PLUTONIUM AND TRITIUM PRODUCED IN THE HANFORD SITE PRODUCTION REACTORS**EXECUTIVE SUMMARY**

In a news release on December 7, 1993, the Secretary of Energy announced declassification action that included totals for plutonium and tritium production in the Hanford Site production reactors. This information was reported as being preliminary because it was not fully supported by documentation. Subsequently, production data were made available from the U.S. Department of Energy-Headquarters (DOE-HQ) records that indicated an increase of about one and one-half metric tons in total plutonium production. The Westinghouse Hanford Company was tasked by the U.S. Department of Energy-Richland Operations Office to substantiate production figures and DOE-HQ data and to provide a defensible report of weapons- (6 wt% ^{240}Pu) and nonweapons- (fuels-) grade (nominally 9 wt% or higher ^{240}Pu) plutonium and tritium production in the Hanford Site production reactors.

The task was divided into three parts. The first part was to determine plutonium and tritium production based on available reported accountability records. The second part was to determine plutonium production independently by calculational checks based on reactor thermal power generation and plutonium conversion factors representing the various reactor fuels. The third part was to resolve differences, if they occurred, in the reported and calculational results.

Reported production of plutonium and tritium is recognized as a process estimate that was refined with operating experience as chemical process data and fuel design models became more complete and sophisticated. The basis for reporting values also changed with time and was reported variously as chemically processed quantities, discharged fuel awaiting processing, and estimated production based on reactor power. The calculated plutonium production determined from reactor power levels and discharged fuel provided a consistent basis on which to compare the reported accountability values. The reported and calculated estimates of plutonium production in annual summaries and total quantities are in very good agreement. The small differences on a yearly comparison are explainable by considering the options used in reporting.

The production of tritium was fully supported by documentation and was included in this study for completeness. A calculational check of the reported tritium accountability was not attempted, nor would it have been feasible due to the lack of definitive operating data.

The quantity of nonweapons- (fuels-) grade plutonium produced was also addressed in this report. The nonweapons-grade plutonium was produced by the Hanford Site reactors from fiscal year (FY) 1963 through FY 1981. The calculational estimates based on fuel discharge fully confirmed the quantities reported by records from DOE-HQ sources.

All references pertaining to plutonium and tritium production have been identified. These references cover the entire plutonium production period from the Hanford Site production reactors with the exception of initial reactor operation through calendar year 1946. There are no accountability records available for October 1944 through December 1946. However, DOE-HQ has provided an undocumented source that places the plutonium production at 493 kg for this period. This quantity was in very good agreement with calculational estimates. The DOE-HQ quantity of plutonium produced was confirmed with a high degree of confidence.

The independent check of the reported plutonium production required a database of reactor production history. The documentation of reactor production history is referenced from 1951 through the end of operation. The period of operation prior to 1951 is consistent with that used in the dose reconstruction study where considerable effort was expended to provide the best estimate of production. Documentation of all available reactor operating data or best-estimate of reactor operating history has been provided in this report.

In summary, the DOE-HQ-reported accountability records of plutonium and tritium production were determined to be the most defensible record of Hanford Site reactor production. The DOE-HQ records were consistently supported by the independent calculational checks and the records of operational data. Total production quantities are 67.4 MT total plutonium, which includes 12.9 MT of nonweapons-grade plutonium. The total tritium production was 10.6 kg.

1.0 INTRODUCTION

The total production quantities of plutonium and tritium from the Hanford Site production reactors were made public by the Secretary of Energy on December 7, 1993. These production numbers included weapons- and nonweapons- (fuels-) grade plutonium, losses to the waste storage tanks, and unprocessed fuel in the storage basins. These production quantities were announced as preliminary at that time based on nonclassified sources.

A difference of about one and one-half metric tons of total plutonium was identified between the U.S. Department of Energy-Headquarters (DOE-HQ) records and the public announcement of December 7, 1993. The purpose of this report is to substantiate the production history of plutonium and tritium by independent calculations and from available and documented references.

Historically, the production of plutonium and other isotopes in the Hanford Site production reactors was estimated from a process flow. At any given time, some plutonium inventory would exist in the reactor core, other plutonium would exist in discharged fuel awaiting chemical processing, and the balance would be in material produced through or undergoing chemical processing (including losses).

The production of plutonium and other isotopes was estimated from fuel exposure, from reactor power production, and from conversion factors adjusted with chemical processing data. These estimates were improved as more processing data and better fuel design models became available. It was recognized from the start of this study that the reporting of plutonium accountability can be, and was, historically determined by three methods. The first method was to estimate production by reactor power operation and plutonium conversion factors. The second method was to determine production from discharged fuel whose power exposure was determined from individual process tube power measurements. The third method was to determine plutonium production from the processed output of the chemical separations plants. Each method will produce identical total quantities of plutonium. However, time delays in reporting will be caused by processing holdup, where applicable. The independent modeling of plutonium production provided very helpful insight in determining the most likely reporting method used at various times.

Two analysis approaches are discussed in this report. One approach computes plutonium production from reactor power data and the other from discharged fuel information. The consistency of the analyses provided supporting data for plutonium production estimates for the first three years of production where production records are not available. The results of these analyses also provided an independent check on the reported plutonium accountability.

The analyses use a database of the reactor production history and a conversion factor model for the individual fuel types. The production history database provides monthly reactor power generation, discharge of fuel by type, quantity of fuel, and fuel exposure history. These operations data were substantiated by full documentation from 1951 to the end of production reactor operation. The database is consistent with estimates of reactor operation

determined by the Hanford environmental dose reconstruction studies for production prior to 1951. The documented plutonium conversion factors for fuels used near the end of reactor operations were used to determine plutonium production from reactor power and discharged fuel during the maximum production operating periods. Conversion factors for the fuels not included in available documentation were determined by state-of-the-art physics computer codes or engineering estimates.

The results of this study show a very good correlation of accountability reporting with operating records. The study also provides documented justification of the results and conclusions made in this report.

2.0 DISCUSSION

The total production quantity of plutonium was determined by independent approaches that involved checking accountability records and making a calculational check. The reported accountability records consisted of semiannual summaries in classified, unclassified, or declassified documents. In those reports that are still classified, the data needed for this report have been declassified. The calculational check involved development of a database characterizing the historical operation of the reactors and the conversion factors for plutonium production. The different approaches are discussed below.

2.1 REPORTED PLUTONIUM AND TRITIUM PRODUCTION VALUES

The reported production values were determined from official accountability reports that summarized the production of plutonium and tritium on a semiannual basis. These reports were written at the time the production occurred when the most knowledgeable resources and detailed data were available to determine the best measurement or estimate of production. However, these reported production values were based on various accounting methods. For example, one reference (Nolan 1982) states that production was based on separated plutonium ready to be shipped offsite from the years 1945 to 1948. During part of 1948 and 1949, plutonium production was based on the quantity through final chemical processing. After that time, plutonium production was based on discharged fuel. It is apparent from personal knowledge and from comparison with calculated results that eventually plutonium production was also determined by estimates of monthly reactor power production.

The reported plutonium production was always forward looking. That is, a report of production was not changed once it was issued. If an adjustment was required from a previous report, this adjustment was made to the current report. The result was that the cumulative production was reasonably close to the accepted total and the final quantity was fully corrected. Comparisons of the cumulative production between reported accountability and calculated estimates generally were free of small fluctuations in annual summaries and thus provided the most consistent comparisons.

Semiannual plutonium and tritium production is listed in Tables 1 and 2, respectively. This production is documented in semiannual reports except for the transition period from July 1976 through March 1977, when the beginning of the fiscal year was changed from July to September. The document number is provided for each reported accountability value. These documents cover the time from January 1948 through the end of production. An estimate of the plutonium production prior to 1948 was given as 493 kg. This estimate was taken from the data provided informally by DOE-HQ. The estimate is in reasonable agreement with a calculational check for that time period. The calculational check will be discussed in Section 2.2.3.

2.2 PLUTONIUM CALCULATIONAL ESTIMATES

The production of plutonium was determined by calculations from reactor powers and historical data for discharged fuel. These calculations were performed as a check of the reported plutonium production based on accountability records. These calculations also provided a consistent basis for comparing and understanding accounting methods. The first calculational method was based on reactor power, the second calculational method was based on exposure and mass of discharged fuel.

The first task of the calculational approach was to develop a database of reactor-power history and fuel-discharge history. The second task of the calculational approach was to determine conversion factors relating power to plutonium. These databases and conversion factors are discussed below.

2.2.1 Reactor History Databases

A historic data library of reactor power production and fuel discharge is essential for the calculational model of plutonium production. Historic reactor power-production data is documented in monthly reports beginning in 1948. A listing of these documents is provided in Appendix A. Prior to 1948, the production was estimated from available data pertaining to reactor operation. Considerable work on dose reconstruction (Heeb and Bates 1994) has provided a best-estimate of reactor operation during the period beginning operation in 1944 through 1971. Fuel-discharge data were available from the TRAC study (Jungfleish 1984 and 1992) for production from 1944 through 1971. The format of the TRAC database was extended to include the balance of N Reactor operation. Reactor power production and fuel discharge beyond 1972 pertained only to N Reactor. The power production was determined from monthly reports referenced in Appendix A. The fuel discharge beyond 1971 was determined from operational records of individual process tube discharges.

A self-consistent check of the reactor power and fuel discharge data was made. Cumulative reactor production and fuel discharge, in gigawatt-days (GWd), is shown in Figure 1 and in Table 3. The agreement between these data are very good. Differences in the reactor production are due to measurement uncertainties in bulk reactor power and in individual tube powers.

N	14,610	14,394
Total	81,651	81,457

Note: Reactor power production is a summation of bulk reactor power. Fuel discharge production is a summation of product of fuel discharge mass and exposure.

2.2.2 Plutonium Conversion Factors

The quantity of plutonium produced typically was estimated from reactor power and discharged fuel by using a plutonium conversion factor with units of grams per megawatt-day (g/MWd). The reactor power was reported in megawatt days (MWd), the fuel exposure was reported in megawatt days per ton (MWd/t), and the fuel discharge quantity was reported in short tons ($t = 2,000 \text{ lb}$).

The plutonium conversion factor and ^{240}Pu content are dependent on the fuel design, uranium enrichment, and exposure. The plutonium conversion factors and ^{240}Pu content are expressed as exposure-dependent polynomials and are described in Appendix B.

The plutonium conversion factors for fuels from the single-pass reactors (B, C, D, DR, F, H, KE, and KW), and for N Reactor MKI fuels were documented in declassified production tables (Perl 1967) for internal- and external-coolant (I&E) fuels that have a central water-cooled annulus. These tables represented a final estimate of plutonium production as determined by the predictive models and as validated with data from chemical-separations measurements. An earlier fuel type used in the single-pass reactors was a solid-slug fuel that had the same outer dimensions as the I&E fuels. The heavier solid-slug fuels had a higher plutonium conversion factor than the I&E fuels. Documentation of plutonium conversion factors and operating conditions is no longer available on which to reconstruct these data. Therefore, plutonium conversion factors were estimated. A corrected plutonium conversion factor for the solid fuel was determined by increasing the coefficients by two percent. This correction is reasonable given expected production of a heavier fuel design and provides very good agreement with the reported accountability results.

Plutonium production from N Reactor fuel was also represented by the same polynomials discussed in Appendix B. The polynomial coefficients for MKIV and MKIA fuels were determined from data in the final revised production tables (Eaves and Toffer 1982). The plutonium coefficients for MKII N Reactor fuel were determined by special calculations with the DCODE N Reactor fuel design analysis code (Thierer 1968). The MKII fuel was a unique N Reactor fuel type that produced tritium.

Plutonium conversion factors were also determined on a reactor-average basis. These plutonium conversion factors were used to estimate plutonium production from reactor power. This approach provides an estimate of the plutonium production that is based on representative fuel types and operating conditions typical of the various reactor operations campaigns. The reactor-average plutonium conversion factor for each reactor was weighted by the power fractions of the base-load fuel and the enriched fuels and their respective plutonium conversion factors. A summary of the reactor-average plutonium conversion factors is listed in Table 4.

2.2.3 Calculated Plutonium Production Estimates

The calculated estimates of plutonium production were made on the basis of reactor power and discharged fuel. These calculational methods were consistent with the methods used historically to estimate plutonium from reactor power and from discharged fuel.

The plutonium production totals estimated from reactor power were determined from a database assembled in Section 2.2.1 and the plutonium conversion factors discussed in Section 2.2.2. Plutonium production based on reactor power for a given month consisted of plutonium discharged in fuel that month and plutonium that was resident in the partially exposed fuel in the reactor core. The plutonium estimates were based on the reactor-averaged conversion factors of the fuels used in the reactors. In the single-pass reactors (B, C, D, DR, F, H, KE, and KW), the production of reactor power consumed to produce tritium was subtracted from the total reactor power. This correction involved a plutonium equivalent, which is the mass of tritium production multiplied by the atomic weight ratio of plutonium and tritium. The plutonium equivalent of tritium production was deleted from the reactor-average plutonium production.

The distinction of weapons- and nonweapons- (fuels-) grade plutonium was not attempted with the calculation from reactor power. The problem was complicated by periods when the reactors were operated in a partial nonweapons-grade mode. The calculational refinement would thus have required extensive analyses. The production of weapons- and nonweapons-grade plutonium was calculated only from fuel discharge information.

The calculation of plutonium production from fuel discharges determined the unique plutonium conversion factor and ^{240}Pu content from the average discharge exposure of each monthly discharge by fuel type. Such a calculation is an accurate and direct method to determine the quantity by nonweapons-grade plutonium. It also provides the needed information to arrive at the split between the weapons and nonweapons grades of plutonium production.

The identity of discharged fuels is generally clear in the discharged-fuel part of the database. Some clarifications are listed to explain some of the data. The first clarification is for thoria. Thoria, being a low-power target, was tracked by the power in adjacent process tubes. Therefore, the power in these tubes, which was generally from enriched fuel, was not included in the power production because it was already included in the discharge of enriched fuel. The second clarification is for N Reactor. The transition from MKI and MKIV base-fuel loadings occurred during the MKII fuel campaign. The database identifies the MKI and MKIV fuels as a single fuel type. The adoption of MKIV fuel was assumed to be after June 1966, which occurred in the middle of the MKII campaign.

Weapons- and nonweapons-grade plutonium consists of a blend of plutonium having a ^{240}Pu content within an accepted minimum and maximum range of a nominal value. Therefore, the distinction between weapons- and nonweapons-grade plutonium is established by a cutoff value for ^{240}Pu content. The weapons- and nonweapons-grade plutonium categories were established for plutonium produced after June 1964 with a cutoff value of 7.4 wt% ^{240}Pu . The cutoff date was consistent with reported values of reactor-grade plutonium that were provided by DOE-HQ. A single cutoff value of ^{240}Pu was used in these calculations. This cutoff value most likely varied from year to year by those reporting plutonium productions. The variations in the ^{240}Pu cutoff would depend on the judgement of borderline cases on whether or not plutonium in certain keys could be blended in the weapons-grade plutonium streams. However, the single ^{240}Pu cutoff value was chosen by some experimentation and gave satisfactory results, which are discussed below.

2.3 COMPARISONS OF REPORTED AND CALCULATED PLUTONIUM PRODUCTION

Annual summaries of the calculated plutonium production estimate and the DOE-HQ-reported plutonium production are listed in Table 5. These summaries show the grades of plutonium as weapons- and nonweapons- (fuels-) grade. Generally, these annual summaries are in good agreement. The differences in each annual reactor total production reflect the delay in reporting resulting from holdup until fuel discharge or from further delays in chemical processing.

The agreement between total annual plutonium production from the estimates based on reactor power and discharged fuel and from reported accountability values are shown in Figure 2. The annual reported accountability in fiscal year (FY) 1947 was a summary of plutonium that included plutonium produced prior to that date. From 1947 through the end of operation, the calculated estimates are in close agreement with reported accountability values. However, some variances are noted caused by annual accountability adjustments that appear to reflect corrections to previous reports. These corrections and differences are minimized when the cumulative totals are compared. The cumulative total plutonium production is shown in Figure 3 for the reported accountability values and for calculated estimates from reactor power and discharged fuel. This figure shows the excellent agreement between these independent methods.

The nonweapons- (fuels-) grade plutonium annual production and cumulative production are shown in Figures 4 and 5, respectively. The production of plutonium calculated from discharged fuel precedes the reported accountability values by about half a year from the time period of FY 1967 through FY 1971. This condition suggests that the reported nonweapons-grade plutonium was based on chemically separated plutonium during this time period. The production of nonweapons-grade plutonium from FY 1972 through FY 1979 shows very close agreement between reported and calculated estimates based on discharged fuel. The agreement between reported and calculated nonweapons-grade plutonium from FY 1980 through the end of production in FY 1983 is also good. The comparison between reported and calculated values in this time period shows that corrections were incorporated into the reported values to compensate for corrections needed in earlier reports. These results indicate that the reported levels of nonweapons-grade plutonium were probably based on chemically separated values before FY 1972, and on the estimates from discharged fuel after and including FY 1972.

3.0 RESULTS

Plutonium and tritium production in the Hanford Site reactors is summarized in Tables 1 and 2. The calculated production of total and fuels-grade plutonium is summarized in Table 6. In this summary, the total plutonium and the fuels-grade plutonium productions are listed for each reactor as determined from the fuel-discharge calculated estimates. The weapons- and nonweapons-grade plutonium totals from reported sources are also listed as a comparison with the calculated estimates. The results in Table 5 demonstrate the good agreement between calculational estimates and reported plutonium production.

KW	12,836	1,789
N	10,965	8,173
Total	67,262	13,040

The reported plutonium production is in complete agreement with the production totals provided informally by DOE-HQ for both the total and fuels-grade plutonium production. The supporting results of the calculational estimate provide details of individual reactor production and an independent verification of the reported results.

4.0 CONCLUSIONS

The primary objective of this study was to substantiate the quantity of weapons- and nonweapons-grade plutonium produced in the Hanford Site production reactors based on Hanford Site records and modeling. A secondary objective of this study was to document the total production of tritium from official accountability records.

The production of plutonium in the Hanford Site production reactors was determined by an extensive check of reported accountability documentation and by two independent calculational checks. The reported accountability documents were issued on a semiannual basis from calendar year 1948 through the end of reactor operation in 1987. The production of plutonium from October 1944 through calendar year 1947 involved production in the B, D, and H Reactors. Production from this time period was from low-power reactor operation and was very small compared to the later power levels of these reactors and of the other Hanford Site production reactors. The estimate of 493 kg from DOE-HQ records is very reasonable for this time period and agrees well with independent calculational estimates. Additionally, the reported plutonium accountability from references from FY 1948 through FY 1989 were found to be in full agreement with DOE-HQ records on a year by year basis. Therefore, the accountability of plutonium production from documented references has been well established.

A check of the reported plutonium accountability was made by two independent calculational estimates. One estimate was based on a database of reactor power production and representative plutonium conversion factors, which were power-weighted conversion factors of various reactor loadings. The other estimate was based on a database of reactor fuel discharge and exposure-dependent conversion factors. The results of the calculational checks were in good agreement with each other and with the reported plutonium accountability. The calculated estimates also provided a consistent basis that supplied insight into understanding the reporting basis of plutonium. The comparison of calculational estimates and reported plutonium accountability was explainable with reasonable understanding of the various reporting practices.

The production of nonweapons- (fuels-) grade plutonium was also compared between the reported quantity informally provided by DOE-HQ and calculational estimates based on discharged fuel. This comparison was in very good agreement. The comparison between reported and calculated estimates indicates that the reported nonweapons-grade plutonium values were based on chemically separated plutonium from FY 1963 through FY 1971. The reported values of nonweapons-grade plutonium for the period of FY 1972 through the end of nonweapons-grade production in FY 1982 were based on discharged fuel.

The reported accountability of tritium was summarized in this document. The documentation for tritium production is fully complete and is the most accurate and reliable source of data available. The annual accountability of tritium fully supports the data received informally from DOE-HQ.

In conclusion, the objectives of this study to provide an accurate and defensible accounting of the weapons-grade and nonweapons-grade plutonium and of tritium production in the Hanford Site reactors has been met.

APPENDIX B

**FORMULAS AND COEFFICIENTS OF PLUTONIUM AND
PLUTONIUM-240 CONTENT IN
HANFORD SITE PRODUCTION REACTOR FUELS**

This page intentionally left blank.

FORMULAS AND COEFFICIENTS OF PLUTONIUM AND PLUTONIUM-240 CONTENT IN HANFORD SITE PRODUCTION REACTOR FUELS

The plutonium producing fuels in the single-pass (once-through cooling) Hanford Site reactors were typically natural or low-enriched metallic uranium clad in aluminum. The earlier fuels were solid rods arranged end to end in a fuel charge. The solid, high-enriched uranium-aluminum fuel rods were also used for early tritium loads. Later, as the power of the reactors increased, the metallic fuel was tube-shaped, with an inner cooling annulus. The typical N Reactor fuels were concentric, low-enriched, metallic uranium tubes with zirconium alloy cladding. The only exceptional fuel design was a MKII fuel with an enriched uranium outer tube and a solid, nonuranium, inner target-material rod.

The fuel designs varied for each reactor type and were also modified with design improvements. These different fuel designs each had unique plutonium production characteristics.

The plutonium buildup in Hanford Site reactor fuels was related to the fission power or heat production measured in a fuel charge. The powers were typically specified in kilowatts (kW) or megawatts (MW). The time-integrated power of exposure of a discharged fuel mass was expressed in megawatt days (MWd/t), where the ton is a short ton (2000 lb).

The production of total plutonium for a particular fuel design is dependent on fuel exposure. Also, the quantity of the ^{240}Pu isotope in the plutonium is dependent on fuel exposure. This dependence is expressed quantitatively as polynomials with exposure as the independent variable. The plutonium conversion factor, with units of gram of plutonium per megawatt-day, is given by the following.

$$\text{Conv fact} = C_0 + C_1E + C_2E^2 + C_3E^3 + C_4E^4 \text{ (g/MWd)} \quad (1)$$

where:

$C_1, C_2, \dots, C_4$ are constants, and
 E = fuel exposure (MWd/t).

The ^{240}Pu isotope content of the plutonium is expressed in percent.

$$^{240}\text{Pu} = C_1E + C_2E^2 + C_3E^3 + C_4E^4 + C_5E^5 \text{ (percent)} \quad (2)$$

where:

$C_1, C_2, \dots, C_4$ are constants independent of those in Equation 1.

The application of these formulas and the coefficients are summarized in Tables B-1, B-2, and B-3. Table B-1 lists the fuel names as they appeared in the expanded TRAC database. A fuel-type number was assigned to each fuel type. The equation numbers are the same, as much as possible, as those in the original references. The equation number 00 was assigned where the fuel was not used. Table B-3 lists the constants used with Equations 1 and 2.

Table B-1. Fuel Types and Identifiers used for Fuel Discharge Calculations of Plutonium Production.

Fuel Type Identifier and Name of Fuel	
Fuel Type	Fuel Name
0	Natural U - Solid Slug Low neutron flux (mgs)
1	Natural U - Solid Slug High neutron flux (mgs)
2	Natural U - Cored Slug Lo mgs
3	Natural U - Cored Slug Hi mgs
4	Natural U - I&E Slug
5	Natural U - N Reactor
6	Enriched U - Solid E slug
7	Enriched U - Solid C slug
8	Enriched U - Solid J slug
9	Enriched U - Cored slug
10	Enriched U - I&E
11	Enriched U - N Reactor .94 (Mark IV Fuel) [Except before Jan 1968 Treat as Mark I]
12	Enriched U - N Reactor 1.25
13	Enriched U - N Reactor 2.10 al clad
14	Enriched U - N Reactor 2.10 zr clad
15	Enriched U - N Reactor hybrid .94 & 1.25
16	Enriched U - N Reactor 1.25 & 2.10
17	Enriched U - N Reactor 1.15 - 1.25 (Mark I-A Fuel)
18	Enriched U - N Reactor 100 - 200
19	Depleted U
20	Special Depleted
21	Natural & Depleted
22	N Reactor Nat & Dep (Natural)
23	Thoria
24	Chalk River

Table B-2. Equation Numbers Used by Reactor and Fuel Type.
