIGROUP NEUTRON SPECTRUM AND DEPLETION CALCULATIONS

The 126-energy-group AMPX master cross-section library, described in Sect. 2 of this report, contains cross-section information of a general nature for solving LMFBR neutronics problems. This section describes the processing of this general multigroup library into problem-dependent, multigroup libraries used in the sophisticated reactor physics codes and then into a problem-dependent, 1-group library for use in ORIGEN2. Section 3.1 describes the approach used for the eight commercial LMFBR models, and Sect. 3.2 describes the somewhat simplified procedure used for the FFTF.

3.1 Spectrum and Depletion Calculations for ORIGEN2 Commercial LMFBR Models

3.1.1 Energy self-shielding

The first step in the sequence of calculations leading to the desired ORIGEN2 cross-section library is to account for the energy self-shielding effects in the resonances of various nuclides. In effect, the master library is transformed into a 126-energy group problem-dependent library via the BONAMI module of the AMPX system. This module accesses problem-independent master cross-section data that contain Bondarenko factors (from MINX), performs a resonance self-shielding calculation based on the iterative Bondarenko method,²⁰ and produces problem-dependent master cross-section data. A BONAMI calculation is performed for each of the five zones (i.e., inner core, outer core, inner axial blanket, outer axial blanket, and radial blanket) in each of the eight commercial LMFBR models considered in this work. The input to this calculation includes a simplified system geometry and approximate composition for each zone.

3.1.2 Spatial self-shielding and collapse to a few groups

The five 126-energy-group, problem-dependent libraries from the BONAMI code are then employed in one-dimensional calculations using the XSDRNPM module of the AMPX system. The purpose of this calculation is (1) to account for the spatial self-shielding effects in each of the zones and (2) to collapse the cross-section library from 126 energy groups to a 9-energy-group structure that will be used in subsequent depletion calculations. Three XSDRNPM calculations are required: one in the radial direction along the core midplane and two in the axial direction (one for the inner core/axial blanket and one for the outer core/axial blanket). The radial calculation is performed using cylindrical geometry with outer radii as follows: inner core, 101.6 cm; outer core, 142.0 cm; radial blanket, 180.6 cm; radial shield, 195.0 cm. The axial calculations are performed using slab geometry with distances from the core midplane as follows: core, 53.9 cm; axial blanket, 87.2 cm; axial shield, 100.0 cm. Other input data required include the approximate composition of each zone, based on prior experience. A 9-energy-group cross-section library, containing all of the nuclides in Table 3, is output for each zone of each reactor.

3.1.3 Fuel depletion calculation

The fuel depletion calculation was performed with the CITATION²¹ computer code, using a two-dimensional R-Z geometry model and the 9-energy-group cross sections from the previous step. Each CITATION calculation was begun with approximate compositions and was continued until equilibrium discharge concentrations were reached. The middle-of-cycle equilibrium compositions were then volume-averaged over the CITATION model zones for use in XSDRNPM. Also produced in this step were burnup-dependent cross sections for some of the major actinides in Table 3.

3.1.4 Determination of neutron-spectrum-averaged parameters

The final step is to use a characteristic neutron energy spectrum as a weighting function to yield average parameters for use in ORIGEN2. This is done by calculating a 126-energy-group neutron spectrum for each zone of the reactor using the XSDRNPM module of AMPX and the exact equilibrium fuel composition from the previous step. The resulting neutron spectra, which are determined using the ENDF/B-V cross sections in Table 4, are used to collapse the 126-energy-group cross sections in Tables 2 and 4 to 1-energy-group cross sections that can be used directly in ORIGEN2. The spectra are also used to collapse energy-dependent fission product yields from ENDF/B-IV¹² to give average yields that can be used in ORIGEN2. Finally, the spectra are cast into two 2-energy-group structures which yield values for the ORIGEN2 flux parameters THERM, RES, and FAST when the methods described in ref. 4 are applied.

3.2 Spectrum Calculation for the FFTF

Because the FFTF is a test reactor rather than a commercial power reactor, it has several unusual properties:

1. It has no axial or radial blankets.
2. It has many test positions, as well as loops that can contain a wide variety of materials that are unknowable at the present time.
3. The fissile and/or fertile materials in the reactor (currently high-grade plutonium in UO_2) may be changed to other materials in the future.
4. The fuel management and longevity in the reactor are subject to change, depending on performance and other requirements.

These considerations make it very difficult to do a generic depletion calculation; its value is vanishingly small, since the variability in items 2-4 above can change the neutron spectrum drastically. The lack of blankets also eliminates much of the value of the depletion calculation. Therefore, the approach taken here was to perform the energy-self-shielding calculations as described previously (i.e., using BONAMI) and then to use XSDRNPM to (1) account for the spatial self-shielding effects, (2) calculate the characteristic 126-energy-group neutron spectrum, (3) calculate effective, 1-energy-group cross sections for ORIGEN2, and (4) calculate the ORIGEN2 flux parameters. The depletion calculation using CITATION was not performed for the FFTF.

3.3 Summary of Relevant Calculated Results

The relevant results of the foregoing sophisticated reactor physics calculations are summarized below.

3.3.1 Characteristic 126-energy-group neutron spectra

A listing of the energy-group structures and the neutron spectra is given in Appendix A for all reactors considered. A graphical representation is also given in Appendix A for the core, axial blanket, and radial blanket regions of the AMOPUUUX and AMO2TTTX, and for the core of the FFTF.

3.3.2 1-energy-group, effective cross sections

The collapse of the multigroup cross sections for the nuclides in Tables 2 and 4, using the 126-energy-group neutron spectrum as a weighting function, yielded 1-group, effective cross sections for these nuclides. A listing of these 1-group cross sections for the core, axial blanket, and radial blanket regions of the AMOPUUUX and the AMO2TTTX, and for the FFTF core is given in Appendix B.

3.3.3 Burnup-dependent cross sections for major actinides

The depletion calculations performed with CITATION yielded the 1-energy-group, effective cross sections (from ENDF/B-IV) for about a dozen actinides (depending on the reactor) at several different

sequential burnups during fuel irradiation. These are output and are incorporated into ORIGEN2 to improve the accuracy of the actinide buildup and depletion calculation. Tables containing these burnup-dependent cross sections for the core, axial blanket, and radial blanket of the AMOPUUUX and the AMO2TTTX and for the core of the FFTF are given in Appendix C.

3.3.4 ORIGEN2 flux parameters THERM, RES, and FAST

The XSDRNPM module of AMPX is used to perform two 2-energy-group calculations for each region of each reactor. When properly manipulated, these yield the ORIGEN2 flux parameters THERM, RES, and FAST. A list of these parameters for the nine LMFBRs considered in this work is given in Table 5.

4. DESCRIPTION OF REACTOR MODELS

This section summarizes the input and output information for the nine LMFBR models that comprise this work. Specifically, the following four aspects of the models are addressed:

1. a description of the fuel assemblies, including the composition of structural materials,
2. the composition of the oxide fuel in each region of each reactor,
3. a summary description of each reactor, and
4. the composition of the discharged fuel from selected regions and reactors.

4.1 LMFBR Fuel Assembly Description and Composition

The eight commercial LMFBRs considered in this work have the same fuel assembly design, although the designs of the radial blanket assembly and the core/axial blanket assembly within each reactor are different (the radial blanket assembly has fewer fuel elements, with a larger diameter). The FFTF assembly design differs from that of the commercial reactors and, of course, has no blankets. A physical description of these assemblies is given in Table 6.

Stainless steel/assembly, kg	115.1	97.5	125.7
Inconel 600/assembly, kg			8.9
Assembly total weight, kg	257.7	300.3	172.2

^aBased on data in ref. 10.^bBased on data in refs. 11 and 22.^cUO₂ insulator pellet and Inconel 600 reflector.^d(Pu,U)O₂ in the core/axial blanket and UO₂ in the radial blanket.

Virtually the entire construction of all of the fuel assemblies is stainless steel 316, with the exception of the FFTF assembly, which contains some Inconel 600. The compositions of these metals, including the anticipated trace impurities, are given in Table 7.

4.2 LMFBR Fuel Composition

The LMFBR fuel pellets contain two groups of elements: the actinides and the nonactinides, which include oxygen and impurities. The initial actinide compositions of the LMFBR core fuels are given in Table 8. These fuel compositions are based on the CITATION calculations described in Sect. 3. The initial composition of the FFTF fuel is based on data in refs. 11, 26, and 27.

The initial actinide compositions of the fuel blankets is as follows: uranium blankets — 2000 g $^{235}\text{U}/\text{MTIHM}$ and 998,000 g $^{238}\text{U}/\text{MTIHM}$; thorium blankets — 100 g $^{230}\text{Th}/\text{MTIHM}$ and 999,900 g $^{232}\text{Th}/\text{MTIHM}$. The ^{230}Th in the thorium blankets is an important precursor of ^{232}U , which is the parent of a highly gamma-active decay chain.

The assumed nonactinide composition of the oxide reactor fuels is given in Table 9. Since specific data are not yet available for the fuels considered in this work, the values in Table 9 are the same as those for light water reactor (LWR) oxide fuels.

4.3 Summary Description of the ORIGEN2 LMFBR Models

Fuel depletion calculations were performed for the nine LMFBRs considered in this work with ORIGEN2, using the input compositions given in Sects. 4.1 and 4.2. Results of these calculations, including irradiation conditions and measurements of the uranium, plutonium, and thorium contents of the fresh and spent fuels, are presented in Tables 10-18. All values have been normalized so that the total reactor power is 3956 MW(t). This corresponds to a net electrical power of 1250 MW(e), using the 31.6% thermal efficiency given in ref. 10. These tables can be readily applied to more advanced designs involving higher thermal efficiencies (assuming the fuel assembly design remains unchanged) by simply

increasing the amount of electricity produced to a value greater than the 3956 MW(t) that forms the basis of the reactor models. Thus, the fuel being charged and discharged to the reactor and its irradiation conditions would be essentially unchanged, but increased temperatures would allow more electricity to be produced from the fuel.

4.4 Discharge Compositions of Selected LMFBR Fuels

The actinide discharge composition of the three U-Pu cycle commercial LMFBR core fuels and the average FFTF fuel are given in Table 19. The effect of recycling plutonium in the LMFBR may be seen by comparison of the AMOPUUUX and AMORUUUX discharge compositions, which indicate that the production of the heavier plutonium and transplutonium nuclides is substantially reduced in the latter. The discharge compositions for all of the blankets are somewhat similar.

The discharge compositions for typical U-Pu cycle axial and radial blankets, as represented by the AMOPUUUX, are given in Table 20.

Table 19. Discharge fuel composition for 1000 kg (one tonne)
of selected core fuels^a

Nuclide	Discharge fuel composition (g/MTIHM)			
	AMOPUUUX ^b	AMORUUUX ^b	EMOPUUUX ^b	FFTF average
²³⁵ U	696	692	1096	4277
