Abstract

During third quarter 1993, samples collected from the four HAC monitoring wells at the H-Area Acid/Caustic Basin received comprehensive analyses and turbidity measurements. Monitoring results that exceeded the final Primary Drinking Water Standards (PDWS) or the Savannah River Site (SRS) flagging criteria or turbidity standard during the quarter are the focus of this report.

Tritium exceeded the final PDWS and aluminum exceeded its Flag 2 criterion in all four HAC wells during third quarter 1993. Iron was elevated in wells HAC 1, 2, and 3. Chromium was reported above the final PDWS in well HAC 2. Lead exceeded its Flag 2 criterion in HAC 1, specific conductance in HAC 3, and manganese in HAC 3. No well samples exceeded the SRS turbidity standard.

H-Area Acid/Caustic Basin

WSRC-TR-93-571 Unclassified

Executive Summary

The four monitoring wells at the H-Area Acid/Caustic Basin are sampled quarterly as part of the Savannah River Site (SRS) Groundwater Monitoring Program and to comply with a consent decree signed May 26, 1988, by the U.S. District Court (District of South Carolina, Aiken Division). During third quarter 1993, samples from the monitoring wells received comprehensive analyses. Monitoring results that exceeded the final Primary Drinking Water Standards (PDWS), the SRS flagging criteria, or the SRS turbidity standard are the focus of this report.

During third quarter 1993, tritium exceeded the final PDWS in all four HAC wells, with activities between 3.7E+01 and 4.6E+01 pCi/mL. Chromium was detected above its PDWS in well HAC 2 at $118 \mu g/L$. Aluminum exceeded its Flag 2 criterion in all four wells. Iron exceeded its Flag 2 criterion in wells HAC 1, 2, and 3. Lead exceeded its Flag 2 criterion in wells HAC 1, specific conductance was elevated in well HAC 2, and manganese was above standard in well HAC 3. No well samples exceeded the SRS turbidity standard.

Introduction

The H-Area Acid/Caustic Basin is southwest of the H-Area Canyon Building and north of the H-Area Tank Farm at the Savannah River Site (SRS). The basin, constructed in the early 1950s, is an unlined earthen pit that received dilute sulfuric acid and sodium hydroxide solutions and other wastes from several areas within SRS. The basin provided an area for the mixing and neutralization of the dilute solutions before their discharge into nearby streams. Disposal of acid/caustic solutions to the H-Area Acid/Caustic Basin was discontinued in 1982; however, the basin received steam condensate from a hose box and drainage from a chemical pad until 1985 (Heffner and Exploration Resources, 1991).

Under the terms of a consent decree signed May 26, 1988, by the U.S. District Court (District of South Carolina, Aiken Division), the basin became subject effective June 1, 1988, to requirements of Subtitle C of the Resource Conservation and Recovery Act (RCRA), the South Carolina Hazardous Waste Management Regulations (SCHWMR), and associated regulations. In the summer of 1988, a network of monitoring wells was proposed for the basin to ensure compliance with SCHWMR; in August 1988, four monitoring wells were installed at the H-Area Acid/Caustic Basin.

The monitoring wells at the H-Area Acid/Caustic Basin are sampled quarterly as part of the SRS Groundwater Monitoring Program and to comply with SCHWMR. The revised Groundwater Quality Assessment Plan (WSRC, 1991), submitted to the South Carolina Department of Health and Environmental Control on April 30, 1991, indicates that the monitoring well network at the H-Area Acid/Caustic Basin is sufficient to detect any degradation of the groundwater due to past operations at the basin.

Discussion

Groundwater Monitoring Data

The groundwater sampling procedure was modified beginning fourth quarter 1992 in response to regulatory guidance and advances in sampling equipment design (EPD/EMS, 1992). The modified procedure requires evacuation of a minimum of two well volumes and stabilization of pH, specific conductance, and turbidity prior to sample collection. Stability is established when a minimum of three successive measurements, taken within a given time period, are within a specified tolerance range. If a well pumps dry before two well volumes are purged or before stabilization is achieved, it must be revisited within 24 hours for the data to be considered from a single sampling event. On the second visit within 24 hours, samples are taken without purging or stability measurements; thus, these samples may not be representative of the groundwater quality.

A further modification in the procedure is that samples collected for metals analyses are not filtered. Thus, the analyses are for total metals rather than dissolved metals.

During third quarter 1993, samples from the four monitoring wells at the H-Area Acid/ Caustic Basin received comprehensive analyses. This report describes monitoring results that exceeded the Safe Drinking Water Act final Primary Drinking Water Standards (PDWS) or screening levels set by the U.S. Environmental Protection Agency (EPA) (Appendix A), the South Carolina final PDWS for lead (Appendix A), other SRS Flag 2 criteria (Appendix B), or the SRS turbidity standard.

The SRS flagging criteria are based on final and proposed PDWS, Secondary Drinking Water Standards, and method detection limits. Constituent levels that equal or exceed the final PDWS, screening levels, or Flag 2 criteria are described as *elevated*.

The final PDWS for individual analytes provided in Appendix A may not always match the SRS flagging criteria provided in Appendix B. The final PDWS are used as guidelines in this compliance report to meet regulatory requirements; the flagging criteria are used by the Environmental Protection Department/Environmental Monitoring Section to identify relative levels of constituents in the groundwater and as guides for scheduling groundwater sampling.

Appendix C presents illustrations of the monitored waste management unit at SRS (Figure 1), the individual monitoring wells (Figure 2), and the flow directions of the groundwater beneath the basin (Figure 3). All figures are aligned to true north. Figure 1 has both SRS grid coordinates and latitude/longitude. Figures 2 and 3 have latitude/longitude coordinates as well as Universal Transverse Mercator (UTM) coordinates. Monitoring results are presented in Appendix D, and a discussion of data quality and useability is in Appendix E.

Analytical Results Exceeding Standards

Results for analytes that exceeded the final PDWS (see Appendix A) during third quarter 1993 are summarized in Table 1 (Appendix D). All four HAC wells contained tritium activities that exceeded the final PDWS, with activities ranging from 3.7E+01 to 4.6E+01 pCi/mL. Well HAC 2 also contained levels of chromium above the final PDWS at $118 \mu g/L$.

Constituents that exceeded other Flag 1 and 2 criteria (see Appendix B) during third quarter 1993 are summarized in Table 2 (Appendix D). Aluminum, which was added to the list of comprehensive analyses beginning first quarter 1993, was elevated in all four wells, with a maximum concentration of $259 \ \mu g/L$ in well HAC 2. Iron exceeded the Flag 2 criterion in wells HAC 1, 2, and 3, with a maximum concentration of $3,080 \ \mu g/L$ in HAC 2. Lead exceeded the Flag 2 criterion in well HAC 1 at $28 \ \mu g/L$, specific conductance was elevated in HAC 2 at 519 μ S/cm, and manganese was elevated in HAC 3 at 85 $\mu g/L$.

Table 3 (Appendix D) presents all of the results for individual wells and indicates those analyses that exceeded holding times and the final PDWS. Modifiers (qualifiers) which may appear in the *Mod* column of Table 3 are defined on pp. D-3 and D-4.

Table 3 also lists the number of well volumes of water purged from each well during third quarter 1993 at the H-Area Acid/Caustic Basin. Wells HAC 1, 2, and 3 went dry before meeting the criteria for purging and stabilization.

Some of the values for earlier quarters presented in Table 1 of this report may differ from the values for the same quarters presented in previous reports because some reanalyses may have been performed by the laboratories after the quarterly reports had gone to press.

Turbidity Results Exceeding Standards

The value of 5 nephelometric turbidity units (NTU), established by EPA (1986) as a general standard for acceptability of groundwater samples, is considered unrealistic for monitoring wells at SRS. Gass (1989) has documented turbidity measurements ranging up to 5,000 NTU from properly designed wells screened in poorly productive formations, such as those screened in the water table. During the 1989 RCRA Compliance Evaluation Inspection, officials from EPA Region IV indicated that the SRS turbidity standard of 50 NTU is conservative. These officials also agreed that water-table wells in this area often correspond to nonaquifer formations, rendering development of these wells more difficult due to the low yield and high proportion of mobile fines typical of these formations (Bergren and Bennett, 1989).

During third quarter 1993, none of the samples exceeded the SRS turbidity standard of 50 NTU (Table 3, Appendix D).

Water Elevations, Flow Directions, and Flow Rates

Water-table elevations and the groundwater flow direction beneath the H-Area Acid/Caustic Basin are shown in Figure 3 (Appendix C). The horizontal gradient at the H-Area Acid/ Caustic Basin is very low. Water elevations from nine nearby wells of the HTF series were included to supply more complete information on groundwater movement beneath the H-Area

and the state of t

Acid/Caustic Basin and facilitate the determination of local flow direction. The northwest groundwater flow direction (using UTM coordinates) determined from this quarter's waterlevel elevations for wells HAC 1, 2, 3, and 4 and HTF 13, 14, 15, 16, 17, 18, 19, 20, and 21 is consistent with the historical flow pattern.

The groundwater flow rate in the water table (Aquifer Zone IIB_2) beneath the H-Area Acid/Caustic Basin is estimated using the following equation:

Flow (ft/day) = <u>Hydraulic Conductivity (ft/day)</u> $\times \frac{dh (ft)}{dl (ft)}$

A hydraulic conductivity constant of 10 ft/day (Geraghty & Miller, 1990) is used as a conservative estimate (i.e., the actual hydraulic conductivity should be somewhat less than 10 ft/day). The effective porosity value is estimated at 20% (Killian et al., 1987), dh is the difference in head, and dl is the length of the flow path to the nearest 10 ft. Flow rate estimates vary depending on the hydraulic gradient between wells, the size of the area under consideration, and the number of data points. For this reason, the estimation of flow rate should be considered accurate to an order of magnitude only.

Flow rate per day is calculated to two significant figures using the above equation. This value is then multiplied by 365 and rounded to two significant figures for the flow rate per year.

Using the above equation with dh = 8 ft and dl = 640 ft (see Figure 3 in Appendix C), the flow rate estimate for groundwater in the water table beneath the H-Area Acid/Caustic Basin is as follows:

 $\frac{10}{0.20} \times \frac{8}{640} = 0.63 \text{ ft/day}$ 0.63 ft/day × 365 days = 230 ft/yr

This result is consistent with those of recent quarters except the apparently anomalous flow rate of 580 ft/yr calculated for fourth quarter 1992.

Results for Upgradient vs. Downgradient Wells

Well HAC 4 is the upgradient well, and HAC 1, 2, and 3 are the downgradient wells at the H-Area Acid/Caustic Basin. During third quarter 1993, tritium and aluminum were detected at elevated levels in the upgradient well. Tritium also exceeded the PDWS in all three downgradient wells, at very similar activities to those in HAC 4. Aluminum also exceeded its Flag 2 criterion in all three downgradient wells. Chromium exceeded the PDWS only in downgradient well HAC 2. Iron, not detected above standards in the upgradient well, exceeded the Flag 2 criterion in all three downgradient wells, as did lead in HAC 1, specific conductance in HAC 2, and manganese in HAC 3.

Third Quarter 1993

Conclusions

Tritium activities exceeded the final PDWS during third quarter 1993 in all four HAC wells, with activities ranging between 3.7E+01 and 4.6E+01 pCi/mL. Because historical records indicate that no radionuclides were disposed of at this waste management unit (Heffner and Exploration Resources, 1991), elevated levels of tritium in the HAC wells are not considered a result of seepage from the acid/caustic basin. Releases of tritium from other facilities within H Area, including the high-level waste tank farm adjacent to the H-Area Acid/Caustic Basin, are possible sources of the tritium.

Chromium was reported above the PDWS in well HAC 2. Aluminum also exceeded standards in all four wells. Iron exceeded the Flag 2 criterion in downgradient wells HAC 1, 2, and 3. Lead exceeded its Flag 2 criterion in well HAC 1, specific conductance in HAC 2, and manganese in HAC 3. Generally, elevated levels of constituents found in downgradient wells but not in upgradient wells at a waste management unit are considered products of the waste management unit.

No well samples exceeded the 50 NTU SRS turbidity standard.

Water-table elevations at the H-Area Acid/Caustic Basin indicate that groundwater flow is toward the northwest at a rate of approximately 230 ft/yr; this flow direction is consistent with the historical flow pattern. The revised Groundwater Quality Assessment Plan (WSRC, 1991) for the unit provides evidence that wells HAC 1, 2, and 3 are consistently downgradient of well HAC 4 and that the monitoring well network is sufficient to detect degradation of the groundwater due to past operations at the basin.

^a This value is the drinking water standard for total trihalomethanes (the sum of bromoform, bromodichloromethane, chloroform, and dibromochloromethane).

^b The standard given is for gross alpha including radium-226 but excluding radon and uranium.

^d Analyses were conducted in 1992 for the following: PCB 1016, PCB 1221, PCB 1232, PCB 1242, PCB 1248, PCB 1254, and PCB 1260.

For double radionuclide analyses where each separate radionuclide has its own standard, the more stringent standard is used.

Appendix B – Flagging Criteria

H-Area Acid/Caustic Basin

Third Quarter 1993

Flagging Criteria

The Savannah River Site Environmental Protection Department/Environmental Monitoring Section (EPD/EMS) flagging criteria are as follows:

- Flag 2 criteria for constituents equal the Safe Drinking Water Act (SDWA) final Primary Drinking Water Standard (PDWS), the SDWA proposed PDWS, or the SDWA Secondary Drinking Water Standard (SDWS). If a constituent does not have a drinking water standard, the Flag 2 criterion equals 10 times the method detection limit (MDL) calculated as the 90th percentile detection limit obtained recently by one of the primary analytical laboratories.
- Flag 1 criteria for constituents equal one-half of the final PDWS, one-half the proposed PDWS, or one-half the SDWS. If a constituent does not have a drinking water standard, the Flag 1 criterion equals 5 times the MDL calculated as the 90th percentile detection limit obtained recently by one of the primary analytical laboratories.
- Flag 0 criteria are assigned to constituent levels below Flag 1 criteria, constituent levels below the sample detection limits, or constituents having no flagging criteria.

The following parameters are not assigned flagging criteria: alkalinity, calcium, color, corrosivity, Eh, magnesium, odor, potassium, silica, sodium, total dissolved solids, total phosphates (as P), total phosphorus, and turbidity. In addition, common laboratory contaminants and cleaners including some phthalates, ketones, and toluene are not assigned flagging criteria.

ň

^b EPD/EMS set this flagging criterion using the 1991 proposed PDWS because the final PDWS in 1977 may have been in error.

When radionuclide analyses are combined, the lower PDWS of the two isotopes is used for flagging.

^d The applied standard is for radium-226.

Key to Reading the Tables

The following abbreviations may appear in the tabular data:

B = sample collected from well using an open bucket bailer BA = Barringer Laboratories, Inc. CN = Clemson Technical Center, Inc.CS = carbon steelD = primary drinking water standard (PDWS) $E = exponential notation (e.g., 1.1E - 09 = 1.1 \times 10^9 = 0.000000011)$ EM = Environmental Protection Department/Environmental Monitoring Section (EPD/EMS) Laboratory GE = General Engineering Laboratories GP = Environmental Physics, Inc. H = holding time1,2,3,4,6,7,8-HPCDD = 1,2,3,4,6,7,8-heptachlorodibenzo-p-dioxin 1,2,3,4,6,7,8-HPCDF = 1,2,3,4,6,7,8-heptachlorodibenzo-p-furan 1,2,3,4,7,8-HXCDD = 1,2,3,4,7,8-hexachlorodibenzo-p-dioxin 1,2,3,4,7,8-HXCDF = 1,2,3,4,7,8-hexachlorodibenzo-p-furan Lindane = gamma-benzene hexachloride mg/L = milligrams per liter Mod = modifiermsl = mean sea levelMSL = million structures per literNTU = turbidity unit P = sample collected from well using a bladder pump PCB = polychlorinated biphenyl1,2,3,7,8-PCDD = 1,2,3,7,8-pentachlorodibenzo-p-dioxin 1,2,3,7,8-PCDF = 1,2,3,7,8-pentachlorodibenzo-p-furan pCi/L = picocuries per literpCi/mL = picocuries per milliliterPDWS = primary drinking water standard pH = pH unit PVC = polyvinyl chloride S = sample collected from well using a single-speed centrifugal downhole pump Sp. conductance = specific conductance SP = Spencer Testing Services, Inc.TCDD = tetrachlorodibenzo-p-dioxin TCDF = tetrachlorodibenzo-p-furanTM = TMA/EberlineTOC = top of casingV = sample collected from well using a variable-speed pump WA = Roy F. Weston, Inc. $\mu g/L = micrograms per liter$ μ S/cm = microsiemens per centimeter

Holding Times

Standard analytical methods include a limit, called holding time, on the maximum elapsed time between sample collection and extraction or analysis by the laboratory. In the data tables, a large dot (\bullet) in the H (holding time) column indicates that holding time was exceeded. Analyses performed beyond holding time may not yield valid results.

The South Carolina Department of Health and Environmental Control allows only 15 minutes to elapse between sampling and analysis for pH. Thus, only field pH measurements can meet the holding time criterion; laboratory pH analyses always will exceed it.

The laboratory procedure used for the determination of specific conductance allows one day to elapse between sampling and analysis. Thus, laboratory specific conductance measurements may exceed the holding time criterion.

Data Rounding

Constituent results in analytical results tables that appear to equal the final PDWS but are not marked in the D (exceeded the final PDWS or screening level) column are below the final PDWS in the database. Values stored in the database contain more significant digits than the reported results. Apparent discrepancies in the tables are due to the rounding of reported results.

Data Qualification

The contract laboratories continually assess their own accuracy and precision according to U.S. Environmental Protection Agency (EPA) guidelines. They submit sample- or batchspecific quality assurance/quality control information either at the same time as analytical results or in a quarterly summary. Properly defined and used result modifiers (also referred to as qualifiers) can be a key component in assessing data useability. Result modifiers designed by Environmental Protection Department/Environmental Monitoring Section and provided to the primary laboratories are defined below. These modifiers appear in the data tables under the column "Mod." The lettered modifiers are based on EPA's STORET codes.

Result modifier	Definition
(Blank)	Data are not qualified. Number should be interpreted exactly as reported.
A	Value reported is the mean of two or more determinations.
J	Value is estimated because quantitation in the sample or in associated quality control samples did not meet specifications.
L	Value is off-scale high. The actual value is not known but is known to be greater than the value shown.
М	Presence of the analyte is verified but not quantified.

Result modifier	Definition
R	Result was rejected because performance requirements in the sample analysis or associated quality control analyses were not met.
т	Analyte was not detected; if present, it was below the criteria for detection.
v	Analyte was detected in an associated method blank.
Y	Result was obtained from an unpreserved or improperly preserved sample. Data may not be accurate.
1	Result may be an underestimation of the true value due to analytical bias.
2	Result may be an overestimation of the true value due to analytical bias.
3	The associated result may be of poor precision (high variability) due to analytical bias.
4	Result is associated with QA results indicating matrix interference.
6	The associated result is from a reanalysis performed out of holding time due to problems with an earlier analysis.

Data Quality/Useability Assessment

Quality assurance/quality control (QA/QC) procedures relating to accuracy and precision of analyses performed on groundwater samples are followed in the field and laboratory and are reviewed prior to publication of results. The Environmental Protection Department/ Environmental Monitoring Section's (EPD/EMS) review of the volume of analytical data acquired each quarter and presented in various reports is an ongoing process; its review of the QA/QC data cannot be completed in time to meet the deadlines for the reports required by the Resource Conservation and Recovery Act and associated regulations. Other site and regulatory personnel can obtain further information on the data quality and useability in a variety of ways, including those described below.

Data Qualification

The contract laboratories continually assess their own accuracy and precision according to U.S. Environmental Protection Agency (EPA) guidelines. They submit sample- or batch-specific QA/QC information either at the same time as analytical results or in a quarterly summary. Properly defined and used result modifiers (also referred to as qualifiers) can be a key component in assessing data useability. Result modifiers designed by EPD/EMS and used by the primary laboratories are presented in Appendix D.

Assessment of Accuracy of the Data

Accuracy, or the nearness of the reported result to the true concentration of a constituent in a sample, can be assessed in several ways.

A laboratory's general accuracy can be judged by analysis of results obtained from known samples. The non-radionuclide contract laboratories analyze commercial reference samples every quarter at EPD/EMS' request. The results of these analyses are presented in the EPD/EMS quarterly report, *The Savannah River Site's Groundwater Monitoring Program*. The primary laboratories also seek or maintain state certification by participating periodically in performance studies; reference samples and analysis of results are provided by EPA. Results of these studies also are published in the EPD/EMS quarterly reports.

Analysis of blanks provides a tool for assessing the accuracy of both sampling and laboratory analysis. Results for all field blanks for the quarter can be found in the EPD/EMS quarterly reports. Any field or laboratory blanks that exceeded established minimums are identified in the same reports, in tables associating them with groundwater samples analyzed in the same batches.

Surrogates, organic compounds similar in chemical behavior to the compounds of interest but not normally found in environmental samples, are used to monitor the effect of the matrix on the accuracy of analyses for organic parameters. For example, for analyses of volatile organics by EPA Method 8240, three surrogate compounds are added to all samples

and blanks in each analytical batch. In analyses of semivolatile organics, three to four acid compounds and three to four base/neutral compounds are used. Other surrogates are used in pesticides analyses. Percent recoveries for surrogate analyses are calculated by laboratory personnel, reported to EPD/EMS, reviewed, and entered into the database, but they are not published. If recoveries are not within specified limits, the laboratory is expected to re-run the samples or attach result qualifiers to the data identifying the anomalous results.

Sample-specific accuracy for both organic and inorganic parameters can be assessed by examination of matrix spike/matrix spike duplicate results. A sample is analyzed unspiked to determine a baseline set of values. A second portion of sample is spiked with known concentrations of compounds appropriate to the analyses being performed, typically 5 volatile organic compounds for volatile organics analyses, 11 semivolatile compounds for semivolatiles, 6 pesticide compounds for pesticides, all metals for metals analyses, and a known quantity of cyanide for cyanide analysis. The percentage of the spike compound that is recovered (i.e., measured in excess of the value obtained for the unspiked sample) is a direct measure of analytical accuracy. EPA requires matrix spike/matrix spike duplicates to be run at least once per 20 samples of similar matrix.

Matrix spike/matrix spike duplicate results are reported to EPD/EMS but are not published. For organic compounds, according to EPA guidelines, no action is taken on the basis of matrix spike/matrix spike duplicate data alone (i.e., no result modifiers are assigned solely on the basis of matrix spike results); however, the results can indicate if a lab is having a systematic problem in the analysis of one or more analytes.

In the case of inorganic compounds, such as metals, the matrix spike sample analysis provides information about the effect of each sample matrix on the digestion and measurement methodology. Data qualifiers can be assigned on the basis of the percentage of spike recovery and are reported in the published results tables.

Assessment of Precision

Precision of the analyses, or agreement of a set of replicate results among themselves, is assessed through the use of duplicates (laboratory-initiated) and blind replicates (provided by EPD/EMS). The results of duplicate and replicate analyses are presented in the results tables of the first, second, and third quarter reports. Duplicate and replicate results are not presented in fourth quarter reports; the results tables present instead only the highest result for each analyte for each quarter of the year.

The laboratories assess precision by calculating the relative percent difference, or RPD, for each pair of laboratory-initiated duplicate results. During 1992, at least one of the contract laboratories used a data qualifier (J3) to modify metals analyses when the RPD for laboratory duplicates was greater than 20%.

Additional statistical comparisons of laboratory duplicate and blind replicate results, both intra- and interlaboratory, are presented in the EPD/EMS quarterly reports. The calculation used for these reports is the MRD, or mean relative difference, which is similar to EPA's RPD except that the MRD provides a single value for all of the analyses of a particular com-

pound, either inter- or intralaboratory, during one quarter. Because detection limits may vary among samples, the MRD requires calculation of a reference detection limit, which is the detection limit at the 90th percentile of the array of limits in the population of all replicate and duplicate analyses for a given analyte during a particular quarter. The MRD is not method-specific.

Method-Specific Accuracy and Precision

The contract laboratories' EPA-approved laboratory procedures include QA/QC requirements as an integral part of the methods. Thus, knowledge of the method used in obtaining data is an important component of determining data useability. EPA has conducted extensive research and development on the methods approved for the analysis of water and waste water; information on the accuracy and precision of the method is available from EPA publications, as is full information on required QA/QC procedures. A listing of the methods used by the primary laboratories during first quarter 1992 is given below along with the source for the method description. Many, if not all, of these sources include presentations of representative accuracy and precision results.

An example of the available method-specific QA/QC information is that for the analysis of metals by EPA Method 6010/200.7 (EPA, 1986/EPA EMSL, 1983). The primary laboratories, General Engineering Laboratories (GE) and Roy F. Weston, Inc. (Weston), use this inductively coupled plasma (ICP) atomic emission spectrometric method.

The following precision and accuracy data are based on the experience of seven laboratories that applied the ICP technique to acid-distilled water matrices that had been dosed with various metal concentrates. (Note: not all seven laboratories analyzed all 14 elements.) The references give results for samples having three concentration ranges; the results here are for samples having the lowest values, similar to actual groundwater results for SRS.

Element	<u>True value (µg/L)</u>	Mean reported value (µg/L)	Mean percent <u>RSD</u> ^a
Aluminum	60	62	33
Arsenic	22	19	23
Beryllium	20	20	9.8
Cadmium	2.5	2.9	16
Chromium	10	10	18
Cobalt	20	20	4.1
Copper	11	11	40
Iron	20	19	15
Lead	24	30	32
Manganese	15	15	6.7
Nickel	30	28	11
Selenium	6	8.5	42

ICP Precision and Accuracy Data

Element	True value (µg/L)	Mean reported <u>value (µg/L</u>)	Mean percent <u>RSD</u> ^a
Vanadium	70	69	2.9
Zinc	16	19	45

Note: In EPA (1986), the column heading is Mean Standard Deviation (%).

^a Relative standard deviation.

As another example, EPA Method 601/8010 (EPA, 1991/EPA, 1986) is used by both GE and Weston for analyses of halogenated volatile organics. In the presentation of the method in both references, the following table gives method-specific accuracy and precision as functions of concentration. Contract laboratories are expected to achieve or at least approach these limits.

Accuracy and Precision as Functions of Concentration for EPA Method 601/8010
