DISCLAIMER

This report was prepared as an account of work sponsored by an agency of the United States Government. Neither the United States Government nor any agency thereof, nor any of their employees, makes any warranty, express or implied, or assumes any legal liability or responsibility for the accuracy, completeness, or usefulness of any information, apparatus, product, or process disclosed, or represents that its use would not infringe privately owned rights. Reference herein to any specific commercial product, process, or service by trade name, trademark, manufacturer, or otherwise does not necessarily constitute or imply its endorsement, recommendation, or favoring by the United States Government or any agency thereof. The views and opinions of authors expressed herein do not necessarily state or reflect those of the United States Government or any agency thereof.
I. Statement of Work

The main objectives of this proposed research work are to refine further the inverse liquid chromatography technique for the study of surface properties of raw coals, treated coals and coal minerals in water, to evaluate relatively surface properties of raw coals, treated coals and coal minerals by inverse liquid chromatography, and to evaluate flotability of various treated coals in conjunction with surface properties of coals.

Coals such as Pittsburgh seam coal, Illinois #6 coal, Wyodak coal are chosen as representatives of high-rank bituminous coal, high volatile bituminous coal and subbituminous coal, respectively. Coal minerals such as pyrite and dolomite are chosen as representative coal minerals.

Alcohols such as methanol, ethanol, isopropanol, isobutanol, tert-butanol, heptanol, 1-hexadecanol, 2-methyl-pentanol, 4-methyl-2-pentanol (methylisobutyl carbinol), n-octanol, s-octanol, and cyclohexanol as probe compounds are utilized to evaluate hydrophilicity of coals and coal minerals.

N-alkanes such as hexane, heptane and octane, and stearic acid are employed as probe compounds to evaluate hydrophobicity of coals and coal minerals. Aromatic compounds such as benzene and toluene as probe compounds are used to examine aromaticity of coal surface. Aromatic acids such as o-cresol m-cresol, p-cresol, phenol and B-naphthol are used to detect aromatic acidic sites of coal surface.

Hydrophilicity, hydrophobicity and aromaticity of surfaces for either raw coals or treated coals in water are relatively determined by evaluating both equilibrium physical/chemical adsorption and dynamic adsorption of probe compounds on various raw coals and treated coals to compare affinities of coals for water.

Dynamic adsorption experiments will be conducted in a batch reactor equipped with a magnetic stirrer. A given amount of raw/treated coals or coal
minerals, and a given amount of an aqueous solution with a known concentration of a probe compound are introduced in a batch reactor at room temperature. Concentrations of probe compounds at various contact durations are determined with a HPLC, equipped with a RI detector.

Equilibrium adsorption experiments are performed in either a batch reactor or a packed column at room temperature. A given amount of coals or coal minerals is packed in an empty HPLC column. An aqueous solution of a probe compound of interest is passed through the bed packed in the column. Concentrations of the effluent from the column are evaluated with the RI detector.

Two students are assigned for the first year to the development of precise laboratory procedures for the inverse liquid chromatography technique, using various probe compounds and coals. This involves developing procedures for the proper operation of a liquid chromatograph. Hydrophilicity, hydrophobicity and aromaticity of raw coals are detected with chromatography. Hydrophilicity and hydrophobicity of coal minerals also are determined with chromatography.

During the second year, the above students begin treating various coals and coal minerals with oxygen and nitrogen, using either a microreactor or an in-situ coal-packed column in a gas chromatograph. Hydrophilicity, hydrophobicity and aromaticity of treated coals are determined with chromatography. Hydrophilicity and hydrophobicity of treated coal minerals also are evaluated with inverse liquid chromatography.

Our research efforts should contribute significantly to the understanding of the nature of coal surface in water, and to developing further the inverse chromatography method for the evaluation of surface properties of coal in water. This work should also provide background data for improving chemical technology in coal cleaning processes.
II project Status

Research activities and efforts of the research project were idle during the period of September-December 1991, although the new research project was planned to begin in September 1991. The PI of this research project has been assigned as acting head of the Chemical Engineering Department since the Fall Semester 1991. The PI was not released from the academic duty in order to carry on this research project during the Fall Semester 1991, but the PI has been released from the academic duty (25 % FTE) in order to carry on this research project for this semester, by hiring Prof. Leo J. Hirth from Auburn University as an adjunct professor.

Several pieces of experimental equipment have been ordered, as shown in Table 1. The major equipment such as the RI detector and the solvent delivery system, placed on order in January 1992, have not been delivered. The strip chart recorder only is on hand.

The coals such as Illinois #6 coal (DECS-2; Randolph county), Adaville #7 coal (DECS-7; Wyoming state, Lincoln county), Wyodak coal (DECS-8; Wyoming state, Campbell county) and Pittsburgh #8 coal (DECS-12; Pennsylvania state, Greene county) have been obtained from the coal bank of the Pennsylvania State University (PSU). The proximate analysis and ultimate analysis of the coals were provided by the PSU coal bank, as shown in Table 2.

Most probe chemicals for the analysis of coal surface properties in water have been placed on order, as shown in Table 3. Pyrite and dolomite were selected as representative coal minerals. Graphite and activated carbon as simulating coal materials, and glass and Teflon as simulating coal mineral materials will be used for preliminary experiments and developments of experimental procedures.
III Future Experimental Plans

The PI visited the Coal Preparation Division of the Pittsburgh Energy Technology Center (PETC) to discuss future initial experimental plans of this research project with the PETC experts (Rohrer, Finseth, Gray, Jones, Rhee, Wen, Warzanski, Lai and Olson). The PETC experts suggested that initial experiments for the analysis of coal surface properties might start with graphite and activated carbon rather than raw coal. The PETC experts agreed on participation of experimental plan processes on request of the PI in order to obtain practically-useful experimental data on coal surface properties and apply these data to real coal cleaning processes. Physical characterizations of coal such as particle distributions, particle sizings, and zeta potential analysis will be accomplished with the help of the PETC experimental equipment.
