7. Abstract This report documents the available summaries of recorded maximum surface levels and maximum waste temperatures of the existing single- and double-shell waste tanks, excluding the 50,000-gal single-shell tanks, and references other sources for more specific data. The purpose of this report is to aid in the structural sensitivity studies performed for the Accelerated Safety Analyses-Phase I effort and in future analyses of the single- and double-shell tanks by compiling a quantitative summary of some of the operating conditions the tanks have experienced.		
8. PURPOSE AND USE OF DOCUMENT - This document was prepared for use within the U.S. Department of Energy and its contractors. It is to be used only to perform, direct, or integrate work under U.S. Department of Energy contracts. This document is not approved for public release until reviewed. PATENT STATUS - This document copy, since it is transmitted in advance of patent clearance, is made available in confidence solely for use in performance of work under contracts with the U.S. Department of Energy. This document is not to be published nor its contents otherwise disseminated or used for purposes other than specified above before patent approval for such release or use has been secured, upon request, from the Patent Counsel, U.S. Department of Energy Field Office, Richland, WA. MAXIMUM SURFACE-LEVEL AND TEMPERATURE HISTORIES FOR HANFORD WASTE TANKS

1.0 INTRODUCTION

Radioactive defense waste resulting from the chemical processing of spent nuclear fuel has been accumulating at the Hanford Site since 1944. This waste is stored in underground waste-storage tanks. The *Hanford Site Tank Farm Facilities Interim Safety Basis* (ISB) (Leach 1993) provides a ready reference to the safety envelope for applicable tank farm facilities and installations. The ISB is intended to facilitate understanding of the safety envelope and its corresponding justification until formal safety analysis report upgrades can be completed.

During preparation of the ISB, tank structural integrity concerns were identified as a key element in defining the safety envelope. These concerns, along with several deficiencies in the technical bases associated with the structural integrity issues and the corresponding operational limits/controls specified for conduct of normal tank farm operations are documented in the ISB. Consequently, a plan was initiated to upgrade the safety envelope technical bases by conducting Accelerated Safety Analyses-Phase I (ASA-Phase I) sensitivity studies (Becker et al. 1994) and additional structural evaluations. The purpose of this report is to facilitate the ASA-Phase I studies and future analyses of the single-shell tanks (SSTs) and double-shell tanks (DSTs) by compiling a quantitative summary of some of the past operating conditions the tanks have experienced during their existence. This report documents the available summaries of recorded maximum surface levels and maximum waste temperatures and references other sources for more specific data.

1.2 DESCRIPTION OF TANKS

Five basic tank design configurations have been used in the waste storage program. Four of these are SST designs, which represent the oldest designs and systems of buried waste storage tanks at the Hanford Site. The fifth configuration, which represents the latest tank design and system configuration, consists of a DST design concept. Typical tank configurations are shown in Figure 1-1.

The tanks are located in seventeen separate groupings referred to as tank farms. These SST and DST farms, located on the Hanford Site in the 200 East and West Areas, are operated by the Westinghouse Hanford Company (WHC) for the U.S. Department of Energy Field Office, Richland, Washington.

500,000 Gallon Single-Shell Tank
Tank Farms: B, BX, C, T, U

750,000 Gallon Single-Shell Tank
Tank Farms: BY, S, TX, TY

1,000,000 Gallon Single-Shell Tank

1,000,000 Gallon Double-Shell Tank
Tank Farms: AN, AP, AW, AY, AZ, SY

* A and AX have flat bottoms

Figure 1-1. Typical High-Level Waste Tank Configurations
At the Hanford Site.

1.3 SINGLE-SHELL TANKS

A total of 149 SSTs were constructed between 1943 and 1964. These are located in twelve separate tank farms. One hundred thirty-three of the tanks have an internal diameter of 75 ft and nominal storage capacities of either 500,000-, 750,000- or 1,000,000-gal of radioactive waste. The tanks are constructed of reinforced concrete with a single internal steel liner that extends across the tank basemat and up the cylindrical sides to the dome shaped roofs. Structurally, the basemat reinforcing steel is extended into the cylindrical concrete tank wall. The height of the dome above the basemat varies from approximately 30 to 43 ft according to the capacity of the tanks. The tanks are buried and the minimum soil depth at the dome crown is 5 ft. The welded carbon steel liner is independent of the reinforced concrete tank and was designed to provide containment of the stored liquid waste. Surface live loads, static and dynamic soil loads, dead loads, and hydrostatic and hydrodynamic loads are carried by the reinforced concrete tank and dome. The remaining 16 SSTs differ in configuration. They have a capacity of 55,000-gal and have been interim stabilized and interim isolated (Hanlon 1994).

1.4 DOUBLE-SHELL TANKS

The twenty-eight DSTs, also buried, were constructed between 1968 and 1986. They are located in six separate tank farms. Four of these tanks, two each in the 241-AZ and -AZ tank farms, have a designed capacity of 1,000,000-gal. The twenty-four remaining tanks have a nominal design capacity of 1,144,000-gal. Geometrically, all of the DSTs are similar. Structurally, they are identical within any single tank farm grouping. Between tank farms, the tank designs are structurally similar with some variations in concrete and rebar strength and in rebar arrangement in the haunch region. The DSTs are 83 ft in external diameter and constructed of reinforced concrete with an internal primary tank and secondary steel liner. They are cylindrical in shape with a dome roof. The height of the dome is approximately 47 ft above the basemat and the minimum soil overburden is 6½ ft at the crown. The welded primary carbon steel tank consists of a base that rests on an 8-in. layer of refractory insulating grout. The secondary welded carbon steel liner is structurally integral with the inner surface of the cylindrical reinforced concrete tank wall and rests on the concrete basemat. The primary tank bottom is separated from the secondary liner by an 8-in. layer of insulating refractory grout.

The primary steel tank provides containment for the stored liquid waste; the secondary steel liner/reinforced concrete tank establishes a redundant leakage barrier. There is a nominal 30-in. annulus between the primary tank cylindrical wall and steel lined reinforced concrete tank cylindrical wall. The reinforced concrete tank and dome carry the surface live loads, the static and dynamic soil loads, and the dead loads. The primary steel tank resists the hydrostatic and hydrodynamic liquid waste loads and the internal pressure.

2.0 SUMMARY

This document provides a summary of the currently available recorded historical waste surface-level and waste temperature data. These data have been summarized to assist in the structural analyses of the principal structural elements of the existing SSTs and DSTs, excluding the 50,000-gal SSTs. This document presents in tabular and graphical form the historical data located and reviewed to date and is a "living" document in that it is to be updated as more data become available. The document also notes reported sources where additional or more detailed information might be found.

Table 2-1 provides a brief orientation and overview of the tanks in each tank farm. Section 3.0 of this report describes the measurement techniques and methods used for monitoring waste tank surface levels and temperatures. Section 4.0 discusses the different sources from which the data summarized in this report were obtained and lists alternative sources that also may contain archived data. Section 5.0 discusses the summarized data. Section 6.0 and 7.0 discuss anomalies in some of the data and conclusions/recommendations, respectively. The appendices contain summaries of surface-level and temperature data.

3.0 MEASUREMENT TECHNIQUES

3.1 SURFACE-LEVEL MEASUREMENT

The surface levels in all of the waste storage tanks are monitored and recorded. The techniques for measurement utilize manual equipment in some tanks and automatic in others; the current ratio of the two methods is roughly fifty-fifty. In each case, the principle of operation is electrical conductivity. The depth of the waste is recorded by monitoring an electrical signal as electrodes contact the liquid surface.

A new system is being tested because the electrical conductivity method tends to fail in tanks that contain small quantities of liquids. The new system involves a pressure-sensitive "donut" that works in both liquid and solid conditions to help reduce data anomalies.

3.1.1 Manual Measurement

Manual measurements are taken by lowering a reel-mounted tape (manual tape) or calibrated insulated wire (zip cord), with attached electrodes, to a point at which they contact the liquid surface. Measurements are visually read from the tape and recorded to the nearest 0.25 in.

Table 2-1. Tank Details Per Tank Farm.

Tank Farm	Tanks per Farm	Capacity, m ³ (gal)	Year(s) Constructed
A (1)	6	4,546 (1,000,000)	1954-1955

	12	2,400 (530,000)	1943-1944

- (1) Single-Shell Tank.
(2) Double-Shell Tank.

3.1.2 Automatic Measurement

Each automatic gauge used to measure surface levels is an instrument provided by the Food Instrument Corporation (FIC). An FIC instrument consists of an electrically driven plummet connected to a calibrated steel tape, a steel tape reel housing, and a controller that automatically raises and lowers the plummet until it contacts the surface of the waste and obtains a reading. The controller can display the data digitally and also transmit the reading to the Computer Automated Surveillance System (CASS). Some tanks have gauges connected to the CASS; others are read manually. A counter is provided for readout of liquid level to the nearest 0.1 in.

Some automatic FIC gauges in several of the tanks containing solids have been modified to indicate intrusions, i.e., an infiltration of liquid into a waste tank beyond a specified level. In intrusion mode, the FIC typically is positioned one to two inches above the surface level of the waste so that it will alarm to the CASS if the surface level rises to a point at which it contacts the plummet. (This system eliminates the need for Tank Farm Operations to measure the surface level on a regular basis and may account for gaps in data.)

3.2 TEMPERATURE MEASUREMENT

Temperature data are recorded via thermocouples placed in the tanks; in the case of AX farm and DSTs, some thermocouples have also been placed in insulating concrete, the lower primary tank knuckle, the secondary tank concrete foundation, or the outer structural concrete. Thermocouples located inside the tanks may be installed through a riser or lowered through a riser in an existing liquid observation well. Multiple thermocouples are attached to a single probe called a thermocouple tree. In SSTs, some tanks do not have any functioning thermocouple trees, while others have one or more functioning thermocouple trees. Each DST has at least one functioning thermocouple tree.

4.0 DATA RETRIEVAL

The search for data documenting temperatures and surface levels for the contents of the waste storage tanks centered on the resources available in the Surveillance and Data Acquisition (S&DA) group. The group is located in the C-wing of the 2750E Building in The 200 East Area of the Hanford Site.

Before the autumn of 1973, the surveillance system depended on manual data collection, transport, manual review and plotting of the data and temporary archiving of the data and plots. The location of data recorded before 1973 is not known, but is presumed to be archived in the Federal Records Center (FRC) in Seattle, Washington. In the autumn of 1973, an upgraded surveillance system was established to collect, log, maintain, and evaluate waste surveillance data (surface-level and temperature readings). That system is managed by the S&DA group, and all information received from the tanks, except the AY and AZ tank farms, goes to the S&DA group for review. Efforts are now underway to incorporate data from the AY and AZ farms into the upgraded surveillance system.

The fact that waste tanks have been present onsite since 1943 means that voluminous quantities of data have been produced and handled by various contractors over the past 50 years. Accounting for and attempting to recover such records inevitably poses challenges to those interested. Retrieval of the data focused on three areas, each of which is discussed below:

- Log books / Raw data
- CASS / SACS
- Other sources.

4.1 LOG BOOKS / RAW DATA

4.1.1 Surface-Level Data

Surveillance surface-level data for SSTs have always been recorded and compiled in log books. As the number of log books increased with the passage of time, the older ones were archived. The specific location of the surface-level data taken before 1973 is unknown, however it is presumed to be archived in Seattle in the FRC. At present, all SST surface-level data gathered from 1973 to 1980 are archived. According to S&DA personnel, the first five boxes listed in Table 3-1 contain the surface-level data sheets as first compiled from the field data as part of the surveillance system. The last two boxes listed in Table 3-1 are referred to as "process engineering data", and contain much of the same data found in the first five boxes, except that the data these boxes contain were prepared by Process Engineering personnel who reassembled it into tabular and graphical form.

Table 4-1. Surface-Level Data Archived at the Federal Records Center, Seattle, Washington.

Type of Data	Tank Farm	Box Number
Surveillance data from 1973 to 1980	A, AX, AY, AZ, B	111504
	BX, BY, C (through C-112)	111505
	C (C-112 through C-204), S	111506
	SX, SY, T	111507
	TX, TY, U	111508
Process engineering data from 6/1/76 to 12/31/84	All	111509 111510

Although detailed surface-level records may not be immediately retrievable, representative quarterly values can be estimated by using accepted formulas relating surface level to total volume (Appendix F). The quarterly data on the volume of total tank contents can be obtained from the waste status summaries of the 156 tanks in use through 1980. These historical summaries appear in *A History of the 200 Area Tank Farms* (Anderson 1990).

Surface-level records after 1980 are currently available in log books in Room C101 of Building 2750E.

4.1.2 Temperature Data

As in the case of surface-level measurements, before the autumn of 1973, temperature readings were taken and recorded, then manually processed. It is not known where the temperature data taken before 1973 is stored, but it is presumed to be archived in the FRC, Seattle, Washington.

Since the upgraded surveillance program began in 1973, temperature data are entered in log books stored in room C102 of the 2750E Building. These temperature data from 1974 to 1987 are being entered in the Surveillance Analysis Computer System (SACS) database as time permits. From 1987 to present, the SACS database is complete regarding located data. Weekly, monthly and daily temperature data are entered as received. Table 4-2 lists temperature data reported by the S&DA group as archived; however, the precise location of the data is unknown. These data are presumed to be archived in the FRC in Seattle. Time limitations prevented the retrieval of archived data under this scope of work; additional data retrieval searches will be conducted as time and funding become available.

4.2 SURVEILLANCE ANALYSIS COMPUTER SYSTEM AND COMPUTER AUTOMATED SURVEILLANCE SYSTEM

A primary source of data for this document is the Surveillance Analysis Computer System (SACS) database. The SACS was started in 1989; its main function is to bring data from CASS in a way that allows the information to be gathered quickly and organized as needed, e.g., graphs, time blocks. Surface-level data is transferred automatically from CASS to SACS; however, the temperature data must be transferred manually to SACS. Although SACS did not start until 1989, information from as long ago as 1974, or even earlier, can be retrieved because of the availability of CASS and manually transferred data. Backlogged data is currently being entered to the system as time permits.

The CASS was started in 1977. It acts as an alarm system for all the waste tanks. The CASS monitors for undesirable conditions as information from each tank is entered, either manually or automatically, depending on the tank.

In general, surface-level data has been verified from the SACS database since July 1989. To date, most anomalies noted in surface-level data recorded in the database have been reconciled and corrected by S&DA personnel.

ITS-2 Profile Temperatures in Tank Bottoms	58099

Recently, the method of retrieving data from SACS changed from script files to PCSACS. This change occurred as a result of an upgrade of the computer system. Therefore some of the data presented in the appendices was gathered with script files and some with PCSACS. The information in the database has not changed, only the retrieval process has changed.

PCSACS is a Microsoft EXCEL¹ based program that is much easier to use than the script files. The PCSACS user searches the database for specific information and/or records by selecting the desired subjects and items from a user-friendly interactive menu. Areas to choose from include the tank identifier, data type, data quality (good, transcribed, or suspect), average/maximum, and time frame. Once the data has been gathered, EXCEL allows the user to arrange the information as needed.

4.3 OTHER SOURCES

Table 4-3 lists the documents reviewed for additional data not contained in previous sources. Many documents were found containing surface-level and temperature data. In most cases the data duplicated measurements already gathered in SACS or in the raw-data readings. Reports containing matching information of the documents already listed have not been included as references.

5.0 DATA PRESENTED

The data presented in Appendices C through F focus on manual tape, automatic FIC measurements, and thermocouple data that have been transmitted or entered to the SACS database from the CASS or the log books.

Appendices G and H are profiles of the surface-level and temperature record envelopes for each tank. These profiles contain the sources from which the data for each tank was gathered and the time period each source covers. Appendices A and B contain data on the highest surface-levels and temperatures located for each tank along with the source from which these data were retrieved. Appendix I lists all documents reviewed while searching for both surface-level and temperature data. Unretrieved records may show higher surface-level and temperature levels than listed in the appendices.

5.1 SURFACE-LEVEL DATA

Appendix A gives the overall maximum surface level for each tank, as determined from data recorded to date. These values may not reflect the actual maximum; however, it is the maximum determined from the references listed and the time span shown in Appendix G.

Table 4-3. Additional Data Not Contained
in Previous Sources.

Document	Subject	Tanks	Dates
RHO-CD-1172 (Mercier, Wonacott, Defigh-Price, 1981)	Temperature	S A AX SX U	1952-60 56-71 66-71 56-69 56-57
HW-83906 A (Bayless, 1964)	Temperature	S,U	1953-55
WHC-MR-00132 (Anderson, 1990)	Total Volume	All SST's AY, AZ, SY	1944-80
HW-56357 (Roberts, 1958)	Surface Level & Temp	A, SX	5/1/58- 5/31/58
ARH-780 (McCullugh, Cartmell)	Temperature	S, TX	1952, 54
ICF Kaiser (Preliminary, 1994)	Surface Level & Temp	A, AX, B, BX, BY, C	- -
RHO-CD-02213 Vol.1-4 (Stalos, Walker)	Surface Level	200 East 200 West	- -
WHC-SD-WM-TI-543 (WHC, 1993)	Surface Level	All DSTs	1981-93

Appendix C lists the quarterly history plots of maximum surface levels taken from the SACS database. Of all the references cited, either in the table above or listed in Section 8.0 below, the SACS records are the most complete. Surface-level data in SACS date from the late 1970's to the early 1980's, depending on the tank being investigated.

Appendix D presents the waste-volume history plots for the double shell tanks from WHC-SD-WM-TI-543 (WHC, 1993). The appendix and WHC-MR-0132 (Anderson, 1990) list the data in the form of waste volume. The equivalent surface-level was determined by means of the waste volume/liquid level formulas of Appendix F.

Appendix G provides a profile of the surface-level record envelope. The profile identifies the references from which the data were retrieved and the time period each reference covers. This profile is especially useful in helping analysts determine which reference to use to establish the time span for a particular surface level in a particular tank.

5.2 TEMPERATURE DATA

Appendix B contains the highest maximum temperature that has been found (from the records reviewed to date) for each tank. The values given in Appendix B may not be the actual maximum temperatures, but it is the maximum value obtained from the references listed and the time span shown in Appendix H.

Appendix E provides a historical record of the maximum temperatures as obtained from the SACS database. The plots consist of graphs from both script files and PCSACS. The temperature data in SACS cover the time period from the early 1970's to early 1990's depending on the tank being investigated. Missing from Appendix E are the 55,000-gal tanks, SX-115, TX-114, TX-116, TX-117, and all tanks in the AY and AZ tank farms because they are non existent in PCSACS.

Appendix H shows the profile of the temperature-record envelope. This profile shows the correlation between the various data sources and the time periods covered and is a convenient tool for determining which document to use when investigating a particular time span.

6.0 DATA ANOMALIES

Inspection of the plots in Appendices C, E, and H may raise questions about certain irregularities that appear to exist in the data. These unusual characteristics may take the form of "spikes" (sudden deviations from an apparent trend in the plotted value), gaps in data (implying that no readings were taken for a prolonged period of time, or records were not found), or perhaps fewer data points plotted than would be expected considering the length of time the tank has been in use. These anomalies may or may not represent erroneous data.

As mentioned earlier, the SACS database does not contain every surface-level and temperature reading ever taken in the tanks. Records of nearly all of the surface-level data for SSTs that have been retrieved begin in the late 1970's or early 1980's. The first readings of the temperature data recorded in the SACS for SSTs generally begin in either the mid-1970s or in the latter 1980's, with some not beginning until 1991.

In general, for DSTs, records of surface level begin with their first receipt of waste or within four years after construction, except for tanks in the AY and AZ farms. For the AY and AZ tanks, the first records of surface level located date from 1989, more than ten years after they were built.

Records located on DST temperature data begin anywhere from three to fifteen years after construction, except for the tanks in AY and AZ farms. Raw temperature data for the AY and AZ tanks prior to 1991 have not been located by this effort.

Not all data in the SACS have been verified by S&DA. Only questionable data that has been brought to S&DA personnel for verification may be considered verified. To verify such data S&DA personnel review it for logical possibilities on a case-by-case basis. Therefore, the potential exists for errors in the database.

What appears to be errors or "bad data" in the database for surface-level measurements may result from instrument malfunction, surface irregularities of the crust, data incorrectly entered into the database (i.e., typographical errors, wrong data descriptors, wrong tank, wrong data field), backlogged data not yet entered to the database, difficulties encountered during the measurement process, or perhaps a misunderstanding of the ways that data were recorded and entered into the database. Once data are determined to be bad, they are flagged as such and will not be read by the files unless the software is instructed to read them.

Some confusion may arise from plotted surface-level data that suddenly rises to a new level and/or are plotted at higher and relatively constant levels than those actually existing in the tank. Either of these phenomena may occur because the tank began operating in intrusion mode. In intrusion mode, the FIC is typically positioned approximately one to two inches above the surface level of the waste such that it will alarm to CASS if the surface level rises to contact the plummet. (Intrusion mode eliminates the need for measuring the surface level on a regular basis and may account for gaps in data.) The height of the plummet also is recorded in the SACS under a data field other than that for automatic FIC measurements. However, because a separate data field has not been established specifically for the intrusion mode, intrusion level data are entered in the data field reserved for radar measurements. This practice results in a variation in the plotted data when the file is executed because, if the intrusion FIC level is higher than the actual surface level during a given quarter, the intrusion FIC reading, rather than the actual surface-level reading, is written to the file.

The nature and sources of the anomalies for the temperature plots are similar to those for the surface-level plots. In addition, the gaps in data that often appear from 1984 through 1988 are the result of administrative controls that minimized the number of temperature readings in an effort to monitor the tanks more efficiently.

7.0 CONCLUSIONS AND RECOMMENDATIONS

A complete history of waste surface level and waste temperature for all waste tanks is not possible at this time. Neither complete data entry nor verification of all tank data can be accomplished by the resources currently available in S&DA. Maximum surface-level and maximum temperature data as taken from the SACS database for each tank are presented herein for the time spans over which it is available. The appendices present these data in both graphical and tabular form. Additional or more detailed waste temperature and waste surface level information may be found in the referenced documents, or data sources provided herein, or possibly from data archived in the FIC.

As funding permits, this review effort should continue, and this report and the summaries in the appendices should be updated and supplemented.

ACCEPTED WASTE VOLUME/SURFACE-LEVEL FORMULAS

Accepted Waste Volume/Liquid Level Formulas²

SST Farms: A, AX, B, BX, BY, C, S, SX, T, TX, TY, U
 DST Farms: AN, AP, AW, AY, AZ, SY

"Vol" volume is in gallons. "LL" is liquid level in inches as determined by FIC or manual tape (MT).

When calculating "LL" note that the values obtained are referenced from the bottom center-line on all tanks. On dish bottom tanks the calculated "LL" may be off by 6 or 12 in. from the FIC or MT measurements.

- (1) For 55,000-gal SST, Type I (B, C, T, and U):

$$\begin{aligned}\text{Vol} &= (\text{LL} - 6 \text{ in.}) \times 196 + 590 && \text{(dish bottom)} \\ \text{LL} &= (\text{Vol} - 590)/196 + 6\end{aligned}$$

- (2) For 530,000-gal SST, Type II (B, BX, C, T, and U) where FICs are on side of tank:

$$\begin{aligned}\text{Vol} &= (\text{LL} - 12 \text{ in.}) \times 2750 + 12,500 && \text{(dish bottom)} \\ \text{LL} &= (\text{Vol} - 12,500)/2750 + 12\end{aligned}$$

- (3) For 758,000-gal SSTs, Type III (BY, S, TX, and TY)

$$\begin{aligned}\text{Vol} &= (\text{LL} - 12 \text{ in.}) \times 2750 + 12,500 && \text{(dish bottom)} \\ \text{LL} &= (\text{Vol} - 12,500)/2750 + 12\end{aligned}$$

- (4) For 1,000,000 gal SST, Type IV (SX):

$$\begin{aligned}\text{Vol} &= (\text{LL} - 12 \text{ in.}) \times 2750 + 18,500 && \text{(dish bottom)} \\ \text{LL} &= (\text{Vol} - 18,500)/2750 + 12\end{aligned}$$

- (5) For 1,000,000-gal SST, Type IV (A, AX):

$$\begin{aligned}\text{Vol} &= \text{LL} \times 2750 && \text{(flat bottom)} \\ \text{LL} &= \text{Vol}/2750\end{aligned}$$

- (6) For 1,000,000-gal and 1,160,000-gal DSTs, Type V (AN, AP, AW, and SY are 1,160,000-gal, while AY and AZ are 1,000,000-gal):

$$\begin{aligned}\text{Vol} &= \text{LL} \times 2750 && \text{(flat bottom)} \\ \text{LL} &= \text{Vol}/2750\end{aligned}$$
