## QUARRY ACCIDENTS IN THE UNITED STATES DURING THE CALENDAR YEAR 1936 1

By William W. Adams 2 and Virginia E. Wrenn's

#### INTRODUCTION

The stone-quarrying and related industries of the United States made large gains in employment in 1936 over 1935, according to reports furnished by operating companies to the Bureau of Mines, United States Department of the Interior. Not only were more men employed, but also increases were made in the number of man-days of labor performed and in the number of man-hours worked in 1936. The increase in employment, however, was accompanied by an increase in the number of accidental deaths and injuries among the workers and by a slight increase in the accident-frequency rate per million man-hours worked. The fact that the larger number of accidents resulted in only a slight increase in the accident rate is explained by the large gain made in the number of man-hours worked during The accident rate in 1936, although higher than in 1935, was the lowest and therefore the best that the industry has experienced in any previous year except 1932 since complete and comparable figures first became available in 1916, a period of 21 years.

Operators' reports to the Bureau of Mines showed that the industry as a whole employed an average of 80,022 men in 1936 and that the men worked a total of 18,874,254 man-days or 147,064,448 man-hours. Accidents in and about the plants caused 91 deaths and 5,717 nonfatal lost-time injuries among the workers. The number of injuries and deaths represented an accident-frequency rate of 39.5 per million man-

hours worked, compared with a rate of 38.2 in 1935.

A major disaster occurred on November 30, 1936, at a quarry in Delta, Pa., in which seven men were killed (two men were not quarry

employees) by an explosives accident.

Pennsylvania, Ohio, California, and New York led all other States in the number of men employed. States having the fewest accidents in proportion to the number of man-hours of exposure to risk were Michigan, Iowa, Kansas, and Alabama. The highest accident rates for States in which the industry employed 1,000 or more men were those for Wisconsin, Washington, Virginia, and California, in the order stated. The relative standing of the States is shown in table 1. The greatest progress in lowering their accident-frequency rates in 1936, compared with 1935, was achieved by North Carolina and West Virginia, as shown in table 2.

<sup>&</sup>lt;sup>1</sup> Work on manuscript completed July 1938. H. Lucile Sims assisted in the preparation of the statistical tables herein presented.

<sup>2</sup> Supervising statistician, employment statistics section, Bureau of Mines.

<sup>3</sup> Employment statistics section, Bureau of Mines.

The statistics of accidents and employment for 1936 covered 1,986 plants in 46 States, while those for 1935 covered 2,076 plants in 46 States and the District of Columbia. The two States in which no commercial quarries were active, or at least from which no plants reported, were Mississippi and North Dakota.

Of the 91 deaths that resulted from accidents, 48 occurred at open quarries and were caused chiefly by explosives and by falls or slides of rock or overburden, 5 occurred at underground quarries or mines, and 38 occurred at crushers, mills, or rock-dressing plants outside the quarries and were due chiefly to machinery, falls of persons, and falling

objects.

Similarly, the reports of nonfatal lost-time injuries showed that, of the 5,717 accidents that occurred during the year, 3,237 were at open quarries and resulted mainly from handling materials, flying objects, falls or slides of rock or overburden, falls of persons, machinery, haulage, and hand tools. Underground quarries or mines reported 297 injuries, the largest number being due to loading rock, haulage equipment, and falls of rock from roof or wall. Mills and other works outside the quarries had 2,183 injuries, chiefly caused by handling

materials, machinery, flying objects, and falls of persons.

The exact accident-severity rate for quarrying and related work in the United States cannot be given for the entire industry without a full and detailed report of each accident that occurred. Manifestly a system of reporting the full particulars of each injury would be too elaborate and costly in as widespread an industry as quarrying. However, the severity rate for the industry as a whole may be estimated with sufficient accuracy for accident-prevention purposes by assigning to each class of injury a specific charge in time lost or length of disability of the injured employees on the basis of full and complete reports from numerous companies operating in various parts of the country. Such reports are received from companies that have participated in annual safety contests conducted by the Bureau of Mines. These contests, known as the National Safety Competition, provide the Bureau with reports showing, among other things, the length of time each injured employee was disabled. Reports for the past few years show that employees receiving temporary injuries lost an average of 24 days from their work. Reports covering permanent partial disability reveal an average of 1,070 days lost per employee, the specific charge for each injury of this class being determined by the nature of the injury and the part of the body affected. Deaths and permanent total injuries were assigned a specific charge of 6,000 lost days each, in accordance with national standards for weighting industrial injuries of those two classes. Application of these time-loss charges to the 5,808 injuries and deaths that occurred during 1936 reveals a period of disability of 909,882 man-days, or an average of 6.19 days lost per thousand man-hours of employment or exposure to risk. The corresponding accident-severity rate for 1935 was 5.23. difference between the two rates was due chiefly to an increase in the number of fatal accidents in 1936.

Table 1.—Relative standing of States having 1,000 or more men employed at quarries, including outside works, classified according to number of men employed, and fatality and injury rates per million man-hours of employment during the year ended Dec. 31, 1936

#### ACKNOWLEDGMENTS

The Bureau of Mines gratefully acknowledges the cooperation of the quarry operators throughout the United States, whose voluntary reports of accidents and employment form the basis of the tables in this bulletin.

#### SCOPE OF STATISTICS

The tables in this bulletin have been compiled by the Bureau of Mines from reports received directly from operators of quarries, and they represent all stages of the quarrying industry. The total figures are based on returns representing 1,986 quarries that were worked all or part of the year. The figures also cover crushing and screening, rock dressing, and the manufacture of lime and cement insofar as

those operations are conducted by the quarry companies.

The Bureau of Mines is authorized to collect data on accidents at mines and quarries, but there is no Federal law that compels operators to supply such data; hence the reports received from operators are voluntary responses to the Bureau's requests for information. Although the figures presented herein may not be complete for the entire industry, every effort has been exerted to make them so, and the figures given are believed to be thoroughly representative of the hazards to which quarry workers are exposed. Moreover, the figures are comparable as between States, a fact extremely significant in view of the lack of uniformity among the States as regards classes of plants covered by State records, classes of accidents covered by State laws, and other factors that tend to make impracticable or impossible comparison of the accident experience of one State with that of another or comprehension of the relative importance of the various causes of accidents in the industry as a whole.

#### CLASSIFICATION OF QUARRIES

The quarries covered by this report have been classified according to the kind of rock produced, as follows: Cement rock, limestone, marble, sandstone, slate, trap rock, and granite. Separate statistical tables are presented for each group and for all groups combined. Clay, sand, and gravel pits are not included.

#### CLASSIFICATION OF INJURIES

From 1915 to 1929 the Bureau's statistics of accidents at quarries divided all injuries into five classes as follows: (1) Fatalities, (2) permanent total disabilities, (3) permanent partial disabilities, (4) temporary disabilities lasting more than 14 days, and (5) temporary disabilities lasting more than the remainder of the day on which the accident occurred but not exceeding 14 days. Beginning with 1930 classes (4) and (5) were consolidated under the general class of temporary injuries.

Figures covering accidents at quarries for the 5-year period 1932-36

are given in table 32, page 56.

#### DEFINITION OF ACCIDENT RATES

All accident rates shown in this publication, except where otherwise stated, have been calculated on the basis of a million man-hours of employment or exposure to risk.

#### ACCIDENTS AT DIFFERENT KINDS OF QUARRIES

Cement rock.—Although the cement industry maintained its leadership in safety among quarry operations in the United States in 1936, its own record for the year was not as good as in 1935. Employment improved, as gains were reported in the number of men employed and in the number of man-hours worked. Operating time per employee was also better, as the average employee worked 45 more days in 1936 than in 1935.

The total working force, or rather the average number of employees for the period during which the mills and quarries were active, comprised 26,004 men, an increase of more than 6 percent. The total working time for the entire force increased 32 percent, the volume of labor having risen from 39 million man-hours in 1935 to nearly 52 million man-hours in 1936. Reports for 1936 showed an average of 1,992 hours of work per employee and a weighted average of 7.3 hours per day per man, compared with 1,607 hours per employee and an average workday of 7.1 hours per man in 1935. Operations were reported by 178 plants in 35 States. Pennsylvania was easily the leading State in number of men working, having more than twice as many employees as California or New York which ranked second and third, respectively. These three States accounted for about a third of the total number of men employed at cement mills and quarries in all States during the year.

Accidents to the men while at work resulted in the death of 23 employees and the injury of 728; the principal causes were handling materials, falls of persons, machinery, flying objects, falling objects, burns, and hand tools. The accident-frequency rate increased to 14.49 per million man-hours worked from 9.53 in 1935; the higher rate

in 1936 was due chiefly to an increase in accidents at the quarries, although mill accidents also increased to some extent. The principal causes of the accidents are shown in table 14. (See tables 13, 14, 16,

and 17.)

Granite.—Reports for 1936 showed a net reduction in the accident rate for the granite industry compared with 1935. The entire improvement was credited to operations in and about the quarries and was sufficient to overcome an increase in the accident rate for operations at rock-dressing plants or elsewhere outside the quarries. The industry also made gains in the number of men employed and larger

gains in the total number of man-hours worked.

Reports from the operating companies revealed a total working force of 8,243 men and a total of 14.7 million man-hours of labor, the former representing an increase of 20 percent and the latter of 39 percent over the records for the preceding year. Men working at the quarries outnumbered those at the outside plants by a ratio of 1 to 0.7. Both classes of employees worked more days per man in 1936, the average for each group of workers being 224 days. Reports for 1936 covered 273 active plants in 27 States. The leading States in number of men working were California, Maine, North Carolina, Massachusetts, Georgia, and Vermont, in the order named.

Accidents resulted in 5 deaths and 763 lost-time injuries among the employees, representing an accident-frequency rate of 52.23 per million man-hours of work or exposure to hazards. The corresponding rate for 1935 was 54.57. Most of the accidents at the quarries were caused by handling materials, flying objects, machinery, falling objects, and drilling. Accidents to employees engaged on rock-dressing or other work outside the quarries were due chiefly to flying objects, handling materials, machinery, and hand tools. (See tables 13, 14, 18,

and 19.)

Limestone.—There was virtually no change in the accident rate for the limestone industry in 1936. Reports covering the quarries, crushers, and finishing plants showed that accidents causing injury or death occurred at a rate of 54.99 per million man-hours of employment compared with 54.72 in 1935. Employment showed gains in the number of quarry workers and the number of men engaged on work outside the quarries. The total working force comprised 24,288 men, exclusive of those employed at plants whose chief product was cement The total number of man-hours of employment and the average number of workdays per man also increased. The number of man-hours worked by the entire industry was 38.4 millions, an increase of 34 percent over 1935, and the number of men employed increased between 6 and 7 percent. The average working time per employee was 194 days, or 1,579 hours, a weighted average of 8.1 hours per day. In the previous year each employee worked 159 days, or 1,257 hours with an average workday of 7.9 hours. These figures are based on operations at 861 plants in 42 States. Information for 26 of these States is given in tables 20 and 21. Pennsylvania, Indiana, and Illinois, in the order stated, employed more men than any other For the country as a whole, reports from the operators showed a little more than twice as many men employed at the limestone quarries as at the crushers and finishing plants, the ratio being 1 employee at the quarries to 0.45 employee outside the quarries.

Accidents at the quarries and outside plants resulted in 34 deaths and 2,075 injuries among the employees. As the total amount of employment or exposure to risk at all plants during the year was over 38 million man-hours, the number of fatalities and injuries represented an accident-frequency rate of 54.99 per million man-hours worked, as previously stated. Outstanding among the causes of accidents to the men who worked in and about the quarries were "handling materials"; other important causes were flying objects, falls or slides of rock or overburden, falls of persons, machinery, and haulage equipment. Accidents to men at crushers and rock-finishing plants were caused mainly by machinery, handling materials, flying objects, and falls of persons. (See tables 13, 14, 20, and 21.)

Marble.—A large increase in employment at marble quarries, as shown by reports from producers for 1936, occurred both in the number of men engaged in the quarrying and finishing of the stone and the number of man-hours of work performed. Substantial gains were also made in the number of workdays and workhours per employee during the year. Accidents to the employees increased in number but not in the same proportion as the increase in the number of workers; hence the accident-frequency rate was more favorable

than in 1935.

Reports from producers showed a total working force of 3,304 men, of whom 932 worked in and about the quarries and 2,372 worked at the outside plants, chiefly on rock dressing. Labor performed during the year totaled 6.7 million man-hours, an average of 2,028 hours per man. The plants were active for an average of 251 days per employee, the weighted average length of shift being 8.1 hours compared with 7.8 hours in 1935. These figures cover the operations of 54 plants in 15 States; the principal marble-quarrying States were Vermont and Tennessee. (See table 16.)

Two men were killed and 250 men were injured by accidents at the quarries and outside plants, representing an accident-frequency rate of 37.60 per million man-hours worked compared with 44.07 in 1935. Two-thirds of the accidents occurred at the outside plants, the principal causes of accidents being handling materials, use of machinery, and falling objects. The main causes of accidents to the men working in and about the quarries were machinery and

handling materials. (See tables 13, 14, 16, and 17.)

Limestone (chief product, lime).—Because of the importance of the lime industry, quarries whose output was used chiefly for the manufacture of lime are classed in this bulletin as a separate group, and separate figures for these quarries and their associated limekilns are presented. Employment showed gains both in number of employees and number of man-hours worked in 1936; but the accident-frequency rate for the group was slightly higher than in 1935. The number of men employed was 9,385, and their working time totaled 20.7 million man-hours, an average of 2,200 hours per man for the year. plants were in operation for 281 days per man, a gain of 14 workdays per man over the preceding year. A slight lengthening of the workday was indicated by the reports, which showed a weighted average of 7.8 hours per day in 1936 compared with 7.6 hours per day in 1935. There were 222 plants in operation in 36 States; Pennsylvania and Ohio had larger numbers of employees than any other State.

Both the number of accidents and their ratio to the number of man-hours of labor performed increased in 1936; 12 men were killed (4 more than in 1935), and 1,118 men were injured (an increase of 257 over 1935), the combined rate for 1936 being 54.72 per million man-hours worked compared with 52.47 in 1935. Accidents at the quarries were due chiefly to handling materials, falls or slides of rock or overburden, flying objects, and haulage; injuries to men employed at the limekilns or elsewhere outside the quarries were caused mainly by handling materials, burns, flying objects, and

machinery. (See tables 13, 14, 22, and 23.) Sandstone.—Outstanding among the achievements of the sandstone industry in 1936 was the progress made in the prevention of accidents, as indicated by a reduction in the accident-frequency rate from 65.89 per million man-hours in 1935 to 48.19 in 1936. accident rate among workers in and about the quarries was reduced 39 percent, which more than canceled an increase of 29 percent in the rate for accidents at rock-dressing and other outside plants and made a net reduction of 27 percent in the combined rate for both groups of employees. The actual number of men injured in 1936 was 249, including 1 man killed. Most of the accidents at the quarries were chargeable to handling materials, hand tools, falls of persons, and flying objects. Machinery was the principal cause of accidents to men working outside the quarries. The reduction in the accident rate was due chiefly to a decline in the rates for accidents caused by handling materials, flying objects, and falls or slides of rock or overburden.

Employment was better in 1936 than in 1935, whether measured by the number of men employed or by the number of man-hours worked. The employees totaled 3,122, of whom 2,119 worked at the quarries and 1,003 at the outside plants, and the working time for all employees was 5.2 million man-hours, an increase of 40 percent over 1935. Operations were conducted by 171 plants in 26 States, with Pennsylvania leading with the largest number of employees. Ranking after Pennsylvania were Ohio and West Virginia. For the industry as a whole, approximately two men were employed on quarrying work to every man employed on related work outside the quarries. (See tables 13, 14, 24, and 25.)

Slate.—An increase of 24 percent in the number of employees and an increase of 58 percent in the number of man-hours worked were reported for 1936 by operators of slate quarries in the United States. The number of men employed in 1936 was 2,565, of whom 907 worked at the quarries and 1,658 were employed on finishing or other work outside the quarries. The working time of the entire personnel was 4.9 million man-hours compared with 3.1 million man-hours in 1935. These figures covered 77 plants in 11 States. More than half of the total number of employees in the industry worked at plants in Pennsylvania. Vermont and Virginia ranked next in number of men employed.

Accidents caused by hazards incident to the work at the plants resulted in the death of 6 employees and in the injury of 254, thus indicating an accident-frequency rate of 53.17 per million man-hours worked compared with 54.89 in 1935. Although the net rate did not change materially, a substantial reduction was reported in the rate

of accidents to the quarry workers, which more than overcame an increase in the rate of accidents to employees working outside the quarries. Most of the accidents to the quarry workers and to the men working at the outside plants were due to handling materials. (See tables 13, 14, 16, and 17.)

Trap rock.—In contrast to all other classes of quarries covered by this publication, trap-rock quarries employed fewer men in 1936 than The decline in the number of workers, however, did not in 1935. result in a smaller volume of work during the year, as the quarries were in operation longer in 1936 than in 1935 and this resulted in a substantial increase in the number of man-hours worked. The number of men employed at all plants was 3,111, a reduction of 385 from the previous year's force, but the number of man-hours worked increased from 4.2 millions in 1935 to 4.8 millions in 1936, or 13 per-The average employee worked 187 days or 1,540 hours during The number of employees at the quarries outnumbered those outside the quarries by a ratio of approximately 1 to 0.6. Operations were reported by 150 plants in 17 States. Massachusetts was the leading State in number of employees, followed by New Jersey, Washington, and Pennsylvania.

Accidents increased in number and in proportion to the number of man-hours worked. In 1936, 8 men were killed and 281 men were injured, representing an accident-frequency rate of 60.33 per million man-hours compared with 53.60 in 1935. The most numerous class of accidents to men at the quarries was that chargeable to handling materials, followed by three classes which ranked equal in the number of injuries, namely, falls or slides of rock or overburden, haulage, and machinery. Machinery was the principal cause of accidents to men working outside the quarries; flying objects ranked second and handling materials third. (See tables 13, 14, 16, and 17.)

### DIMENSION-STONE AND NONDIMENSION-STONE QUARRIES

Methods employed in quarrying stone and in handling the stone immediately after it has been quarried are governed largely by the ultimate use to which the material is to be put. Stone for building or monumental purposes must be quarried and handled with greater care than stone that can be used without regard to its shape or form or that will later be crushed or powdered for use as flux or aggregates or in the manufacture of cement or lime. Thus the quarrying or preparation of stone may be divided, from the viewpoint of the safety engineer, into two main classes: (1) Building or dimension stone and (2) crushed or nondimension stone. The characteristic hazards of quarrying occur with different degrees of frequency in these two classes of quarrying operations. Stone that is used in substantially

the form and size that it was when loaded at the quarry face forms only a small part of the total quantity of stone produced and accounts for only a small number of employees in the quarrying industry. (See tables 26 and 27.) Thus accident rates for the two classes of quarries may be compared more clearly if this small group is omitted and the two classes of operations are divided only on the basis of whether the stone is or is not to be crushed.

Reports from operating companies for 1936 showed an accident-frequency rate of 46.06 per million man-hours of employment for dimension-stone plants and 38.21 for nondimension-stone plants. Only a few years ago, rates of this kind usually appeared in the reverse order, the rates for nondimension-stone plants being less favorable than those for dimension-stone plants. Since 1926 an intensive safety campaign has been in progress in the crushed-stone industry. This campaign includes an annual competition for awards for outstanding achievement in the prevention of accidents known as the National Crushed Stone Association Safety Competition; the contest is conducted by the United States Bureau of Mines in cooperation with the Association. It is highly probable that the safety contests have largely contributed to the improvement in the accident record of the crushed-stone industry during that period.

The accident rates and the number of men employed at these two classes of quarries are shown in tables 26 to 30.

### NONFATAL-INJURY RATES FROM MAIN CAUSES OF ACCIDENTS INSIDE OPEN QUARRIES IN PRINCIPAL QUARRYING STATES

Forty-six States were represented in the reports received by the Bureau of Mines from quarry-operating companies for 1936. Only North Dakota and Mississippi did not furnish reports, and these two States probably would have been represented if it had been possible to learn the name and address of every pit and hillside quarry from which stone is extracted.

Although quarry activity is so widely distributed throughout the country, 58 percent of the employees and 60 percent of the nonfatal injuries in the quarry pits in 1936 were accounted for by operations in only 10 States. The 10 leading States, in the order of the number of men working inside the pits, were Pennsylvania, California, Illinois, New York, Missouri, Ohio, Virginia, Indiana, Vermont, and Michigan. The nonfatal-injury rates for these 10 States are shown in table 31 for seven principal causes of accidents in open-quarrying operations in the United States. About 80 percent of all nonfatal injuries at open

quarries throughout the country are due to these seven causes.

The leading cause of injuries at open-pit quarries was handling materials. Accidents from this cause resulted in an injury rate of 18.47 for the country as a whole; the highest rate for any of the 10 leading States was 49.31 for Missouri and the lowest was 3.86 for Michigan. Accidents from flying objects ranked second among the dangers to which quarry workers were exposed. The injury rate for this hazard was 6.85 per million man-hours worked inside the open-quarry pits, the highest rate being 24.65 for Missouri and the lowest 2.64 for Ohio. Ranking third as a cause of accidental injuries were falls or slides of rock or overburden with an injury rate of 5.37, a high of 17.00 for Virginia, and a low of 1.31 for New York. The next hazard in the order of frequency of accidental injuries was falls of persons. This class of accidents resulted in an injury rate of 4.71 for the United States as a whole, the highest rate among the 10 leading States being 7.97 for Indiana and the lowest 1.59 for Vermont. Machinery accidents resulted in an injury rate of 4.51 for the United States, 9.27 for California, and 2.21 for Michigan. A rate of 4.01 was reported for accidents caused by haulage equipment; the highest rate for this class of accidents was 5.69 for Missouri and the lowest rate 0.55 for Michigan. Hand-tool accidents resulted in a rate of 3.75 for the United States, a high of 7.52 for New York, and a low of 0.53 for Vermont.

Table 31 shows the accident rates for the 7 principal classes of non-

fatal injuries in the 10 principal quarry States for 1936.

Table 31.—Nonfatal-injury rates per million man-hours of employment inside open quarries, during the year ended Dec. 31, 1936, in principal quarrying States, by chief causes of accidents

### COMPARATIVE SEVERITY OF INJURIES

The proportion of accidents of any given degree of severity varies from year to year. Figures for a single year would hardly represent a normal distribution of quarry accidents according to the seriousness of injury. A classification of all accidents reported for 1936 shows that, of every 1,000 accidents reported, 16 caused death, 1 resulted in permanent total disability, 29 caused permanent partial disability, and 954 caused temporary disability lasting more than the remainder of the day on which the accident occurred. A large number of accidents, not included in standard statistics compiled by the Bureau of Mines for the quarrying industry or for other industries by other organizations, cause disability to the employees for perhaps a few minutes or a few hours; these are usually recorded, if at all, only by the companies at whose plants the accidents occur, as it is virtually impossible to obtain complete records of them on a national scale. Accidents of this class probably amount to 25 to 40 percent of the total number of accidents in the quarrying industry. If this class of accidents is omitted and only so-called "lost-time" or "disabling" injuries are included, a typical distribution of quarry accidents, classified by severity, is indicated by figures covering the past 5 years, 1932-36. These figures show that, of each 1,000 accidents, 14 resulted in the death of the injured worker, 1 caused permanent total disability, 29 caused permanent partial disability, and 956 caused temporary disability. Thus the year 1936 was close to normal in its distribution of accidents according to severity of injury, although fatalities increased somewhat in relative importance and temporary injuries declined slightly.

The last column of table 32 shows accident rates per million manhours of employment for each of these four classes of accidents.

### RATIO OF INJURIES TO FATALITIES

If the quarrying and related industries are considered as a whole, 63 disabling nonfatal injuries occurred for each fatal accident reported This ratio of injuries to fatalities may be computed during 1936. from the number of accidents shown in table 11. Accidents outside the quarries had a higher mortality ratio than those that occurred at the quarries. This fact was indicated by the figures for the two classes of work, which showed 1 fatality to 67 injuries for the quarries and 1 fatality to 57 injuries for work outside the quarries. In this respect the accident situation in 1936 differed from that in 1935, when the ratio of fatalities to nonfatal injuries was 1 to 77 for accidents connected with quarrying and 1 to 90 for accidents outside the quarries. The most serious cause of fatal accidents at the quarry proper—falls or slides of rock or overburden—had a ratio of 1 death to every 22 injuries. The ratio of injuries to fatalities for each of the principal causes of accidents in the industry may be judged approximately or computed exactly from the figures given in table 11.

Table 32.—All quarries: Number of fatalities and injuries, and fatality and injury rates, per million man-hours of employment, classified by severity of injury, 1927-36

¹ Permanent total disability: Loss of both legs or arms, ¹ leg and ¹ arm, total loss of eyesight, paralysis, or other condition permanently incapacitating workman from doing any work of a gainful occupation.
² Permanent partial disability: Loss of ¹ foct, leg, hand, or eye, ¹ or more fingers, ¹ or more toes, any dislocation where ligaments are severed, or any other injury known in surgery to be permanent partial.

### UNDERGROUND QUARRIES

Although quarrying is characteristically an industry in which the employees work above ground, the Bureau of Mines canvass for 1936 revealed that 93 plants might be classed as mines because all work involved in the extraction of the stone was performed underground. The number of plants in operation was 11 more than the number reported in 1935. Most of the underground quarries produced limestone or cement rock, but a few were reported as producing other kinds

dislocation where ligaments are severed, or any other injury known in surgery to be permanent partie disability.

2 Disability for more than remainder of day of accident.

Accident rates for 1927-31 computed on basis of man-hours worked, the number of man-hours for 1927-30 being estimated by assuming that all companies operated the same number of hours per man per day as did those companies actually reporting length of day.

of stone. The combined accident-frequency rate for the entire group was 58.34 per million man-hours of employment underground. Operations in 23 States were represented by the 93 underground quarries, and the number of men working underground was 2,686. Contrary to what might be expected, as accidents usually occur with relatively greater frequency underground than above ground in most mineral industries, the accident rate for the underground quarries was lower and therefore more favorable than the rate for open quarries. fact would suggest that the underground quarries are operated or controlled by companies whose operating policies include sound accident-prevention methods, as no other reason appears to account for the more-favorable accident rate for underground quarrying whose inherent hazards normally are believed to exceed those of quarries above ground where work is done by natural, rather than artificial light.

Table 33 gives the record of employment and accidents for under-

ground quarrying for the calendar year 1936.

Includes quarries that produced limestone used chiefly for making lime.
 Includes Alabama, Colorado, Georgia, Maine, Maryland, Massachusetts, Michigan, Nevada, New York, Oregon, Rhode Island, Vermont, Virginia, and Wyoming.

### ACCIDENTS AT CEMENT MILLS

The accident rate for the cement industry, including the quarrying of the stone and its manufacture into cement, was shown in table 13 to have been 14.49 per million man-hours of employment in 1936. Contrasted with this, the rate for the mills only—that is, excluding extraction of the stone and hauling it to the mill—was only 11.35 per million man-hours of employment at the mills. Similar rates for cement mills in different States are given in table 34; the figures range from a rate of 0.38 for Ohio to one of 33.84 for California.

Falls of persons were responsible for more injuries than any other class of hazards to which cement-mill workers were exposed in 1936. Other leading causes of accidents at the mills were handling materials, machinery, falling objects, burns, flying objects, and hand tools.

Table 34.—Accident rates, men employed, etc., at cement mills (including crushers and miscellaneous work) during the year ended Dec. 31, 1936

### PLANTS OPERATED WITHOUT FATAL ACCIDENTS

How few quarrying companies have the misfortune to record the death of an employee by accident is shown by the reports which the Bureau of Mines received from operating companies for 1936. Although 1,986 plants were active during the year, 74 plants accounted for the 91 fatal accidents in the entire industry. The Bureau's canvass of the industry for 1935 covered 2,076 active plants, of which only 46 reported deaths of employees by accidents, the number of employees killed being 51. The 74 plants at which 91 men were killed in 1936 employed 9,389 men, which is only 12 percent of the total number of men working in the entire industry in 1936. In

other words, 88 percent of all men working in the quarrying and related industries during 1936 were employed at plants that did not have a fatal accident. This record compares favorably with that for bituminous-coal mines for 1935 (figure not available for 1936) of 63 percent of the employees accounted for by mines that operated without a fatal accident. The quarrying industry also ranks favorably in this respect when compared with mining other than coal mining, the record for which in 1935 (figure for 1936 not available) showed 76 percent of the men working at mines that did not have a fatal accident during the year.

The proportion of the quarry industry that was free from fatal accidents in 1936 is shown for the United States as a whole and for

each State separately in tables 35, 36, and 37.

### LONG-TIME TREND OF ACCIDENT RATES IN THE QUARRY INDUSTRY

Statistics of accidents in the quarrying and related industries in the United States first became available when the Bureau of Mines collected reports from the operating companies for the calendar year 1911. The present bulletin, covering 1936, is the twenty-sixth annual

publication on the subject.

During the last 14 of the 26 years for which comparable figures are available, the trend of the yearly accident rates for the industry has shown a gratifying downward course. During the first 5 years for which annual reports were collected the rate for nonfatal injuries rose rapidly, probably owing more to increasing coverage of slight or minor injuries by the companies' reports than to an actual increase in the number of accidents. This probability is strengthened by the accident rates during the years immediately following 1915. It is believed that by 1916 the reports from the operators reflected the actual number of nonfatal injuries with reasonable accuracy. After 1917 the accident rates dropped to a favorable low point for the 3 years 1918 to 1920, inclusive, and returned in 1921 to a level more in alinement with those for 1916 and 1917. For 1921 the nonfatal-injury rate was 62.16 per million man-hours of employment, and only twice (in 1923 and 1924) since that year has the injury rate been higher than that for 1921. The lowest injury rate recorded since 1916 was The rate for 1936 increased to 38.87. 37.73 for 1935.

Although the reports from the operating companies for 1911 to 1915 are believed to have been deficient in that they probably did not

include all of the minor nonfatal injuries that actually were sustained, it is reasonable to believe that the reports were complete, or substantially so, as to fatal accidents during those and later years. Failure of an operating company to remember and report the death of an employee is possible but not probable, although minor bruises, cuts, or other slight nonfatal injuries might easily have been overlooked when the accident reports for the Bureau of Mines were prepared by the operating company at the close of the year. It is believed that this situation prevailed, as regards nonfatal injuries, from 1911 to 1915.

The accident rates for fatal accidents during the 26 years 1911 to 1936 reached a high point in 1914, when the death rate was 0.94 per million man-hours of employment. Subsequent high points were 0.82 in 1920, 0.68 in 1922, and 0.67 in 1933. The 1933 rate was influenced by the loss of seven lives in a single disaster at a quarry in North Carolina. Notwithstanding the irregular course of the yearly fatality rates since 1911, their general trend has been decidedly downward. This shows the effectiveness of the accident-prevention work that has been conducted by the quarrying and related industries for many years. The figures covering the 26-year period are shown in table 38. Figure 1 presents graphically accident-frequency rates in the quarrying industry of the United States for the same period.

¹ Man-hours for 1911-23 computed on assumption that weighted average length of workday was 9.36 hours as shown by reports from representative operating companies for 1924.
² Injury rates for years previous to 1916 are believed not to be representative owing to probable incompleteness of reports of slight or minor injuries.

### NONCOMMERCIAL QUARRIES

The Bureau of Mines, in its canvass of accidents and employment at quarries in the United States for 1936, received reports from many plants that were operated by noncommercial agencies, such as States, counties, cities, and the Works Progress Administration. It is not believed that the reports received represented all operations of a noncommercial character, and it is impossible to state the extent of coverage represented by the reports. All reports received, however, were tabulated, and the results are shown in tables 41 to 44.

The reports on noncommercial quarries covered 272 plants operating in 30 States and having a total working force of 10,267 men and a total of 13.7 million man-hours of labor performed, an average of 174 days or 1,331 hours per man. The reports showed a weighted average workday of 7.6 hours. States having the largest number of employees were Kansas, Iowa, and New York. Most of the quarries reported

that the stone produced was used chiefly for surfacing roads.

As stated, it is not known whether or not accidents to the employees were completely covered by the reports. When no accidents were shown on the report form it was assumed that none occurred. The number of accidents reported included 6 fatalities and 710 nonfatal lost-time injuries. These figures showed a fatality rate of 0.44 and an injury rate of 51.96 per million man-hours of work done by all employees during the year. Included among the nonfatal injuries were 11 cases of permanent partial disability and 699 of temporary injury. No accidents involved permanent total disability, according to the reports from the operating agencies.

All of the plants for which reports were received were open quarries. Two fatal accidents to the quarry men were caused by explosives, two by machinery, and one by flying objects. Nonfatal injuries resulted mainly from handling materials; this cause accounted for more than a third of the total number of injuries to employees inside the quarries. Other important causes of accidents were flying objects, falls of persons, hand tools, haulage equipment, and falls or slides of rock or overburden. A total of 90 accidents occurred outside the quarries, of which the chief causes were hand tools, machinery, and haulage. One fatal accident also was attributed to haulage equipment

outside the quarries.
