Longitudinal Instability of an Induction Linac with Acceleration*

Lloyd Smith and Edward P. Lee

Berkeley, California 94720 USA

Abstract

The question arises as to what effect acceleration, which so far has been ignored, has on the longitudinal instability of an induction linac. The answer is not much for the anticipated acceleration rate (1 - 2 MeV/m) and minimum e-folding distance for the instability (50 - 500 meters). However, total unstable growth is significantly reduced over distances which are long enough for appreciable acceleration to occur. The purpose of this note is to record a calculation of the instability, including a constant acceleration rate. Some interesting features emerge - for example, the velocity of the head is a more convenient independent variable than axial position and, for an initial sinusoidal perturbation of velocity in time, the number of oscillations along the pulse is constant; as the pulse shortens in time the frequency increases.

I. BASIC EQUATIONS AND UNPERTURBED SOLUTION

We start, as in previous work, with the one-dimensional cold fluid equations, neglecting the space charge force, and adopting a parallel R-C circuit for the perturbed electric field from the induction modules:

$$\partial \lambda / \partial t + \partial I / \partial z = 0 \quad (1)$$

$$\partial v / \partial t + v \partial v / \partial z = E_0 + E \quad (2)$$

$$\partial E / \partial t + E / \tau = -e \Delta I / mC \quad (3)$$

where E_0 is the applied field (multiplied by e/m), C is the circuit capacity and $\tau = RC$. The circuit parameters, R and C , might in general depend on axial position. E and ΔI are the perturbed components of electric field and beam current, while I , λ , and v are total beam current line charge and velocity.

The velocity of the head is given by:

$$v_H^2 = v_i^2 + 2az \quad (4)$$

where a is the constant acceleration and v_i is the head velocity at $z = 0$, where the initial perturbation occurs.

We change the independent variables (z, t) to $\bar{z} = z$ and:

$$\bar{t} = t - \int_0^z \frac{dz}{v_H} \quad (5)$$

Eliminating λ , the fluid equations become:

$$\frac{\partial}{\partial \bar{t}} \left(\frac{1}{v} - \frac{1}{v_H} \right) I + \frac{\partial I}{\partial \bar{z}} = 0 \quad (1')$$

$$v \left(\frac{1}{v} - \frac{1}{v_H} \right) \frac{\partial v}{\partial \bar{t}} + v \frac{\partial I}{\partial \bar{z}} = E_0 + E \quad (2')$$

$$\frac{\partial E}{\partial \bar{t}} + \frac{E}{\tau} = -\frac{e \Delta I}{mC} \quad (3')$$

II. CASE OF INCREASING CURRENT

For the unperturbed pulse, we take $I = v_H I_i / v_i$, independent of time during the pulse and lasting for a time, $T = v_i T_i / v_H$. The velocity during the pulse is given by (1'):

$$v = \frac{v_H}{1 - \frac{a\bar{t}}{v_H}} \quad (6)$$

Note that aT/v_H is the velocity tilt $\Delta\beta/\beta$. In the GeV energy range, this quantity is quite small. The required voltage wave shape as a function of z and t is given by (2'):

$$E_0 = a \frac{\left(1 - \frac{3a\bar{t}}{v_H} \right)}{\left(1 - \frac{a\bar{t}}{v_H} \right)^3} = a \left[1 - 3 \left(\frac{a\bar{t}}{v_H} \right)^2 \right] \quad (7)$$

III. INSTABILITY

*This work supported by the Director, Office of Energy Research, Office of Fusion Energy, of the U. S. Department of Energy under Contract No. DE-AC03-76SF00098.

The next step is to find equations for a linearized perturbation of the unperturbed quantities. This process is rather messy because the unperturbed quantities also depend

on $\bar{z}$ and $\bar{t}$. However, the equations are greatly simplified by replacing $\bar{z}$ and $\bar{t}$ by v_H and a scaled time:

$$v_H = \sqrt{v_i^2 + 2a\bar{z}} \quad , \quad (8)$$

$$t' = \frac{v_H}{v_i} \bar{t} \quad ,$$

and taking the perturbed quantities to be of the form:

$$I + \Delta I = \frac{v_H}{v_i} I_i (1 + u) \quad , \quad (9)$$

$$\Delta v = \left(1 - \frac{a\bar{t}}{v_H}\right) \hat{v} \quad .$$

The equations for u , $\hat{v}$, and E are:

$$\frac{\partial u}{\partial v_H} = \frac{1}{av_i} \frac{\partial}{\partial t'} \left(1 - \frac{av_i}{v_H^2} t'\right)^3 \hat{v} \quad , \quad (10)$$

$$\frac{\partial \hat{v}}{\partial v_H} = \frac{1}{a} E \quad , \quad (11)$$

$$\frac{\partial E}{\partial t'} + \frac{v_i}{v_H} \frac{E}{\tau} = -k^2 v_i^3 u \quad , \quad (12)$$

$$k^2 = \frac{eI_i}{mCv_i^3} \quad . \quad (13)$$

These equations are of the same form as those for the unaccelerated case except for the cubed parenthesis in (10) and the factor, v_i/v_H in (12). The equations are exact in the sense that at/v is not yet assumed to be small. The duration in t' is:

$$T' = \frac{v_H}{v_i} \bar{T} = T_i \quad ,$$

which means that a disturbance maintains the same relative position in time as the pulse shortens and the rate of change in real time increases. In particular, a sinusoidal perturbation would retain the same number of cycles over the pulse duration, as mentioned above.

Equation (12) is simplified if we assume that the gap capacity is independent of position but that the matched resistance is inversely proportional to the current (directly proportional to pulse duration). Equation (12) is then:

$$\partial E / \partial t' + E / \tau_i = -k^2 v_i^3 u \quad ,$$

where τ_i is the time constant at $z=0$.

Furthermore, the extra terms in the cubed parenthesis in (10) appear to give corrections of order $\Delta\beta/\beta$ and can be neglected. The equations then have the same form as for the unaccelerated case; if the initial perturbation is:

$$\hat{v}(z=0) = \delta e^{i\omega t} \quad ,$$

a particular solution for $\hat{v}$ is:

$$\begin{aligned} \hat{v} &= \delta e^{i\omega t'} \cos \left[\frac{kv_i}{a} \sqrt{\frac{i\omega\tau_i}{1+i\omega\tau_i}} (v_H - v_i) \right] \\ &= \delta e^{i\omega \frac{v_H}{v_i} \bar{t}} \cos \left[kz \sqrt{\frac{i\omega\tau_i}{1+i\omega\tau_i}} \frac{2v_i}{v_H + v_i} \right] \quad . \end{aligned} \quad (14)$$

For $a=0$, we have $v_i = v$ and the e-folding rate with z is the imaginary part of $\sqrt{i\omega\tau/(1+i\omega\tau)} k$. The maximum growth rate is $k/\sqrt{8}$, which occurs when $\omega\tau = 1/\sqrt{3}$. For $a \neq 0$ and z large, $v_H \sim \sqrt{2a\bar{z}}$ and the perturbation only grows exponentially with $z^{1/2}$. However, if $k \sim (50 \text{ meters})^{-1}$, the accelerating gradient $\sim 1 \text{ MeV/meter}$ and a perturbation occurs at $\sim 1 \text{ GeV}$, there are many e-foldings before v_H is significantly greater than v_i . The coasting beams assumption is then good enough to show the nature of the problem, however it is of interest to examine the breakdown of this approximation over long distances.

IV. CASE OF CONSTANT CURRENT

So far we have computed the instability growth rate for a pulse where the current increases proportional to $v_H(z)$, i.e. approximately fixed pulse length in meters. It is also of interest to compute growth for the case of constant current, where pulse length increases proportional to v_H but pulse duration T is constant. This could be the preferred approach at high energy if a practical lower limit on pulse duration for the synthesis of acceleration waveforms is observed (say $T > 100 \text{ ns}$). In this case the unperturbed velocity of the entire pulse is $v(z) = v_H(z) = \sqrt{v_i^2 + 2a\bar{z}}$, and in place of eqns. (1') - (3') we have for the perturbed components Δv , ΔI , E :

$$v^2 \partial \Delta I / \partial \bar{z} = \partial \Delta v / \partial \bar{t} \quad , \quad (1'')$$

$$\partial(v\Delta v) / \partial \bar{z} = E \quad , \quad (2'')$$

$$\partial E / \partial \bar{t} + E / \tau = -e\Delta I / mC \quad . \quad (3'')$$

Since E_0 and I are both constant it is reasonable to assume R and C are separately constant, since for efficient energy transfer we scale

$$R \propto E_0/I \text{ and } RC = \tau \propto T \propto I^{-1} \quad .$$

With these assumptions eqns. (1" - 3") yield an equation for Δv :

$$\left(\frac{\partial}{\partial t} + \frac{1}{\tau}\right) \frac{\partial^2}{\partial z^2} (v\Delta v) = -\frac{eI}{mC} \frac{1}{v^3} \frac{\partial}{\partial t} (v\Delta v) \quad (15)$$

Taking an initial perturbation, $\Delta v = \delta e^{i\omega t}$, with ω real, we have

$$\frac{\partial^2 v\Delta v}{\partial z^2} = -k^2 \frac{i\omega\tau}{1+i\omega\tau} \left(\frac{v_i}{v}\right)^3 (v\Delta v) \quad (16)$$

where k is given by eqn. (13).

In general, eqn. (16) is solved by the bessel functions J_2 and N_2 of the argument x :

$$x = k\sqrt{\frac{i\omega\tau}{1+i\omega\tau}} \frac{2v_i^{3/2}}{a} (\sqrt{v} - \sqrt{v_i}) \quad (17)$$

A convenient asymptotic form, obtained by the WKB method, is

$$\Delta v \approx \delta e^{i\omega t} (v_i / v)^{1/4} \cos(x) \quad (18)$$

Again, for small z growth is identical with that of the coasting beam. However, for large z a perturbation increases exponentially with $z^{1/4}$. This reduced rate of growth reflects the dilution of line charge density during acceleration at constant current. Note that the number of wavelength within the pulse ($= \omega T/2\pi$) remains constant, as before.

V. SUMMARY

In order to compare growth formulas for the three cases we have examined (drifting beam, constant line charge

density, and constant current), it is convenient to define a scale length proportional to v_i^2 :

$$z_0 = v_i^2/2a, \quad v_H = v_i \sqrt{1+z/z_0} \quad ,$$

$$\text{Coasting Beam: } \Delta v \propto \cos kz \sqrt{\frac{i\omega\tau}{1+i\omega\tau}} \quad ,$$

Current proportional to v :

$$\Delta v \propto \cos \left[kz \sqrt{\frac{i\omega\tau}{1+i\omega\tau}} \frac{2}{1+(1+z/z_0)^{1/2}} \right] \quad ,$$

Constant Current:

$$\Delta v \propto \left(\frac{1}{1+z/z_0}\right)^{1/8} \cos \left[kz \sqrt{\frac{i\omega\tau}{1+i\omega\tau}} \frac{2}{1+(1+z/z_0)^{1/2}} \cdot \frac{2}{1+(1+z/z_0)^{1/4}} \right] \quad .$$

Keeping in mind that z_0 will be in the range 100 m - 2000 m, the following table gives the predicted reductions in the exponential of growth.

Note that for short distances of a few hundred meters ($z \leq z_0$) the coasting beam growth rate is an adequate approximation. At most, a few e-folds of growth are expected in this distance, and feedforward correction might be applied to eliminate further growth. However, when long distances ($z \gg z_0$) without use of corrections are considered, it is seen from Table I that very substantial reductions of total growth are predicted.
