1.0 INTRODUCTION

New software engineering tools and object-oriented design have a great impact on the software development process. But in high energy physics all major packages were implemented in FORTRAN and porting of these codes to another language is rather complicated, primarily because of their huge size and heavy use of FORTRAN mathematical libraries. But some intrinsic accelerator concepts, such as nested structure of modern accelerators, look very pretty when implemented with the object-oriented approach. In this paper we present the object-oriented version of ZLIB, a numerical library for differential algebra, and show how the modern approaches can simplify the development and support of accelerator codes, decrease code size, and allow description of complex mathematical transformations by simple language.

2.0 TRUNCATED POWER SERIES

The truncated power series (TPS) expansion of the arbitrary function $U(z)$ is defined as:

$$U(z) = \sum_{k=0}^{\Omega} u(k)z^k,$$

where

$$z^T = [z_1, z_2, ..., z_n],$$

$$z^k = z_1^{k_1} z_2^{k_2} ... z_n^{k_n},$$

$$k = \sum_{i=1}^{n} k_i, \text{ for } 0 \leq k_i \leq \Omega.$$

In the new object-oriented version of ZLIB, TPS is considered as C++ class ZSeries, which includes overloaded assignment, additive, multiplicative operators and two additional functions dif and poisson (Appendix A). To simplify the form of the TPS transformation equations we include the additional private member order [order $\Omega$ of TPS expansion in Eq. (1)] and several rules for its usage. Below we describe the main elements of class ZSeries and their relationship with the subroutines of the previous FORTRAN version of ZLIB. Full description of fundamental TPS operations may be found in a users guide for ZLIB 1.0.1.

2.1 Definitions

In expressions and examples in this report we will use the following notation:

- $U, V, W$ are the instances of class ZSeries;
- $c$ is constant or variable of the double type;
ZLIB_ORDER is global variable, which determines the maximum TPS order;

ZLIB_DIM is global variable, which determines the phase-space dimension.

The parameters ZLIB_ORDER and ZLIB_DIM must be defined by user before all assignment operators, because they determine memory allocation for members of class ZSeries.

2.2 Assignment Operators

An assignment operator is used to set a ZSeries variable to constant or another ZSeries value. This operator returns void and so a vague statement (a = b) = c will result in a syntax error. Here is the summary of different cases of assignment operator:

2.2.1 Operator =
1. W = c ;
   \[ w(k) = c \quad \text{for} \quad 0 \leq k \leq W.\text{order} \]
   W.\text{order} = 0 .

2. W = U ;
   \[ w(k) = u(k) \quad \text{for} \quad 0 \leq k \leq U.\text{order} \]
   W.\text{order} = U.\text{order} .

2.2.2 Operators += and -=
1. W += c ;
   \[ w(k) = w(k) + c \quad \text{for} \quad k = 0 , \]
   \[ w(k) = w(k) \quad \text{for} \quad 0 < k \leq W.\text{order} . \]

2. W += U ;
   \[ W(z) = \sum_{k=0}^{W.\text{order}} w(k)z^k + \sum_{k=0}^{U.\text{order}} u(k)z^k , \]
   W.\text{order} = \max(W.\text{order}, U.\text{order}) .

3. W -= c; and W -= U;
   These subtraction operators are determined similar to addition (Section 2.2.2).

2.2.3 Operator *=
1. W *= c ;
   \[ w(k) = w(k) * c \quad \text{for} \quad 0 \leq k \leq W.\text{order} . \]
2. \( W = U \);

\[ W(z) = \sum_{k=0}^{W.\text{order}} w(k)z^k \times \sum_{k=0}^{U.\text{order}} u(k)z^k , \]

\[ W.\text{order} = \min(W.\text{order} + U.\text{order} \cdot \text{ZLIB\_ORDER}) . \]

2.2.4 Operator /=

1. \( W / c \);

\[ w(k) = w(k)/c \quad \text{for } 0 \leq k \leq W.\text{order}. \]

2. \( W / U \);

The implementation of this operator is based on two functions: multiplication (Section 2.2.3) and inversion \( 1/U \) (Section 2.4) and defined as:

\[ W* = (1/U) . \]

2.3 Additive and Multiplicative Operators

Additive (+ and -) and multiplicative (* and /) operators are similar to corresponding assignment operators (Sections 2.2.2, 2.2.3 and 2.2.4), but unlike assignment operators they return reference to \text{tmpZSeries}, temporary instance of class \text{ZSeries}, which is created as a result of the expression. This allows user to write usual mathematical expressions as:

\[ W* = (U - c)/V * c + \ldots \]

2.4 Inverse Operator

Inversion of the object \( U \) is expressed as a Taylor expansion of \( 1/(1 + V) \), where \( V = \left(U - u(0)\right)/u(0): \)

\[ W = 1./U = \frac{1}{u(0) \left(1 + \frac{U-u(0)}{u(0)}\right)} \]

\[ = \frac{1}{u(0)} \cdot \sum_{n=0}^{U.\text{tmpOrder}} (-1)^n \left(\frac{U - u(0)}{u(0)}\right)^n . \]

The implementation of this expression is based on \text{ZSeries} multiplicative and additive operators (Appendix B).
2.5 Functions

This object-oriented version of ZLIB supports two functions \texttt{dif} and \texttt{poisson}. As in the case of additive and multiplicative operators (Section 2.3), these functions return reference to temporary object \texttt{tmpZSeries} and may be combined with other operators in the complex expression.

2.5.1 Derivative

The function \texttt{dif(U, iv)} returns the partial derivative \((\partial/\partial z_i)v)U(\bar{z})\).

2.5.2 Poisson Bracket

Poisson bracket is the main operator of differential algebra. It associated with a Lie operator : \(U(\bar{z})\) : as in Reference 2:

\[
\text{poisson}(U, V) \equiv: U(\bar{z}) : V(\bar{z}) \equiv [U(\bar{z}), V(\bar{z})] = -\left(\frac{\partial U(\bar{z})}{\partial \bar{z}}\right)^T S \left(\frac{\partial V(\bar{z})}{\partial \bar{z}}\right),
\]

where \(S\) is the symplectic identity.

2.6 Access Operators

Access operators may be used to change directly the private members of class \texttt{ZSeries} (coefficients of the TPS and its order \texttt{order}) and some specific rules of the transformation of \texttt{order}, described in Section 2.3. These rules may be generalized and expressed as the following:

\textbf{Rule 1} The order of the object \(W\), created by constructor \texttt{ZSeries::ZSeries()}, is equal to zero, i.e., for the new object \(W\).\texttt{order} = 0;

\textbf{Rule 2} The order of the object \(W\) in the left side of an assignment operator \(W = U\) is determined by the order of \(U\), i.e., \(W\).\texttt{order} = \(U\).\texttt{order}.

\textbf{Rule 3} The order of the object \(W\), which is obtained as a result of additive operations (+, −, +, and −) is equal to the maximum order of items \(U\) and \(V\), i.e., \(W\).\texttt{order} = \text{max}(\(U\).\texttt{order}, \(V\).\texttt{order}).

\textbf{Rule 4} The order of the object \(W\), which is obtained as a result of multiplicative operations (\(*\), /, \(*\) and \(/\) or binary functions (\texttt{poisson(U,V)}) is equal to \text{min}((\(U\).\texttt{order} + \(V\).\texttt{order}), ZLIB\_ORDER).

\textit{* These rules are valid also for the expressions with the constant \(c\), regarding its order to be zero.}
2.6.1 Operator()(int)

This operator (round brackets) allows user to temporarily change the order \( W.\text{order} \) of the object \( W \) in the intermediate expression. To assign new order \texttt{newOrder} "permanently" user could use the following construction:

\[
U = U(\texttt{newOrder}) .
\]

2.6.2 Operator()(int, int)

The second parameter in \texttt{operator()} allows user to bypass Rule 4 for multiplicative operators (Section 2.6) in accordance with the following definition:

\[
W = U \times V(V.\text{order}, V.\text{mltOrder})
\]

\[
W.\text{order} = \min(V.\text{mltOrder}, W.\text{mltOrder}(\text{from Rule 4})) .
\]

We used \texttt{operator()} in the implementation of the inverse operator for the order of \( 1/U \) not to exceed the order of \( U \) (Section 2.4 and Appendix B).

2.6.3 Operator[ ]

The subscripting operator[ ](int i) of the object \( U \) returns the reference to its private member \( U.z[i] \), which represents the i-th coefficient \( u(i) \) of the TPS expansion in Eq. (1).

3.0 MAPS

Map \( \hat{U}(\vec{z}) \) is the development of concept of the truncated power series (TPS) and defined as the m-dimensional vector of TPS expansions, Eq. (1):

\[
\hat{U}(\vec{z}) = \sum_{k=0}^{\Omega} \vec{u}(\vec{k}) z^k ,
\]

where

\[
\vec{u}(\vec{k})^T = [u_1(\vec{k}), u_2(\vec{k}), \ldots, u_m(\vec{k})] ,
\]

\[ k = \sum_{i=1}^{n} k_i, \text{ for } 0 \leq k_i \leq \Omega .\]

In the object-oriented version of ZLIB the map is considered as an object of C++ class \texttt{ZMap}, which naturally was derived from the class \texttt{ZSeries} (Appendix C). Moreover, all arithmetical operators of class \texttt{Zmap} follow the same Rules (Section 2.6) and are based on \texttt{ZSeries} multiplicative and additive operators. This leads to similar implementation of member functions for these two classes. For example, compare inverse operator for \texttt{ZMap} (Appendix D) and \texttt{ZSeries} (Appendix B). Below we describe only the essential distinction between these classes and the additional \texttt{ZMap} functions.
3.1 Unit Map
Unlike the truncated power series the unit map I is defined as a vector:
1. \( I = 1 \);
\[ I(z) = z, \]
\( \text{I.order} = 1 \).

3.2 Operator\[ ]
The subscripting operator[ ](int i) of the object M (the instance of class ZMap) returns the reference to its private member M.z[i] the instance of class ZSeries) which represents the i-th member \( u_i \) of the m-dimensional vector \( \tilde{u} \) in Eq. (2).

3.3 Function Poisson (ZSeries& _ ZMap&)
Function poisson(V, M) returns the Poisson bracket: \( V(\tilde{z}) : \tilde{M}(\tilde{z}) \equiv [V(\tilde{z}), \tilde{M}(\tilde{z})]. \)
Its implementation is based on the similar ZSeries function as:

\[
\text{ZMap& poisson(ZSeries& V, ZMap& M)}
\{
\ldots
\text{for(int i = 1; i < ZLIB_DIM; i + +)}
\text{bracket[i] = poisson(V, M[i]);}
\text{return(bracket);}
\}
\]

where \( \text{bracket} \) is the temporary instance of class ZMap.

4.0 TRACKING
Tracking is one of the most important procedures in accelerator codes. In our “language” it is defined simply and naturally:
\[ y = M \times x; \]
where \( M \) is the ZMap object, and \( x \) and \( y \), the instances of class Particle (Appendix D), consist of the particle coordinates correspondingly before and after one turn. For multi-particle tracking user may use usual C++ operators:
main()
{
    ZMap M;
    Particle ** x;
    ...
    for(int i = 1; i <= numberParticles; i++)
        for(int j = 0; j < numberTurns; j++)
            x[i][j + 1] = M * x[i][j];
    ...
}

5.0 CONCLUSION

In this report we have described a new object-oriented version of the ZLIB package. ZLIB++ defines two classes (ZSeries and ZMap) to represent specific accelerator objects. We argued that simple C operators (such as =, +, -, /, *) are naturally suited to implement different mathematical algorithms with these objects. It enables one to write simple, self-documented programs for applications of numerical methods of differential algebra in high energy physics.

ZLIB++ was designed to be a foundation for further developments. New classes could be naturally derived from the base ones, enabling expansion of the package in the open architecture style.
ACKNOWLEDGEMENTS

We would like to thank Dr. G. Bourianoff for his strong support and for various helpful discussions.
