Surface Water Transport of Tritium to the Savannah River 1992-1993

SUMMARY

A network of remote, automated samplers are used to collect water samples in the five major streams from SRS which flow into the Savannah River. Concentration monitored during 1992 and 1993 at the various sampling points are used to study the effect of site releases on the environmental and public health of Savannah River water users below the site. Automated samplers are also maintained at locations downriver of the SRS and at the mouth of the Savannah River in Savannah, Georgia.

In the event of an unanticipated release to the Savannah River, the network of samplers provide a rapid response to help characterize the release and predict its impact on water treatment facilities at Beaufort, South Carolina and Port Wentworth, Georgia on the Savannah River below SRS. This report summarizes the data and its dosimetry impact for 1992 and 1993.

INTRODUCTION

The Savannah River Site (SRS) is a U. S. Department of Energy (DOE) complex which occupies approximately 770 km² in Aiken and Barnwell counties of South Carolina. Many operations that produce and handle radionuclides at the SRS may result in the release of small quantities of tritium to the environment. Tritium, though of small dose consequence, is the major contributor of all the radionuclide doses to the offsite population from SRS.

Historically tritium was released from reactor operations, recovery of transuranic elements, recovery of tritium, heavy water reprocessing and laboratory research. Tritiated liquid effluents were released to streams directly or through seepage basin and burial ground outcropping. The reactor areas and the reactor materials area are all now permanently shut down or in cold standby. The separations areas continue limited operations in support of waste cleanup. Other operations at the SRS include such onsite waste management facilities as the F- and H-Area Effluent Treatment Facilities

(ETF) and the Defense Waste Processing Facility (DWPF). These SRS operations also release low levels of tritium to the SRS environment.

To evaluate the continual reduction in the low level SRS tritiated effluent transport and subsequent impact on the local and the downstream population, the Savannah River Technology Center (SRTC), Environmental Technology Section (ETS) has established a network of remote automated samplers in the Savannah River watershed beginning with the major streams from SRS that feed the Savannah River, Figure 1. These streams, which receive direct liquid effluent discharges from various SRS operations, are not used as commercial sources of water.

Remote automated samplers are also located in the Savannah River downriver of SRS, Figure 2. The Savannah River is used for drinking water near Beaufort and Jasper counties of South Carolina and Port Wentworth, Georgia. The Savannah River estuary also has an extensive commercial shellfish industry where samples are collected near Skidaway Island at high and low tide.

RESULTS

The Environmental Technology Section routinely collects water samples by operating battery-powered automatic samplers to collect samples at programmed intervals. For remote operation purposes each sampler is programmed to collect a sample at 6-hour intervals and combine three successive samples to form an 18-hour composite. All sample bottles used in these two techniques are rinsed with deionized water prior to use.

Upper Three Runs Creek

Upper Three Runs Creek is the only SRS stream with headwaters arising off the site and has the largest natural flow of any SRS stream. Its main tributaries are Tinker Creek and Tims Branch. Beginning in 1988, Upper Three Runs Creek began receiving ETF discharges. The ETF collects and treats routine process wastewater, contaminated canyon facility cooling water, and the tank farm storm water from F- and H-Areas. The ETF removes radioactive and nonradioactive contaminants, except tritium, from process effluents before discharge to Upper Three Runs Creek. The M Area ETF treats wastewater before discharge to Tims Branch. Storm water and waste water from

the SRTC also feeds into Upper Three Runs Creek. All of the 545 km² Upper Three Runs Creek watershed is on SRS or directly adjacent to the SRS boundary. Local washout/deposition of SRS atmospheric tritium releases also contributes to Upper Three Runs Creek tritium concentrations. The Upper Three Runs Creek tritium concentrations are shown in Figure 3 and listed in Table 2. The 1992 average tritium concentration in Upper Three Runs Creek was 4.79 ± 8.77 pCi/mL, with an annual range of <1 to 85 pCi/mL. The 1993 (data shown in Figure 4 and listed in Table 3) average tritium concentration was 2.03 ± 1.77 pCi/mL. The 1993 annual range was <1 to 9 pCi/mL.

Beaver Dam Creek

Beaver Dam Creek is the smallest of the SRS streams that discharge to the Savannah River. It is 5 km long with a water shed of less than 26 km². D Area surface runoff goes to the Beaver Dam Creek. The facilities currently operating in D Area include a heavy water reprocessing facility and a laboratory that analyzes process effluent samples. At Beaver Dam Creek the 1992 average tritium concentration was 7.38 ± 11.46 pCi/mL, with an annual range of <1 to 65 pCi/mL, shown in Figure 5 and listed in Table 4. The 1993 average tritium concentration was 4.82 ± 14.19 pCi/mL, with an annual range of <1 to 88 pCi/mL. The 1993 data is shown in Figure 6 and listed in Table 5.

Four Mile Creek

Four Mile Creek begins near the center of the SRS and flow southwesterly to the Savannah River. The Four Mile Creek watershed drains about 57 km² and contains the highest levels of tritium found in SRS streams. Four Mile Creek receives process effluents, seepage basin and Burial Ground migration, and surface runoff from F, H, and C Areas. Greater than 99% of the tritium now transported by the Four Mile Creek is a result of migration from the F- and H-Area seepage basins and the Burial Ground. The average tritium concentrations in Four Mile Creek have increased in recent years because of the reduction in flow from shutdown of C Reactor while ground water migration releases remained constant. The extended periods in 1992 of decreased tritium levels at Four Mile Creek indicate dilution with increased river flow due to rainfall. The periods of high river flow during Spring and Fall correlate well with the periods of decreased tritium concentration in Four Mile Creek. The 1992 average tritium

concentration in Four Mile Creek was 207.41 ± 124.91 pCi/mL, with an annual range of <1 to 410 pCi/mL, shown in Figure 7 and listed in Table 6. Four Mile Creek tritium concentrations were unusually low through April of 1993. The average concentration during this period was 0.66 ± 0.98 pCi/mL. During May the concentrations returned to expected levels and averaged 260.95 ± 39.44 pCi/mL through the end of the year. The 1993 annual range was <1 to 343 pCi/mL. The 1993 data is shown in Figure 8 and listed in Table 7.

Steel Creek

Steel Creek flows southwesterly about 3 km from the P-Area outfall to the headwaters of the L Lake. Flow from the outfall of L Lake dam travels 5 km before entering the Savannah River swamp and then another 3 km before entering the Savannah River. Pen Branch joins Steel Creek about 0.4 km from the mouth of Steel Creek on the Savannah River. The Steel Creek watershed has an area of 91 km^2 , not including Pen Branch. The Pen Branch watershed is about 55 km^2 . K Area is the only SRS facility that discharges to Pen Branch. During 1992, K Reactor restart testing was underway through most of the year. After the December, 1991 K Reactor heat exchanger leak, the problem heat exchanger was replaced and heavy water recirculation began again in April, 1992. The K-Area cooling tower tie in was discontinued. K Reactor restart testing was stopped and heavy water was removed as K Reactor was put into a cold standby status. Tritium levels at the K Reactor outfall were monitored continuously in 1992 by an ETS designed continuous tritium monitor. The monitor was put into place after the unanticipated December, 1991 tritium release. Tritium in the outfall leading to Pen Branch following installation never exceeded the monitor's alarm limit of 3000 pCi/mL. The 1992 average tritium concentration for Steel Creek/Pen Branch was 12.55 ± 7.46 pCi/mL, with an annual range of <1 to 28 pCi/mL, shown in Figure 9 and listed in Table 8. The 1993 average tritium concentration was 7.73 ± 5.83 pCi/mL, with an annual range of <1 to 20 pCi/mL. The 1993 data is shown in Figure 10 and listed in Table 9.

Lower Three Runs Creek

Lower Three Runs Creek has the second largest watershed of the SRS streams, about 153 km^2 . The overflow from Par Pond to the Lower Three Runs Creek has decreased with the shutdown of P- and R-Reactors. The shutdown of P- and R-Reactors has also decreased the release of tritium to the stream. No groundwater migration sources of

tritium to the Lower Three Runs Creek system have been identified. The primary source of tritium to Lower Three Runs Creek is PAR Pond. The 1992 average tritium concentration for Lower Three Runs Creek was 0.90 ± 0.81 pCi/mL, with an annual range of <1 to 5 pCi/mL, shown in Figure 11 and listed in Table 10. The 1993 average tritium concentration was 1.06 ± 0.77 pCi/mL, with an annual range of <1 to 3 pCi/mL. The 1993 data is shown in Figure 12 and listed in Table 11. These average concentrations are typical of the tritium concentration in PAR Pond.

Savannah River at Highway 301

Tritium from the SRS accounts for most of the radioactivity found in the Savannah River. Essentially all tritium released from SRS to onsite watersheds or directly to onsite streams remains soluble. Except for minor evaporative losses, these SRS streams transport tritium to the Savannah River. The first sampling point downriver of all SRS tributaries is the Highway 301 location. There is approximately 1 day transport time from SRS discharge to the Savannah River to the Highway 301 sampling location. The 1992 average tritium concentration for the Savannah River at Highway 301 was 2.27 ± 1.27 pCi/mL, with an annual range of <1 to 7 pCi/mL, shown in Figure 13 and listed in Table 12. The 1993 average tritium concentration was 1.37 ± 0.89 pCi/mL, with an annual range of <1 to 5 pCi/mL. The 1993 data is shown in Figure 14 and listed in Table 13.

Beaufort Jasper Water Treatment Plant

The Beaufort and Jasper County water treatment plant downriver of SRS supplies water to approximately 50,000 residential customers. The Beaufort-Jasper Lift Station uses pumps to lift Savannah River water into a supply canal above the river flood plain. Water in the supply canal flows by gravity for about 29 km to the water treatment plant. Dilution from surface and groundwater decreases tritium concentrations over the 129 km distance and two days transport time between Highway 301 and the Beaufort-Jasper Lift Station. Surface water and groundwater inflow to the river along with rainfall contributions increases the river flow 20% between Highway 301 and the lift station. Tritium concentrations at Highway 301 provide a conservative and reliable estimate for concentrations to be expected downriver. The 1992 average tritium concentration for the Savannah River at the Beaufort-Jasper Lift Station was 1.38 ± 0.69 pCi/mL, with an annual range of <1 to 4 pCi/mL, shown in Figure 15 and listed in Table 14. The 1993

average tritium concentration at the Beaufort-Jasper Lift Station was 1.30 ± 1.00 pCi/mL, with an annual range of <1 to 5 pCi/mL, shown in Figure 16 and listed in Table 15.

Savannah River Estuary

Automatic samplers at the mouth of the Savannah River, Skidaway Island, were installed and timed to collect samples at high and low tide. The Savannah River transport at the mouth is controlled by fresh water flow, coastal currents and predominantly by tidal action. The tritium concentration at the mouth of the Savannah River varies with tide. At low tide, the river water dominates flow and the tritium concentrations are higher. At high tide, the incoming tide dominates flow and the tritium concentrations are lower. The average at low tide was 0.63 ± 0.54 pCi/mL and the average at high tide was 0.53 ± 0.44 pCi/mL. The Skidaway Island sampling set, shown in Figures 17 through 20 and listed in Tables 16 through 19, was not continuous during 1992 due to sampler failures and scheduling difficulties.

Savannah River water is eventually flushed to the Gulf Stream and transported out of the southeastern coastal region. The amount of time it takes to remove a pollutant plume, in this case tritium, from the estuary is called the flushing time. Flushing time is a very complex characteristic to estimate for a conservative pollutant like tritium. Simplifying assumptions like complete vertical mixing and constant source and flow will lead to underestimates of the flushing time.

Radiation Dose From Drinking Water

Radiation dose from tritium in the river water can be calculated using LADTAP XL (Hamby 1991a), a spreadsheet program which emulates LADTAP II (ORNL 1980). LADTAP II was developed for the NRC and was based on Regulatory Guide 1.109 (USNRC 1977). Radiation dose was calculated for a hypothetical individual at Highway 301 who consumed maximum quantities of water (directly from the river), fish, and who boats and swims in the Savannah River. Annually the individual drinks 730 liters of untreated river water, eats 19 kg of fish caught in the river, and swims in the river for 8.9 hours (Hamby 1991b). Table 1 shows the resulting doses. The most significant pathway is water ingestion which accounts for more than 90% of the dose. A similar calculation was done for the Beaufort-Jasper lift station and is also reported in Table 1.

In this case the hypothetical individual is exposed only to the water ingestion pathway. No credit is taken for surface water dilution of the river water as it flows down a canal to the water treatment plant. The highest dose from Table 1 is 0.1 mrem from one year of exposure.

Table 1. Tritium Dose from Various Pathways for One Year of Exposure.

<u>Location</u>	<u>Dose (mrem)</u>			<u>Total</u>
	<u>Water Ingestion</u>	<u>Fish Ingestion</u>	<u>Swimming</u>	
Hwy 301 (92)	1.0×10^{-01}	2.4×10^{-03}	4.5×10^{-05}	1.1×10^{-01}
Hwy 301 (93)	6.3×10^{-02}	1.5×10^{-03}	2.7×10^{-05}	6.4×10^{-02}
BJ Lift Station (92)	6.3×10^{-02}			6.3×10^{-02}
BJ Lift Station (93)	6.0×10^{-02}			6.0×10^{-02}

Risk

The risk from 0.1 mrem/yr can be expressed in various ways. First, this dose can be compared to the annual dose from naturally occurring radioactive material, about 300 mrem. The yearly risk from tritium in river water is equivalent to about 3 hours of exposure to the naturally occurring radioactive material. Second, the dose can be compared to the EPA regulatory limit of 4 mrem per year from man-made radioactive material in drinking water. The tritium dose is forty times less than the EPA limit. Third, the risk of the tritium dose causing cancer can be calculated based on the International Commission on Radiological Protection estimate of one fatal cancer per 2000 person-rem (ICRP 1991). The individual would have a 10% chance of a fatal cancer from the tritium after drinking the water, eating the fish, and using the river for 2,000,000 years. Clearly, the risk is vanishingly small.
