ACKNOWLEDGMENT

Research sponsored by the U.S. Department of Energy, Carbon Dioxide Research Program, Atmospheric and Climate Research Division, Office of Health and Environmental Research and by the National Aeronautics and Space Administration, and by the Environmental Protection Agency.

ABSTRACT

The existing National Center for Atmospheric Research (NCAR) code in the Hamburg Oceanic Carbon Cycle Circulation Model and the Hamburg Large-Scale Geostrophic Ocean General Circulation Model was modernized and reduced in size while still producing an equivalent end result. A reduction in the size of the existing code from more than 50,000 lines to approximately 7,500 lines in the new code has made the new code much easier to maintain. The existing code in the Hamburg model uses legacy NCAR (including even emulated CALCOMP subroutines) graphics to display graphical output. The new code uses only current (version 3.1) NCAR subroutines.

1. INTRODUCTION

The Hamburg Large-Scale Geostrophic (LSG) ocean general circulation model and the Hamburg Oceanic Carbon Cycle circulation model calculate the motion of oceanic carbon cycle tracers.¹ The LSG model calculations are used as "fixed" input into the carbon cycle model.² With each of these models a post-processor capable of processing the data and displaying it graphically for the user in a variety of different ways was included. Both the LSG and the carbon cycle post-processors are capable of showing section plots, where the data are retrieved from a specific ocean, and map plots, where the data are retrieved from all the oceans. The LSG post-processor is also capable of generating a velocity map plot, a meridional section plot and a line plot of certain carbon cycle tracers in the ocean. The carbon cycle post-processor contains a plot that shows the model versus the geosec (measured) data in the form of a line graph. All these plots in the Hamburg post-processors use old National Center for Atmospheric Research (NCAR) calls and "CALCOMP" emulation, where every point is virtually plotted and the color is calculated for each point. These NCAR calls were to be removed from the existing code, and a new code developed with more modern NCAR calls. A significant reduction in the size of code was obtained, making the new post-processor much easier to maintain.

2. DISCUSSION

After examining the current NCAR utility set, it was decided that the new model would primarily use the following packages: CONPACK, PLOTCHAR, LABELBAR, AUTOGRAPH, EZMAPA, EZMAP, and VELVCT. CONPACK is a contour plotting package that constructs contour plots from rectangular arrays of data by a method of scanning, done by ARSCAM, and contour plotting, done by CONPACK. This package "provides a 'tool kit' of FORTRAN subroutines that may be called in various combinations in order to draw different styles of contour plots."³ PLOTCHAR is a character plotting package that allows the user three qualities of characters along with numerous fonts.³ LABELBAR is a plotting package that is used to "create a labeled, filled, rectangular bar to serve as a key for a filled plot."³ AUTOGRAPH is "a graphics package enabling the user to draw graphs, each with a labelled background and each displaying one or more curves."⁴ EZMAPA and EZMAP are both map-drawing packages: EZMAPA provides a color-fill interface while still using the built-in packages that EZMAP has to offer, such as continent drawing.⁴ VELVCT is a two-dimensional velocity package where arrows are plotted to show direction and magnitude at a particular point on the plot.⁴ These packages give the post-processor an interface that is easily maintainable and much shorter than the original Hamburg post-processor. The first goal was to create a carbon cycle post-processor using the new NCAR calls, while displaying the same information in a manner similar to the Hamburg post-processor.

All source code is archived on the Computing Applications Division workstation complex, and all source code listings for the new post-processors are included in the Appendixes of this paper.

The top level post-processor logical flow is outlined in Fig. 1. First, an overview (quicklook) of simulation data compared with measurements is generated. Second, a "map" plot series (horizontal cuts at various depths) is created. Third, a "section" plot series (vertical cuts within various oceans) is produced.

The quicklook section of the carbon cycle post-processor shows the model vs the geosec (measured) data. This code reads the needed data from PROFIL and quick.dat, two files created in the Hamburg model and used by the

Fig. 1. Overview flow chart for carbon cycle model.

post-processors (see Fig. 2). The plot shows five windows, each plotting the model and geosecs data of different carbon cycle tracers in a specified ocean. The data are scanned, and the minimum and maximum of both lines for one window are found so that both lines are scaled the same. Then the AUTOGRAPH routine EZXY is called twice, once for the model data curve and once for the geosecs data curve, for each window. The informational labels are added by PLOTCHAR.

The map-plotting code is devised to read in map input data, and then enter a loop where the refinement and the plotting will take place (see Fig. 3). The map input is created by a csh-script and gives the user the choice of which maps are to be plotted and at which depth they are to be plotted. After retrieving the name of the plot file using subroutine READINPUT, the correct three-dimensional data file is read in by a series of two-dimensional reads. This step is done so that each layer is read in individually and either discarded because it was not selected or used in further manipulation. This procedure is all done in the subroutine CHOOSEMAP. CHOOSEMAP also calls the correct subroutines for refinement and plotting of the data. The refinement of the data has been disabled presently because unsmoothed and unrefined data are desired. This procedure is indicated in the flow charts by circled subroutines and dotted flow arrows. This process is used for all twenty-six possible maps, and any additional information needed on relevant subroutines can be found in the comments of the program itself.

The plotting section of the maps, PLOTMAP, uses CONPACK, LABELBAR, and EZMAPA calls (see Fig. 4). CONPACK is set up with many user-callable routines that allow the user to specify exactly how the map should look and what should be displayed on it. CONPACK must be set up by a series of initialization calls that give the user some choice in what is used and what is not used. These subroutines take the two-dimensional data array and place them into a work array, where the data are manipulated so that they are usable by CONPACK. The work array must have plenty of space and is always much larger than the data array because CONPACK must add the choices we have set earlier and any inherent choices that it needs to put the contours on the screen.

The contours are then scanned by the NCAR routine ARSCAM, where color is matched to each contour. The contours are divided evenly throughout the data value range, and continents are blocked out by use of special value numbers. These special value numbers are present to tell CONPACK not to plot those numbers. These have been introduced into the data before coming to CONPACK using the continent scheme used in the Hamburg model. Those gridpoints with these special values are left without color; then the subroutine MAPOVR, which uses EZMAPA and EZMAP calls, is called to fill the continents in with a patterned form. The mapping of contour colors to informational values is done by LABELBAR and displayed on the screen according to initialization values set by the program; all informational labels on the map are done by PLOTCHAR.

The section plot is handled much the same way as the map plot (see Fig. 5). This code is designed to read in the section data input, manipulate these data and call routines for plotting. As in the map plot, almost all the refinement process has been turned off for the time being. The plotting subroutine, PLOTSEC, is much the same as the map subroutine (see Fig. 6). The only difference is in the size of the viewing window, a few informational labels and the presence of a small continental map with a line showing the section of the ocean where the data are located. This map is produced with a smaller viewing window but uses the same EZMAPA and EZMAP subroutines used for the continents in the map plots. The section line is drawn with the AUTOGRAPH routine EZXY, which takes two one-dimensional arrays and uses them to find the line.

The last item to be done with the carbon cycle post-processor was to bring all three plot packages together and run them consecutively. This step was made easier because the carbon cycle side of the Hamburg model is executed from a csh-script in which each plot type is a separate entity. This aspect of the Hamburg model is followed in the new model and executed through a script also. A few slight differences are noted in these scripts. The new script contains a makefile, which is used to compile and build the programs.

Fig. 2. Flow chart of quicklook.f program in carbon cycle model.

Fig. 4. Flow chart for the plot map.

Fig.5. Flow chart for a section plot in the carbon cycle model.

Fig.6. Flow chart for plotting a section.

The second task was to create a large-scale geostrophic (LSG) post-processor much the same as the carbon cycle post-processor (see Fig. 7). This goal was made much easier because the carbon cycle and LSG post-processors have two plots in common, the map and section plots. As previously mentioned, the LSG post-processor is capable of generating map and section plots, but it also generates a horizontal velocity plot, a meridional circulation plot and a zonally integrated flux plots. The map and section plots in the carbon cycle post-processor were reused as much as possible. The only modifications needed to these two plots were how the data were read and the point where the data were read; thus these two plot types will not be discussed again, but the code can be found in the Appendix of this paper. The secondary tasks were to create codes for a horizontal velocity plot, a meridional circulation plot, and zonally integrated flux plots and then a script to integrate everything.

The horizontal velocity plot is a basic map plot showing speeds (via color) of certain model velocities with an arrow overlay to show the direction of the velocity. This task was accomplished by using the map code and adding the velocity arrow plot (see Fig. 8). In order to do this the data arrays were saved in separate arrays and then sent to the plot package VELVCT. VELVCT takes the X and Y two-dimensional data arrays and looks at them in order to decide which direction the data are to point. The package takes these data and scales the arrows according to the velocity at that point. This effect was not exactly the one desired. The desired effect was achieved by a manipulation of the data. The data were manipulated so that when the velocity was calculated by the package it always equaled 1. In doing this the direction of the arrow was preserved, but the magnitude of every arrow was the same. All arrows with a magnitude less than 0.2 were omitted from the plot.

The meridional circulation plot (see Fig. 9) is very similar to the section plots used before. The difference between them lies entirely in the fact that the contours of this section are not color filled, they are simply line contours in which positive contours are red, negative contours are green and zero contours are blue. This plot was achieved by changing the section plotting code so that the ARSCAM subroutine, which color fills the contours, was removed and replaced by the simple contour part of CONPACK. Everything else in the meridional circulation is the same as the section plots used in both models. The zonally integrated flux plot is used for heat transport, salt transport, integrated fresh water flux, and integrated heat flux. Each of these plots shows the concentration of these tracers in the Atlantic ocean, the Pacific ocean, the Indian ocean and a global average. These plots use the plot package AUTOGRAPH (subroutine EZY) which takes a one-dimensional array and plots it using the number of positions in the array as the X dimension.

The last thing done to integrate the large-scale geostrophic post-processor was to write a csh-script that would run the program. This task was much easier to integrate than the carbon cycle post-processor because this post-processor begins after the Hamburg model has already created the data file. This data file has only the cuts of the data that are needed for the plots, and therefore no manipulation is needed to get the correct data. After this, all that had to be done in the csh-script was to compile and build the program and run it. The compile and build process is done with a makefile for the same reasons as the carbon cycle post-processor.

The third task was to create a portable plotting code in anticipation of the use of a different climate package. This step required an independent plotting code for each of the plots. The map, section, velocity, and meridional section plots all contain their own plotting code because of the slight appearance differences between them. They all use a generic two-dimensional array, where array size may be varied by a change in the relevant parameters. There was no need to have a generic quicklook line graph plotting code for the carbon cycle post-processor or a generic line graph plotting code for the LSG post-processor, since these plots are highly Hamburg-specific and easily replicated with the addition of a few lines of NCAR AUTOGRAPH routine calls.

Fig. 7. Overview of LSG post-processor.

Fig. 8. Plot interface for arrow plots.

Fig. 9. Plot interface for meridional circulation plot.

3. SUMMARY

Figures 10 and 11 show the graph of a map plot and illustrate that the information from the new code and the information from the Hamburg code are equivalent. Figure 10 was generated by the Hamburg model, and Fig. 11 was generated by the new code. The most significant improvement with the new post-processor is a reduction in the maintenance required vis-a-vis the Hamburg post-processors. This reduction was achieved by the modernization of the NCAR code and a significant reduction in the size of the code, from more than 50,000 lines to approximately 7,500 lines.

APPENDIX A

Overview of Building and Execution of Post-processor

In building and executing the new model, the tar archive will first need to be extracted. After this has been completed there should be a directory hierarchy, where "postdir" would contain the carbon cycle post-processor files and "lsgmodel" would contain the LSG post-processor files. After this step the programs can be built and executed using the csh-script "carbproc.job" for the carbon cycle post-processor and the "readplodat.job" script for the LSG post-processor. After execution, three GKS meta files will have been created in the carbon cycle directory and one in the LSG directory. The carbon cycle files will be named med map*.cgm, sec*.cgm, and quick*.cgm, where * signifies the years that are being run, and the LSG file will be named lsg.cgm. In addition, when executing the new model there are a few data files that must be present. These files and their usage are explained in the respective script files.

C
C
C * PARAMETERS *
C
C IE --- THE FIRST DIMENSION OF THE ARRAYS TO BE SENT TO CONPACK.
C JE --- THE SECOND DIMENSION OF THE ARRAYS TO BE SENT TO CONPACK
C KE --- THE LAYER DIMENSION OF THOSE ARRAYS BEFORE THEY ARE
C REDUCED TO TWO DIMENSIONAL ARRAYS.
C NMAP --- NMAP IS THE NUMBER OF MAPS ALLOWED TO HAVE. THERE SHOULD
C BE AN EQUAL NUMBER OF FILES OF WHICH THE NAMES ARE STORED
C IN CFIL AT THE PRESENT TIME IN THE PROCESSOR FOR THIS
C FILE THERE ARE 26 ALLOWED CHOICE BUT AT THIS LEVEL ONLY
C 25 ARE ALLOWED TO BE CHOSEN BECAUSE THE SILICON FILE IS
C NOT PROCESSED IN PROFILE F
C IMAX --- MAXIMUM ALLOWABLE FIRST DIMENSION THIS IS USED FOR
C ARRAYS IN THE REFINEMENT PROCESS
C JMAX --- MAXIMUM ALLOWABLE SECOND DIMENSION THIS IS USED FOR
C ARRAYS IN THE REFINEMENT PROCESS.
C KMAX --- MAXIMUM ALLOWABLE THIRD DIMENSION WHICH CORRESPONDS TO
C THE LAYER DIMENSION.
C IWA --- THE DIMENSION OF THE INTEGER WORK ARRAY AND THE REAL
C WORK ARRAY, USED IN THE NCAR INTERFACE
C IMA --- THE DIMENSION OF THE DATA ARRAY THAT IS USED IN THE NCAR
C INTERFACE.
C NV --- THE NUMBER OF POSSIBLE DEPTH LAYERS.
C NS --- DIMENSION OF THE VARIABLES USED BY THE USER DEFINED
C SUBROUTINE COLRAM IN THE NCAR INTERFACE
C MSHIFT --- CONSTANT THAT IS USED FOR THE SMOOTH AND REFINEMENT ROUTINES
C RMASK --- CONSTANT USED TO GIVE NCAR A SPECIAL VALUE SO THAT IT
C DOES NOT TRY AND CONTOUR THE CONTINENTS INTO THE DATA
C ITEXTCLR --- THIS IS THE COLOR OF THE TEXT THAT IS PLACED ON THE MAP
C AND ALSO THE COLOR OF THE BORDERS
C
C * VARIABLES *
C
C CNAME --- ARRAY THAT IS USED TO READ THE INPUT FILE THAT IS CREATED
C BY THE PROCESSOR. IT HOLDS THE HEADER FOR THE PLOT.
C IPAPL --- ARRAY THAT IS USED TO READ THE INPUT FILE THAT IS CREATED
C BY THE PROCESSOR. IT HOLDS ZERO FOR NOT PLOTTING A
C PARTICULAR MAP AND ONE IF THAT MAP NEEDS TO BE PLOTTED
C CFIL --- ARRAY THAT HOLDS THE NAMES OF THE FILES THAT ARE TO BE
C USED IN THE PROGRAM
C ILAY --- ARRAY THAT IS READ FROM THE MAP INPUT AND HOLDS A ZERO
C IF A MAP IS NOT TO BE PLOTTED AND ONE IF IT IS
C VAL --- ARRAY THAT HOLDS DATA TO BE USED IN A REFINEMENT PROCESS
C HEADER --- HOLDS THE SPECIFIC HEADER FOR THE PARTICULAR MAP THAT IS
C BEING PLOTTED

C TEXT6 --- HOLDS THE CREATION DATE OF THE DATA FOR WHICH THE MAP IS
C TO BE PLOTTED
C IVAL --- INTEGER VALUE THAT IS USED IN THE REFINEMENT PROCESS
C IFINE --- INTEGER VALUE THAT TELLS THE REFINEMENT HOW FINE IT NEEDS
C TO BE
C DEPTP --- ARRAY THAT HOLDS THE DEPTH OF THE DATA IT IS USED TO
C DETERMINE IF THE POINT IS ON THE CONTINENTS OR IN THE
C OCEAN
C CHOSEN --- ARRAY THAT HOLDS THE DATA THAT IS TO BE PLOTTED IT IS
C A TWO DIMENSIONAL ARRAY THAT IS READ FROM THE PARTICULAR
C FILE ASKED FOR BY THE USER
C TITLE --- THE TITLE OF THIS SERIES OF MAPS
C RWRK --- REAL WORK ARRAY USED BY THE NCAR SUBROUTINES
C IWRK --- INTEGER WORK ARRAY USED BY THE NCAR SUBROUTINES
C IAMA --- INTEGER DATA ARRAY USED BY THE NCAR SUBROUTINES
C XCRA --- REAL ARRAY USED BY ARSCAM AND SENT TO THE USER DEFINED
C SUBROUTINE COLRAM TO HOLD THE X COORDINATES OF PART OF
C THE DATA.
C YCRA --- REAL ARRAY USED BY ARSCAM AND SENT TO THE USER DEFINED
C SUBROUTINE COLRAM TO HOLD THE Y COORDINATES OF PART OF
C THE DATA.
C IAIA --- USED BY THE USER DEFINED SUBROUTINE COLRAM TO HOLD NAI
C PAIRS OF IDENTIFIERS FOR THE AREA DEFINED BY XCS AND
C YCS
C IAGA --- USED IN CONJUNCTION IAIA FOR EACH VALUE OF I FROM 1 TO
C NAI, IAIA(I) IS THE AREA IDENTIFIER FOR THE AREA WITH
C RESPECT TO THE GROUP OF FIXES SPECIFIED BY THE GROUP
C IDENTIFIER(IAGA)
C ARRAY --- AN ARRAY USED TO HOLD THE DATA WHILE IT IS BEING
C PROCESSED.
C ZDAT --- THE DATA ARRAY THAT HOLDS THE FINAL DATA THAT IS SENT
C TO THE NCAR INTERFACE (IT IS TWO DIMENSIONAL SINGLE
C PRECISION)
C MHZ --- A LOGICAL DATA ARRAY THAT HOLDS WHETHER A POINT IS TRUE
C OR FALSE DEPENDING ON THE DEPTH
C ZLAYER --- HOLDS THE POSSIBLE DEPTH LEVELS TO BE USED BY REFIN AND
C THE NCAR INTERFACE.
C LAYER --- HOLDS WHAT LEVEL(LAYER) THE PROGRAM IS RUNNING AT AND
C USES IT IN THE NCAR INTERFACE
C MHZIO --- HOLDS ROW 101 OF THE MHZ ARRAY

C
C**** *CALIBR* - CALIBRATES C13, C14 VALUES
C
C      CHRISTOPH HEINZE      MPI HAMBURG      88/01/29.
C
C      PURPOSE.
C      -----
C      *CALI10* CALIBRATES C-13, C-14 VALUES OF OCEAN AND ATMOSPHERE;
C      THUS FIXES ABSOL. C13-, C-14-INVENTORY;
C      FINAL C13-, C-14-VALUES ARE GIVEN IN CONVENTIONAL
C      NOTATIONS AS D13C RELATIVE TO PDB STANDARD AND AS
C      BIG D14C WITH FRACTIONATION CORRECTION FOR C13
C
C** INTERFACE.
C      -----
C      *CALL* *CALI10*
C
C      METHOD.
C      -----
C      D13C (RELATIVE TO PDB STANDARD, UREY (1947), CF. KEELING
C      (1981)) IN DEEP EASTERN PACIFIC BELOW 3000 M IS SET TO 0
C      ACCORDING TO MEASUREMENTS (KROONHUCK ET AL. (1970), CF.
C      BROECKER AND PENG (1982)) YIELDING FACTOR FOR CONVERSION
C      OF MODEL C13/C12 RATIO INTO ABSOLUTE C13 CONCENTRATIONS
C      THE DEEP PACIFIC VALUES ARE CHOSEN AS REFERENCE SINCE THEY
C      ARE THE BEST APPROXIMATE PRE-ANTHROPOGENIC VALUES.
C      WITH THE ABSOLUTE C13 CONCENTRATIONS C13 IS REPORTED
C      AS D13C RELATIVE TO PDB STANDARD.
C      BIG D14C (RELATIVE TO NBS OXALIC ACID STANDARD WITH
C      FRACTIONATION CORRECTION FOR C13, STUIVER AND POLLACH (1977),
C      BROECKER AND OLSON (1961), CF. KEELING (1981)) IN NORTH EAST
C      ATLANTIC SURFACE WATER IS SET TO 50 ACCORDING TO PRE-PCMB
C      C14 VALUES (CF. BROECKER AND PENG (1982)) YIELDING FACTOR
C      FOR CONVERSION OF MODEL C14/(C12+C13) RATIO INTO ABSOLUTE
C      C14 CONCENTRATIONS.
C      THE NORTH ATLANTIC SURFACE VALUES ARE USED AS REFERENCE,
C      SINCE THEY ARE THE BEST APPROXIMATELY KNOWN PRE-ANTHROPOGENIC
C      SURFACE WATER VALUES. SURFACE WATER VALUES INSTEAD
C      OF DEEP WATER VALUES ARE USED AS
C      REFERENCE IN ORDER TO HAVE A BETTER CONTROL OF THE
C      SIMULATION OF DEEP WATER PRODUCTION AND GAS EXCHANGE
C      BETWEEN OCEAN AND ATMOSPHERE.
C      WITH THE ABSOLUTE C14 CONCENTRATIONS C14 IS
C      REPORTED AS BIG D14C ACCORDING TO THE SIMPLIFIED
C      FORMULA SUGGESTED BY BROECKER AND OLSON (1961).
C
C      EXTENALS.
C      -----
C      NONE.
