EXECUTIVE SUMMARY**Phase Report 1C – Outfalls Investigation****RCRA Field Investigation****Technical Area 21 Operable Unit (OU 1106)****Los Alamos National Laboratory**

This phase report summarizes the results of field investigations conducted in 1992 at Technical Area 21 of Los Alamos National Laboratory, as prescribed by the RCRA Facility Investigation work plan for the Technical Area 21 operable unit (also known as OU 1106). This phase report is the last part of a three-part phase report describing the results of field work conducted in 1992 at this operable unit. Phase Report 1A, issued on 14 June 1993, summarized site geologic characterization activities. Phase report 1B, issued on 28 January 1994, included an assessment of site-wide surface soil background, airborne emissions deposition, and contamination in the locations of two former air filtration buildings.

The investigations assessed in Phase Report 1C include field radiation surveys and surface and near-surface sampling to characterize potential contamination at 25 outfalls and septic systems listed as SWMUs in the RFI work plan. Based on the RFI data, it is recommended that no further action is warranted for 8 SWMUs and further action is recommended for 3 SWMUs addressed in this phase report. For 14 SWMUs which represent no immediate threat to human health or environment, deferral of further action/no further action decisions is recommended until outstanding analytical data are received, sampling of adjacent SWMUs is completed, or decisions are made about the baseline risk assessment approach.

TABLE OF CONTENTS

LIST OF APPENDICES	vi
LIST OF TABLES	vii
LIST OF FIGURES	x
LIST OF MAPS	xii
1.0 INVESTIGATION OVERVIEW	1-1
1.1 Operable Unit Background Information	1-2
1.1.1 Operable Unit Description	1-2
1.1.2 Site History	1-2
1.1.3 Previous Investigations	1-5
1.2 Investigation Status	1-5
1.3 Regulatory Relevance	1-6
2.0 OUTFALLS INVESTIGATION ASSESSMENT	2-1
2.1 INTRODUCTION	2-1
2.1.1 Description of the Investigation	2-2
2.1.2 Field Activities	2-2
2.1.3 Data Assessment Methodology	2-4
2.1.4 Data Quality Assessment	2-9
2.1.4.1 Data Quality	2-9
2.1.4.2 Overview of Data Management	2-10
2.1.4.2.1 Data Management Process Description	2-10
2.1.4.2.2 Data Management Issues	2-12
2.1.4.3 Data Quality Summary	2-15
2.1.4.3.1 Representativeness	2-15
2.1.4.3.2 Completeness	2-15
2.1.4.3.3 Analytical Sensitivity	2-17
2.1.4.3.4 Precision	2-18
2.1.4.3.5 Accuracy	2-20
2.1.4.4 Special Concerns and Issues	2-21
2.1.4.4.1 Gamma Spectroscopy	2-21
2.1.4.5 Geodetic Survey Data	2-22
2.1.4.6 Conclusions	2-24

3.0	ABOVE-GROUND TANKS AND DRAIN LINES	3-1
3.1	SWMU 21-004(d)	3-1
3.1.1	Site Process and Sampling History	3-1
3.1.2	RFI Activities and Data Presentation	3-2
3.1.3	Data Assessment	3-3
3.1.4	Conclusions and Recommendations	3-4
3.1.5	QA/QC Sample Summary	3-4
4.0	UNDERGROUND SEEPAGE PITS	4-1
4.1	SWMU 21-006(b)	4-1
4.1.1	Site Process and Sampling History	4-1
4.1.2	RFI Activities and Data Presentation	4-2
4.1.3	Data Assessment	4-2
4.1.4	Conclusions and Recommendations	4-3
4.1.5	QA/QC Sample Summary	4-3
5.0	NEW INDUSTRIAL WASTE TREATMENT PLANT	5-1
5.1	SWMU 21-011(k)	5-1
5.1.1	Site Process and Sampling History	5-1
5.1.2	RFI Activities and Data Presentation	5-2
5.1.3	Data Assessment	5-3

INVESTIGATION OVERVIEW

1.0 INVESTIGATION OVERVIEW

This document, Phase Report 1C, reports the results of 1992 field investigations conducted according to the Resource Conservation and Recovery Act (RCRA) Facility Investigation (RFI) Work Plan for Environmental Restoration for the Technical Area (TA)-21 Operable Unit (OU) (LANL 1991a), as amended by an addendum and approved by Region 6 of the U.S. Environmental Protection Agency (EPA) (LANL 1991b; EPA 1992). This work was conducted as part of the Environmental Restoration (ER) Program of the Los Alamos National Laboratory (the Laboratory). The TA-21 OU is referred to interchangeably in this report as OU 1106. The work plan was prepared as required by the Hazardous and Solid Waste Amendment (HSWA) Module VIII of the RCRA Operating Permit for the Laboratory (EPA 1990).

Phase Report 1C is the last part of an initial three-part RFI phase report to be issued for the TA-21 RFI. The first part (Phase Report 1A), issued on June 14, 1993, included the results of studies of the site geology, fractures, stratigraphy, petrography, mineralogy, and geomorphology (LANL 1993a). The second part (Phase Report 1B), issued on 28 January 1994, assessed results from soil sampling activities conducted in 1992, which could not be reported earlier because of delays in receiving analytical results (LANL 1994). Included in Phase Report 1B are results from investigations of site-wide background, airborne emissions deposition and possible contamination of two former filter building locations. In all, 18 potential release sites listed as Solid Waste Management Units (SWMUs) in the RFI work plan were addressed in full or in part by the investigations reported in Phase Report 1B. This third document, Phase Report 1C, addresses 25 outfalls and septic systems listed as SWMUs in the RFI work plan. Aspects of the work reported in this phase report have been reported in quarterly technical progress reports presented to EPA Region 6 (LANL 1993a).

1.1 Operable Unit Background Information

1.1.1 Operable Unit Description

Figures 1.1-1 and 1.1-2 show the location of Technical Area (TA)-21 regionally and in relation to other operable units of the Laboratory. Technical Area-21 is located on the northern edge of the Laboratory and has a mesa-top elevation of about 7,000 ft. The site is centrally located on the Pajarito Plateau, roughly midway between the steep flanks of the Jemez Mountains to the west and White Rock Canyon of the Rio Grande to the east. The bedrock throughout the operable unit is the Bandelier Tuff, which consists locally of approximately 800 ft of volcanic ash deposits. Groundwater lies within the underlying Puye Formation at a depth of approximately 1,150 ft below the mesa top. Shallow alluvial and perched aquifers have been identified in Los Alamos Canyon. The RFI Work Plan, the ER Program's Installation Work Plan (IWP) (LANL 1993), and TA-21 Phase Report 1A contain additional details of the geologic setting of TA-21.

TA-21 occupies 311 acres and is centered on DP Mesa, immediately east-southeast of the Los Alamos townsite. The operable unit area extends from the mesa top to the stream channels in the adjacent canyons, DP Canyon to the north and Los Alamos Canyon to the south. Additional information relevant to general site conditions of TA-21 and vicinity is presented in the RFI work plan.

1.1.2 Site History

TA-21 was used primarily for plutonium research and metal production and related activities from 1945 to 1978. Subsequent unrelated office and small scale research activities have continued at the site to the present time. Because the major industrial activities at TA-21 were related to plutonium

production, the major waste disposal activities were plutonium related. Hazardous and radioactive constituents are likely to have been present in many waste streams as a result of the process chemistry.

The RFI work plan lists 29 SWMUs for the OU, subdivided into 112 SWMU subunits, which resulted from these activities. Of these 112 SWMUs, 68 were listed in Table A of the original Laboratory HSWA Module VIII. Table B of the HSWA Module lists 37 of these 112 SWMUs as "priority" SWMUs. This phase report addresses 1 SWMU from Table B, 13 SWMUs from Table A, and 2 SWMUs which were not cited in the original HSWA module. Nine units listed in the RFI work plan, but not in the original HSWA module, were added recently to the revised SWMU list. SWMUs on the revised list are referred to as "January 94" SWMUs to reflect the date of the last proposed revision. An additional 2 SWMUs were addressed in this report which are not HSWA or proposed HSWA SWMUs. These are referred to either as RCRA SWMUs or "work plan SWMUs." A "work plan SWMU" is defined as a unit not appearing in the HSWA module but called a SWMU in the work plan. A summary of the SWMUs addressed in Phase Reports 1A, 1B, and 1C is given in Table 1.1-1.

The SWMUs at TA-21 may be placed into the following four conceptual categories:

- deep liquid releases, such as seepage pits and absorption beds into which plutonium-bearing liquids were discharged (these include Material Disposal Areas (MDAs) T, U and V);
- near-surface liquid releases, such as discharges from septic systems, that may have contained industrial liquid wastes;

- subsurface solid waste disposal areas, such as MDAs A and B, where contaminated equipment, industrial materials, stabilized process residues, and solid radioactive or hazardous wastes were buried in shallow trenches or isolated shafts; and
- surface contamination areas, such as outfalls, stack emissions fallout, and surface spills, where limited quantities of contaminants were released to the land surface.

Outfall SWMUs are categorized in the RFI work plan as follows:

- SWMU 21-004, Aboveground Tanks and Drain Lines
- SWMU 21-006, Underground Seepage Pits
- SWMU 21-011, New Industrial Waste Treatment Plant
- SWMU 21-022, Acid Waste Lines and Sumps
- SWMU 21-023, Decommissioned Septic Systems
- SWMU 21-024, Inactive Septic Systems/Outfalls
- SWMU 21-026, Wastewater Treatment Plan, and
- SWMU 21-027, Surface Discharge

Table 1.1-2 summarizes the outfalls at TA-21. Figures 1.1-3 and 1.1-4 show the locations of TA-21 outfalls, centered around the western and eastern sections of the industrial area of TA-21 (referred to as DP West and DP East, respectively). Map 1 provides additional detail on the locations of TA-21 outfalls.

Detailed historical data regarding TA-21 are presented in RFI work plan Chapter 3, TA-21 Operable Unit Background Information. Information on environmental setting, geology, and surface and groundwater

hydrology for the Pajarito Plateau and TA-21 was summarized in RFI work plan Chapter 4, Environmental Setting. Additional relevant information is contained in the IWP and Phase Reports 1A and 1B. The grouping of TA-21 SWMUs into conceptual categories and a discussion of potential migration pathways of importance for each type of SWMU are presented in RFI work plan Chapter 5, Potential Contaminant Migration Pathways. Surface run-off, infiltration, and vapor-phase movement were identified as pathways of potential concern for outfalls.

1.1.3 Previous Investigations

The studies described in Phase Reports 1A and 1B were the first TA-21 RFI field activities formally reported, other than quarterly technical progress reports. Extensive environmental and operational monitoring has been conducted at TA-21 in the past. These studies are highly relevant to the RFI and are summarized in RFI work plan Chapter 4, Environmental Setting, and in Chapters 13 through 20 that detail the current knowledge for each SWMU. Specifically, Chapter 15 summarizes prior data for outfalls. In addition, preliminary TA-21 RFI field data is reported on a continuing basis in ER quarterly technical progress reports submitted to EPA Region 6. Relevant information from previous investigations supplements the outfalls investigations in Chapters 2 through 10 of this report.

1.2 Investigation Status

The updated TA-21 RFI schedule is summarized in Figure 1.2-1. Together, Phase Reports 1A, 1B, and 1C cover the activities identified as investigation Sequence 2 in this figure. The Sequence 2 investigation covers the portions of the RFI work plan listed in Table 1.1-2 of Phase Report 1C. Delays in receiving analytical reports, which led to the splitting of the first phase report into three parts, have been documented in quarterly technical progress reports to EPA (LANL 1992b, LANL 1993b, LANL

1993c). Notice of the need to split the report also was documented in correspondence to EPA (DOE 1993). Some data are outstanding from borehole analyses conducted as part of the outfalls investigation. When these data are received and assessed, they will be reported in an addendum to this phase report.

1.3 Regulatory Relevance

Investigations described in this phase report were specified in the amended TA-21 OU RFI work plan, as approved by EPA Region 6. The investigations satisfy requirements of the HSWA Module VIII of the Laboratory's RCRA Operating Permit. The data assessments and conclusions reached in Phase Report 1B and this report only address the regulatory status of the SWMUs listed in Table 1.1-1 of this chapter.

☒ Completed

Notes: Sample analysis tasks 12.4, 13.2 and 15 are behind schedule due to slow return of laboratory results.

CHAPTER 2

OUTFALLS INVESTIGATION ASSESSMENT

2.0 OUTFALLS INVESTIGATION ASSESSMENT

2.1 INTRODUCTION

The general purpose of the outfalls investigation assessed in this document is to characterize contamination at 25 outfall and septic system units listed as SWMUs in the RFI work plan. Of these 25 units, 13 are listed in Table A of the Laboratory's original HSWA Module VIII and one is listed in Table B (priority SWMUs) of the Module, and two were not cited in the original HSWA module. Nine additional units were added to the "January 1994" LANL SWMU list revision. Two units identified as non-HSWA SWMUs are listed in the RFI work plan. These 25 units are referred to in this phase report as "non-HSWA SWMUs" or "work plan SWMUs." Outfall-specific sampling plans are given in Chapter 15 of the TA-21 RFI work plan. Table 2.1-1 lists SWMU categories, phase report sections, individual SWMUs, and associated RFI work plan subsections.

Analytical laboratory data (1993 samples) have not been received for 14 of the SWMUs addressed in this phase report. Recommendations will be deferred for these SWMUs until the outstanding data are received and assessed. These data will be summarized in an addendum to this phase report. Table 2.1-2 presents a summary of the status of each SWMU, including eight recommended for no further action (NFA), fourteen for deferred decision, one for follow-on sampling, and two for corrective action.

Table 2.1-2 also contains the site ranking score (SRS) associated with each SWMU. The SRS for each SWMU was developed by LANL based on the potential source term, exposure pathways, receptor locations, and resulting risk. The ranking system was put in place to determine which SWMUs might

pose an immediate concern for human health and environment and would be potential candidates for expedited corrective action.

2.1.1 Description of the Investigation

General site background information is given in Chapter 1 of this phase report and in the RFI work plan. In this report, details of the field sampling conducted in 1992 and 1993, and the subsequent data assessment of the 1992 samples, are given. Map 1 at the end of this phase report illustrates the outfall locations across the operable unit.

Field surveys; surface, near-surface, and subsurface sampling; and laboratory analyses were performed as a part of this investigation in 1992 and 1993. Table 2.1-3 summarizes the number of samples collected versus the number planned. The analytical laboratory data from the 1992 outfall investigations are assessed in this report. Analytical laboratory data from the 1993 investigations have not been received and validated in time for inclusion in this phase report. These data will be reported in an addendum to this phase report.

2.1.2 Field Activities

The outfalls investigation included surface radiation surveys for gross alpha and low-energy gamma count rates. If elevated levels were detected, radiation surveys also were conducted for gamma exposure rate and total gamma. All equipment maintenance, calibration, and surveys were performed to the specifications of ER Program Standard Operating Procedures.

These surveys were used to bias sampling locations according to the rationale laid out in the RFI work plan. One of three soil sampling strategies (A, B, or C) was used at each of the sampled outfalls.

Strategy A If a drainage pattern was identified by the field radiological survey, surface, or near-surface soil samples (0-6 in. or at other depth intervals as specified in the SWMU-specific field sampling plans) were taken from the contaminated areas that define the pattern.

Strategy B If no pattern of contamination was found using Strategy A, two groups of three surface soil samples were taken downgradient from the best identified location of the outfall. For each group, three sampling points were spaced at nominal 5-ft intervals in a line across the probable drainage path. These three sample groups were placed at roughly 15-ft intervals down the flow path between the outfall and the mesa edge. The spacing between these sample groups varied depending on the proximity to the mesa edge, the need to sample a bench (relatively flat geologic outcrop along the canyon wall) below the mesa edge, and other factors.

Strategy C If no pattern of contamination was found using Strategy A for drainages with well-defined channels (assumed to be stable channels), surface soil sampling was done in the channel. In general, one sample location was located at the point of discharge and at least one additional location was sampled in a pooling area or likely sedimentation point 15 to 50 ft from the discharge point.

Field sampling included the collection of 0-6 in. surface samples, near-surface samples on 6 in. intervals to a maximum depth of 18 in., and shallow borehole samples to 20 ft. The samples were subject to the following measurements in a field screening laboratory: gross alpha, gross beta, total gamma, and gamma spectrometry. Not all samples were subject to the full suite of field laboratory parameters. A limitation in field screening laboratory data use was the qualitative reporting of gamma-emitting radionuclide levels from gamma spectrometry. This limitation particularly impacts low-level cesium-137 analyses, which were done only by gamma spectrometry.

Analyses were carried out by laboratories both external and internal to the Laboratory. The laboratory analyses fell into four categories: radionuclides, inorganics, volatile organics, and semi-volatile organics. Specific analytes for each outfall investigation are defined in Chapter 15 of the RFI work plan.

2.1.3 Data Assessment Methodology

The four primary categories of outfalls data are 1) field survey, 2) field laboratory, 3) analytical laboratory, and 4) quality assurance/quality control (QA/QC). Individual SWMU discussions present tables of all reported analyte concentrations from reconnaissance sampling as reported in the RFI work plan. Analytical laboratory data from 1992 samples are condensed into tabular form showing only those analyte concentrations exceeding the 95.5 percentile of applicable baseline categories, as developed in Phase Report 1B (LANL 1994). A description of these baseline categories and the basis of comparison to SWMU data are described in following sections. Analyte concentrations are also compared to screening action levels (SALs), as specified in Appendix J of the Installation Work Plan

(LANL 1993). Data tables also will be available on the Laboratory's Facility for Information Management and Display (FIMAD) database.

Comparison to Expected Contaminants

Where possible, historical sampling data and process knowledge were reviewed to develop a target group of analytes for the outfalls. If a reported analyte did not appear to be related to the historical process, it was discussed in the outfall section with respect to other sources.

Identification of Contamination Trends

Data were addressed to identify contamination trends. In the case of outfall SWMUs 21-011(k) and 21-024(i), isopleth maps were prepared (Maps 2 and 3). Analytical data were assessed for expected ratios of analytes, upgradient concentrations of contaminants, analyte concentration changes with depth and lateral distance from suspected sources, and impacts from man-made soil disturbances.

Underground lines are considered part of outfall SWMUs, although they were not specifically investigated as part of the SWMU. The following assumptions used in the characterization of the outfall SWMUs apply to underground lines.

- Contamination not present at either the outfall mouth or associated tank – the line is assumed to be clean.

- Contamination present at the outfall mouth or associated tank – the line is assumed to be contaminated.
- Contamination not present at the outfall mouth, but an associated tank has not been investigated – the line has not been characterized.

Comparison to Baseline Analyte Concentrations, Regional Background, and SALs

As discussed in detail in Appendix A of Phase Report 1B (LANL 1994) and shown on Map 1, distributions for inorganics and radionuclides fall into four baseline areas: non-process area, process area, and two special impact areas. The non-process area is located outside the industrial area of TA-21. The process area is approximately coincident with the industrial area and has been impacted by general operations at TA-21. The two special impact areas have been impacted by distinct processes, including operation of the Tritium Systems Test Assembly (TSTA – special impact area 2), and transport of contaminants downgradient from Material Disposal Areas (MDA) A and T (special impact area 1).

The means and 95.5 percentiles for the four baseline distributions, as developed in Phase Report 1B, are presented in Tables 2.1-4 – 2.1-6. While both normal and lognormal distribution parameters are presented for analytes within each baseline category, only the normal 95.5 percentile is used in the assessment of outfall data. Because the lognormal 95.5 percentile generally exceeds the normal 95.5 percentile, it is more conservative to make comparisons to the normal distribution 95.5 percentile (EPA 1992a).

The applicable baselines first were identified for each outfall. Individual analyte concentrations from discrete samples then were compared to the mean and 95.5 percentile of applicable baseline distributions. If an outfall had sample concentrations less than the applicable 95.5 percentiles, analyte concentrations were assumed not to be impacted by the outfall. Outfalls with multiple analyte concentrations exceeding the applicable 95.5 percentiles were assumed to be contaminated by outfall processes and were compared to SALs. A summary of outfall data exceeding applicable 95.5 percentiles is presented in Appendix B, while Appendix C presents all sample data reported above laboratory detection limits.

SALs are defined in Appendix J of the IWP for chemical class A and B carcinogens, chemical class C carcinogens, non-carcinogenic toxic chemicals, and radionuclides. SALs were developed by the Laboratory based on a set of residential exposure pathways and the assumption that the contaminant in question was the only contaminant present. The target risk or dose for each of these categories is:

Class A and B carcinogens	-	10^{-6} risk
Class C	-	10^{-5} risk
Non-carcinogenic, toxic	-	reference dose (RfD)
Radionuclides	-	10 mrem annual incremental dose

When data are compared to SALs, the presence of multiple contaminants must be considered. In general, the contaminant to SAL ratios are summed for all contaminants. If the sum of the ratios is less than one, target doses and risks are assumed not to be exceeded. Outfalls for which SAL ratio sums are below one and the contamination nature and extent is adequately characterized are recommended for no NFA. Two aspects of the SAL comparisons should be noted: 1) the most

conservative SAL was used for chromium (chromium VI – 400 ug/g) and 2) because SALs for beryllium and arsenic are lower than regional background levels, the applicable 95.5 percentile baseline was used in determining whether soil contamination is present.

No Further Action

If all SWMU analyte concentrations were found to be within the applicable baseline and decreasing lateral and vertical concentration gradients were decreasing, the outfall was recommended for NFA. For outfalls with analyte concentrations above the 95.5 percentile of applicable baseline categories, analytes were compared to risk-based SALs, as summarized in Table 2.1-7.

Analyte comparisons to baselines were performed only for radionuclides and inorganics. As outlined in Appendix A of Phase Report 1B, organic baselines were not developed because organic constituent levels at TA-21 are not of concern.

Organics detected at outfall SWMUs were assessed with respect to potential on-site and off-site sources, including analytical laboratory contaminants.

A supplemental statistical treatment and graphical presentation of outfalls data are presented in Appendix A. Conclusions from this higher level study are consistent with the assessment given in chapters 2–10 of this report.

Recommendations for Further Action

Further action recommendations include additional surface, near-surface, or borehole sampling, radiological field surveys, and interim corrective actions, such as fencing. Where follow-on sampling is recommended in this phase report, procedures described in Appendix A of the RFI work plan, or their equivalents, will be used unless noted otherwise. A general exception to the QAPjP is that detection limits will be revised upwards to correlate more reasonably with decision levels discussed in the IWP, i.e., SALs.

Deferred Decision

Analytical data from sampling performed in 1993 of some SWMUs has not been received in its entirety. Recommendations for these SWMUs are deferred until outstanding data is received and assessed. In a few cases, decisions are deferred pending baseline risk assessment. A recommendation for disposition of these SWMUs will be made in an addendum to this phase report.

2.1.4 Data Quality Assessment

2.1.4.1 Data Quality

This section summarizes data quality assessments for the data resulting from the outfalls investigation reported in this phase report. The overall requirements for data quality assurance were specified in the Laboratory's Generic Quality Assurance Project Plan (QAPjP), as presented in the Installation Work Plan (LANL 1993c). The QAPjP specifies quality assurance requirements for field sampling, field

measurements, and analytical laboratory data. Quality assurance objectives for precision, accuracy, analytical sensitivity, representativeness, completeness, and comparability (PARCC) are defined in the QAPjP. Appendix A of the TA-21 RFI Work Plan summarizes the specific objectives for the TA-21 operable unit.

For ease in presentation, this data quality summary is organized around the PARCC parameters. Within that organization, the data from each investigation are discussed as appropriate. Some problems were encountered in completing the data quality assessment. The primary issues were related to the batching of QA samples with field samples and the ability to relate samples to batches and QA results within the existing electronic data management system. The issues are explained and evaluated further in appropriate sections of this chapter.

In summary, despite these problems, the data acquired in the FY92 investigations and presented in this phase report are acceptable and usable for all purposes intended.

2.1.4.2 Overview of Data Management

The data management system, from collection of samples through reporting of results, is reviewed in this section. The purpose is to identify the important stages in the process and the problematic parts of the process which may impact data quality or the ability to assess data quality.

2.1.4.2.1 Data Management Process Description

The data collection and management process used for the TA-21 RFI is briefly summarized below.

Collection

The collection of field samples is accompanied by the collection of field QA samples: trip blanks, equipment rinsate blanks, field reagent blanks, and field duplicates. The number of field QA samples added is a percentage of the number of planned field samples, typically 5% to 10%. Each day of sampling, the field team delivered its samples to the ER Program's Sample Coordination Facility (SCF). It was recognized that the number and type of field QA samples submitted on any given day would vary. However, it was intended that all field samples and field QA samples submitted in a single day remain intact as a batch during laboratory analysis.

Distribution

Upon delivery to the SCF, field sample sets sometimes were combined and usually were supplemented with additional performance assessment QA samples, but were always maintained intact and submitted to the appropriate analytical laboratory as a batch. The SCF identified the batches by assigning a unique analytical request number, which was documented on an analytical service agreement. This document identified the sample number assigned by the field team, the sample number assigned by the SCF, the analyses to be performed, and any quality assurance samples associated with the request. The request number generally is used to track and retrieve sample information. Table 2.1-8 summarizes laboratory request numbers associated with each suite of analytes requested for each investigation.

Analysis

Sample batches were submitted to analytical laboratories based on laboratory capabilities and capacity. The several different types of analytical suites (radiological and inorganic) for an individual sample were often conducted by different laboratories. Sample aliquots were collected in the field in separate

sample containers for each type of analysis. The analytical methods employed by the laboratories are detailed in the QAPjP.

Reporting

Upon completion of sample analyses, analytical reports were prepared by the SCF. Each report was assigned a unique report number and referenced the request number. The analytical reports identify the analytical results for field samples and associated QA samples, the analytical methods, the analyst, and the laboratory performing the analyses. Data review is documented by the reviewer's initials on the final page of the report.

Data Management

Analytical results were entered into the FIMAD data management system to provide a means for reviewing the large volume of data and for accessing the results for data assessment including statistical analysis. Each of the samples addressed in this phase report was analyzed for one or more of the following categories of analytes: radiological, inorganics, semi-volatiles, and volatiles. Each category includes from five to 66 individual analytes, resulting in a large data set to be managed.

2.1.4.2.2 Data Management Issues

Issues impacting data quality or the ability to assess data quality are identified below for each stage in the data collection and management process.

Collection issues

Field collection of samples and submission of QA samples was conducted as planned for the TA-21 RFI.

Distribution issues

Distribution of samples to analytical laboratories was conducted as planned for the TA-21 RFI.

Analysis issues

In some cases, sample batches sent to an analytical laboratory were split (i.e., rebatched) at the contract laboratory to expedite analyses. Rebatching was not realized by the operable unit team until after much of the data had been received and entered into FIMAD. In some cases, quality assurance samples were batched separately from the corresponding field samples.

Each laboratory batch was addressed in one analytical report. Thus, a single request number (indicating the intended batch) may have resulted in more than one report number (indicating actual batches) if the laboratory split a batch. This problem did not become evident to the operable unit team until most data had been entered into FIMAD without inclusion of the report number as a separate field. Subsequently, new data have been entered into FIMAD with inclusion of the report number. In addition, some data were resubmitted to FIMAD with the report number. At present, some records in FIMAD include the report number and others do not. This inconsistency currently makes it impossible to efficiently correlate field samples with their associated quality assurance samples. Manual review of hard copy reports is ongoing.

Reporting issues

Multiple reporting. When errors were detected in data reports, a new analytical report was issued by the SCF. Depending on the severity of the error and the amount of data that changed, the new report sometimes carried a new report number. This created a situation where two reports with different report numbers provided sometimes different results for the same sample analysis. Whether or not a new report number was issued, all revised data were entered into FIMAD. To avoid loss of older data in the database, no data were overwritten, and multiple data records for individual samples have resulted. During use of the information in the FIMAD database, care must be taken to ensure that the correct value is chosen from multiple entries.

Data management issues

Incomplete information in the database. Early in the RFI, most data were entered into FIMAD without inclusion of the report number as a separate field, as discussed above. Some records in FIMAD include the report number and others do not. This inconsistency currently makes it impossible to efficiently correlate field samples with their associated quality assurance samples. For specific assessments, manual access to hard copy data reports must be employed.

It has been determined that insufficient information is available at this time to electronically verify the intactness of the batches of samples and assess their association with QA/QC samples. This assessment should be possible when the FIMAD database is revised.

At present, data qualifiers are not uploaded to FIMAD, resulting in the lack of that information within the electronic database. The result is a need to refer to hard copy analytical reports to complete some data assessment activities.

In the near future, the FIMAD database will be purged and all analytical data will be resubmitted to eliminate duplicate reporting and to supply report numbers for all data. The new data will be verified prior to release to other users and should allow a complete assessment of data quality, especially measures of precision and accuracy. Due to the difficulties described above, evaluation of data precision and accuracy was performed as if each SWMU dataset was a laboratory batch.

2.1.4.3 Data Quality Summary

2.1.4.3.1 Representativeness

The RFI work plan provides the primary guidance to ensure that collected samples are representative of the environment being assessed. If the samples are collected as specified in the work plan, and if conditions at the sampling locations are as expected, the samples are considered to be suitably representative. However, outfall sampling usually was biased to the location of the suspected outfall drainage. The samples collected were representative of soils in the outfall drainage. In some cases, areas with elevated instrument readings, or areas where runoff was expected to accumulate, were sampled to ensure the highest probability of sampling the most highly contaminated soil.

2.1.4.3.2 Completeness

Completeness will be assessed in this phase report as the percentage of usable analytical results reported, based on the number planned for the investigation. This is a less stringent definition of completeness than for some investigations. The decision to use this definition is explained in the following paragraphs.

For all the outfalls investigation reported in this phase report, the number of samples submitted to the laboratory for analysis and reported to the operable unit team was in excellent agreement with the sampling plan. The percentage of results reported is very high, as shown in Table 2.1-9.

Other aspects of the assessment of completeness include:

- The processing of matrix spike and matrix spike duplicate QA samples with each analytical batch by the analytical laboratory to document analytical recovery and provide a measure of analytical precision.
- The submission for analysis of field QA samples to document inadvertent contamination of samples and to provide a measure of sample variability. The frequency specification and the actual frequency achieved is summarized in Table 2.1-10 for all 1992 RFI investigations combined.

These measures of completeness are less rigorous than in other assessments which include analytical laboratory compliance with the exact analytical technique specified in the QAPjP or assessment of every sample batch with its associated quality assurance samples. There are two facets to acceptance of a less stringent definition for completeness. First, the FIMAD database does not currently include all of the information needed to relate samples to their analytical batches and associated quality assurance samples. In addition, it is known that in some cases the submitted batches were split and that the associated analytical results cannot be correlated with specific QA samples. However, in all cases where the assessments have been made, the judgment is that the sample analysis results are acceptable and usable for all intended purposes of this investigation. In addition, the less stringent

completion criteria are reasonable for investigations such as these where the purpose is to determine whether any contaminant release occurred.

In addition, inconsistencies in analytical techniques occurred relative to the QAPjP. If use of the prescribed analytical technique is a strict criterion for judging acceptability, some analyses for these investigations would be unusable and the completeness measure would be much lower. In reviewing the data and analysis information, however, it has been judged that the analyses done by the various techniques are usable, even if they differ slightly from those specified in the QAPjP.

2.1.4.3.3 Analytical Sensitivity

A review of all of the 1992 RFI analytical data (including outfalls, grid, and filter buildings) available on FIMAD was conducted to determine consistency of reported instrument detection limits with practical quantitative limits (PQLs) prescribed in the QAPjP. Reported detection limits for sample are displayed in FIMAD data records as a value preceded by the symbol "<" or "-".

All detection limits for radiological analyses complied with the PQLs in the QAPjP, with the exception of analyses performed by gamma spectrometry. The gamma spectrometry americium-241 detection limit (0.2 pCi/g) exceeded the PQL, but remains far below any decision level for these investigations. This departure from the QAPjP has no practical impact on the RFI objectives or data useability.

The QAPjP did not provide inorganic PQLs for soil samples. For this reason, detection limits for the PQLs were those associated with quality assurance samples. A large portion of the inorganic soil sample results were reported as ug/L, most likely due to data transcription errors. This issue is under

investigation and will be addressed in an addendum to this phase report. The percentage of data reported in ug/L varied from 4% for antimony to 82% for iron, and most frequently were between 25% and 45% for the entire 1992 RFI investigation. Reported sample detection limits for beryllium and magnesium (between 1 and 10 ug/L for beryllium and between 1 and 100 ug/L for magnesium) always exceeded the PQLs. Aluminum and arsenic complied with the PQL requirement 4% and 9% of the time respectively for the entire 1992 RFI investigation. All other inorganic analyte detection limits fell below the PQLs from 20-66% of the time. Ranges of values varied widely from 1-10 ug/L to 2-10 mg/L. Because the range of detection limits were far below decision levels for target analytes of the investigation, data useability was unaffected by deviations from the PQLs.

Except for one sample where the reported detection limit for each volatile organic analyte exceeded the PQL by a factor of 50, all reported detection limits for volatile organic compounds were very near the PQLs. Reported detection limits for semi-volatile organic compounds ranged from 330-3300 ug/kg for all analytes. These detection limits met or were better than PQL requirements for 37% of the analytes for the entire 1992 RFI investigation. Detection limits for the remaining analytes were above the PQL. Again, deviations from the PQLs do not significantly impact data useability for the purposes of these investigations.

2.1.4.3.4 Precision

Assessment of the compliance for the 1992 RFI data with PARCC precision objectives described below was done with the assumption that the samples collected at each SWMU made up a laboratory batch.

Analytical precision is calculated by expressing, as a percentage, the difference between the results of analysis of duplicate samples relative to the average of those results for a given analyte. Precision is expressed as a relative percent difference (RPD). The quality assurance objectives for inorganic and radionuclide analyses are different from those of organic analysis.

Inorganics Analysis

The quality assurance objective for precision for metals analysis is + or - 20 % RPD for sample values greater than 10 times the instrument detection limit. This RPD is for replicate analyses, as specified by Method 6010, Inductively Coupled Plasma-Atomic Emission Spectroscopy in U.S. EPA SW-846.

Organic Analysis

Analytical precision for organic analysis (GS/MS), under the criteria of U.S. EPA SW-846, is measured by comparing the recovery of a select number of target analytes in duplicate samples or blanks (e.g., matrix spike/matrix spike duplicate). The quality assurance objectives for precision of organic analysis (expressed by the RPD for analysis of matrix spike and matrix spike duplicate samples) are presented in Table V.11 of the QAPjP. In some instances, MS/MSD recoveries are reported in ug/g due to data transcription errors. This issue is under investigation and will be assessed in an addendum to this phase report.

Radionuclide Analysis

For the purpose of evaluating data discussed in this report, radionuclide precision criteria will be the same as the inorganic criteria specified in the QAPjP; + or - 20% RPD for sample values greater than ten times the instrument detection limit.

2.1.4.3.5 Accuracy

Assessment of the compliance of 1992 RFI outfalls data with PARCC accuracy objectives described below was done with the assumption that each SWMU dataset comprised a laboratory batch.

Analytical accuracy was calculated by expressing, as a percent, the recovery of a standard reference material or analyte that had been added to the sample (or standard matrix) at a known concentration before analysis. The spiked (fortified) concentration used was specified by laboratory quality control requirements as detailed in the applicable U.S. EPA SW-846 method.

Inorganic Analysis

Analytical accuracy for metals is measured from analysis of a spiked replicate sample and a sample spiked with the analyte of interest (analyte spike). The quality assurance objectives for accuracy in metals analysis, for these quality control samples, are taken from the U.S. EPA SW-846 Method 6010 and are summarized below.

<u>Sample</u>	<u>Recovery %</u>
Spike replicate	80-120
Analyte spike	75-125

In some instances MS/MSD recoveries are reported as 0% due to data transcription errors. This issue is under investigation and will be assessed in an addendum to this phase report.

Organic Analysis

For organic analysis (gas chromatography (GC) and GC/Mass Spectrometry (MS)), analytical accuracy is obtained from the surrogate recovery measured in each sample and blank or from the analysis of samples or blanks spiked with a select number of target analytes.

The U.S. EPA SW-846 quality assurance objectives for accuracy for organic surrogate spike recovery are summarized in Table V.12 of the QAPjP. The U.S. EPA SW-846 quality assurance objectives for precision and accuracy of matrix spike analyses are given in Table V.11 of the QAPjP. In some instances, MS/MSD recoveries are reported in ug/g due to data transcription errors. This issue is under investigation and will be assessed in an addendum to this phase report.

2.1.4.4 Special Concerns and Issues

The following issues are not directly related to PARCC requirements, but do represent deviations from the planned analytical program and potentially impact data quality.

2.1.4.4.1 Gamma Spectroscopy

Gamma spectroscopy was performed on all samples collected in the investigations described in this phase report. Preliminary gamma scans were performed in the field laboratory. These data were used primarily as screening information prior to sample shipping. More sensitive gamma spectroscopy analysis also were performed in an analytical laboratory on all samples submitted for laboratory analysis. In a deviation from the QAPjP, the performing laboratory reported non-quantitative gamma spectroscopy data, where the intent was quantitative analyses.

The gamma spectrometry data were intended primarily to address the presence of cesium-137 in the outfalls soil investigation. This need can be fulfilled in a qualitative sense using the reported gamma spectroscopy data. A further check which reduces the need for quantitative gamma spectral analysis is provided by the gross gamma measurements made on all samples in the field laboratory. For cesium-137, this technique has a detection limit of approximately 4 pCi/g. For the outfalls investigation, gross gamma levels were rarely reported above the detection limit, and then only marginally so.

2.1.4.5 Geodetic Survey Data

Specific attention has been given to verifying the accuracy of the coordinate data representing the locations of sampling points, as determined by geodetic surveys and reported in a final survey report. The geodetic survey coordinates were checked for validity prior to final entry into FIMAD. A total of 89 sampling locations were surveyed for the outfalls investigation reported in this phase report.

Survey coordinates initially provided in a draft survey report were loaded into a temporary FIMAD file and plotted on a base map for review to screen for major discrepancies. The planned locations for sampling were also displayed on the base map for ease of comparison. Errors resulting primarily from data entry were corrected and revised coordinates were entered into a temporary FIMAD file.

Subsequently, a point by point comparison was made to identify points which deviated from the planned locations, and to identify the group of points which were placed based on field information (for which no planned location was available). Based on field notes, the plotted location of each of these points was verified to confirm that the deviations from planned locations were appropriate and that the field-placed locations were correct.

Following the validity check described above, the temporary FIMAD data file was plotted and rechecked prior to approval for the permanent download into FIMAD.

2.1.4.6 Conclusions

Difficulties in accessing data through the FIMAD data management system have prevented a complete data quality assessment at this time. Quality related issues include the breaking of analytical batches by the analytical laboratories, resulting in the separation of field samples from their associated QA samples, transcription errors, and a general inability to efficiently relate samples to their analytical batches and QA samples within the existing electronic data management system.

This assessment of data quality for the TA-21 RFI is specific to the intended purposes of the outfalls investigation reported in this phase report. The purposes of the investigation focus on identifying whether contaminants are present, determining whether contaminants were released, and determining requirements if any, for further action. With consideration of those investigation objectives, the data acquired in the FY92 investigations and presented in this phase report are determined to be acceptable and usable for all intended purposes, even though not all measures of quality can be assessed at this time.

CHAPTER 3

ABOVE-GROUND TANKS AND DRAIN LINES

3.0 ABOVE-GROUND TANKS AND DRAIN LINES

SWMUs 21-004(a-c) are underground tanks which will be addressed in future investigations as described in Section 14.3 of the RFI work plan. SWMU 21-004(d) is the drain line from these tanks.

3.1 SWMU 21-004(d)

This outfall is addressed in Section 15.8, Surface Drainage North of Building TA-21-155, of the RFI work plan. SWMU 21-004(d) falls within the process baseline area and the two special impact baseline areas. The outfall and sampling locations at SWMU 21-004(d) are shown on Figure 3.1-1. The assessment of the RFI data for SWMU 21-004(d) leads to a recommendation for no further action.

3.1.1 Site Process and Sampling History

This outfall received overflow discharges from an acid waste pumping station, structure TA-21-223, that carried waste from DP East to DP West for treatment at the new liquid radioactive waste treatment facility (Building TA-21-257). Based on past activities at DP East, this outfall may have received discharges of diluted laboratory and chilled water system waste liquids. These discharges may have contained mercury, tritium, polonium, actinium, and plutonium-239/240. Over time, the outfall release configuration has changed. The initial release point was located just north of the perimeter road at a concrete bulkhead. In later years, the outfall pipe was extended approximately 60 ft from the bulkhead in a northwestern downgradient direction into DP Canyon. Later, the outfall was connected to two tanks that were installed for containment of treatment facility overflow which was released previously at 21-004(d).

One sample was collected at SWMU 21-004(d) about 2 ft downslope of the bulkhead during 1988 reconnaissance sampling. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics and pesticides/PCBs, and target analyte list metals. Standard analytical procedures of commercial laboratories were used for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium. Mercury, plutonium-239/240, and tritium were previously reported above regional background levels in the sample collected in 1988 (see approximate location on Figure 3.1-1). Low levels of oil and grease also were reported for this sample (LANL 1991a). Analytical results of the 1988 reconnaissance sampling are shown in Table 3.1-1.

3.1.2 RFI Activities and Data Presentation

The characterization of SWMU 21-004(d) was performed in 1992 as presented in the RFI work plan, except for the addition of americium-241 analysis.

The 1992 work consisted of a radiological field survey and the collection of soil samples from six locations according to sampling Strategy B. As originally planned, one surface (0-6 in.) and two near-surface (6-12 in. and 12-18 in.) samples were collected at each location. The approximate location of the outfall, its drainage pathway, and the SWMU sample locations are shown on Figure 3.1-1. The radiation survey identified in the figure was expanded to include the area where samples were collected.

Sampling location 21-1415 is in the area where SWMUs 21-024(h) and 21-004(d) drainages meet. Sample results for this location are discussed in Section 8.8 with SWMU 21-024(h) investigation results.

Table 3.1-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

3.1.3 Data Assessment

No inorganic analytes were detected above the applicable baseline 95.5 percentile.

The radiological field survey activities indicated background levels of alpha, gamma, and low-energy gamma emitters.

As indicated in Table 3.1-2, several radionuclides were detected above the 95.5 percentile of applicable baseline category. Tritium concentrations as high as 1,700 nCi/l were detected, which is approximately one-tenth the SAL, 1.5×10^4 nCi/l. Tritium concentrations increase with depth at locations 21-1408 and 21-1409. The lateral extent of tritium contamination is judged to be reasonably defined, with lower concentrations at downgradient locations 21-1410, 21-1411, and 21-1472.

Thorium-228 and strontium-90 were reported marginally above the applicable baseline 95.5 percentile at locations 21-1409 and 21-1408, respectively. Based on the low levels and knowledge of processes that fed this outfall, these concentrations do not indicate contamination from the outfall releases.

Acetone and methylene chloride (common laboratory contaminants) were the only volatile organics detected in the samples collected at SWMU 21-004(d). Acetone was detected in all soil samples analyzed for volatile organics in concentrations up to 88 ug/g and also in all three blanks at concentrations up to 62 ug/l. Methylene chloride was detected in relatively low concentrations, all below 14 ug/g. These concentrations are not judged to be indicative of organic site contamination.

3.1.4 Conclusions and Recommendations

It is judged that the investigation adequately characterized the nature and extent of contamination at SWMU 21-004(d). All contaminant levels (including tritium) were shown to be far below SALs. Therefore, it is recommended that no further action is warranted for this SWMU.

3.1.5 QA/QC Sample Summary

Analytes detected in blanks associated with SWMU 21-004(d) are listed in Table 3.1-4. No semi-volatile organics were detected in field rinsate and field reagent blanks collected at this SWMU. The field rinsate blank associated with this SWMU indicated no radionuclide contamination. The results of the field rinsate and field reagent blanks associated with this SWMU showed no detectable concentrations for 24 of the 25 inorganic analytes and 61 of the 62 volatile organics. The field trip blank associated with this SWMU showed no detectable concentrations for 61 of the 62 volatile organics.

Two laboratory duplicate analyses for radionuclides were performed. In the first duplicate, four of the seven radionuclide analytes from the 12-18 in. sample collected at location 21-1407 met the precision criteria specified in section 2.1.4 of this report. In the second duplicate, three of the six (no duplicate tritium analysis was performed) analytes from the 0-6 in. sample collected from location 21-1411 met the precision criteria specified in section 2.1.4 of this report. Three additional tritium laboratory duplicate analyses were performed on the samples collected from SWMU 21-004(d). One of these analyses met the precision criteria specified in section 2.1.4 of this report.

One inorganic MS/MSD analysis (0 to 6 in. sample collected from location 21-1407) was performed on the samples collected from SWMU 21-004(d). All recoveries were reported in FIMAD as 0%. Therefore, the accuracy criteria for these analytes, as specified in the QAPjP, could not be evaluated at this time.

Table 3.1-3 lists analytes that did not meet the precision criteria specified in the QAPjP.

Recoveries for organic MS/MSD analyses performed on the 0 to 6 in. and 12 to 18 in. samples collected from location 21-1408, and the 0 to 6 in. samples collected from location 21-1407 were reported in FIMAD in ug/g rather than percent recoveries. Therefore, precision and accuracy criteria could not be evaluated at this time.

Analytes detected in blanks associated with SWMU 21-004(d) are listed in Table 3.1-4.

Table 3.1-1 1988 outfall reconnaissance sampling – SWMU 21-004(d).

CHAPTER 4

UNDERGROUND SEEPAGE PITS

4.0 UNDERGROUND SEEPAGE PITS

SWMUs 21-006(a-f) are seepage pits which will be addressed in future investigations as described in Sections 17.2 and 18.3 of the RFI work plan. SWMU 21-006(b) was the only seepage pit with a known drain line.

4.1 SWMU 21-006(b)

The outfall portion of SWMU 21-006(b) is addressed in Section 15.9 of the RFI work plan and is located within the process baseline area. The outfall and sampling locations at SWMU 21-006(b) are shown on Figure 4.1-1. Because only a portion of SWMU 21-006(b) has been investigated, this SWMU is recommended for a deferred decision. However, the assessment of the available RFI data will likely lead to a recommendation of no further action.

4.1.1 Site Process and Sampling History

This outfall consists of a 3-in drain line which received acid wastes from building TA-21-2. The line passes southward through sump TA-21-118 and then to Los Alamos Canyon. The discharge point is approximately eight feet above the bench, immediately below the canyon edge. The system was built to accept waste from the ethyl ether extraction process, which was part of an early plutonium purification process at TA-21.

One sample was collected at SWMU 21-006(b) during 1988 reconnaissance sampling at the approximate location indicated on Figure 4.1-1. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics, pesticides/PCBs, and target

analyte list metals. Standard analyses were used for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium. The reported tritium concentration of 31 nCi/l was well above regional background levels. Lead, cesium-137, and plutonium-239/240 were reported slightly above regional background levels. Toluene also was reported above the detection limit in this sample. Analytical results are shown in Table 4.1-1.

4.1.2 RFI Activities and Data Presentation

Characterization of SWMU 21-006(b) was performed as prescribed in the RFI work plan, except at location 21-1358. The RFI work plan called for a 0-6 in. sample to be collected at location 21-1358, but refusal was encountered at 4 in. due to bedrock. Americium-241 was added to the analyte list for all samples.

The 1992 investigation consisted of a radiological field survey and the collection of surface (0-6 in.) samples from six locations according to sampling Strategy B.

4.1.3 Data Assessment

No inorganic analytes were detected above the applicable baseline 95.5 percentile.

Americium-241 was the only analyte detected above the non-process area baseline 95.5 percentile, at a concentration of 0.104 pCi/g at location 21-1360. This concentration did not exceed the process area baseline 95.5 percentile and is well below the SAL of 22 pCi/g. Thus, americium-241 is not of concern for SWMU 21-006(b).

Cesium-137 was reported at a concentration of 1.5 pCi/g in the 1988 reconnaissance sample. Because analytical laboratory gamma spectrometry was not performed on the 1992 samples, a lower detection limit for cesium-137 (4 pCi/g) was set by the field laboratory. Because gross gamma results were all reported below the lower detection limit, it is unlikely that cesium-137 levels exist at SWMU 21-006(b) above the SAL of 4 pCi/g.

The field survey indicated background levels of alpha and gamma emitters and slightly elevated levels of low-energy gamma emitters.

No semi-volatile or volatile organics were detected in the RFI samples collected from SWMU 21-006(b). No inorganics were detected above the non-process area baseline 95.5 percentile.

4.1.4 Conclusions and Recommendations

A decision on the disposition of this SWMU will be deferred until the seepage pit investigation has been completed. However, all analyte levels at the outfall were within the process area baseline 95.5 percentile and below SALs. Also, it is judged that the nature and extent of contamination has been characterized adequately. It is likely that a recommendation for no further action will be made after investigation of the seepage pit.

4.1.5 QA/QC Sample Summary

Because of the limited number of samples collected at this outfall and the frequency at which QA/QC samples are collected, no field reagent, field rinsate, or field trip blanks were associated with SWMU 21-006(b).

All laboratory duplicate radionuclide analyses met the precision criteria specified in the QAPjP. Inorganic precision criteria, as specified in section 2.1.4 of this report, were met for 10 of the 25 analytes. Twenty-four of the 25 MS recoveries and 23 of the 25 MSD recoveries met the inorganic accuracy criteria, as specified in the QAPjP, for the 0-6 in. sample collected from location 21-1355. Table 4.1-2 lists inorganics that did not meet the precision criteria specified in the QAPjP.

An organic MS/MSD analysis also was performed on the samples collected from 0-6 in. at location 21-1355. Because all organic MS/MSD recoveries were reported in FIMAD in ug/g, organic precision and accuracy criteria could not be evaluated at this time. The MS and MSD recoveries for manganese were 51% and 55.6%, respectively. The MS and MSD recoveries for lead were 139.7 and 194.7%, respectively, which exceed the inorganic accuracy criteria specified in the QAPjP.

CHAPTER 5

NEW INDUSTRIAL WASTE TREATMENT PLANT

5.0 NEW INDUSTRIAL WASTE TREATMENT PLANT

This chapter addresses an outfall associated with the new industrial waste treatment plant and is described in Section 15.4 of the RFI work plan.

5.1 SWMU 21-011(k)

SWMU 21-011(k) falls within special impact area 1, as shown on Map 1. The outfall and sampling locations at SWMU 21-011(k) are shown on Figure 5.1-1. SWMU 21-011(k) contains multiple contaminants above SALs and is recommended for interim fencing and further investigation.

5.1.1 Site Process and Sampling History

The outfall discharge line carried industrial waste water from the new industrial waste treatment plant (building TA-21-257) through two holding tanks to a discharge point on the south slope of DP Canyon. The wastes were liquids remaining after treatment of plutonium extraction process effluents and probably contained a variety of radioactive and chemical constituents. Untreated wastes from Building TA-21-35 (old industrial waste treatment plant) were also discharged in the vicinity of the outfall. Although this outfall is no longer active, it is identified by National Pollution Discharge Elimination System (NPDES) No. EPA050050. A 4-in. pipe ending about 55 ft north of the perimeter road is presumed to be the discharge point. A gently sloping, rocky surface extends from the outfall pipe approximately 30 ft to the canyon rim.

SWMU 21-011(k) was sampled as part of a DOE Headquarters Environmental Survey at the Laboratory. One surface (0-3 in.) sample was collected from each of three locations, as shown (approximate

location) on Figure 5.1-1. Sample LA30201 was collected 23 ft from the end of the outfall pipe. Samples LA30202 and LA30203 were collected from the canyon rim, approximately 35 ft from LA30201. Analytical results are given in Table 5.1-1. Cadmium, copper, nickel, uranium-235, uranium-238, plutonium-238, plutonium-239/240, thorium-230/232, americium-241, strontium-90, potassium-40, cesium-137, and protactinium-233 were detected in concentrations above regional background. Levels of plutonium, cesium-137, and strontium-90 were especially pronounced.

5.1.2 RFI Activities and Data Presentation

Characterization of SWMU 21-011(k) was performed as originally prescribed in the RFI work plan, except for location 21-1416. The RFI work plan called for 0-6 in. and 6-12 in. samples to be collected at location 21-1416, but refusal was encountered at 5 in. due to bedrock. Follow-on work was conducted in 1993, as discussed below, because of the elevated radioactivity levels noted in the 1992 investigation.

The 1992 investigation consisted of a radiological field survey and the collection of soil samples at three locations according to sampling Strategy A. With the exception noted above, one surface (0-6 in.) and two near-surface (6-12 in. and 12-18 in.) samples were collected at each location.

A 1993 follow-on characterization of SWMU 21-011(k) included a radiological survey with direct reading instruments to further delineate the contamination extent and to provide a rationale for the selection of follow-on soil sampling locations. Eight additional sampling locations, shown on Figure 5.1-1, were selected based on the radiological survey, which extended to the bottom of DP Canyon including small drainage channels leading from the discharge point. Surface (0-6 in.) samples were collected at all locations and near-surface (6-12 in. and 12-18 in.) samples were collected at three

locations. Analytical data from 1993 samples were not available for inclusion in this phase report, but will be presented in an addendum to this phase report.

In addition to the locations specifically selected for characterization of 21-011(k), one grid location (21-1142) sampled in the 1992 surface soil investigation fell within the immediate area of this outfall. The data from this grid location were included in the assessment for this SWMU.

Table 5.1-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile in the 1992 samples.

5.1.3 Data Assessment

Consistent with earlier sampling of this outfall, slightly elevated levels of cadmium, copper, nickel, lead, silver, zinc, and uranium were detected in the RFI investigation. The levels of these constituents all exceed the process area baseline but individually are well below SALs. The sum of inorganic SAL fractions approaches one.

Direct alpha readings were generally near background levels, except for one location that was approximately 20 times greater than background. The highest levels of alpha-emitting radionuclides were detected in samples collected from location 21-1416, which is the sample location nearest the discharge point. The limited number of elevated alpha survey readings indicates that contamination is slightly below the surface, out of detector range. Beta-gamma, gamma, and low-energy gamma readings exceeded background.

A summary of the radiological surveys performed in 1992 and 1993 are given in Table 5.1-3. Map 2 consists of an isopleth map based on the 1993 gamma exposure rate data. The 1992 characterization of SWMU 21-011(k) was performed over a 20-ft by 60-ft area around the discharge point and drainage channel.

Levels of americium-241, plutonium-238, plutonium-239/240, and strontium-90 were detected far above SALs. Elevated tritium levels were also detected, but the levels were below screening action levels. The soil samples collected in 1992 were analyzed using gamma spectrometry. The laboratory results were reported in such a fashion that it was impossible to determine analyte concentrations quantitatively from the gamma spectrometry data.

The highest reported gross gamma level was 3000 pCi/g, which limits the maximum cesium-137 concentration for SWMU 21-011(k) samples analyzed in 1992 and 1993. This radionuclide is probably the most significant contributor to the overall gamma exposure rate, with lessor contributions from americium-241 and strontium-90. Elevated beta-gamma survey results in Table 5.1-3 are corroborated by the elevated strontium-90 concentrations. The elevated gross alpha and low-energy gamma survey data are consistent with the elevated concentrations of americium-241, plutonium-238, and plutonium-239/240 detected in laboratory analyses.

In every case presented in Table 5.1-2, subsurface contaminant levels are much lower than in the surface layer, consistent with strong retardation of downward contaminant movement. In addition, levels decrease rapidly downgradient from the assumed discharge point. However, even these reduced values were observed to exceed SALs in some cases.

Grid location 21-1142, which is approximately 80 ft east and crossgradient of the outfall mouth, shows only uranium slightly exceeding the 95.5 percentile of applicable baseline.

A mound of dirt of unknown origin containing various forms of apparent excavation debris exhibited elevated gamma and low-energy gamma readings. This dirt pile was sampled in 1993 to a depth of 18". Analytical results for these samples were not available for inclusion in this phase report but will be presented in an addendum to this phase report.

No volatile organics were detected in five samples collected at this SWMU. Volatile organic analyses were not performed on five samples because holding times were missed. Five new samples taken from the same locations were resubmitted for analyses in 1993. Di-n-butyl phthalate, a common laboratory contaminant, was detected in the 6-12 in. sample collected at location 21-1418 at a concentration of 600 ug/kg, and bis(2-ethylhexyl) phthalate, another common laboratory contaminant, was detected in the 12-18 in. sample collected at location 21-1418 at a concentration of 340 ug/kg. The available data suggests that organic site contamination, if any, is not at a level of concern at SWMU 21-011(k).

5.1.4 Conclusions and Recommendations

While the concentrations summarized in Table 5.1-2 indicate decreasing concentrations with depth and distance from the discharge point, a number of analytes were detected in the deepest samples at concentrations that exceed SALs. When received, analytical data from 1993 samples will be used to further define the vertical and lateral extent of contamination. It is expected that further sampling will be needed to more adequately characterize the depth of contamination. A Phase 2 sampling plan will

be designed based on characterization activities performed to date and will take into account local drainage features. This sampling plan will be presented in an addendum to this phase report.

As an interim action, the area in the vicinity of SWMU 21-011(k) with exposure rates above 50 micro-R per hour (as shown on Map 2) will be fenced. The selection of this exposure rate was based on a plausible site exposure scenario leading to a maximum annual incremental dose of 10 mR. Fencing of this area is scheduled for completion in March, 1994, weather permitting. The fence will remain in place until remedial actions have been selected and completed.

5.1.5 QA/QC Sample Summary

An inorganic MS/MSD analysis was performed on the 0 to 6 in. sample collected from location 21-1135. Inorganic accuracy criteria, as specified in the QAPjP, were met for 22 of the 25 analytes for both MS and MSD analyses. Two additional MS recoveries also fell within the inorganic accuracy criteria. Table 5.1-4 lists analytes that did not meet the accuracy criteria specified in the QAPjP.

Because laboratory duplicate inorganic analyses were not reported, inorganic precision criteria, as specified in the QAPjP, could not be evaluated.

Most volatile organic analyses were not performed because holding times were missed. The only MS/MSD recoveries reported for volatile organics were for 1,4-dichlorobenzene. Because volatile and

semi-volatile organic recoveries were listed in FIMAD in ug/kg, accuracy and precision criteria, as specified in the QAPjP, could not be evaluated at this time.

CHAPTER 6

ACID WASTE LINES AND SUMPS

6.0 ACID WASTE LINES AND SUMPS

SWMUs 21-022(a-h) are acid waste lines and sumps which will be addressed in future investigations. SWMUs 21-022(b-e) and (g) are lines that drain acid sumps covered in section 18.8 of the RFI work plan. SWMUs 21-022(a,f,h) are acid sumps covered in section 17.5 of the RFI work plan.

6.1 SWMU 21-022(h)

Outfall SWMU 21-022(h) is addressed in Section 15.4 of the RFI work plan and falls within the process baseline area. Details of the outfall and associated sampling locations at SWMU 21-022(h) are shown on Figure 6.1-1. The data assessment in this section indicates that the nature and extent of contamination at SWMU 21-022(h) has been defined. However, some analyte levels are above SALs are thus the SWMU may be a candidate for baseline risk assessment. Additionally, the sump associated with this outfall has not been characterized. This leads to the recommendation that the disposition of this outfall be deferred until the investigation is completed.

6.1.1 Site Process and Sampling History

SWMU 21-022(h) is associated with NPDES outfall No. EPA03A032 and currently discharges treated cooling water. The outfall previously discharged industrial wastewater and received discharge from the basement floor and roof drains of Building TA-21-150, formerly referred to as the plutonium fuel service building. The existing line is a 24-in. corrugated metal pipe which extends south to the edge of Los Alamos Canyon. Below the discharge area is a broad, gently sloping area with no well defined channel.

No previous sampling data is available. However, based on process knowledge, potential contaminants include plutonium, uranium, mercury, lead, organics, and various acids (LANL 1991).

6.1.2 RFI Activities and Data Presentation

Sampling at SWMU 21-022(h) was executed as specified in the RFI work plan, except at location 21-1382. The RFI work plan called for 0-6 in., 6-12 in., and 12-18 in. samples to be collected at location 21-1382, but refusal was encountered at 12 in. due to bedrock. Americium-241 was added to the analyte list and isotopic thorium analyses were not performed.

The 1992 investigation activities performed at SWMU 21-022(h) consisted of a radiological field survey and the collection of samples from three locations according to sampling Strategy C. One surface (0-6 in.) and two near-surface (6-12 in. and 12-18 in.) samples were collected at location 21-1380 and 21-1381. One surface (0-6 in.) and one near-surface (6-12 in.) sample were collected from location 21-1382. Grid sample location 21-1125 is approximately 15 ft northeast of location 21-1380, upgradient of the drainage channel and outfall mouth of SWMU 21-022(h). This grid sample was included in the data assessment of this SWMU.

Table 6.1-1 presents a summary of RFI analyte concentrations detected above the applicable baseline 95.5 percentile.

6.1.3 Data Assessment

Copper and lead were reported at concentrations exceeding the process area baseline. The maximum copper concentration is approximately 2% of its SAL, and the maximum lead concentration is approximately 25% of its SAL.

Levels of plutonium-238 and plutonium-239/240 were substantially above the process area baseline, but individually were below SALs. The ratio of plutonium-238 to plutonium-239/240 differs markedly from the ratio observed for grid samples and other outfalls. The maximum plutonium-238 concentration is approximately 33% of its SAL, while the maximum plutonium 239/240 concentration is approximately 55% of its SAL. Americium-241 is the only radionuclide detected above the process area 95.5 percentile (0.549 pCi/g) in the neighboring grid sample at location 21-1125.

Field radiological surveys performed in 1992 indicated background levels of alpha emitters and slightly elevated levels of gamma emitters and low-energy gamma emitters.

Acetone and toluene were the only volatile organics detected in the soil samples collected from SWMU 21-022(h). Acetone was reported in all three surface samples at concentrations up to 37 ug/kg and in two near-surface samples at concentrations up to 53 ug/kg. Toluene was reported in one surface sample at a concentration of 14 ug/kg and in one near-surface sample at a concentration of 5.8 ug/kg. Since both toluene and acetone are common laboratory contaminants, and were detected in relatively low concentrations in the samples, these results are not considered to be indicative of significant site organic contamination.

Six semi-volatile organics were detected at low levels in surface samples collected from SWMU 21-022(h), as shown in Table 6.1-2. The presence of four of these compounds was confirmed with a field duplicate sample. The maximum benzo[b]fluoranthene concentration at location 21-1380 slightly exceeded the SAL. However, all detected semi-volatiles are either widespread environmental contaminants (pthalates) or polyaromatic hydrocarbons typical of paving materials. The detected organic concentrations are judged not to be indicative of significant organic contamination at the SWMU.

Contamination at this SWMU decreases markedly with depth and with one exception, the maximum analyte concentrations observed are well below SALs. The lateral extent of contamination appears to be defined adequately, with the highest concentrations identified at location 21-1380, near the assumed discharge point.

6.1.4 Conclusions and Recommendations

Because the nature and extent of contamination is judged to be adequately defined by the RFI investigation, it is recommended that no further field investigation associated with the outfall portion of SWMU 21-022(h) be performed. Since one analyte exceeds the SAL and the sum of the remaining SAL fractions is 55%, this SWMU may be a candidate for future risk assessment. This SWMU has not been fully characterized because the associated sump will be investigated at a later time. Therefore, it is recommended that a decision on the disposition of this SWMU be deferred.

6.1.5 QA/QC Sample Summary

Because of the limited number of samples collected at this outfall, the frequency at which QA/QC samples were collected, and the batching strategy, no field rinsate, field reagent, or field trip blanks collected in 1992 were directly associated with SWMU 21-022(h) samples.

A radionuclide laboratory duplicate was performed on the 0-6 in. sample collected at location 21-1382. Only selected members of the radionuclide suite were chosen in the laboratory for duplicate analysis. Radionuclide precision criteria, as specified in the QAPjP, were met for all four sets of results. Because no inorganic laboratory duplicates were performed on QA samples batched with SWMU 21-022(h) samples, inorganic precision criteria could not be evaluated.

Similarly, because no MS/MSD analyses were performed, organic accuracy and precision criteria and inorganic accuracy criteria could not be evaluated directly.

Table 6.1-1 Analytes detected above the 95.5 percentile of applicable baseline categories at SWMU 21-022(h).

Analyte	Location ID	Applicable Category	95.5 Percentile*	SAL*	Surface (0-6 in.)*	Near-Surface (6-12 in.)*	Near-Surface (12-18 in.)*

CHAPTER 7

DECOMMISSIONED SEPTIC SYSTEMS

7.0 DECOMMISSIONED SEPTIC SYSTEMS

SWMUs 21-023(a,b,d) are decommissioned septic systems which will be addressed during decontamination and decommissioning activities as described in the RFI work plan Section 18.3. SWMU 21-023(c) is the only decommissioned septic system with a drain line to the environment and is discussed below.

7.1 SWMU 21-023(c)

Outfall SWMU 21-023(c) is addressed in Section 15.2 of the RFI work plan and is located within the non-process baseline area. The outfall and sampling locations at SWMU 21-023(c) are shown on Figure 7.1-1. The assessment of the available RFI data for SWMU 21-023(c) indicates that additional samples may be needed in the pooling area below the outfall mouth to define the extent of contamination. However, a decision for further sampling at this SWMU will be deferred until outstanding data are received and assessed.

7.1.1 Site Process and Sampling History

This septic system previously received sewage from building TA-21-33, the former waste treatment laboratory where research into the recovery of plutonium from liquid process wastes was performed. The precise location of the septic tank and discharge point was unknown at the outset of the investigation. A concrete tank associated with the septic system was removed in 1965.

Liquid waste streams from the septic system may have contained small quantities of organics such as hexane, pentaether, and tri-n-butyl phosphate. Other possible contaminants include nitrates, chlorides, mercury, americium, plutonium, tritium, cobalt, uranium, and zirconium.

One sample was collected from the presumed discharge point during 1988 reconnaissance sampling. Because the outfall location was unknown at the time of reconnaissance sampling, the sampling was done approximately 35 ft upgradient of the true outfall mouth. The outfall mouth was identified during the 1992 RFI sampling. Reported analytes from the 1988 reconnaissance sampling are shown in Table 7.1-1. The approximate location of the 1988 reconnaissance sample is shown on Figure 7.1-1. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics, pesticides/PCBs, and target analyte list metals. Standard commercial laboratory procedures were used for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium. Plutonium-239/240 and tritium were reported slightly above regional background levels. Low levels of oil and grease also were reported (LANL 1991a).

7.1.2 RFI Activities and Data Presentation

Sampling at SWMU 21-023(c) was executed as specified in the RFI work plan, with two exceptions. Americium-241 analyses were added for all samples and the shallow borehole samples were analyzed for isotopic uranium rather than total uranium. All follow-on surface and near-surface samples collected in 1993 were in addition to those specified in the RFI work plan.

The 1992 investigation at SWMU 21-023(c) included a radiological field survey and the collection of six surface soil samples according to sampling Strategy A. Two surface samples were not collected

to the specified depth of 6 in. because bedrock was encountered. A 0-3 in. sample was collected at location 21-1339 and a 0-4 in. sample was collected at location 21-1335.

Table 7.1-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile. With the exceptions noted above, the sampling interval was 0-6 in.

Because of the elevated radionuclide levels identified in the 1992 RFI data, follow-on sampling was conducted in the 1993 field season. Follow-on sampling activities included collection of 0-6 in. soil samples from eight locations. Near-surface (6-12 in. and 12-18 in.) samples were collected from three of these eight locations. A 20-ft borehole was drilled and sampled in 5 ft intervals, downgradient of tank TA-21-62 to determine if leakage occurred. Radiological field survey activities performed in 1993 identified a contaminated pooling area below the mesa rim. A surface soil sample (0-6 in.) and two near-surface samples (6-12 in. and 12-18 in.) were collected from this pooling area, as part of the follow-on sampling. Analytical results for this sampling were unavailable for inclusion in this phase report and will be reported in an addendum to this phase report.

7.1.3 Data Assessment

The radiological survey indicated background levels of alpha and gamma emitters and slightly elevated (1.5 times background) levels of low-energy gamma emitters. Contaminant levels appear to decrease downgradient from the pooling area.

Arsenic, cadmium, chromium, copper, nickel, lead, and zinc exceeded the applicable baseline 95.5 percentile. Maximum chromium concentrations were approximately 80% of the hexavalent chromium SAL. In general, maximum inorganic concentrations are noted at locations 21-1336 and 21-1337.

Significantly elevated americium-241 and plutonium-239/240 levels were detected in the 1992 RFI samples. Concentrations of americium-241, plutonium-238, plutonium-239/240, strontium-90, and uranium exceeded the applicable baseline 95.5 percentile. Previous sampling results did not indicate that these analytes should be present in elevated concentrations at the outfall. Maximum americium-241 and plutonium-239 concentrations exceeded their respective SALs by more than a factor of 10. Radionuclide concentrations generally increase at the furthest downgradient sampling locations (21-1330 and 21-1340).

No volatile organics were detected in the samples collected from SWMU 21-023(c). Benzoic acid, the only semi-volatile organic detected, was reported at a concentration of 360 ug/kg from sample location 21-1388.

7.1.4 Conclusions and Recommendations

Analysis of 1993 samples will determine whether the downgradient extent of contamination has been adequately characterized and may determine the requirement for additional lateral sampling across the drainage area. Shallow borehole samples collected in 1993 will provide information to evaluate downward migration of these contaminants near the former tank location.

Radiological survey data from 1993 indicates additional sampling may be required in the pooling area. Because multiple analyte concentrations well above SALs were detected, some form of remedial action may be required for this SWMU, following baseline risk assessment. However, a decision on whether further sampling will be required at SWMU 21-023(c) will be deferred until outstanding data are received and assessed.

7.1.5 QA/QC Sample Summary

No volatile or semi-volatile analytes were detected in the field reagent or field rinsate blanks associated with SWMU 21-023(c). The field rinsate blank associated with this SWMU indicated no radionuclide contamination, and no detectable concentrations for 19 of the 25 inorganic analytes.

Laboratory duplicate analyses for americium-241, plutonium-238, and plutonium-239/240 were run on three samples. All analyses met the precision criteria specified in the QAPjP.

Laboratory duplicate analyses were performed on a field rinsate blank associated with location 21-1338, on the 0-6 in. sample collected at location 21-1335, and on the 0-6 in. sample collected at location 21-1337. Inorganic precision criteria, as specified in the QAPjP, were met for 23 of the 25 analytes for the field rinsate blank, for 22 of the 25 analytes for the sample from location 21-1335, and all of the analytes for the sample from location 21-1337.

Table 7.1-3 lists the analytes detected in a rinsate sample collected at SWMU 21-023(c). No radionuclides were detected in blanks at concentrations above ten times the detection limit.

Inorganic and organic MS/MSD analyses were run on the sample collected from location 21-1337. Because organic recoveries were listed in FIMAD in ug/kg, organic precision and accuracy criteria, as specified in the QAPjP, could not be evaluated at this time. An MS/MSD analysis also was run for inorganics on the sample collected from location 21-1338. Because recoveries for both inorganic MS/MSD analyses were listed in FIMAD as 0%, inorganic accuracy criteria, as specified in the QAPjP, could not be assessed at this time.

Inorganic analytes that did not meet the precision criteria, as specified in the QAPJP, are listed in Table 7.1-4.

CHAPTER 8

INACTIVE SEPTIC SYSTEMS/OUTFALLS

8.0 INACTIVE SEPTIC SYSTEMS/OUTFALLS**8.1 SWMU 21-024(a)**

Outfall SWMU 21-024(a) is addressed in Section 15.2 of the RFI work plan and is located within the process area and special impact area 1. The outfall and sampling locations at SWMU 21-024(a) are shown on Figure 8.1-1. A decision on the final status of SWMU 21-024(a) will be deferred until analytical laboratory data from samples submitted in 1993 are received and assessed.

8.1.1 Site Process and Sampling History

This septic system routed sewage from Building TA-21-9 (old steam plant) through a concrete septic tank (abandoned in place) to the surface on the north rim of Los Alamos Canyon. A portion of the line and septic tank TA-21-53, south of the perimeter road and Building TA-21-9, were removed.

The RFI work plan indicates that the outfall may contain fuel oil from the boiler and blowdown constituents such as sulfite and copper salts. Releases from blowdown lines which are not part of SWMU 21-024(a) may commingle with releases from this SWMU. Liquid wastes received from the old steam plant may have contained elevated concentrations of cadmium, chromium, copper, iron, lead, nickel, and zinc.

No previous environmental data are available for SWMU 21-024(a).

8.1.2 RFI Activities and Data Presentation

Sampling at SWMU 21-024(a) was executed as specified in the RFI work plan, except that americium-241 was added to the analyte list and the borehole samples were analyzed for isotopic uranium rather than total uranium.

The 1992 investigation consisted of a radiological field survey and collection of samples from six locations according to sampling Strategy B. One surface (0-6 in.) and two near-surface (6-12 in. and 12-18 in.) samples were collected at each location. In addition to the locations specifically selected for characterization of SWMU 21-024(a), one grid location (21-1144) sampled in the surface soil investigation fell within the immediate area and was included in the data assessment for this SWMU.

Table 8.1-1 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile. Surface soil concentrations were significantly higher than those concentrations detected in near-surface soils.

The 1993 sampling activities performed at SWMU 21-024(a) included the placement of a shallow borehole downgradient of tank TA-21-53 to determine if leakage occurred. Analytical results for this sampling were unavailable for inclusion in this phase report and will be included in an addendum to this phase report.

8.1.3 Data Assessment

Copper, lead, and zinc concentrations exceeded the applicable baseline 95.5 percentile but are well below SALs. Chromium and nickel concentrations increased with depth at location 21-1390 and the maximum lead concentration was approximately 40% of SAL.

Uranium and strontium-90 concentrations exceeded the applicable baseline 95.5 percentile. The maximum uranium concentration was approximately 33% of its SAL, while strontium-90 marginally exceeded the applicable baseline 95.5 percentile. The radionuclide concentrations decreased with depth.

The radiological survey indicated background levels of alpha, gamma, and low-energy gamma emitters. At grid location 21-1144, lead and copper concentrations were slightly above the 95.5 percentile of baseline. Copper was reported at 4.5 and 2.5 times the 95.5 percentile for the 0-1 in. and 0-6 in samples, respectively. All other analytes from this sample were below the applicable baseline.

Acetone and toluene were reported at levels ranging from 9.9 ug/kg to 55 ug/kg in samples collected at SWMU 21-024(a). Acetone also was reported for three associated blank samples at concentrations up to 42 ug/l. Bis(2-ethylhexyl)phthalate and diethyl phthalate were reported for concentrations of 890 and 680 ug/kg, respectively. These analytes are common laboratory and environmental contaminants and the reported levels are judged not to be indicative of significant site contamination.

8.1.4 Conclusions and Recommendations

Analyte levels were not detected in concentrations above the SALs and the extent of contamination at the discharge point was judged to be adequately characterized, pending assessment of the analytical results of the borehole sampled in 1993. A recommendation on the disposition of SWMU 21-024(a) will be deferred until outstanding borehole analyses are assessed. Based on information to date, it is expected that no further action will be recommended for this SWMU.

8.1.5 QA/QC Sample Summary

No detectable inorganic or semi-volatile organic contamination was reported in a field reagent blank associated with this SWMU.

No detectable semi-volatile organic contamination was reported in a field rinsate blank associated with this SWMU. No detectable volatile contamination was reported for 61 of the 62 analytes in field reagent, field rinsate, or field trip blanks associated with this SWMU.

The field rinsate blank associated with this SWMU indicated no radionuclide contamination and no detectable concentrations for 24 of the 25 inorganic analytes. Cobalt was reported at a concentration of 10.5 ug/l in this blank.

Laboratory duplicate analyses for inorganics showed excellent internal agreement. Nickel was the only inorganic analyte that did not meet the precision criteria defined in the QAPjP. In this case, the RPD was 31%. Laboratory duplicate analyses for radionuclides were in excellent agreement, with the exception of plutonium-239/240 and plutonium-238, which had RPDs of 56% and -31%, respectively.

Acetone was reported for one field blank, one trip blank, and one rinsate blank at levels of 38, 24, and 42 ug/l, respectively.

An MS/MSD was run on the 6 to 12 in. sample collected at location 21-1389. Benzene, chlorobenzene, 1-1-dichlorethene, toluene, and trichlorethene were reported in both the MS/MSD and soil sample from this location. Since these analytes are routinely spiked in the MS/MSD samples, it is reasonable to assume that some residue associated with MS/MSD analysis was left in analytical equipment, thus contaminating the soil sample analysis. No other volatile organics were reported in the sample.

Because MS/MSD values in the inorganic data set were listed in FIMAD as 0%, precision criteria for these analytes could not be evaluated. However, analytical data appear to yield reasonable values in comparison to other outfall data sets.

All volatile organic MS/MSD recoveries were listed in FIMAD in ug/l or ug/kg and no MS/MSD analyses were performed on semi-volatile organic analytes. Therefore, organic precision and accuracy criteria could not be evaluated at this time.

8.2 SWMU 21-024(b)

This septic system is addressed in Section 15.3 of the RFI work plan and falls within the process baseline area. The outfall and sampling locations at SWMU 21-024(b) are shown on Figure 8.2-1. SWMU 21-024(b) has analyte levels exceeding SALs, an undefined extent of contamination, and outstanding borehole data. A decision on the need for a follow-on sampling plan will be deferred until shallow borehole data are received and assessed.

8.2.1 Site Process and Sampling History

This septic system routed sewage from Building TA-21-17 through a concrete septic tank to a discharge point on the surface south of Building TA-21-5. The outfall currently consists of cast iron pipe that emerges from backfill inside the industrial fence and discharges on a gentle slope. No clearly defined drainage channel exists.

One sample was collected at the discharge point of SWMU 21-024(b) during 1988 reconnaissance sampling at the approximate location shown on Figure 8.2-1. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics, pesticides/PCBs, and target analyte list metals. Standard commercial laboratory procedures were used for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium.

Americium-241, plutonium-239/240, tritium, and lead were reported above regional background levels. Low levels of oil, grease, and methylene chloride (a common laboratory reagent) also were reported. Analytical results of the 1988 reconnaissance sampling are shown in Table 8.2-1.

8.2.2 RFI Activities and Data Presentation

The 1992 RFI activities consisted of a radiological field survey and the collection of soil samples from three locations according to sampling Strategy C. One surface (0-6 in.) and two near-surface (6-12 in. and 12-18 in.) samples were collected at each location.

Sampling at SWMU 21-024(b) was executed as specified in the RFI work plan, with the exception of shallow borehole sampling intervals and analyses performed during 1993. Borehole samples were collected at depths of 2 ft, 4 ft, 6 ft, and 8 ft instead of at 5-ft intervals to 20 ft. This modification was implemented because the tank was partially exposed at the ground surface and assessing lateral contaminant dispersion from the tank was achievable with shallower sampling. Americium-241 was added to the analyte list for all samples collected in 1992 and 1993, and the shallow borehole samples were analyzed for isotopic uranium rather than total uranium. No isotopic thorium analyses were performed on the 6-12 in. sample collected from location 21-1379.

Table 8.2-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

The 1993 sampling activities performed at SWMU 21-024(b) included the placement of a shallow borehole near the suspected location of the septic tank. Analytical results for this sampling were unavailable prior to preparation of Phase Report 1C and will be included in an addendum to this phase report. In addition to the locations specifically selected for characterization of SWMU 21-024(b), one grid location (21-1119) sampled in the 1992 surface soil investigation fell approximately 15 ft crossgradient from outfall location 21-1379. The grid data from this location were included in the assessment for this SWMU.

8.2.3 Data Assessment

Arsenic, chromium, nickel, selenium, and zinc exhibit maximum concentrations slightly above the applicable baseline 95.5 percentile. All maximum inorganic concentrations are less than 6% of the SALs.

Americium-241, plutonium-239/240, tritium, and uranium concentrations were reported above the applicable baseline 95.5 percentile in several samples. For the 0-6 in. sample at location 21-1379, the plutonium-239/240 concentrations exceeded the SAL by slightly more than an order of magnitude. Elevated americium-241 and plutonium-239/240 concentrations also were noted in near-surface samples, but decreased significantly with depth.

Both americium-241 and plutonium-239/240 at grid location 21-1119 were slightly above the 95.5 percentile of the applicable baseline, indicating that this location is outside or near the lateral extent of contamination.

The radiological survey indicated background levels of alpha and low-energy gamma emitters and slightly elevated levels of gamma emitters (up to 1.5 times background).

Acetone and toluene were the only volatile organics reported for samples collected from SWMU 21-024(b). Acetone was reported for a near surface sample at a concentration of 22 ug/kg, and toluene was reported in near surface samples at concentrations of 17 and 18 ug/kg. Since both toluene and acetone are common laboratory contaminants and were detected in relatively low concentrations, the reported levels are not likely to be indicative of significant site contamination.

Several semi-volatile organics which are frequently found in the environment were reported at low levels for the 6-12 in. sample collected from location 21-1379, as listed in Table 8.2-3. The levels are far below SALs and are unlikely to be indicative of site contamination.

For most analytes, highest levels were reported for the 0-6 in. sample at the furthest downgradient sample location.

8.2.4 Conclusions and Recommendations

Because the maximum plutonium 239/240 concentration greatly exceeds its SAL for one sample, further downgradient sampling may be needed to adequately characterize the lateral extent of contamination at this SWMU. However, a decision for follow-on investigation will be deferred to an addendum to this phase report, after the outstanding laboratory data from the 1993 borehole sample have been received and assessed.

8.2.5 QA/QC Sample Summary

No detectable volatile organic contamination was reported for 61 of the 62 analytes in the field trip blank associated with this SWMU. Acetone was reported in one field trip blank at a concentration of 44 ug/l.

An inorganic laboratory duplicate was performed on the 0-6 in. sample collected at location 21-1377. Sixteen of the 25 analytes met the precision criteria specified in the QAPjP. Radionuclide laboratory duplicate analyses were performed on samples collected at locations 21-1377, 21-1378, and 21-1379.

Only selected members of the radionuclide suite were chosen in the laboratory for duplicate analysis. Eight of the nine sets of results met the precision criteria as specified in section 2.1.4 of the report.

Table 8.2-4 lists the radionuclides and inorganics that did not meet the precision criteria as specified in the QAPjP.

An inorganic MS/MSD analysis was performed on the 0-6 in. sample collected from location 21-1377. Because recoveries were listed in FIMAD as 0%, inorganic accuracy criteria could not be evaluated at this time.

A semi-volatile organic and 1,4-dichlorobenzene (one of the six analytes in a standard VOA MS/MSD analysis) MS/MSD analysis was performed on the 6 to 12 in. samples collected from location 21-1378. Because recoveries were listed in FIMAD in ug/g instead of percent, organic precision and accuracy criteria could not be evaluated at this time.

8.3 SWMU 21-024(c)

Outfall SWMU 21-024(c) is addressed in Section 15.3 of the RFI work plan and is located within the process area and special impact area 1. The location of the outfall, its drainage pathway, and sampling locations are shown on Figure 8.3-1. Because borehole analytical data have not yet been received, a decision on the disposition of this SWMU will be deferred. Current data indicate that this SWMU has multiple analytes exceeding SALs and thus is a candidate for baseline risk assessment.

8.3.1 Site Process and Sampling History

SWMU 21-024(c) consists of a septic tank and associated outfall that routed sewage from Building TA-21-54 (now removed) through a concrete septic tank to the surface on the north rim of Los Alamos Canyon. The septic tank is located south of the PCB storage area and the outfall line surfaces above a gentle slope approximately 15 ft from the canyon edge in a vaguely defined channel.

One sample was collected in the outfall channel 8 ft from the end of the outfall pipe during 1988 reconnaissance sampling at the approximate location shown on Figure 8.3-1. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics and pesticides/PCBs, and target analyte list metals. Standard commercial laboratory procedures were used for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium. Zinc, copper, lead, mercury, americium-241, plutonium-238 and 239/240, tritium, and uranium isotopes were reported above regional background.

Analytical results of the 1988 reconnaissance sampling are shown in Table 8.3-1.

8.3.2 RFI Activities and Data Presentation

Sampling at SWMU 21-024(c) was executed as prescribed in the RFI work plan, except that americium-241 was added to the analyte list for all samples. Although PCB analysis was identified in the RFI work plan for this SWMU, these analyses were not performed for any of the samples because PCBs are associated with upgradient SWMU 21-003. Borehole samples were analyzed for isotopic uranium, rather than total uranium. Sample results from SWMU 21-003 will be used to assess the requirement for further PCB sampling at this SWMU.

The 1992 investigation consisted of a radiological field survey and the collection of soil samples from two locations according to sampling Strategy C. One surface (0-6 in.) and one near-surface (6-12 in.) sample were collected from each location.

Table 8.3-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

Follow-on sampling investigations in 1993 consisted of a radiological field survey and the placement of a 20-ft borehole in the suspected vicinity of the septic tank. One sample was collected from each 5-ft interval of the borehole. Analytical data for these samples were not available for inclusion in this phase report but will be included in an addendum to this phase report.

8.3.3 Data Assessment

Silver, arsenic, cadmium, chromium, copper, nickel, lead, and vanadium were detected at concentrations in excess of the applicable area baseline 95.5 percentile. Arsenic, chromium, and lead

were reported above SALs at location 21-1391. Inorganic contaminants show a marked concentration decrease from the 0-6 in. sample to the 6-12 in. sample, indicating that downward migration has been restricted. The maximum reported inorganic concentrations generally were higher than those reported in the 1988 reconnaissance sample.

Americium-241, tritium, plutonium-239/240, strontium, and uranium were reported in concentrations substantially greater than the applicable baseline 95.5 percentile. Tritium concentrations ranged from 437 to 7,100 nCi/l in the 0-6 in. samples and ranged from 99 to 1,300 nCi/l in the associated 6-12 in. samples. Uranium was the only radionuclide analyte that exceeded its SAL (0-6 in. sample from location 21-1391).

Inorganic and radionuclide concentrations were higher in the 0-6 in. samples than in the 6-12 in. samples, and were markedly lower in the downgradient sample. The radiological field survey indicated background levels of alpha, gamma, and low-energy gamma emitters.

Low levels of organics listed in Table 8.3-4 were reported for samples collected at SWMU 21-024(c). Acetone was reported in the field blank collected at the outfall. All of these analytes are common laboratory or environmental contaminants, and their detection at low levels is not likely to be indicative of significant site organic contamination.

8.3.4 Conclusions and Recommendations

A decision on the recommended disposition of SWMU 21-024(c) will be deferred until outstanding analytical data are received. Current data indicate that this SWMU may be a candidate for baseline risk assessment.

8.3.5 QA/QC Sample Summary

The field rinsate blank associated with this SWMU indicated no radionuclide contamination, and no detectable semi-volatile and volatile organic concentrations were reported. No detectable concentrations were reported for 21 of the 25 inorganics in the field rinsate blank or for 23 of the 25 inorganics in the laboratory duplicate of the field rinsate blank.

No detectable concentrations were reported for 61 of the 62 volatile organics in the field trip and field reagent blanks associated with this SWMU. No detectable inorganic concentrations were reported in the field reagent blank associated with this SWMU.

An inorganic laboratory duplicate analysis was performed on the field rinsate blank associated with this SWMU. Twenty-four of the 25 analytes met the precision criteria specified in the QAPjP.

Radionuclide laboratory duplicates were performed on samples collected at locations 21-1391, and 21-1392. Only selected members of the radionuclide suite were chosen in the laboratory for duplicate analysis. Twelve of the 16 sets of results met the precision criteria specified in section 2.1.4 of this report.

An MS/MSD analysis was performed on the 6-12 in. sample collected from location 21-1391. All inorganic recoveries met the accuracy criteria specified in the QAPjP. The only volatile organic for which MS/MSD recoveries were reported was 1,4-dichlorobenzene. Because semi-volatile organic and 1,4-dichlorobenzene recoveries are listed in FIMAD in ug/kg, precision and accuracy criteria cannot be evaluated at this time.

The analytes listed in Table 8.3-5 were detected in blanks collected at SWMU 21-024(c). No semi-volatile organics were detected in the rinsate blank.

Inorganic and radionuclide laboratory duplicates showed reasonable agreement with one another. Analytes not meeting the precision criteria, as specified in the QAPjP, are listed in Table 8.3-6.

8.4 SWMU 21-024(d)

Outfall SWMU 21-024(d) is addressed in Section 15.3 of the RFI work plan and is located within the process area. The outfall and sampling locations at SWMU 21-024(d) are shown on Figure 8.4-1. The assessment of the available RFI data for SWMU 21-024(d) performed in this section will likely lead to a recommendation of no further action. However, that decision will be deferred until 1993 borehole data are received and assessed.

8.4.1 Site Process and Sampling History

This outfall routed sewage from Building TA-21-1 (removed in 1965) through concrete septic systems to a discharge point at the cliff on the north rim of Los Alamos Canyon.

One sample was collected 8 ft from the outfall marker during 1988 reconnaissance sampling as shown on Figure 8.4-1. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics and pesticides/PCBs, and target analyte list metals. Standard analyses also were conducted for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium. Mercury, americium-241, plutonium-238, plutonium-239/240, oil, and grease were detected at levels above regional background. A substantially elevated tritium level was found.

Analytical results of the 1988 reconnaissance sampling are shown in Table 8.4-1.

8.4.2 RFI Activities and Data Presentation

Sampling at SWMU 21-024(d) was executed as prescribed in the RFI work plan, with the exception of the sampling intervals on the shallow borehole samples and analyses that were performed. Shallow borehole samples were collected at depths of 2 ft, 4 ft, 6 ft and 8 ft rather than at 5-ft intervals to a depth of 20 ft. This change was made because the top portion of the tank was visible above ground. Therefore the sampling depth of 20 ft specified in the RFI work plan was not necessary to characterize leakage from the tanks. Americium-241 was added to the analyte list for all samples and shallow borehole samples were analyzed for isotopic uranium rather than total uranium.

The 1992 investigation included a radiological survey of the discharge area at the canyon rim and on the bench immediately below and the collection of soil samples from two locations. One surface (0-6 in.) sample was collected at the canyon rim in a small pooling area 13 ft south of the outfall discharge point. One surface (0-6 in.) sample and two near-surface (6-12 in. and 12-18 in.) samples were collected from an area where the effluent collected on the bench below the discharge point.

In addition to the locations specifically selected for characterization of 21-024(d), one grid location (21-1096) sampled in the 1992 surface soil investigation is located approximately 20 ft outside the drainage channel to the west. The analytical results from 21-1096 were included in the assessment for this SWMU.

Table 8.4-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

In 1993, an 8-ft borehole was placed in the suspected vicinity of the associated septic tank. One sample was collected from each 2-ft interval. Analytical data for these samples were not available for inclusion in this phase report, but will be reported in an addendum to this phase report.

8.4.3 Data Assessment

Silver and lead were reported slightly above the applicable baseline 95.5 percentile but were below SALs. The maximum lead concentration was identified in the 12-18 in. sample at approximately 30% of the SAL. Elevated silver concentrations were reported in the 0-6 in. and 6-12 in. samples collected from location 21-1348, decreasing to just above the non-process area baseline 95.5 percentile in the 12-18 in. sample.

Levels of americium-241 above the process area baseline were detected in both the 0-6 in. and 6-12 in. samples from the bench. Tritium concentrations above the process area baseline 95.5 percentile were detected at only one location (on the bench), but were elevated in all three samples, (0-6 in., 6-12 in., and 12-18 in.) from this sampling location. Plutonium-239/240 was detected above the process area baseline 95.5 percentile in three of four samples. Uranium was detected slightly above the process area baseline 95.5 percentile in the 0-6 in. sample collected from the bench. In general, radionuclide concentrations decreased with depth. The plutonium-239/240 concentration exceeded the SAL in the 0-6 in. sample from location 21-1348. None of the analytical data from grid location 21-1096 were above the process area baseline 95.5 percentile. The RFI data indicate that levels of contamination from this outfall are low and restricted to the discharge point area.

The radiological survey indicated background levels of alpha and gamma emitters and slightly elevated levels of low-energy gamma emitters at approximately 1.5 times background.

No semi-volatile organics were detected in the samples collected from SWMU 21-024(d). Acetone was the only volatile organic reported (33 ug/g) in the samples collected at this SWMU. However acetone also was detected in a field trip blank associated with this SWMU at 40 ug/l.

8.4.4 Conclusions and Recommendations

Because SALs were marginally exceeded for only one analyte (plutonium-239/240) of one surface sample and the contamination levels decrease with depth, no further action is likely to be necessary at this SWMU. Since the top of the concrete tank is exposed and accessible, useful information may be obtained by sampling the material in the bottom of the tank. However, a recommendation for final disposition of this SWMU will be deferred until the outstanding borehole data from the vicinity of the septic tank are received and assessed, and reported in an addendum to this phase report. If these results are consistent with the available data, the SWMU will be recommended for no further action.

8.4.5 QA/QC Sample Summary

Although the programmatic frequency of QA samples met all requirements of the QAPjP, this and several other SWMUs did not have QA/QC samples associated with their relatively limited number of RFI samples.

No detectable concentrations were reported for 61 of the 62 volatile organics in the field trip blank associated with this SWMU.

An inorganic laboratory duplicate analysis was performed on the 0-6 in. sample collected at location 21-1347. Twenty-four of the 25 analytes met the precision criteria specified in the QAPjP. Acetone was detected at a concentration of 40 ug/l in a field trip blank associated with this outfall.

An inorganic MS/MSD analysis was performed on the 0-6 in. sample collected from location 21-1347. Inorganic accuracy criteria, as specified in the QAPjP, were met for 21 of the 25 analytes for both MS and MSD analyses. Table 8.4-3 lists inorganic MS/MSD recoveries that did not meet the accuracy criteria specified in the QAPjP.

Laboratory duplicate analyses performed for inorganics met precision requirements with the exception of nickel, which had an RPD of -24%. No laboratory duplicate analyses were performed on radionuclides.

A semi-volatile organic and 1,4-dichlorobenzene (one of the six analytes in a standard semi-volatile MS/MSD analysis) MS/MSD analysis was performed on the 0-6 in. sample collected from location 21-1347. No MS/MSD analyses were performed on any other volatile organics. Because recoveries were listed in FIMAD in ug/kg, organic precision and accuracy criteria, as specified in the QAPjP, could not be evaluated at this time.

8.5 SWMU 21-024(e)

Outfall SWMU 21-024(e) is addressed in Section 15.3 of the RFI work plan and is located in the process baseline area. The outfall and sampling locations at SWMU 21-024(e) are shown on Figure 8.5-1. The assessment of the available RFI data for SWMU 21-024(d) indicates that further sampling or baseline risk assessment might be needed. However, that decision will be deferred until 1993 borehole data is received.

8.5.1 Site Process and Sampling History

SWMU 21-024(e) consists of a septic system that routed sewage from Building TA-21-20 (contaminated laundry facility removed in 1965) through a steel tank to a discharge point about 20 ft from the southern edge of DP Mesa. The septic tank and outfall are located south of MDA V. The outfall area is broad and open with a poorly defined channel.

One sample was collected from SWMU 21-024(e) during reconnaissance sampling in 1988 as shown on Figure 8.5-1. The sample was collected from the drainage pathway directly below the outfall. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics and pesticides/PCBs, and target analyte list metals. Standard analyses also were performed for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium.

Mercury, zinc, americium-241, plutonium-238, uranium-234, uranium-238, and cesium-137 were reported in concentrations slightly above regional background levels. Levels of plutonium-239/240 and

tritium substantially exceeded regional background. Analytical results are shown in Table 8.5-1 and the approximate sampling location is shown on Figure 8.5-1.

8.5.2 RFI Activities and Data Presentation

Sampling at SWMU 21-024(e) was executed as prescribed in the RFI work plan, with the exception of sampling depths for the surface and near-surface samples and the analyses performed on borehole samples. The RFI work plan called for a 0-6 in. sample and a 6-12 in. sample to be collected at each location. Refusal was encountered at 4 in. at location 21-1342, and at 11 in. at location 21-1341 because of bedrock. Americium-241 was added to the analyte list for all samples, and isotopic uranium, rather than total uranium, analyses were performed on the borehole samples.

The 1992 investigation consisted of a radiological field survey and the collection of soil samples from two locations according to sampling Strategy C. Two samples (0-6 in. and 6-11 in.) were collected from location 21-1341 and one sample (0-4 in.) was collected from location 21-1342.

In addition to the locations specifically selected for the characterization of SWMU 21-024(e), one grid location (21-1079) sampled in the 1992 surface soil investigation is located in the outfall channel. The analytical results from location 21-1079 were included in the assessment for this SWMU.

Table 8.5-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

As a part of the 1993 field investigations, a 20-ft borehole was placed in the suspected vicinity of the septic tank. One sample was collected from each 5-ft interval. Analytical data for these samples are not available for inclusion in this phase report, but will be reported in an addendum to this phase report.

8.5.3 Data Assessment

Cadmium, chromium, copper, lead, selenium, vanadium, and zinc were detected in concentrations slightly above the applicable baseline 95.5 percentile but well below SALs.

Americium-241, uranium, tritium, plutonium-238, and plutonium-239/240, were detected in concentrations well above the applicable baseline 95.5 percentile. All levels were well below SALs except for plutonium-239/240 in the 0-6 in. sample at location 21-1341. Radionuclide concentrations substantially decreased with sample depth and are substantially higher at upgradient location 21-1341. Data from grid location 21-1079 corroborate the assessment described above. The radiological field survey indicated background levels of alpha, gamma, and low-energy gamma emitters.

A low level of trichlorofluoromethane was reported in the 0-6 in. field duplicate sample collected from location 21-1341. Since this result was not confirmed in the soil sample collected from this same depth and location and the detected concentration is small, it is likely that no organic site contamination is present. No trichlorofluoromethane was detected in the QA samples at this SWMU.

All contaminant levels decrease with sample depth and distance from the discharge point. All maximum concentrations were detected in the samples collected from location 21-1341.

8.5.4 Conclusions and Recommendations

Available RFI data indicate that the extent of contamination associated with the discharge point has been characterized adequately. Because plutonium-239/240 was reported above the SAL in one sample baseline risk assessment might be required for this SWMU. However, a recommendation for disposition of this SWMU will be deferred until outstanding borehole data are reported and assessed.

8.5.5 QA/QC Sample Summary

The field rinsate blank associated with this SWMU indicated no radionuclide contamination. No volatile organics were detected in this sample. No detectable concentrations were reported for 21 of the 25 inorganics, and for 63 of the 64 semi-volatile organics.

No detectable concentrations of volatile and semi-volatile organics were reported in the field reagent sample associated with this SWMU. No detectable concentrations were reported for 22 of the 25 inorganics.

Radionuclide laboratory duplicate analyses were performed on samples collected at location 21-1341. Only selected members of the radionuclide suite were chosen in the laboratory for duplicate analysis. Three of the six sets of results met the precision criteria specified in section 2.1.4 of this report.

No MS/MSD analyses were performed on the samples collected from SWMU 21-024(e). Therefore the organic precision and accuracy criteria and inorganic accuracy criteria, as specified in the QAPJP, could not be evaluated.

The radionuclides listed in Table 8.5-3 did not meet the precision criteria specified in section 2.1.4 of this report. Because laboratory duplicate analyses were not performed on inorganics, inorganic precision criteria, as specified in the QAPjP, could not be evaluated.

The semi-volatile organics and inorganics listed in Table 8.5-4 were detected in blanks collected at SWMU 21-024(e).

8.6 SWMU 21-024(f)

Outfall SWMU 21-024(f) is addressed in Section 15.9 of the RFI work plan and is located in the non-process baseline area. The outfall and sampling locations at SWMU 21-024(f) are shown on Figure 8.1-6. Because borehole analytical data are outstanding, it is recommended that a decision on the disposition of this SWMU be deferred. It is likely that no further action will be recommended when the outstanding data is received and assessed.

8.6.1 Site Process and Sampling History

SWMU 21-024(f) previously discharged sewage from Building TA-21-45 (Safety Training Building, now removed) through a steel septic tank to the surface on the north rim of DP Mesa. Currently there is no surface expression of the septic tank. Tank effluent discharged into a 3-ft by 2-ft deep pit.

One sample was collected from the center of the pit during 1988 reconnaissance sampling at the approximate location indicated on Figure 8.6-1. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics and pesticides/PCBs, and target analyte list metals. Standard analyses were used for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium.

Mercury, cesium-137, plutonium-239/240, and tritium were reported in concentrations slightly above regional background. Low levels of oil and grease also were reported. Analytical results are shown in Table 8.6-1.

8.6.2 RFI Activities and Data Presentation

Sampling at SWMU 21-024(f) was executed as prescribed in the RFI work plan, except that americium-241 was added to the analyte list for all samples and the shallow borehole samples were analyzed for isotopic uranium rather than total uranium.

In 1992 soil samples were collected from the eastern, western, and northern sides of the pit. One surface (0-6 in.), and two near-surface (6-12 in. and 12-18 in.) samples were collected from each location.

Table 8.6-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

The 1993 sampling activities at SWMU 21-024(f) consisted of a land survey and the drilling of a 10-ft shallow borehole in the pit area. Samples were collected from 2.5 ft, 5 ft, and 7.5 ft and 10 ft. A second borehole was placed in the vicinity of the tank, and sampled at 5-ft intervals to a depth of 20 ft. Analytical results for these samples were unavailable for inclusion in this phase report but will be assessed and reported in an addendum to this phase report.

8.6.3 Data Assessment

Cadmium and chromium were detected slightly above the non-process baseline 95.5 percentile, but at 5% or less of SALs.

Elevated plutonium-239/240 in the 1988 reconnaissance sample was confirmed in the 1992 sampling. No elevated tritium levels were detected in the samples collected in 1992. All analytes exhibit decreasing concentration with depth. Other reported maximum radionuclide concentrations were significantly below associated SALs, with the plutonium-239/240 concentration in the 0-6 in. sample at location 21-1432 approximately 58% of its SAL.

A radiological field survey performed throughout a 50-ft radius around the pit in 1992 indicated background levels of alpha, gamma, and low-energy gamma emitters.

No semi-volatile organics were detected in samples collected from SWMU 21-024(f). Acetone, methylene chloride, and toluene were the only volatile organics reported. Acetone was reported for two surface samples at concentrations up to 35 ug/kg, and in six near-surface samples at concentrations up to 55 ug/kg. Toluene was reported for one near-surface sample at a concentration of 8 ug/kg and methylene chloride was reported for one near-surface sample at a concentration of 7 ug/kg. Because all three of these analytes are common laboratory contaminants and were reported in low concentrations in the samples, these detections are not likely to be indicative of site contamination.

8.6.4 Conclusions and Recommendations

Because only one analyte (plutonium-239/240) approached a significant fraction (approximately 58%) of its SAL and the lateral and vertical extent of contamination is defined adequately at the discharge point, no further action is warranted for the discharge point. However, a recommendation for disposition of the SWMU will be deferred until outstanding borehole data are received, assessed and reported in an addendum to this phase report. It is likely that no further action will be recommended once the outstanding data is received and assessed.

8.6.5 QA/QC Sample Summary

Although the programmatic frequency of QA samples met all requirements of the QAPjP, this and several other SWMUs did not have QA/QC samples associated with their relatively limited number of RFI samples.

An inorganic laboratory duplicate analysis was performed on the 0-6 in. sample collected at location 21-1431. Twenty-two of the 25 analytes met the precision criteria specified in the QAPjP.

Radionuclide laboratory duplicate analyses were performed on samples collected at location 21-1341. Only selected members of the radionuclide suite were chosen in the laboratory for duplicate analysis. Two of the seven sets of results met the precision criteria specified in section 2.1.4 of this report.

Because MS/MSD analyses for organics were not performed on samples collected from SWMU 21-024(f), organic precision and accuracy criteria could not be evaluated.

An inorganic MS/MSD analysis was performed on the 0-6 in. sample collected from location 21-1431. Because recoveries were listed in FIMAD as 0%, inorganic accuracy criteria, as specified in the QAPjP, could not be evaluated at this time.

The radionuclides and inorganics listed in Table 8.6-3 did not meet the precision criteria.

8.7 SWMU 21-024(g)

Outfall SWMU 21-024(g) is addressed in Section 15.2 of the RFI work plan and is located in the process baseline area. The outfall and sampling locations at SWMU 21-024(g) are shown on Figure 8.7-1. It is recommended that a decision on the disposition of SWMU 21-024(g) be deferred until outstanding borehole analytical data are received and assessed.

8.7.1 Site Process and Sampling History

Outfall SWMU 21-024(g) was a septic system that routed sewage from Buildings TA-21-71 (warehouse) and TA-21-31 (electronics shop) through a concrete septic tank (abandoned in place) to the surface on the north rim of DP Canyon.

Two samples were collected at SWMU 21-024(g) during 1988 reconnaissance sampling. The samples were analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics and pesticides/PCBs, and target analyte list metals. Standard analytical methods were used for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium.

Cesium-137, plutonium-239/240, uranium-238, tetrachloroethene, cadmium, copper, lead, nickel, and mercury were reported slightly above regional background. Arsenic was reported slightly above the detection limit and well above regional background in one sample. Tritium was detected in another sample. Analytical results of the 1988 reconnaissance sampling are shown in Table 8.7-1.

8.7.2 RFI Activities and Data Presentation

Sampling at SWMU 21-024(g) was executed as prescribed in the RFI work plan, except that americium-241 was added to the analyte list for all samples and the shallow borehole samples were analyzed for isotopic uranium rather than total uranium.

The 1992 investigation consisted of a radiological field survey and collection of soil samples from six locations according to sampling Strategy B. One surface (0-6 in.) and one near-surface (6-12 in.) sample were collected from each location.

Table 8.7-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

The 1993 sampling activities performed at SWMU 21-024(g) consisted of a land survey to locate septic tank TA-21-125 and the drilling of a 20-ft shallow borehole near the downgradient side of the tank. One borehole sample was collected from each five feet interval. Analytical results for these samples were unavailable prior to preparation of this phase report and will be assessed in an addendum to this phase report.

8.7.3 Data Assessment

The inorganic constituents arsenic, cadmium, chromium, copper, manganese, nickel, lead, selenium, vanadium, and zinc were reported at concentrations above the non-process area baseline 95.5 percentile. In general, maximum inorganic concentrations range from <1% to 15% of their associated

SALs and the sum of SAL fractions is less than 50%. The presence of these inorganic contaminants is reasonable based on process knowledge.

The radionuclides americium-241, tritium, plutonium-238, plutonium-239/240, strontium, and uranium were reported in concentrations above the applicable baseline 95.5 percentile. Americium-241, plutonium-238, and strontium-90 levels only slightly exceed the 95.5 percentile, and all are less than 10% of SALs. Maximum plutonium-239/240 and uranium concentrations are approximately 80% and 30% of SALs, respectively, in surface samples.

Gamma spectrometry was requested as part of the analytical suite for samples collected at SWMU 21-024(g) to detect cesium-137. Assessment of these data has been delayed due to the reporting format, in section 2.1.4.4 of this report.

The 1992 radiological survey indicated background levels of alpha, gamma, and low-energy gamma emitters. Field laboratory analysis yielded results of 4.8 pCi/g of gross gamma emitters for one sample from location 21-1425, marginally above the detection limit of 4.0 pCi/g. Field laboratory analysis for gross alpha, gross beta, and gross gamma for all other samples were reported as less than detection limits. These gross gamma results place an upper limit of 4.8 pCi/g on the maximum cesium-137 levels that could be present.

Acetone, a common laboratory contaminant, was detected in five samples in concentrations up to 37 ug/kg. These concentrations are not indicative of significant site organic contamination.

8.7.4 Conclusions and Recommendations

Reported contaminant levels are slightly higher in the downgradient set of samples at locations 21-1428, 21-1429, 21-1430 than in the upgradient set of samples locations 21-1425, 21-1426, 21-1427. The highest concentration levels were detected in samples at the greatest perpendicular distance from the suspected flow line of the outfall (21-1425, 21-1427, 21-1428, and 21-1430). For example, copper concentrations at locations 21-1428 and 21-1430 are over twice the 21-1429 concentration. These results indicate that the lateral extent of contamination has not been completely delineated. However, all analyte levels are below SALs. Analyte concentrations decrease with depth near the discharge point.

A recommendation on the disposition of SWMU 21-024(g) will be deferred until outstanding borehole analyses are reported and assessed.

8.7.5 QA/QC Sample Summary

Although the programmatic frequency of QA samples met all requirements of the QAPjP, this and several other SWMUs did not have QA/QC samples associated with their relatively limited number of RFI samples.

Tritium laboratory duplicate analyses were performed on four samples. One of the four sets of results met the precision criteria specified in section 2.1.4 of this report. The relative percent difference for tritium laboratory duplicate analyses for the 0-6 in. sample, the 0-6 in. field duplicate sample, and the 6-12 in. sample collected from location 21-1430 were -28%, -48%, and -23%, respectively.

A volatile organic MS/MSD analysis was performed on 6-12 in. samples collected from locations 21-1427 and 21-1428. Because recoveries were listed in FIMAD in ug/kg, organic accuracy and precision criteria, as specified in QAPjP, could not be evaluated at this time.

Because inorganic laboratory duplicate or MS/MSD analyses were not performed, therefore the inorganic accuracy and precision criteria, as specified in the QAPjP, could not be evaluated.

8.8 SWMU 21-024(h)

The outfall portion of SWMU 21-024(h) is addressed in Section 15.8 of the RFI work plan and is located within both the process area and special impact areas 1 and 2. The outfall and sampling locations at SWMU 21-024(h) are shown on Figure 8.1-8. Because borehole analytical data were not received prior to the writing of this report, it is recommended that a decision on the disposition of this SWMU be deferred. Current data indicate that baseline risk assessment may be required for SWMU 21-024(h).

8.8.1 Site Process and Sampling History

SWMU 21-024(h) discharged sewage from Building TA-21-151 through septic tank TA-21-163 to the surface on the north rim of DP Mesa. The lower drainage area of this SWMU overlaps that of SWMU 21-004(d).

One sample was collected at SWMU 21-024(h) during 1988 reconnaissance sampling at the approximate location indicated in Figure 8.8-1. The sample was analyzed according to CLP SOW protocol for the target compound list volatile organics, semi-volatile organics and pesticides/PCBs, and target analyte list metals, and by standard procedures of commercial laboratories for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium.

Americium-241, tritium, and plutonium-239/240 were reported above regional background levels. Low levels of oil and grease also were reported. Plutonium-238 was not reported as a contaminant in historical sampling data. However, process knowledge and contaminant levels at other SWMUs

associated with Building TA-21-151 suggests the possibility of plutonium-238 at SWMU 21-024(h). Analytical results of the 1988 reconnaissance sampling are shown in Table 8.8-1.

8.8.2 RFI Activities and Data Presentation

Sampling at SWMU 21-024(h) was executed as defined in the RFI work plan, with the exception of sampling depth at location 21-1414 and the analyses that were performed. The RFI work plan called for 0-6 in., 6-12 in., and 12-18 in. samples to be collected at location 21-1414, but refusal was encountered at 12 in. due to bedrock. Americium-241 was added to the analyte list and the shallow borehole samples were analyzed for isotopic uranium rather than total uranium.

The 1992 investigation consisted of a radiological field survey and the collection of samples from three locations according to Strategy C. One surface (0-6 in.) and two near-surface (6-12 in. and 12-18 in.) samples were collected from locations 21-1413 and 21-1415. One surface (0-6 in.) and one near-surface (6-12 in.) samples were collected from location 21-1414. Location 21-1415 is in the area where the drainages for SWMU 21-024(h) and SWMU 21-004(d) meet.

Table 8.8-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

During 1993, a 20-ft borehole was placed in the suspected vicinity of tank TA-21-163. One sample was collected from each 5-ft interval. Analytical results for these samples were unavailable for inclusion in this phase report but will be reported in an addendum to this phase report.

8.8.3 Data Assessment

No inorganic analytes were detected above the process area baseline 95.5 percentile.

The radionuclides americium-241, plutonium-239/240, uranium, and thorium-228 were reported in maximum concentrations above the applicable baseline 95.5 percentile. Uranium and thorium-228 exhibited increasing concentration with depth, while a maximum plutonium-239 concentration of 33 pCi/g was noted in the 6-12 in. sample at location 21-1414. This concentration exceeded the plutonium-239/240 SAL in only one sample. The maximum uranium concentration was approximately 55% of its SAL.

Although the work plan also indicated elevated tritium levels might be encountered because of the proximity to DP East, the 1992 sample results did not confirm elevated tritium concentrations.

Field survey activities performed in 1992 indicate background levels of alpha emitters and slightly elevated levels of gamma emitters and low-energy gamma emitters (1.5 times background).

Acetone and methylene chloride were the only volatile organics reported for samples collected from SWMU 21-024(h). Acetone was detected in a surface sample at a concentration of 15 ug/kg and in near-surface samples at concentrations up to 32 ug/kg. Methylene chloride was reported for a near-surface sample at a concentration of 16 ug/kg. Because both methylene chloride and acetone are common laboratory contaminants and were reported in low concentrations in the samples, these analytes do not warrant further investigation.

No semi-volatile organics were detected in the samples collected from SWMU 21-024(h).

8.8.4 Conclusions and Recommendations

Plutonium-239/240 concentrations increased in the 6-12 in. depth sample at location 21-1414, but decreased in the 12-18 in. sample at location 21-1413. This location is in the drainage channel downgradient of the outfall. Further investigations directed at identifying the lateral extent of contamination will be identified in an addendum to this phase report, upon receipt and assessment of outstanding laboratory data.

It is recommended that a decision on the disposition of this SWMU be deferred until outstanding data are received, assessed, and reported in an addendum to this phase report. Because SALs were exceeded for one sample, baseline risk assessment may be needed.

8.8.5 QA/QC Sample Summary

Although the programmatic frequency of QA samples met all requirements of the QAPjP, this and several other SWMUs did not have QA/QC samples associated with their relatively limited number of RFI samples.

An inorganic laboratory duplicate analysis was performed on the 0-6 in. sample collected at location 21-1415. Twenty-two of the 25 analytes met the precision criteria specified in the QAPjP.

Table 8.8-3 lists the radionuclides and inorganic analytes that did not meet the precision requirements specified in the QAPjP and in section 2.1.4 of this report.

An organic MS/MSD analysis was performed on the 6-12 in. sample collected from location 21-1415. Because recoveries were listed in FIMAD in ug/kg, organic accuracy and precision criteria, as specified in the QAPjP, could not be evaluated at this time.

An inorganic MS/MSD analysis was performed on the 0-6 in. sample collected from location 21-1415. Because recoveries were listed in FIMAD at 0%, inorganic accuracy criteria, as specified in the QAPjP, could not be evaluated at this time. Analytical data appear to yield reasonable values in comparison to other outfall data sets and regional background.

8.9 SWMU 21-024(i)

The outfall portion of SWMU 21-024(i) is addressed in Section 15.3 of the RFI work plan and is located within both the process area and special impact area 2. The outfall and sampling locations at SWMU 21-024(i) are shown on Figure 8.9-1. SWMU 21-024(i) contains multiple contaminants above SALs and has been selected for further investigation and possible interim fencing.

8.9.1 Site Process and Sampling History

Outfall SWMU 21-024(i) is a septic system that routed sewage from Building TA-21-152 through a concrete septic tank (abandoned in place) to the surface outside of Building TA-21-109. Cooling tower blowdown also was routed to this outfall. The system discharges through a 6-in VCP line into a broad, gentle sloping area about 30 ft from the south cliff edge of DP Mesa. Previous activities indicate that the outfall may contain low levels of laboratory organics and inorganics due to research that was conducted at Building TA-21-152.

One sample was collected from SWMU 21-024(i) during 1988 reconnaissance sampling. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics, pesticides/PCBs, and target analyte list metals. Analyses were also conducted for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium.

Barium, chromium, copper, lead, mercury, selenium, vanadium, zinc, cadmium, plutonium-238, radium-226, radium-235, and uranium-238 were reported slightly above regional background. Uranium-234

and tritium levels were substantially above regional background. Analytical results of the 1988 reconnaissance sampling are shown in Table 8.9-1.

8.9.2 RFI Activities and Data Presentation

Sampling at SWMU 21-024(i) was executed as prescribed by the RFI work plan, except that americium-241 was added to the analyte list for all samples and the borehole samples were analyzed for isotopic uranium rather than total uranium. The surface and near-surface samples collected in 1993 were supplemental to those specified in the RFI work plan.

The 1992 investigation activities performed at SWMU 21-024(i) included a radiological field survey and collection of soil samples from three locations according to Strategy A. One surface (0-6 in.) and one near-surface (6-12 in.) sample were collected from each location.

Follow-on sampling was performed at SWMU 21-024(i) because radiological field surveys performed in 1992 indicated elevated gross alpha activity. In 1993, a radiological survey was performed to better define the extent of contamination. This survey confirmed that contamination is fairly localized along the drainage pathway. Approximately 40 measurements were made in and around the drainage channel.

Eight soil sampling locations were selected based on the supplemental radiological survey performed in 1993. These samples were biased to locations of elevated radioactivity, and in most cases were located outside the drainage pathway. Surface (0-6 in.) samples were collected at all eight locations and near-surface (6-12 in. and 12-18 in.) samples were collected at three of the eight locations. A dirt pile is located at the mesa edge to the east of the drainage pathway and may be due to soil removal

from the drainage area. One 0-6 in. sample was taken from this pile. Other surface samples were taken at the edge of the contaminated area delineated in the radiological survey. Analytical data from these samples were not available for inclusion in this phase report but will be included in an addendum to this phase report. In addition to the locations specifically selected for characterization of 21-024(i), one grid location (21-1194) sampled in the 1992 surface soil investigation is approximately 10 ft east of sample location 21-1599. The analytical results from grid location 21-1194 were included in the data assessment for this SWMU.

Additional 1993 investigations included a 20-ft borehole that was drilled adjacent to inactive septic tank TA-21-181. One sample was collected from each 5-ft interval as specified in the RFI work plan. Results will be reported in an addendum to this phase report after data are received and assessed.

Table 8.9-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

8.9.3 Data Assessment

The inorganics arsenic, barium, chromium, copper, nickel, lead selenium, vanadium, and zinc were reported above the applicable baseline 95.5 percentile. Individually, none of the maximum analyte concentrations exceeds its SAL, except for arsenic. The maximum lead concentration is approximately 60% of its SAL, and the maximum chromium concentration is approximately 40% of its SAL. All inorganic analyte concentrations decrease with depth and in all cases are below the applicable baseline 95.5 percentile at a depth of 12-18 in. The detected inorganic concentrations are consistent with operations in Buildings TA-21-166 and TA-21-167 which fed the SWMU 21-024(i) outfall.

The radionuclides americium-241, tritium, strontium-90, and uranium were detected above the applicable baseline 95.5 percentile. The maximum uranium concentration at location 21-1397 (0-6 in. samples) exceeds the SAL. All other uranium concentrations in the 0-6 in. and 6-12 in. depths range from 35-80% of the SAL. The alpha-emitting radionuclide concentrations in Table 8.9-2 are lower than anticipated, given the radiological survey results in Table 8.9-3 and elevated gross alpha levels (up to 331.5 pCi/g) reported by the field laboratory.

Assessment of raw gamma spectrometry data indicated the presence of actinium-227 and progeny, which could account for the elevated field instrument readings. Further assessment of the gamma spectrometry data is proceeding. A second possibility is the presence of a thin surface layer concentrated in uranium activity, that is substantially diluted in the remainder of the 0-6 in. sample. A concentrated surface layer of uranium could result in elevated field instrument readings. For all analytes sampled in the entire soil profile (to 18 in. depth) during 1992 investigations, the highest surface concentrations were noted at the furthest downgradient location, 21-1397. All analytes from grid location 21-1194 were below the applicable baseline 95.5 percentile, indicating that contamination at SWMU 21-024(i) is isolated to the drainage channel.

The radiological survey indicated maximum alpha activity several orders of magnitude above background. Total gamma and low-energy gamma levels also were above background values. A summary of these data is presented in Table 8.9-3 and alpha count rate isopleths are shown on Map 3 .

Toluene was the only volatile organic reported and di-n-butyl phthalate was the only semi-volatile organic reported, both at low concentrations. Both compounds are common laboratory contaminants and the levels probably are not indicative of significant organic site contamination.

8.9.4 Conclusions and Recommendations

Significant levels of alpha-emitting radionuclides are present at this SWMU. When outstanding data are received and assessed with currently available data, they will be reported in an addendum to this phase report. This addendum will include any follow-on sampling plans and any plans for voluntary corrective actions. Based on data currently in hand, soil removal may be needed at SWMU 21-024(i). In the interim, temporary fencing and/or posting probably will be installed to prevent inadvertent intrusion into the most highly contaminated portion of the presently uncontrolled area.

8.9.5 QA/QC Sample Summary

Although the programmatic frequency of QA samples met all requirements of the QAPjP, this and several other SWMUs did not have QA/QC samples associated with their relatively limited number of RFI samples.

An inorganic laboratory duplicate analysis was performed on the 6-12 in. sample collected at location 21-1395. Nine of the 25 analytes met the precision criteria specified in the QAPjP. Table 8.9-4 lists the inorganics that did not meet the precision criteria specified in the QAPjP.

Because no radiological laboratory duplicates were not performed on the samples collected at SWMU 21-024(i), precision criteria, as specified in section 2.1.4 of this report, could not be evaluated. An inorganic MS analysis was performed on the 6-12 in. sample collection from location 21-1395. Because recoveries were listed in FIMAD in ug/g and no MSD recoveries accompanied these MS values, inorganic accuracy criteria, as specified in section 2.1.4 of this report, could not be evaluated at this

time. No organic MS/MSD analyses were performed on the samples collected from SWMU 21-024(i). Thus, no organic precision or accuracy criteria, as specified in the QAPjP, could be evaluated.

8.10 SWMUs 21-024(j)/21-024(k)

Septic system outfall SWMUs 21-024(j,k) are addressed in Section 15.6 of the RFI work plan and are located within both the process baseline area and special impact areas 1 and 2. The outfall locations of SWMU 21-024(j,k) are shown on Figures 8.10-1 and 8.10-2, respectively.

The only RFI activities planned for these SWMUs were shallow boreholes. No surface or near-surface investigations were specified in the RFI work plan. The borehole investigation schedules for 1992 were not performed due to issues regarding the potential for radioactive airborne emissions under the National Emissions Standards for Hazardous Air Pollutants (NESHAPS). Boreholes were installed and sampled in 1993 as prescribed by the RFI work plan, except that americium-241 was added to the analyte list and the samples were analyzed for isotopic uranium rather than total uranium. The results of the investigations were not received in time for inclusion in this phase report. When the results are received and assessed, they will be reported in an addendum to this phase report.

8.11 SWMU 21-024(I)

The outfall portion of SWMU 21-024(I) is addressed in Section 15.2 of the RFI work plan and is located in the process baseline area. The outfall and sampling locations at SWMU 21-024(I) are shown on Figure 8.11-1. Based on the assessment in this section, the nature and extent of contamination at SWMU 21-024(I) has been adequately defined with no significantly elevated analyte concentrations. Therefore, no further action is recommended for this SWMU.

8.11.1 Site Process and Sampling History

SWMU 21-024(I) received liquid waste from the floor drain of the mechanical room, Building TA-21-21, formerly used as a vault that stored plutonium and uranium metals. The outfall line ran north toward DP Canyon, but the precise location of the outfall had not been determined before the 1992 RFI field work began.

One sample was collected at SWMU 21-024(I) during 1988 reconnaissance sampling, where indicated on Figure 8.11-1. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics, pesticides/PCBs, and target analyte list metals. Analyses also were conducted according to standard commercial laboratory procedures for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium.

Americium-241, plutonium-239/240, tritium, and zinc were reported above background. The only organic contaminants reported were low levels of methylene chloride (a common laboratory

contaminant), polynuclear aromatic hydrocarbons (common constituents of asphalt), and oil/grease. Analytical results of 1988 reconnaissance sampling are shown in Table 8.11-1.

8.11.2 RFI Activities and Data Presentation

Sampling at SWMU 21-024(I) was executed as prescribed in the RFI work plan except that americium-241 was added to the analyte list.

The 1992 investigation consisted of a geophysical field survey to locate the drain line and discharge point, a radiological field survey, and the collection of surface (0-6 in.) samples from six locations according to sampling Strategy B.

Table 8.11-2 presents a summary of analyte concentration detected above the applicable baseline 95.5 percentile.

8.11.3 Data Assessment

No inorganics were detected above the applicable baseline 95.5 percentile.

Plutonium-238 concentrations range from 0.054–0.19 pCi/g, within the applicable area baseline 95.5 percentile, except for the maximum concentration of 12.1 pCi/g in the 0-6 in. sample at location 21-1422. This value is approximately one-half the SAL.

Radiological surveys indicated background levels of alpha, gamma, and low-energy gamma emitters.

Acetone and methylene chloride were reported at concentrations of 9 ug/kg and 20 ug/kg, respectively. Both organics are common laboratory contaminants and the reported levels are not indicative of organic contamination.

Geophysical surveys located the drain line at SWMU 21-024(I), but not the precise location of the discharge point (end of drain line). The drain line is shown on Figure 8.11-1.

8.11.4 Conclusions and Recommendations

Based on the assessment in this section, the RFI sampling adequately characterized the nature and extent of contamination at SWMU 21-024(I) and showed that all analyte levels are below SALs. Therefore, it is recommended that no further action is required for this SWMU.

8.11.5 QA/QC Sample Summary

Although the programmatic frequency of QA samples met all requirements of the QAPjP, this and several other SWMUs did not have QA/QC samples associated with their relatively limited number of RFI samples.

An inorganic laboratory duplicate analysis was performed on the 0-6 in. sample collected at location 21-1422. Twenty of the 25 analytes met the precision criteria specified in the QAPjP.

Radionuclide laboratory duplicates were performed on samples collected at locations 21-1422 and 21-1424. Only selected members of the radionuclide suite were chosen in the laboratory for duplicate analysis. Two of the five sets of results met the precision criteria specified in section 2.1.4.

Table 8.11-3 lists of inorganic and radiological analytes that did not meet the precision criteria specified in the QAPjP and in section 2.1.4.

An inorganic MS/MSD analysis was performed on the 0-6 in. sample collected from location 21-1424. Because recoveries were listed in FIMAD as 0%, accuracy criteria, as specified in the QAPjP, could not be evaluated at this time. Analytical data appear to yield reasonable values in comparison to other outfall data sets and regional background.

Because organic MS/MSD analyses were not performed for samples from this SWMU, precision and accuracy criteria, as specified in the QAPjP, could not be evaluated.

8.12 SWMUs 21-024(m)/21-027(b)

Outfall SWMUs 21-024(m) and 21-027(b) are addressed in Section 15.7 of the RFI work plan and both are located within the process area and special impact areas 1 and 2. Because these two SWMUs are co-located, they are assessed together. The outfalls and sampling locations at SWMUs 21-024(m) and 21-027(b) are shown on Figure 8.12-1. Based on the assessment in this section, the nature and extent of contamination at SWMU 21-024(m)/21-027(b) has been adequately defined and no contaminant levels of concern are present. Therefore, SWMUs 21-024(m) and 21-027(b) are recommended for no further action.

8.12.1 Site Process and Sampling History

SWMUs 21-024(m) and 21-027(b) have separate histories and origins but drain into the same area, resulting in a common sampling plan. Each SWMU's history will be discussed separately, but the investigation and resulting data assessment were conducted as a single effort. The common discharge area is on the south edge of DP Mesa, directly south of Building TA-21-207.

SWMU 21-024(m) is reported to be a vitrified clay pipe that exits Building TA-21-209, the high-temperature chemistry laboratory. The outfall was not located precisely in the field. An 8-in. corrugated metal pipe discharges water at the approximate site where the discharge point was expected to be located. This pipe appears to come from a storm drain below the lawn area of Building TA-21-209. The construction of this pipe may have destroyed the SWMU 21-024(m) outfall line. A 12-in. corrugated metal pipe with no labeling also is adjacent to the storm drain. The origin of this pipe is unknown, but it is unlikely that either of these pipes is the drain line for SWMU 21-024(m).

SWMU 21-027(b) consists of two outfall lines, one of which is an active NPDES permitted outfall No. EPA03A034. This outfall discharges treated cooling water from cooling towers TA-21-166 and TA-21-167. Formerly, these cooling towers discharged through the drain line for SWMU 21-024(i). The second outfall line associated with SWMU 21-027(b) apparently receives discharges from a cooling tower associated with Building TA-21-152. This outfall line could not be located during the RFI site reconnaissance. A LANL report on NPDES outfalls states that this outfall was eliminated.

8.12.2 RFI Activities and Data Presentation

Sampling at SWMUs 21-024(m) and 21-027(b) was executed in 1992 as prescribed in the RFI work plan, except that americium-241 was added to the analyte list.

The investigation consisted of a radiological field survey and collection of samples from two locations according to sampling Strategy C. One surface (0-6 in.) and two near-surface (6-12 in., and 12-18 in.) samples were collected from each location.

8.12.3 Data Assessment

No radionuclide or inorganic analytes were reported above their applicable baseline categories. No volatile or semi-volatile analytes were detected. No gross alpha, beta, or gamma levels were detected above detection limits by field laboratory analyses.

The field survey indicated background levels of alpha and gamma emitters and slightly elevated low-energy gamma emitters (1.5 times background at maximum reading).

8.12.4 Conclusions and Recommendations

A recommendation of no further action is proposed for SWMUs 21-024(m) and 21-027(b) because no radionuclide or inorganic analytes were detected above the applicable baseline 95.5 percentile or SALs. Although the actual drain pipe was not located, sample locations were placed in and around a well-defined drainage channel which would have received outfall releases.

8.12.5 QA/QC Sample Summary

The field rinsate blank associated with this SWMU indicated no radionuclide contamination and no detectable volatile or semi-volatile organic concentrations were reported. No detectable concentrations were reported for 22 of the 25 inorganics.

No detectable concentrations were reported for 61 of the 62 volatile organics and for 22 of the 25 inorganics in the field reagent blank associated with this SWMU. No detectable semi-volatile organic concentrations were reported in this blank.

An inorganic laboratory duplicate analysis was performed on the 0-6 in. sample collected at location 21-1394. Eighteen of the 25 analytes met the precision criteria specified in the QAPjP.

Radionuclide laboratory duplicates were performed on samples collected at location 21-1394. Only selected members of the radionuclide suite were chosen in the laboratory for duplicate analysis. Nine of the ten sets of results met the precision criteria specified in section 2.1.4. Laboratory duplicates performed for radionuclide analytes displayed generally good agreement with one another.

A list of radionuclides and inorganics that did not meet the precision criteria specified in section 2.1.4 of this report are listed in Table 8.12-1.

The inorganic analytes listed in Table 8.12-2 were detected in blanks collected at SWMU 21-024(m)/27(b). Acetone, a common laboratory contaminant, was reported in a field reagent blank at a concentration of 76 ug/l.

An inorganic MS/MSD analysis was performed on the 0-6 in. sample collected from location 21-1394. Because recoveries were listed in FIMAD as 0%, accuracy criteria as specified in the QAPjP could not be evaluated at this time. However, analytical data appear to yield reasonable value in comparison to other outfall data sets and regional background.

A semi-volatile organic and 1,4-dichlorobenzene MS/MSD analysis was performed on the 0-6 in. sample collected from location 21-1394. Because recoveries were listed in FIMAD in ug/kg, organic accuracy and precision criteria, as specified in the QAPjP, could not be evaluated at this time.

Table 8.12-1 QA/QC sample summary – inorganic radionuclide data precision – SWMUs 21-024(m) and 21-027(b).

Analyte	Location ID	Sample Depth	Sample Concentration	Laboratory Duplicate Concentration	Relative Percent Difference
Plutonium-239	21-1394	0-6 in.	0.137 pCi/g	0.088 pCi/g	156
Arsenic	21-1394	0-6 in.	2.2 ug/g	1.3 ug/g	169

8.13 SWMU 21-024(n)

The outfall portion of SWMU 21-024(n) is addressed in Section 15.4 of the RFI work plan and is located within both the process baseline area and special impact areas 1 and 2. The outfall and sampling locations at SWMU 21-024(n) are shown on Figure 8.13-1. Assessment of the RFI data for SWMU 21-024(n) leads to a recommendation of no further action.

8.13.1 Site Process and Sampling History

SWMU 21-024(n) received liquid wastes from a drain exiting Building TA-21-155 and discharges northward into DP Canyon. This building has been a warehouse and laboratory. The drain consists of corrugated metal pipe exiting a concrete bulkhead and discharging onto a gravel road adjacent to MDA U.

One sample was collected at the discharge point during 1988 reconnaissance sampling. Analytical results of 1988 reconnaissance sampling are shown in Table 8.13-1. The approximate location of the 1988 reconnaissance sample is shown on Figure 8.13-1. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics, pesticides/PCBs, and target analyte list metals. Standard laboratory analyses also were performed for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium.

Zinc and plutonium-239/240 were reported slightly above regional background. Low levels of oil and grease also were reported (LANL 1991). Tritium was reported substantially above background but well below the SAL.

8.13.2 RFI Activities and Data Presentation

Characterization of SWMU 21-024(n) was performed in 1992 as prescribed by the RFI work plan, except that americium-241 was added to the analyte list and isotopic thorium analyses were not performed.

The investigation consisted of a radiological field survey and the collection of soil samples from three locations according to sampling Strategy C. The sampling locations were placed at the discharge point and in the ditch which carries discharges to DP Canyon. One surface (0-6 in.) and two near-surface (6-12 in. and 12-18 in.) samples were collected from each location.

Table 8.13-2 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

8.13.3 Data Assessment

Chromium was the only inorganic analyte detected above the applicable baseline 95.5 percentile. The maximum chromium concentration was approximately 10% of the SAL at location 21-1404 and levels decreased with depth.

Tritium and uranium were detected slightly above the applicable baseline 95.5 percentile and were less than 12% of their respective SALs. Tritium concentrations were consistently 11–15 nCi/l at all sampling depths and exhibited a vertical concentration gradient similar to other outfall SWMUs.

The radiological survey indicated background levels of alpha, gamma, and low-energy gamma emitters. Field laboratory screening indicated gross alpha, beta, and gamma levels below detection limits.

Acetone was detected in seven soil samples. The greatest concentration detected in soils was 34 ug/kg, but acetone also was detected in three blanks associated with this SWMU at a concentrations up to 46 ug/l. Tetrachloroethylene was tentatively identified in a sample collected from location 21-1402. It is judged that these analyte concentrations do not warrant further investigation.

8.13.4 Conclusions and Recommendations

Several analytes slightly exceed the applicable baseline 95.5 percentile, but the levels are a small fraction SALs. A minor concentration increase for all analytes was noted in the 6-12 in. depth, but in general decreased in the 12-18 in. depth. The data assessment indicates that the nature and extent of contamination was characterized adequately and no analyte level exceeded SALs. Therefore, it is recommended that no further action is warranted for SWMU 21-024(n).

8.13.5 QA/QC Sample Summary

The field rinsate blank associated with this SWMU indicated no radionuclide contamination for 5 of the 6 analytes, and no detectable semi-volatile organic concentrations were reported. No detectable concentrations were reported for 24 of the 25 inorganics or for 61 of the 62 volatile organics.

No detectable concentrations were reported for 60 of the 62 volatile organics and for 24 of the 25 inorganics in the field reagent blank associated with this SWMU. No detectable semi-volatile organic concentrations were reported in this blank.

No detectable concentrations were reported for 61 of the 62 volatile organics in the field trip blank associated with this SWMU.

A laboratory duplicate analysis was performed on the 12-18 in. sample collected at location 21-1402 for strontium-90. The reported results for this analysis meets the precision criteria specified in section 2.1.4.

The analytes listed in Table 8.13-3 were detected in blanks collected at SWMU 21-024(n).

Because inorganic laboratory duplicates or MS/MSD analyses were not performed on the samples collected from SWMU 21-024(n), inorganic accuracy and precision criteria, as specified in the QAPjP, could not be evaluated.

An organic MS/MSD analysis was performed on the 6-12 in. sample collected from locations 21-1403. Because recoveries were listed in FIMAD in ug/kg, organic accuracy and precision criteria, as specified in the QAPjP, could not be evaluated at this time.

8.14 SWMU 21-024(o)

The outfall portion of SWMU 21-024(o) is addressed in Section 15.4 of the RFI work plan and is located within the process baseline area. The outfall and sampling locations at SWMU 21-024(o) are shown on Figure 8.14-1. Based on the assessment in this section, the nature and extent of contamination have been defined adequately at SWMU 21-024(o) and no contaminant levels above SALs were identified. Therefore, no further action is recommended for this SWMU.

8.14.1 Site Process and Sampling History

SWMU 21-024(o) is a 4-in VCP drain reported to have served Building TA-21-46, an old diesel plant which later was converted to a warehouse. The drain discharges south into Los Alamos Canyon. The area around the probable discharge point is broad and gently sloping but the flow pattern is apparent.

One sample was collected within a few feet of the discharge point during 1988 reconnaissance sampling at the approximate location shown on Figure 8.14-1. The sample was analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics, pesticides/PCBs, and target analyte list metals. Standard analyses were performed for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium.

Tritium was reported slightly above regional background. Low levels of oil and grease also were reported. Analytical results of the 1988 reconnaissance sampling are shown in Table 8.14-1.

8.14.2 RFI Activities and Data Presentation

Characterization of SWMU 21-024(o) was performed in 1992 as prescribed in the RFI work plan, except that americium-241 was added to the analyte list and isotopic thorium analyses were not performed.

The investigation included a radiological field survey and collection of samples from two locations according to sampling Strategy C. One surface (0-6 in.) and two near surface (6-12 in. and 12-18 in.) samples were collected from each location.

Table 8.14-2 lists the semi-volatile organics that were detected, all at levels well below SALs. Sample locations, concentrations, depth are given for each detection.

8.14.3 Data Assessment

No inorganic or radionuclide analytes were detected above the applicable baseline 95.5 percentile.

The field survey indicated background levels of alpha, gamma, and low-energy gamma emitters. Beta measurements were not included as part of the field survey. No volatile organics were detected in the samples collected from SWMU 21-024(o).

The elevated semi-volatile organics are consistent with operation of the diesel plant. Benzo[b]fluoranthene was detected at a concentration approximately 75% of its SAL, while all other semi-volatiles were less than 10% of their SALs. Field notes also indicated asphalt pieces near the

sampling area, consistent with the detected semi-volatile compounds. These concentrations are below SALs and are not likely to be indicative of significant site contamination by organics.

8.14.4 Conclusions and Recommendations

Because the nature and extent of contamination was adequately characterized and all analyte levels were below applicable baseline 95.5 percentiles and SALs, no further action is recommended for this SWMU. Organic analytes were consistent with the components of asphalt and were noted in the sampling vicinity.

8.14.5 QA/QC Sample Summary

Although the programmatic frequency of QA samples met all requirements of the QAPjP, this and several other SWMUs did not have QA/QC samples associated with their relatively limited number of RFI samples. No MS/MSD or laboratory duplicate analyses were performed at SWMU 21-024(o).

CHAPTER 9

WASTEWATER TREATMENT PLANT

9.0 WASTEWATER TREATMENT PLANT

This chapter addresses outfall SWMU 21-026(d), associated with the wastewater treatment plant. SWMUs 21-026(a-c) also are associated with the wastewater treatment plant and are addressed in Chapter 14 of the RFI work plan.

9.1 SWMU 21-026(d)

The outfall portion of SWMU 21-026(d) is addressed in Section 15.4 of the RFI work plan and is within the non-process baseline area. The outfall and sampling locations at SWMU 21-026(d) are shown on Figure 9.1-1. The data assessment in this chapter indicates the nature and extent of contamination were defined adequately at SWMU 21-026(d) and detected analyte concentrations were below SALs. No further action is recommended for this SWMU.

9.1.1 Site Process and Sampling History

Outfall SWMU 21-026(d) receives liquid wastes from the sewage treatment plant, Building TA-21-272. This outfall currently is permitted as NPDES outfall No. EPASSS055. Discharge flows into a concrete channel on the north edge of DP Mesa and runs down a natural drainage to a tributary of DP canyon. Prior assays of the effluent indicated the presence of gross alpha, beta, gamma, and tritium levels, but specific radionuclides were not identified. Small amounts of any TA-21 contaminants could have entered the septic system, although most would have been removed by the sewage treatment plant before being discharged at the outfall. Tritium is a notable exception to this generalization.

9.1.2 RFI Activities and Data Presentation

Characterization of SWMU 21-026(d) was conducted in 1992 as prescribed in the RFI work plan except that americium-241 was added to the analyte list and isotopic thorium analyses were not performed.

The 1992 investigation consisted of a radiological field survey and the collection of samples from four locations according to sampling Strategy C. A surface (0-6 in.) sample was collected at each location, and two near-surface (6-12 in. and 12-18 in.) samples were collected at location 21-1401.

Table 9.1-1 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

9.1.3 Data Assessment

The inorganic analytes silver, cadmium, chromium, copper, nickel, and zinc were detected above the applicable baseline 95.5 percentile in 0-6 in. surface samples. The maximum chromium concentration was approximately 45% of its SAL, while all other inorganic analytes were less than 10% of their SALs. All inorganic analyte concentrations decreased with depth.

Americium-241, tritium, and plutonium-239 were the only radionuclides detected in concentrations exceeding the applicable baseline 95.5 percentile. Maximum americium-241 and plutonium 239/240 concentrations marginally exceeded the applicable 95.5 percentile baseline and were less than 10% of their SALs. Tritium was detected at less than 1% of its SAL. All radionuclide concentrations decreased with depth.

No elevated inorganic or radionuclide concentrations were observed in near surface (6-12 in.) samples. The greatest silver and tritium concentrations were detected at location 21-1400 (the furthest downgradient sample location). The maximum concentrations of other analytes were detected at other sample locations. The maximum silver and tritium values were detected in the 0-6 in. layer, and are not indicative of concentrations that would require further investigation.

The field survey indicated background levels of alpha emitters, gamma emitters, and low-energy gamma emitters.

Acetone was detected at a concentration of 24 ug/kg in one sample collected from SWMU 21-024(d) but also was detected up to 26 ug/l in two of the blanks associated with this outfall. Numerous semi-volatile organics were detected at concentrations up to 11,900 ug/g at SWMU 21-026(d), as listed in Table 9.1-2. Of these semi-volatiles, benzo[a]anthracene, benzo[b]fluoranthene, and indeno[1,2,3-cd]pyrene were detected in maximum concentrations at least four times their SALs. Chrysene was detected at a maximum concentration approximately 50% of its SAL. The detected semi-volatile organics are characteristic of paving materials, and are not indicative of contamination requiring further investigation.

The highest concentrations of semi-volatile organics were detected in the 6-12 in. sample collected from location 21-1401. No semi-volatile organics were detected in the 12-18 in. sample collected at this location. Only small amounts of semi-volatile organics were detected in the sample collected from location 21-1400, the only sample location downgradient of 21-1401.

9.1.4 Conclusions and Recommendations

Assessment of the RFI data indicates that the nature and extent of contamination has been adequately characterized and that inorganic and radionuclide levels are well below SALs. Although some semi-volatiles were reported above SALs, they are consistent with paving materials in the area. Therefore, it is recommended that no further action is required for SWMU 21-026(d).

9.1.5 QA/QC Sample Summary

The field rinsate blank associated with this SWMU indicated no radionuclide contamination. No detectable semi-volatile organic concentrations were reported in this sample. No detectable concentrations were reported for 23 of the 25 inorganics or for 61 of the 62 volatile organics.

No detectable concentrations were reported for 61 of the 62 volatile organics or for 24 of the 25 inorganics in the field reagent blank associated with this SWMU. No detectable semi-volatile organic concentrations were reported in this blank.

No analytes were reported in the field trip blank associated with this SWMU.

An inorganic MS/MSD analysis was performed on the 0-6 in. sample collected from location 21-1399. Inorganic accuracy criteria, as specified in the QAPjP, were met for 23 of the 25 analytes for both MS and MSD analyses.

An inorganic laboratory duplicate analysis was performed on the 0-6 in. sample collected at location 21-1399. Eleven of the 25 analytes met the precision criteria specified in the QAPjP.

A radionuclide laboratory duplicate analysis was performed on the sample collected at location 21-1399. Only selected members of the radionuclide suite were chosen in the laboratory for duplicate analysis. All three sets of results met the precision criteria specified in section 2.1.4 of this report.

Table 9.1-3 lists inorganic analytes that did not meet the precision criteria as specified in the QAPjP.

An inorganic MS/MSD analysis was performed on the 0-6 in. sample collected from location 21-1399.

Table 9.1-4 lists inorganic analytes that did not meet the accuracy criteria specified in the QAPjP.

An MS/MSD analysis was performed on a field trip blank associated with SWMU 21-026(d). Because recoveries were listed in FIMAD in ug/kg and ug/l, organic precision and accuracy criteria, as specified in the QAPjP, could not be evaluated at this time.

Arsenic was reported for a field reagent blank at a concentration of 5.2 ug/l and iron and magnesium were reported for field rinsate blanks at 13.7 ug/l and 61.2 ug/l, respectively.

CHAPTER 10

SURFACE DISCHARGE

10.0 SURFACE DISCHARGE**10.1 SWMU 21-027(a)**

Outfall SWMU 21-027(a) is addressed in Section 15.5 of the RFI work plan and is located within the process baseline area. The outfall and sampling locations at SWMU 21-027(a) are shown on Figure 10.1-1. Assessment of the available RFI data for SWMU 21-027(a) suggests that further radiological surveys and field sampling may be necessary. However, a decision on the disposition of this SWMU will be deferred until 1993 borehole data are received and assessed.

10.1.1 Site Process and Sampling History

SWMU 21-027(a) receives liquid wastes from Building TA-21-3. The drain line extends from the southwest corner of Building TA-21-3 to the southwest corner of the cooling tower TA-21-143, where the line discharges into a ponding area. This ponding area also received NPDES-permitted discharges of treated cooling water from the cooling tower. Discharges collected in the ponding area enter a 24 in. corrugated metal pipe that releases at the mesa edge.

Two samples were collected from SWMU 21-027(a) during 1988 reconnaissance sampling. The samples were analyzed according to CLP SOW protocol for target compound list volatile organics, semi-volatile organics and pesticides/PCBs, and target analyte list metals. Standard analyses were performed for americium-241, cesium-137, plutonium-238, plutonium-239/240, radium-226, strontium-90, thorium-232, uranium-234, uranium-235, uranium-238, and tritium. Three samples were also collected from this SWMU as part of a DOE Headquarters Environmental Survey.

Cadmium, chromium, copper, lead, zinc, and mercury were detected well above regional background but generally below SALs. Americium-241, plutonium-238, plutonium-239/240, uranium-234, uranium-235, uranium-238, thorium-232, strontium-90, and cesium-137 were detected in some samples above regional background. Toluene and trichloroethane also were reported at very low levels for these samples. Polynuclear aromatics were identified in samples collected at this SWMU, but the drainage pathway leading to the outfall is lined with asphalt. Analytical results of the 1988 reconnaissance sampling are shown in Table 10.1-1. Analytical results of the DOE Environmental Survey samples are shown in Table 10.1-2. The approximate location of the 1988 reconnaissance samples and the DOE Headquarters Environmental Survey samples are shown in Figure 10.1-1.

10.1.2 RFI Activities and Data Presentation

Characterization at SWMU 21-027(a) was performed in 1992 as prescribed in the RFI work plan, with the exception of the sample locations on the bench below the mesa edge and the analyses that were performed. Bedrock at the proposed sampling locations required sampling locations to be moved slightly to allow the required sample volumes to be retrieved. Americium-241 was added to the analyte list and the shallow borehole samples were analyzed for isotopic uranium rather than total uranium.

The investigation included a radiological field survey and collection of samples from five locations on the mesa top and nine locations on the bench below the mesa edge. One surface (0-6 in.) sample was collected at each location.

Table 10.1-3 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

Two 20-ft boreholes were completed in the ponding area to the south of the cooling tower during 1993. One sample was collected at each five-ft interval in the boreholes. Analytical results were not available for the inclusion in Phase Report 1C, but will be assessed in a phase report addendum. In addition to the locations specifically selected for characterization of 21-027(a), one grid location (21-1289) sampled in the 1992 surface soil investigation was approximately 30 ft east of the outfall channel on the bench. The analytical results for 12-1289 were included in the data assessment for this SWMU.

10.1.3 Data Assessment

The inorganic analytes arsenic, cadmium, chromium, copper nickel, lead, and zinc were detected above their applicable baseline 95.5 percentiles. Chromium exceeded the chromium (VI) SAL at several sampling locations, while other inorganic analytes (except arsenic) were less than 10% of their SALs.

Radionuclide analytes americium-241, tritium, plutonium-238, plutonium-239/240, and uranium were detected above applicable baseline 95.5 percentiles. With the exception of tritium, each radionuclide concentration exceeded its SAL at two or more locations. Tritium was found in concentrations substantially above the process area baseline, on the bench below the mesa edge. The tritium SAL was not exceeded in any of these samples. Field radiological surveys were not prescribed in the RFI work plan and were not carried out.

No near-surface data is currently available to determine vertical migration of contaminants. Neighboring grid location 21-1289 sample data show no analytes above the applicable 95.5 percentile baseline. This would indicate that lateral contamination from this outfall has not occurred.

Previous process knowledge and sample results indicate that enriched uranium (higher uranium-234 and uranium-235 concentrations) might be present in the soil at this SWMU. Because the 1992 RFI samples were analyzed for total uranium, a direct comparison of RFI data to previous isotopic data is not possible.

10.1.4 Conclusions and Recommendations

A recommendation on the disposition of SWMU 21-027(a) will be deferred until outstanding borehole analytical data are received and assessed. However, a follow-on radiological survey and additional near-surface and shallow borehole samples may be needed. Isotopic uranium analyses will be included in the analytical suites for these samples. In addition, isotopic uranium analyses on samples archived from the 1992 investigation have been requested. The results of these analyses will be summarized in a phase report addendum.

10.1.5 QA/QC Sample Summary

The field rinsate blank associated with this SWMU indicated no radionuclide contamination. No detectable inorganics or semi-volatile organics were detected in this blank. Analytical results for this sample were given for only three volatile organics. No detectable concentrations were reported.

No detectable concentrations were reported for 23 of the 25 inorganics in the field reagent blank associated with this SWMU. No detectable volatile or semi-volatile organic concentrations were reported in this blank.

No detectable concentrations were reported in the field trip blank associated with this SWMU.

A radionuclide laboratory duplicate was performed on the sample collected at location 21-1367. Only selected members of the radionuclide suite were chosen in the laboratory for duplicate analysis. Five of the seven sets of results met the precision criteria specified in section 2.1.4 of this report.

A volatile organic MS/MSD analysis was performed on the 0-6 in. sample collected from location 21-1370. Because recoveries were listed in FIMAD in ug/kg, organic precision and accuracy criteria, as specified in the QAPjP, could not be evaluated at this time.

Because inorganic laboratory duplicates or MS/MSD analyses were not performed, inorganic precision and accuracy criteria, as specified in the QAPjP, could not be evaluated.

Table 10.1-4 lists the radionuclides that did not meet the precision criteria specified in the QAPjP.

Table 10.1-5 lists inorganics and volatile organics that were detected in blanks collected at SWMU 21-027(a).

10.2 SWMU 21-027(c)

Outfall SWMU 21-027(c) is addressed in Section 15.2 of the RFI work plan and is located within the process baseline area. Details of the outfall and sampling locations at SWMU 21-027(c) are shown on Figure 10.2-1. Based on the RFI data assessment of SWMU 21-027(c) in this section, a baseline risk assessment may be necessary. A decision on the disposition of this SWMU will be deferred until neighboring SWMUs are assessed.

10.2.1 Site Process and Sampling History

SWMU 21-027(c) was reported to be a 4-in VCP line (abandoned in place) that exited former Building TA-21-6, which included a cafeteria and machine shop. The line discharged to the south on DP Mesa. Based on the known use of Building TA-21-6, only organic solvents and oils are likely to be present in this outfall. The outfall discharges 50 ft inside the perimeter fence in a broad, gently sloping area with no readily identified channel. No prior sampling data are available for this SWMU.

10.2.2 RFI Activities and Data Presentation

Sampling at SWMU 21-027(c) was executed as prescribed in the RFI work plan except that americium-241 and isotopic thorium analyses were added to the analyte list. The investigation included a radiological field survey and the collection of six surface (0-6 in.) soil samples according to sampling Strategy C.

Table 10.2-1 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

10.2.3 Data Assessment

Arsenic, and calcium were detected above their applicable area baseline 95.5 percentile. A maximum lead concentration of 103 ug/g was noted at location 21-1350, while all other lead concentrations were below the applicable area baseline.

Despite the available process knowledge which suggested no radiological contamination would be associated with this outfall, americium-241 and plutonium-239/240 were detected above the 95.5 percentile of process area baseline. It appears that the radionuclide concentrations are attributable to the outfall, since 21-1100, a neighboring grid sample, does not show elevated concentrations. The maximum plutonium-239/240 concentrations exceeded the SAL for two samples.

The radiological field survey indicated background levels of alpha, gamma, and low-energy gamma emitters.

Acetone, a common laboratory contaminant, was the only volatile organic reported for the soil samples. Semi-volatile organics were reported at low levels for a field duplicate sample collected at SWMU 21-027(c). Because semi-volatile organics were not detected in the associated sample, the detections are assumed to be due laboratory or field contamination.

10.2.4 Conclusions and Recommendations

Because some SALs were exceeded at this SWMU, a recommendation on the disposition of this SWMU will be deferred until characterization of other SWMUs in this area are completed. It is anticipated that,

at that time, the disposition of the SWMU will be determined by the outcome of a baseline risk assessment.

10.2.5 QA/QC Sample Summary

The field rinsate blank associated with this SWMU indicated no radionuclide contamination. No detectable inorganic, volatile or semi-volatile organic concentrations were reported in this sample.

No detectable concentrations were reported for 61 of the 62 volatile organics in the field reagent blank associated with this SWMU. No detectable inorganic or semi-volatile organic concentrations were reported in this blank.

No detectable concentrations were reported in the two field trip blanks associated with this SWMU.

An inorganic laboratory duplicate analysis was performed on the 0-6 in. sample collected at location 21-1353. Thirteen of the 25 analytes met the precision criteria specified in the QAPjP.

Radionuclide laboratory duplicate analyses were performed on the samples collected at locations 21-1349 and 21-1351. Only selected members of the radionuclide suite were chosen in the laboratory for duplicate analysis. All five sets of results met the precision criteria specified in section 2.1.4 of this report.

Table 10.2-2 lists inorganic analytes that did not meet the precision criteria specified in the QAPjP. All radionuclides met the precision criteria specified in the QAPjP.

Inorganic MS/MSD analyses were performed on a field rinsate blank associated with this SWMU and on the 0-6 in. sample collected from locations 21-1353. Table 10.2-2 lists inorganics that did not meet the accuracy criteria specified in the QAPjP.

Because no organic MS/MSD analyses were performed, organic accuracy and precision criteria, as specified in the QAPjP, could not be evaluated.

Acetone was reported for a field reagent blank collected at SWMU 21-027(c) at a concentration of 21 ug/l.

10.3 SWMU 21-027(d)

Outfall SWMU 21-027(d) is addressed in Section 15.2 of the RFI work plan and is located in the non-process baseline area. Details of the outfall and sampling locations at SWMU 21-027(d) are shown on Figure 10.3-1. Based on the RFI data assessment in this section, no further action is recommended for SWMU 21-027(c).

10.3.1 Site Process and Sampling History

SWMU 21-027(d) originated in the catch basin around a fuel tank and discharges over the mesa edge into Los Alamos Canyon. The drain line was removed in March 1965. No quantitative data were available on this outfall prior to the RFI investigation. The only expected contaminants are organics from petroleum products and possibly some contaminants from adjacent SWMU 21-023(c).

10.3.2 RFI Activities and Data Presentation

Characterization of SWMU 21-027(d) was performed in 1992 as prescribed by the RFI work plan except for the sampling depth at location 21-1333 and the analyses that were performed. The RFI work plan called for a 0-6 in. sample to be collected at location 21-1333, but refusal was encountered at 1 in. due to bedrock. Americium-241 and isotopic thorium were added to the analyte list.

The 1992 sampling activities performed at SWMU 21-027(d) consisted of a radiological field survey and the collection of surface {0-6 in. (5) and 0-1 in. (1)} soil samples from six locations according to sampling Strategy B.

Table 10.3-1 presents a summary of analyte concentrations detected above the applicable baseline 95.5 percentile.

10.3.3 Data Assessment

Cadmium was the only inorganic analyte reported above the non-process area baseline 95.5 percentile. All inorganic concentrations were less than 2% of the SALs. Elevated levels were noted only in upgradient sample locations 21-1329, 21-1330, and 21-1331.

Americium-241 and plutonium-239/240 were reported above the non-process area baseline 95.5 percentile at location 21-1331. The maximum plutonium concentration was approximately 25% of its SAL. As with the inorganics, radionuclides are slightly elevated in upgradient samples.

The radiological field survey indicated slightly elevated levels of low-energy gamma emitters, but sample analyses did not confirm contamination of this nature. The survey results may be due to contamination at SWMU 21-023(c), which is located within 50 ft of SWMU 21-027(d). All other instrument readings taken at this outfall were at or near background levels.

No organics were detected in the samples collected from SWMU 21-027(d).

10.3.4 Conclusions and Recommendations

The data assessment in this section indicate that the nature and extent of contamination at SWMU 21-027(d) have been adequately characterized and that levels are less than SALs. Therefore, no further action is recommended.

10.3.5 QA/QC Sample Summary

Due to the limited number of samples collected at this outfall and the frequency at which QA/QC samples are collected, none of the field trip, field reagent, or field rinsate blanks collected in 1992 were associated with SWMU 21-027(d).

Radionuclide laboratory duplicate analyses were performed on the samples collected at locations 21-1330 and 21-1334. Only selected members of the radionuclide suite were chosen in the laboratory for duplicate analysis. All four sets of results met the precision criteria specified in section 2.1.4 of this report.

Because inorganic laboratory duplicates were not performed, inorganic precision criteria could not be evaluated.

Because no MS/MSD analyses were performed at this SWMU, organic precision and accuracy criteria and inorganic precision criteria, as specified in the QAPjP, could not be evaluated.

APPENDIX A

GRAPHICAL DISPLAYS AND STATISTICAL TESTS FOR OUTFALLS DATA

A.0 Graphical displays and statistical tests for outfall results

A.1 Introduction

This appendix presents figures that display the results from the outfall investigations for each radionuclide (except the isotopes of uranium and thorium, available at only some of the outfalls) and inorganic constituent. This type of presentation shows at a glance which outfalls look unusually high for a given element, and what kind of variability is found both within and between outfalls for the generally small sample sizes (only four outfalls have more than 9 observations and half have 6 or fewer).

Two statistical tests to compare observations with baseline distributions and one comparison with the upper limit of baseline distributions (as opposed to the 95.5th percentile that is used in Phase Report 1C as a cutoff level for including data in tables) were also performed. In place of the special impact area baselines used in Phase Report 1C, a spatially variable background distribution has been used for four isotopes exhibiting large variability and significant spatial trends across the site: Pu-238, Pu-239, Am-241, and tritium.

What the plots in this appendix do not show are lateral and vertical trends within each outfall. For these the reader is referred to the tables in Chapters 3 through 10, which are organized to present this information for analytes with concentrations above baseline.

A.2 Graphical Displays

Two figures are included for each analyte:

- 1) Side-by-side "box plots" are generated from a data set as follows: Five percentiles are estimated nonparametrically from the data for each outfall: the 5th, 25th, 50th (the median), 75th, and 95th. The central box extends from the 25th to the 75th

percentile, with a white line through the middle indicating the median. The "whiskers" are drawn out to the 5th and 95th percentiles. Finally, a detached line below the 5th percentile represents the observed sample minimum, and a detached line above the 95th percentile, the observed sample maximum. As the distributions are skewed, more nearly lognormal than normal, logarithmic y-axes are used.

- 2) Symbol plots of individual observations are needed to supplement the box plots, which are not very meaningful when the quantiles are based on only three to five observations, although they show the comparison between outfalls quite dramatically. Symbols represent both the analytical method used and whether the observation was above or below detection level. Open symbols in these plots correspond to above-detect measurements, and filled symbols to below-detect results, shown at 1/2 the reported detection level.

Shown for comparison on both types of plots indications of the baseline distribution and of the distribution of the nearest (procedurally comparable) neighbors from the 0-6" grid. Also shown if within a reasonable range (which is not the case for many inorganics) is the SAL. There are three choices for background:

Regional background is used only if virtually all 0-6" measurements were below detect (Antimony, Molybdenum, and Thallium.) Plots show mean and maximum for these.

OU background (the baseline distribution) is used for most elements. Plots show median and maximum of 0-6" grid samples analyzed by comparable method (Round 1 ETVA for arsenic, selenium and silver; all methods for lead; Round 2 6010 for other inorganics; all 0-6" samples for radionuclides). The maximum is computed without outliers as shown in Table A-1 and also without the grid observation from 21-1079 in every case. (The 0-6" observation at 21-1079 has been included in these plots with the other samples from outfall PRS 21-024(e)). Where more than half of the grid

observations were below detection level, then what is shown as the median is 1/2 the median reported detection level.

Local background (a spatially varying background distribution estimated by kriging) is used for Pu238, Pu239/240, Am241 and tritium only. In these cases the plots show the median and 99.9th percentiles at each PRS as estimated by kriging and provided in Table A-2. (Ordinary kriging, as described by Cressie, 1991, is used.)

Neighbors are selected as follows, omitting outliers shown in Table E-2:

- o For elements where Round 1 data are not used, the neighbors are either the six nearest 0-6" Round 2 grid points, generally within 500-600 feet of the PRS but sometimes up to 1000 feet away, or (rarely) more than six neighbors within 500 feet.
- o For elements where Round 2 data are not used, the neighbors are six or seven 0-6" grid points within 400 feet of the PRS, or (rarely) six points out to larger distances, never more than 560 feet.
- o Where data from both rounds are used (in particular, for all radionuclides), these are all 0-6" grid points within 400 feet, of which there are six to ten in all cases.

The plots show the median and maximum values observed at these neighboring points. The same neighbors are also used for the Wilcoxon comparison, described below. The symbols at the bottom of the box plots correspond to the results of three tests described in the following section.

A.2 Tests Comparing Outfall and Grid Sampling Results

Two statistical tests were performed using the observations from each outfall, considered as a set of independent observations from that outfall. Insofar as the observations from different depths in a single borehole may not be independent, the significance levels

associated with these tests probably require adjustment, but it is not clear in which direction.

1) Comparison with background

This is performed by comparing the number of observations above the 90th or 95th percentile of the background distribution (whether defined for the whole OU or spatially varying, as described in Section A.1.) The 90th percentile is used when there are fewer than eight observations from an outfall, and the 95th when there are eight or more, in order to achieve approximately comparable levels of significance with the small sample sizes involved, as discussed in the attachment to this appendix. Significant results are shown in the second columns of Tables A-3 through A-23.

2) Comparison with neighbors

The nonparametric Wilcoxon rank-sum test (see, for example, Lehmann, 1975) is used to compare the observations from a PRS with neighboring 0-6" grid observations. Positive results (meaning that the PRS observations appear to be significantly higher than the grid neighbors) are shown in the fourth column of Tables A-3 through A-23. "Significance" at the 5% level was required except for outfalls with only 4 or 5 observations, where significance at the 10% level was accepted.

Also shown in Tables A-3 through A-23, in the third column, is whether or not any observation exceeded the local background maximum (or, in the cases of the spatially variable local backgrounds, the 99.9th percentile of the kriged background). For this purpose (and also for the purpose of the binomial test described above), analytical method differences were scrutinized, and results were sometimes not considered significant if they appeared to be due to the use of a different method (usually ICPMS) at the PRS than on the grid. This affects results for beryllium, and occasionally for other elements.

The symbols at the bottom of the box plots correspond to these three columns of the tables. "+" means that the binomial test for being different from local background was significant. "#" means that at least one observation exceeded local background (omitting <DLs and some that seem to be entirely method problems). Finally, "*" means the Wilcoxon comparison with neighbors was significant.

The fifth column of Tables A-3 through A-23, if present, indicates that at least one SAL was exceeded at the PRS.

There were no positive results for PRS 21-027(b), hence no table.

Table A-1. Outliers Deleted for Background and Neighbor Comparisons

Analyte	Method	Loc.	Value	Units
Pu-238	RAS	21-1086	18.66	pCi/g
Tritium	LS	21-1190	152.7	nCi/l
Antimony	6010	21-1224	23.7	ppm
Arsenic	ETVAA	21-1055	9.9	ppm
Beryllium	6010	21-1017	2.5	ppm
Copper	6010	21-1006	57.4	ppm
Molybdenum	6010	21-1224	5.9	ppm
Silver	FAA	21-1030	10.8	ppm

Attachment: Binomial Tests To Determine Whether Observations at a PRS Exceed Local Background

In order to compare small samples with a background distribution described only by its upper tail quantiles, we consider whether "too many" of the observations in the sample exceed these quantiles. The null hypothesis is that the sample of size N comes from the background distribution, in which case the probability that n of the N observations will exceed the q th quantile of that background is

$$P_q = \sum_{i=n}^N \binom{N}{i} (1-q)^i q^{N-i}.$$

(Of course, this use of the binomial formula assumes that the N observations are independent, which is probably not the case, as they never come from more than three boreholes, and sometimes as few as one.)

Table A-24 shows choices of n for $q = .9$ or $.95$ that result in tests with significance levels (P_q 's) below 0.05, in most cases, well below, except for the fact that (*) may be too small by an undetermined amount because of correlation. The last column of Table A-24 indicates the number of outfalls with this sample size.

Table A-24. Binomial Tests

N	n	q	P _q	#PRSs
3	2	.9	0.028

APPENDIX B

DATA TABLES FOR ANALYTES EXCEEDING THE 95.5 PERCENTILE OF THEIR RESPECTIVE BASELINE

Outfalls Laboratory Radiological Data

The data in this appendix represent only detectable levels of organics and analytical values exceeding the 95.5 percentile of the applicable baseline data. A complete set of data is available on the Facility for Information Management and Display database.

The following table lists definitions for acrocymys used in the appendices:

FE	rinsate blank
FB	trip blank
FR	field blank
NS	near-surface soil sample
SU	surface soil sample
FD	field duplicate
ETVAA	electro thermal vapor atomic absorbtion
PTCG	photothermal gas chromatography
FAA	flame atomic absorbtion
RAS	radio alpha spectroscopy
PC	proportional counting
DNA	delayed neutron activation
GCMS	gas chromatography mass spectroscopy
ICPES	inductively-coupled plasma emmissions spectroscopy

Laboratory Radiological Data
Analyte Values Exceeding the 95.5 Percentile of Their Respective Baseline

APPENDIX C

DATA TABLES FOR ANALYTES EXCEEDING DETECTION LIMITS

The data in this appendix represent only detectable levels of radiological, inorganic, and organic analytical values. A complete set of data is available on the Facility for Information Management and Display database.

The following table lists definitions for acrocymys used in the appendices:

FE	rinsate blank
FB	trip blank
FR	field blank
NS	near-surface soil sample
SU	surface soil sample
FD	field duplicate
D	laboratory duplicate
R	laboratory replicate
ETVAA	electro thermal vapor atomic absorbtion
PTCG	photothermal gas chromatography
FAA	flame atomic absorbtion
RAS	radio alpha spectroscopy
PC	proportional counting
DNA	delayed neutron activation
GCMS	gas chromatography mass spectroscopy
ICPES	inductively-coupled plasma emmissions spectroscopy

Outfalls Laboratory Radiological Data
