SYN3D: A SINGLE-CHANNEL, SPATIAL FLUX SYNTHESIS CODE FOR DIFFUSION THEORY CALCULATIONS

by

C. H. Adams

ABSTRACT

This report is a user's manual for SYN3D, a computer code which uses single-channel, spatial flux synthesis to calculate approximate solutions to two- and three-dimensional, finite-difference, multigroup neutron diffusion theory equations. SYN3D is designed to run in conjunction with any one of several one- and two-dimensional, finite-difference codes (required to generate the synthesis expansion functions) currently being used in the fast reactor community. The report describes the theory and equations, the use of the code, and the implementation on the IBM 370/195 and CDC 7600 of the version of SYN3D available through the Argonne Code Center.

1. INTRODUCTION

This report is a user's manual for SYN3D, a computer code which uses single-channel, spatial flux synthesis to calculate approximate solutions to two- and three-dimensional, finite-difference, multigroup neutron diffusion theory equations.

SYN3D is designed to run in conjunction with any one of several one- and two-dimensional finite-difference codes (required to generate the synthesis expansion functions) currently being used in the fast reactor community. Most of the data for a calculation must be supplied in the formats of the Standard Interface Files defined by the Committee on Computer Code Coordination (CCCC). Appendix A of this report is the computer code abstract for SYN3D.

SYN3D is operational at Argonne National Laboratory within the ARC System of reactor analysis codes and has been sent, in stand-alone form, to the Argonne Code Center for distribution to other laboratories. Sections II, III and IV of this report cover material of interest to users of both the ARC System and Code Center versions of the code; Section V deals with the Code Center version only. Users who have just received SYN3D from the Code Center and who are faced with the task of bringing the code up on their machine should read Section V first; it describes the contents of the Code Center tapes and outlines the steps necessary to implement SYN3D in stand-alone form on the IBM 370/195 and CDC 7600.

II. SYNTHESIS THEORY AND EQUATIONS

In this section we develop the synthesis approximation used in SYN3D from the mesh-box-centered, diffusion theory, finite-difference equations and describe the solution of the resulting synthesis equations.

A. Diffusion Theory Difference Equations

There are two finite-difference forms of the neutron diffusion equations currently used in reactor analysis. In the derivation of the first, the fluxes in the differential equations are expanded in Taylor series about the mesh points (i.e. the intersections of the mesh lines in two dimensions and mesh planes in three). The PDQ code contains this formulation.^{1,2} The other difference equations are derived by expanding the fluxes about a point at the center of a mesh block. The codes 2DB, 3DB, DIF2D, CITATION and VENTURE use this approach.³⁻⁶ SYN3D is designed to calculate an approximate solution for the second type of difference equation, which is the form most frequently used in fast reactor analysis.

In x-y-z geometry the three-dimensional, finite-difference equations associated with the mesh block defined by x mesh interval i, y mesh interval j, and z mesh interval k in energy group g can be written:

$$\begin{aligned}
 & - d_{i+1jk}^{xg} \left[\phi_{i+1jk}^g - \phi_{ijk}^g \right] \Delta y_j \Delta z_k + d_{ijk}^{xg} \left[\phi_{ijk}^g - \phi_{i-1jk}^g \right] \Delta y_j \Delta z_k \\
 & - d_{ij+1k}^{yg} \left[\phi_{ij+1k}^g - \phi_{ijk}^g \right] \Delta x_i \Delta z_k + d_{ijk}^{yg} \left[\phi_{ijk}^g - \phi_{ij-1k}^g \right] \Delta x_i \Delta z_k \quad (1) \\
 & - d_{ijk+1}^{zg} \left[\phi_{ijk+1}^g - \phi_{ijk}^g \right] \Delta x_i \Delta y_j + d_{ijk}^{zg} \left[\phi_{ijk}^g - \phi_{ijk-1}^g \right] \Delta x_i \Delta y_j \\
 & + \sum_g v_{ijk} r_{ijk}^{gg'} \phi_{ijk}^g - v_{ijk} s_{ijk}^g = 0,
 \end{aligned}$$

$$i = 1 \dots I, \quad j = 1 \dots J, \quad k = 1 \dots K, \quad g = 1 \dots G.$$

I is the number of x mesh intervals, J is the number of y mesh intervals, and K is the number of axial mesh intervals. G is the number of energy groups. No equations are written for those mesh blocks which contain a blackness theory material.

ϕ_{ijk}^g is the discrete group flux associated with mesh block (i,j,k). ϕ_{ijk}^g is identically zero if mesh block (i,j,k) is in a blackness theory region. If $i = 0$ or $I + 1$, $j = 0$ or $J + 1$, or $k = 0$ or $K + 1$ the ϕ_{ijk}^g 's are exterior fluxes and their definition depends on the boundary conditions at the corresponding boundary of the model. For homogeneous boundary conditions of the form

$$C_1^g D_{\hat{n}}^g + \nabla \phi^g + C_2^g \phi^g = 0 \quad (2)$$

where $\hat{n}$ is the outward normal unit vector, the exterior fluxes for the boundary are identically zero; the boundary condition is specified by the definition of the d 's (see below). Equation (2) includes the cases of zero flux [$C_1^g = 0$], zero current [$C_2^g = 0$] and logarithmic (or extrapolated) conditions. The exterior fluxes at a boundary with periodic conditions are identically equal to the first interior fluxes on one of the other boundary surfaces of the model.

The three types of d 's [d_{ijk}^{xg} , d_{ijk}^{yg} , d_{ijk}^{zg}] are defined similarly, and so it is necessary to discuss only one of them [d_{ijk}^{xg}]. If the mesh blocks (i,j,k) and $(i-1,j,k)$ are within the boundaries of the model, and neither contains a blackness theory material,

$$d_{ijk}^{xg} = \frac{2D_{i-1jk}^g D_{ijk}^g}{\Delta x_i D_{i-1jk}^g + \Delta x_{i-1} D_{ijk}^g}, \quad (3)$$

$$i = 1 \dots I, \quad j = 1 \dots J, \quad k = 1 \dots K, \quad g = 1 \dots G.$$

D_{ijk}^g is the group g diffusion coefficient for mesh block (i,j,k) and Δx_i , Δy_j , and Δz_k define its size. If one of the mesh blocks is outside the boundary of the model (the cases $i = 1$ and $i = I + 1$), but that boundary surface has a periodic boundary condition, then Eq. (3) still holds if it is understood that the exterior mesh block is identical to a corresponding interior mesh block on some other boundary.

SYN3D permits anisotropic diffusion coefficients. The value of D_{ijk}^g appearing in the expression for d_{ijk}^{xg} may be different from the value of D_{ijk}^g appearing in d_{ijk}^{yg} .

For the homogeneous boundary condition given by Eq. (2) at $i = 1$ as well as when there is an internal interface between a blackness theory material in mesh block $(i - 1, j, k)$ and an ordinary material in (i, j, k) ,

$$d_{ijk}^{xg} = \frac{D_{ijk}^g C_2^g}{D_{ijk}^g C_1^g + \frac{1}{2} \Delta x_i C_2^g}. \quad (4)$$

In the case of a blackness theory boundary, $\hat{n}$ in Eq. (2) is the unit normal into the blackness region at the interface. When Eq. (2) is the boundary condition at $i = I$, and for an internal interface between a blackness theory material in mesh block (i, j, k) and an ordinary material in $(i - 1, j, k)$,

$$d_{ijk}^{xg} = \frac{D_{i-1jk}^g C_2^g}{D_{i-1jk}^g C_1^g + \frac{1}{2} \Delta x_{i-1} C_2^g}. \quad (5)$$

If both $(i-1, j, k)$ and (i, j, k) contain blackness theory material d_{ijk}^{xg} is not defined, because the only two equations in which it could appear are never written.

The remaining notation in Eq. (1) is simpler to define. v_{ijk} is the volume of mesh block (i, j, k) . $r_{ijk}^{gg'}$ is basically the combination of macroscopic cross sections representing absorption, scattering, and fission. s_{ijk}^g is an inhomogeneous source. With the proper definitions of $r_{ijk}^{gg'}$ and s_{ijk}^g , Eq. (1) becomes the statement of an eigenvalue problem, an outer iteration of an eigenvalue problem, a distributed source problem, or even one time step of an implicit space-time calculation. To cast Eq. (1) in the form of the eigenvalue problem, for example,

$$\begin{aligned} s_{ijk}^g &= 0, \\ r_{ijk}^{gg'} &= \Sigma_R^{g\delta} \delta_{gg'} + \Sigma_S^{g+g'} - \lambda \chi^g v \Sigma_f^{g'}, \end{aligned} \quad (6)$$

where Σ_R^g is the total macroscopic cross section for removal from group g , $\Sigma_S^{g+g'}$ is the cross section for scattering into group g from g' , χ^g is the fission spectrum and $v \Sigma_f^{g'}$ is the cross section for neutron production by fission. λ is the eigenvalue, and $\delta_{gg'}$ is the Kronecker delta.

In r-z and triangular geometries the finite-difference equations are similar to Eq. (1) if one alters some definitions. In r-z geometry the "x" dimension is the radial dimension, and the leakage finite-difference coefficient away from external boundaries and blackness regions becomes

$$d_{ijk}^{xg} = \frac{2D_{i-1,j,k}^g D_{i,j,k}^g}{\Delta x_i D_{i-1,j,k}^g + \Delta x_{i-1} D_{i,j,k}^g} \quad (2\pi x_i) \quad (7)$$

where x_i is the radial position of the interface between mesh interval $i-1$ and i . The leakage coefficients at boundaries (Eqs. (4) and (5)) are also multiplied by $2\pi x_i$. Now v_i is the volume of an annulus.

For geometries which have triangular mesh in the plane, each mesh cell couples to 3 other cells in the plane rather than to 4. The coupling between internal mesh triangles $(i-1, j, k)$ and (i, j, k) is

$$d_{ijk}^{xg} = \frac{2\sqrt{3} D_{i-1,j,k}^g D_{i,j,k}^g}{D_{i-1,j,k}^g + D_{i,j,k}^g} \quad (8)$$

and no Δy_i appears multiplying the term (as in Eq. (1)). When one side of a triangle is an exterior (or blackness region) boundary the coefficient is given by

$$d_{ijk}^{xg} = \frac{D_{ijk}^g C_2^g}{2\sqrt{3} D_{ijk}^g C_1^g + \Delta x C_2^g} (2\sqrt{3} \Delta x) . \quad (9)$$

Δx is not subscripted since in regular triangular mesh there is only one characteristic length, the side of a triangle. When the triangular mesh is bisected by a boundary, and the flux, therefore, is defined for a point on the boundary,

$$d_{ijk}^{xg} = \frac{C_2^g}{4 C_1^g D_{ijk}} (2\sqrt{3} \Delta x) . \quad (10)$$

B. The Single-Channel Synthesis Approximation

The equations and capabilities of SYN3D are based on Kaplan's blending method.⁷ Kaplan suggested that the three-dimensional neutron flux can often be approximated by the trial function

$$\phi_{ijk}^g = \sum_{n=1}^N a_{nk}^g H_{nij}^g . \quad (11)$$

The planar expansion functions, H_{nij}^g , are known functions, precalculated by the user. They should be the best practical estimates of the planar flux distributions encountered at various axial positions. The combining coefficients, a_{nk}^g , are the unknowns of the synthesis calculation. Equation (11) states the basic, single-channel synthesis approximation; a more elaborate approximation, multichannel synthesis, is discussed briefly in a later section of this report.

The literature already contains a number of derivations of synthesis difference equations.⁸⁻¹⁴ The derivations shown later in this report borrow features of a number of them and are built around the premise that synthesis should be viewed as an approximate method of solving the finite-difference equations; nowhere in this report do we use the differential form of the diffusion equation. This is a realistic approach, since we know that expansion functions must come from finite-difference calculations, and it avoids the problem of trial function discontinuities which arises when one starts from the differential form.^{9,12,15-17}

The discrete combining coefficients in Eq. (11) represent a potentially large number ($N \times K \times G$) of unknowns, and SYN3D offers two ways to reduce that number. First, if one of the expansion functions, H_n , is characteristic of a limited axial zone of the model, and there is no reason to think its

presence may help the solution away from that zone, one can simply set the corresponding combining coefficients, a_{nk}^g , equal to zero for ranges of values of k . This is the discrete analog to the treatment of the continuous equations suggested in Ref. 18 and has the effect of excluding particular expansion functions from the trial function in particular axial zones. Carried to the extreme that only one combining coefficient in each group remains unknown for each mesh interval, Eq. (11) reduces to the one-function-per-zone synthesis form proposed by Meyer.¹⁹ In a variation of this procedure, setting to zero all those combining coefficients associated with a particular n and g offers a mechanism for specifying different numbers of expansion functions for each energy group.

The second way to reduce the number of unknowns is by group collapsing.²⁰ Group-collapsed synthesis is not to be confused with group collapsed cross section; it simply means that the user specifies some prescription for expressing the G combining coefficients for the G group fluxes of one expansion function in terms of a smaller number, G' , of unknowns. In this work we will allow linear transformations of the form

$$a_{nk}^g = \sum_{b=1}^{G'} u^{gb} a_{nk}^b . \quad (12)$$

Note that we have limited ourselves to one collapsing scheme for all expansion functions and regions of the model. To see how group collapsing might be applied, consider the example of a four-group model collapsed to two groups. If the matrix u was given by

$$u = \begin{pmatrix} 1 & 0 \\ 1 & 0 \\ 0 & 1 \\ 0 & 1 \end{pmatrix} , \quad (13)$$

then the synthesis trial functions [Eq. (11)] for each group flux become

$$\begin{aligned} \phi_{ijk}^1 &= \sum_{n=1}^N a_{nk}^1 \psi_{nij}^1 & \phi_{ijk}^2 &= \sum_{n=1}^N a_{nk}^1 \psi_{nij}^2 \\ \phi_{ijk}^3 &= \sum_{n=1}^N a_{nk}^2 \psi_{nij}^3 & \phi_{ijk}^4 &= \sum_{n=1}^N a_{nk}^2 \psi_{nij}^4 \end{aligned} \quad (14)$$

A single set of combining coefficients, a^1 , is used for both the group 1 and group 2 trial functions. Another set, a^2 , is used with groups 3 and 4. In this example the number of unknowns has been reduced by a factor of 2.

One constraint should be applied to the definition of the matrix elements, u^{gb} , to assure that the individual expansion function spectra

are recoverable from the group-collapsed synthesis trial function [Eq. (11)], and that is

$$\sum_{b=1}^{G'} u^{gb} = \text{the same value for all } g. \quad (15)$$

This constraint is desirable since the user has supplied expansion functions which should have spectra characteristic of the various regions of the model.

With the group-collapsing option added, the synthesis trial function becomes

$$\phi_{ijk}^g = \sum_{b=1}^{G'} u^{gb} \sum_{n=1}^N a_{nk}^b H_{nij}^g. \quad (16)$$

Note that Eq. (16) reduces to the statement of group-dependent synthesis (Eq. (11)) when u^{gb} is the unit matrix.

So far we have discussed only the trial function for the direct flux. For a variational derivation of the synthesis equations and for perturbation theory, an adjoint flux is required.

$$\phi_{ijk}^{*g} = \sum_{b=1}^{G'} u^{*gb} \sum_{n=1}^N a_{nk}^{*b} H_{nij}^{*g} \quad (17)$$

u^* is the adjoint group-collapsing scheme, which does not have to be the same as the direct group-collapsing matrix, u . a^* is the adjoint combining coefficient. H_n^* is a user-supplied expansion function for the adjoint trial function and is usually called a weighting function. In order to keep the synthesis equations in a form convenient to solve, there must be the same number of nonzero adjoint combining coefficients, a_{nk}^{*b} , as there are direct, a_{nk}^b , at each axial mesh interval, k .

C. Derivation of the Synthesis Equations

There are two methods commonly used to derive synthesis equations. We first outline the most straightforward of them, the weighted residuals (or weight-and-integrate) approach, and next show a derivation from a variational principle.

Weighted Residuals

For the weighted residuals method, start by substituting the synthesis trial function (Eq. (16)) into the finite-difference equation (Eq. (1)). Then multiply each equation for a particular axial mesh interval (i.e. each combination of i, j, g for one k) by the factor

$$u^{*gb'} H_{n'ij}^g, \quad (18)$$

and sum the weighted equations over the indices i, j and g . Repeat this procedure for a total number of multipliers (Eq. (18)) equal to the number of combining coefficients for a single value of k , making sure that each time the combination of collapsed group (b') and expansion function (n') for the multiplier is unique. We shall account later for the fact that some of the combining coefficients may be zero (i.e. that certain expansion functions have been dropped where it is felt that they are not needed). For now we will treat the calculation as if all expansion functions are used everywhere.

When the dust settles, the synthesis equations are:

$$\begin{aligned} & \sum_{b=1}^G \sum_{n=1}^N a_{nk}^b \left[\sum_{g=1}^G u^{*gb'} \sum_{g'=1}^G u^{g'b} \sum_{i=1}^I \sum_{j=1}^J H_{n'ij}^{*g} v_{ijk} r_{ijk}^{gg'} H_{nij}^{g'} \right] \\ & + \sum_{b=1}^G \sum_{n=1}^N a_{nk}^b \Delta z_k \left[\sum_{g=1}^G u^{*gb'} u^{gb} \left\{ \sum_{j=1}^J H_{n'1j}^{*g} d_{1jk}^{xg} \Delta y_j \left(H_{n1j}^g - H_{n0j}^g \right) \right. \right. \\ & + \sum_{i=2}^I \sum_{j=1}^J \left(H_{n'i j}^{*g} - H_{n'i-1j}^{*g} \right) d_{ijk}^{xg} \Delta y_j \left(H_{nij}^g - H_{ni-1j}^g \right) \\ & - \sum_{j=1}^J H_{n'i+1j}^{*g} d_{i+1jk}^{xg} \Delta y_j \left(H_{ni+1j}^g - H_{ni1j}^g \right) \\ & + \sum_{i=1}^I H_{n'i1}^{*g} d_{i1k}^{yg} \Delta x_i \left(H_{ni1}^g - H_{ni0}^g \right) \\ & + \sum_{i=1}^I \sum_{j=2}^J \left(H_{n'i j}^{*g} - H_{n'i j-1}^{*g} \right) d_{ijk}^{yg} \Delta x_i \left(H_{nij}^g - H_{nij-1}^g \right) \\ & \left. \left. - \sum_{i=1}^I H_{n'iJ+1}^{*g} d_{iJ+1k}^{yg} \Delta x_i \left(H_{niJ+1}^g - H_{niJ}^g \right) \right\} \right] \\ & - \sum_{b=1}^{G'} \sum_{n=1}^N \left(a_{nk+1}^b - a_{nk}^b \right) \left[\sum_{g=1}^G u^{*gb'} u^{gb} \left\{ \sum_{i=1}^I \sum_{j=1}^J H_{n'ij}^{*g} d_{ijk+1}^{zg} \Delta x_i \Delta y_j H_{nij}^g \right\} \right] \\ & + \sum_{b=1}^{G'} \sum_{n=1}^N \left(a_{nk}^b - a_{nk-1}^b \right) \left[\sum_{g=1}^G u^{*gb'} u^{gb} \left\{ \sum_{i=1}^I \sum_{j=1}^J H_{n'ij}^{*g} d_{ijk}^{zg} \Delta x_i \Delta y_j H_{nij}^g \right\} \right] \\ & - \sum_{g=1}^G u^{*gb'} \left\{ \sum_{i=1}^I \sum_{j=1}^J H_{n'ij}^{*g} v_{ijk} s_{ijk}^g \right\} = 0 \quad (19) \end{aligned}$$

for each combination of k , b and n for which a weighting was performed.

To reduce Eq. (19) to a form which is a convenient basis for a practical computer code we will restrict the axial boundary conditions to the form given in Eq. (2) (zero flux, zero current or extrapolated boundary conditions) and introduce new notation. Periodic conditions will not be allowed at the top and bottom of the model, which means that

$$a_{n0}^b = a_{nK+1}^b = 0 \quad (20)$$

for all n and b in Eq. (19).

We introduce a new subscript, m , which identifies a unique combination of collapsed group (b) and expansion function (n).

$$a_{mk} = a_{nk}^b \quad (21)$$

The maximum value of m , which is the maximum number of combining coefficients associated with a single mesh interval, is M .

$$M = G \times N. \quad (22)$$

There is a comparable index, m' , associated with the weighting functions. By redefining some of the multiple summations in Eq. (19) we can write the synthesis equations.

$$\begin{aligned} 0 = & - \sum_{m=1}^M \frac{1}{\Delta z_k} D_{m' mk} a_{mk-1} - \sum_{m=1}^M \frac{1}{\Delta z_{k+1}} D_{m' mk+1} a_{mk+1} \\ & + \sum_{m=1}^M \left[\frac{1}{\Delta z_k} D_{m' mk} + \frac{1}{\Delta z_{k+1}} D_{m' mk+1} + \Delta z_k R_{m' mk} \right] a_{mk} - \Delta z_k S_{m' k} \quad (23) \\ & m' = 1 \dots M, \quad K = 1 \dots K, \end{aligned}$$

subject to the condition given by Eq. (20). The definitions of the matrices $D_{m' mk}$ and $R_{m' mk}$ and the vector $S_{m' k}$ are:

$$\begin{aligned} R_{m' mk} = & \sum_{g=1}^G u^{g b'} \sum_{g'=1}^G u^{g' b} \sum_{i=1}^I \sum_{j=1}^J H_{n' i j}^{* g} \Delta x_i \Delta y_j r_{i j k}^{g g'} H_{n i j}^{g'} \\ & + \sum_{g=1}^G u^{g b'} u^{g b} \left\{ \sum_{j=1}^J H_{n i k}^{* g} d_{i j k}^{x g} \Delta y_j \left(H_{n i j}^g - H_{n 0 j}^g \right) \right\} \end{aligned}$$

$$\begin{aligned}
& + \sum_{i=2}^I \sum_{j=1}^J \left(H_{n'ij}^{*g} - H_{n'i-1j}^{*g} \right) d_{ijk}^{xg} \Delta y_j \left(H_{nij}^g - H_{ni-1j}^g \right) \\
& - \sum_{j=1}^J H_{n'I+1j}^{*g} d_{I+1jk}^{xg} \Delta y_j \left(H_{nI+1j}^g - H_{nIj}^g \right) \\
& + \sum_{i=1}^I H_{n'ii}^{*g} d_{ilk}^{yg} \Delta x_i \left(H_{nii}^g - H_{ni0}^g \right) \\
& + \sum_{i=1}^I \sum_{j=2}^J \left(H_{n'ij}^{*g} - H_{n'ij-1}^{*g} \right) d_{ijk}^{yg} \Delta x_i \left(H_{nij}^g - H_{nij-1}^g \right) \\
& - \sum_{i=1}^I H_{n'iJ+1}^{*g} d_{iJ+1k}^{yg} \Delta x_i \left(H_{niJ+1}^g - H_{niJ}^g \right) \Big\} \quad (24)
\end{aligned}$$

$$D_{m'mk} = \sum_{g=1}^G u^{*gb} u^{gb} \sum_{i=1}^I \sum_{j=1}^J H_{n'ij}^{*g} d_{ijk}^{zg} \Delta x_i \Delta y_j \Delta z_k H_{nij}^g \quad (25)$$

$$S_{m'k} = \sum_{g=1}^G u^{*gb} \sum_{i=1}^I \sum_{j=1}^J H_{n'ij}^{*g} \Delta x_i \Delta y_j s_{ijk}^g \quad (26)$$

In order to define $D_{m'mk}$ by a single expression it is necessary to define Δz_{k+1} in $D_{m'mk+1}$. The definition is arbitrary, since it is cancelled by the inverse mesh spacing when $D_{m'mk+1}$ is used in Eq. (23).

We pointed out earlier that expansion functions can be eliminated from the trial function over ranges of axial mesh intervals by setting their combining coefficients identically equal to zero. We can modify Eq. (23) to imply this if we define the symbol

$$\sum_{\substack{m \text{ at} \\ k}} \quad (27)$$

to mean the sum over only those values of m at axial mesh interval k which correspond to nonzero combining coefficients, a_{mk} . When the number of unknowns is reduced in this way it becomes necessary to reduce the number of equations. In order that the reduced set of synthesis equations remains in a block-tridiagonal form which is convenient for numerical inversions, we will require that when a combining coefficient is eliminated the corresponding equation that must be dropped be one associated with the same mesh point. Therefore, the " $m' = 1 \dots M$ " in Eq. (23) is replaced by " m' at k ", implying that Eq. (23) is written only for certain values of m' at each mesh interval.

The final form of the synthesis equations can now be written,

$$\begin{aligned}
 0 = & - \sum_{m \text{ at } k-1} \frac{1}{\Delta z_k} D_{m' mk} a_{mk-1} - \sum_{m \text{ at } k+1} \frac{1}{\Delta z_{k+1}} D_{m' mk+1} a_{mk+1} \\
 & + \sum_{m \text{ at } k} \left[\frac{1}{\Delta z_k} D_{m' mk} + \frac{1}{\Delta z_{k+1}} D_{m' mk+1} + \Delta z_k R_{m' mk} \right] a_{mk} \\
 & - \Delta z_k S_{m' k}, \quad m' \text{ at } k, \quad k = 1 \dots K
 \end{aligned} \tag{28}$$

A Variational Derivation

Consider the following functional:

$$\begin{aligned}
 & \sum_{g=1}^G \sum_{j=1}^J \sum_{k=1}^K \Delta y_j \Delta z_k \left\{ \phi_{1jk}^{*g} d_{1jk}^{xg} (\phi_{1jk}^g - \phi_{0jk}^g) - \phi_{1jk}^{*g} d_{1+1jk}^{xg} (\phi_{1+1jk}^g - \phi_{1jk}^g) \right. \\
 & \quad \left. + \sum_{i=2}^I (\phi_{ijk}^{*g} - \phi_{i-1jk}^{*g}) d_{ijk}^{xg} (\phi_{ijk}^g - \phi_{i-1jk}^g) \right\} \\
 & + \sum_{g=1}^G \sum_{i=1}^I \sum_{k=1}^K \Delta x_i \Delta z_k \left\{ \phi_{i1k}^{*g} d_{i1k}^{yg} (\phi_{i1k}^g - \phi_{i0k}^g) - \phi_{iJk}^{*g} d_{iJ+1k}^{yg} (\phi_{iJ+1k}^g - \phi_{iJk}^g) \right. \\
 & \quad \left. + \sum_{j=2}^J (\phi_{ijk}^{*g} - \phi_{ij-1k}^{*g}) d_{ijk}^{yg} (\phi_{ijk}^g - \phi_{ij-1k}^g) \right\} \\
 & + \sum_{g=1}^G \sum_{i=1}^I \sum_{j=1}^J \Delta x_i \Delta y_j \left\{ \phi_{ij1}^{*g} d_{ij1}^{zg} (\phi_{ij1}^g - \phi_{ij0}^g) - \phi_{ijK}^{*g} d_{ijK+1}^{zg} (\phi_{ijK+1}^g - \phi_{ijK}^g) \right. \\
 & \quad \left. + \sum_{k=2}^K (\phi_{ijk}^{*g} - \phi_{ijk-1}^{*g}) d_{ijk}^{zg} (\phi_{ijk}^g - \phi_{ijk-1}^g) \right\} \\
 & + \sum_{g=1}^G \sum_{g'-1}^G \sum_{i=1}^I \sum_{j=1}^J \sum_{k=1}^K \phi_{ijk}^{*g} v_{ijk} r_{ijk}^{gg'} \phi_{ijk}^{g'} \\
 & - \sum_{g=1}^G \sum_{i=1}^I \sum_{j=1}^J \sum_{k=1}^K v_{ijk} \left(\phi_{ijk}^{*g} S_{ijk}^g + S_{ijk}^{*g} \phi_{ijk}^g \right).
 \end{aligned} \tag{29}$$

ϕ_{ijk}^{*g} is the discrete adjoint group flux and ϕ_{ijk}^{*g} an adjoint source for mesh block (i,j,k) . The other quantities were defined when they appeared earlier in Eq. (1). It is straightforward to show that requiring the functional to

be stationary with respect to arbitrary variations of the discrete adjoint fluxes leads to the set of difference equations given in Eq. (1) for any of the allowed types of boundary conditions.

For boundary conditions in the form of Eq. (2) recall that the exterior fluxes (ϕ_{0jk}^g , ϕ_{I+1jk}^g , ϕ_{i0k}^g , etc.) are identically zero. When those terms are dropped from Eq. (29) the symmetry of the remaining expression should make it clear that requiring variations with respect to the direct flux be zero leads to the usual adjoint difference equations. To show that the same is true when there are periodic boundary conditions one must replace the exterior discrete fluxes in Eq. (29) by the appropriate internal fluxes before calculating the variations. For example, if an x-y-z geometry model has quarter-core symmetry the boundary conditions are periodic at the surfaces $i = 1$ and $j = 1$. The external fluxes are redefined by

$$\begin{aligned}\phi_{0jk}^g &= \phi_{j1k}^g, & \phi_{i0k}^g &= \phi_{1ik}^g, \\ \phi_{0jk}^{*g} &= \phi_{j1k}^{*g}, & \phi_{i0k}^{*g} &= \phi_{1ik}^{*g},\end{aligned}\quad (30)$$

There are also identities relating the coefficients in the leakage terms at the periodic boundary.

$$\begin{aligned}\Delta x_i &= \Delta y_i \quad i = 1 \dots I, & \Delta x_0 &= \Delta y_1 = \Delta x_2 = \Delta y_0 \\ d_{1jk}^{xg} &= \frac{2D_{0jk}^g D_{1jk}^g}{\Delta x_1 D_{0jk}^g + \Delta x_0 D_{jk}^g} = \frac{2D_{j1k}^g D_{1jk}^g}{\Delta x_1 D_{j1k}^g + \Delta y_1 D_{1jk}^g} = d_{j1k}^{yg}.\end{aligned}\quad (31)$$

With the identities shown in Eqs. (30) and (31), one can show that adjoint equations with periodic boundary conditions can be derived from the functional given by Eq. (29).

To derive the synthesis equations, first substitute the trial functions for the direct flux [Eq. (16)] and adjoint flux [Eq. (17)] into the functional [Eq. (29)]. One can reduce the result to

$$\begin{aligned}& \sum_{k=1}^{K+1} \sum_{m=1}^M \sum_{n=1}^M \frac{1}{\Delta z_k} \left(a_{m-k}^* - a_{m-k-1}^* \right) D_{m-nk} \left(a_{nk} - a_{nk-1} \right) \\ & + \sum_{k=1}^K \sum_{m=1}^M \sum_{n=1}^M \Delta z_k a_{m-k}^* R_{m-nk} a_{nk} \\ & - \sum_{k=1}^K \sum_{m=1}^M \Delta z_k a_{m-k}^* S_{m-k} - \sum_{k=1}^K \sum_{n=1}^M \Delta z_k a_{nk} S_{nk}^*\end{aligned}\quad (32)$$

by using the definitions given in Eqs. (24) - (26) and

$$S_{mk}^* = \sum_{g=1}^G u_{gb}^g \sum_{i=1}^I \sum_{j=1}^J H_{nij}^g \Delta x_i \Delta y_j s_{ijk}^* . \quad (33)$$

Setting the variations of this functional with respect to nonzero, adjoint combining coefficients equal to zero leads directly to the direct synthesis equations derived in the last section [Eq. (28)]. Following the same procedure with the direct combining coefficients leads to a set of adjoint synthesis equations.

$$\begin{aligned} 0 = & - \sum_{m \text{ at } k-1} \frac{1}{\Delta z_k} D_{m-k} a_{m-k-1}^* - \sum_{m \text{ at } k+1} \frac{1}{\Delta z_{k+1}} D_{m-k+1} a_{m-k+1}^* \\ & + \sum_{m \text{ at } k} \left[\frac{1}{\Delta z_k} D_{m-k} + \frac{1}{\Delta z_{k+1}} D_{m-k+1} + \Delta z_k R_{m-k} \right] a_{m-k}^* - \Delta z_k S_{mk}^* , \\ & m \text{ at } k, \quad k = 1 \dots K . \end{aligned} \quad (34)$$

It should be emphasized that the adjoint variables in a synthesis calculation are combining coefficients, a_{mk}^* , and not fluxes. Whether or not the adjoint trial function [Eq. (17)] is a good approximation to the adjoint flux depends on the user's choice of weighting function. It is very common in practical calculations to use the expansion functions for weighting functions also, and this might be a poor choice in situations where the adjoint is required. In particular, when sodium void reactivity distributions are to be calculated by perturbation theory it may be necessary to generate weighting functions from two-dimensional adjoint calculations.

When the groups are not collapsed in a synthesis calculation the adjoint combining coefficients will, as best they can, reproduce the adjoint spectrum. If the groups are partially collapsed and direct flux weighting is used, however, it will be virtually impossible for the adjoint trial function to yield reasonable spectra. It has been found that results can be improved if the direct flux expansion coefficients are scaled before being used as weighting functions.^{20,21}

$$H_{nij}^{*g} = w_{ij}^g H_{nij}^g . \quad (35)$$

D. The Solution of the Synthesis Eigenvalue Equations

Equation (28) can be written in the form of an eigenvalue problem if we drop the inhomogeneous source and break up R_{m-k} into its fission and non-fission components.

$$R_{m',mk} = E_{m',mk} - \lambda F_{m',mk} \quad (36)$$

m' at k , $k = 1 \dots K$

$E_{m',mk}$ includes the planar leakage, scattering and absorption components of Equation (24). $F_{m',mk}$ is the fission part of Eq. (24). λ is the eigenvalue ($1/k$).

Fission Source Iteration with Wielandt Acceleration

SYND solves Eq. (28), modified by the Eq. (36), by the fission source iteration method with the convergence accelerated by Wielandt (or fractional) iteration.²² The statement of one iteration of the solution can be written as a matrix equation,

$$-A_k^- a_{k-1} + A_k^+ a_{k+1} + A_k^0 a_k = S_k, \quad k = 1 \dots K, \quad (37)$$

where a_k is the unknown vector of combining coefficients ($a_{m'}$, m at k) associated with mesh interval k and A_k^- , A_k^+ , A_k^0 and S_k are defined by

$$(A_k^-)_{m',m} = \frac{1}{\Delta z_k} D_{m',mk} \quad (38)$$

$$(A_k^+)_{m',m} = \frac{1}{\Delta z_{k+1}} D_{m',mk+1} \quad (39)$$

$$(S_k)_{m'} = \sum_{\substack{m \text{ at} \\ k}} \Delta z_k (\lambda - \lambda_0) F_{m',mk} a_{mk}^i \quad (40)$$

$$(A_k^0)_{m',m} = \frac{1}{\Delta z_k} D_{m',mk} + \frac{1}{\Delta z_{k+1}} D_{m',mk+1} + \Delta z_k \left(k_{m',mk} - \lambda_0 F_{m',mk} \right) \quad (41)$$

a_{mk}^i is the combining coefficient from the previous iteration. λ_0 is an estimate of the eigenvalue. When λ_0 is a few percent less than the fundamental eigenvalue (the estimated k is greater than the fundamental k) most problems converge in a very few iterations. An estimate of k is one of the input parameters to the code; when none is provided SYND falls back on a straight fission source iteration ($\lambda_0 = 0$).

SYND requires that for each axial mesh interval the number of group-weighting functions used (i.e. the number of equations) be the same as the number of combining coefficients. This means that the matrix A is square. However, since the number of combining coefficients may change from one mesh interval to the next the matrices A_k^- and A_k^+ may be non-square. Note that, because of Eq. (20), the first term of Eq. (37) vanishes for $k = 1$, and the second term vanishes for $k = K$.

The convergence criterion used in SYND is that the eigenvalue, λ , not change by more than an input criterion on two successive iterations.

Solution by Forward Elimination, Backward Substitution

The solution of the block-tridiagonal source problem (Eq. (37)) is performed by the forward elimination, backward substitution technique (a specialization of Gauss reduction).²³ The first step is to sweep through the axial mesh generating the following set of matrices, H_k , and vectors, Q_k .

$$\begin{aligned} \text{at } k = 1, \quad H_1 &= [A_1^0]^{-1} A_1^+ \\ Q_1 &= [A_1^0]^{-1} S_1 \end{aligned} \quad (42)$$

$$\begin{aligned} \text{at } k = 2 \dots K - 1, \quad H_k &= [A_k^0 - A_k^- H_{k-1}]^{-1} A_k^+ \\ Q_k &= [A_k^0 - A_k^- H_{k-1}]^{-1} [A_k^- Q_{k-1} + S_k] \end{aligned} \quad (43)$$

$$\text{at } k = K, \quad Q_K = [A_K^0 - A_K^- H_{K-1}]^{-1} [A_K^- Q_{K-1} + S_K] \quad (44)$$

The second step, the backward substitution, is

$$\text{at } k = K, \quad a_K = Q_K \quad (45)$$

$$\text{at } k = K - 1 \dots 1, \quad a_k = Q_k + H_k a_{k+1} \quad (46)$$

Scaling and Differencing

The realities of computer arithmetic can lead to two problems with the synthesis equations. The first occurs when numbers generated during the calculation exceed the maximum or minimum magnitudes allowed by the computer. This can happen during the inversion of Eq. (37) when the normalizations of the expansion functions are unusually large (or small) and/or when the spectra of the expansion functions span too many orders of magnitude. Matrix inversion routines which calculate the determinant are especially vulnerable. This is simply a problem with normalization; when it occurs there is probably nothing fundamentally wrong with the synthesis calculation.

The second problem, linear dependence, was very early recognized as a potential nuisance,⁷ but to our knowledge it has never caused much difficulty. If a set of expansion functions in one group is "almost" linearly dependent the inversion of Eq. (37) will fail. The best defense against this, of course, is to know enough about the expansion functions to avoid this situation by dropping superfluous group fluxes from one or more expansion functions (an option available in SYN3D).

As insurance against either of these two problems arising, a transformation is performed on Eq. (37) during its solution. The transformation has the effect of a change of variables from the original synthesis approximation

$$\phi_{ijk}^y = \sum_{n=1}^N a_{nk}^g H_{nij}^g, \quad (47)$$

where H_n^g is the input expansion function, to

$$\phi_{ijk}^g = \sum_{n=1}^N b_{nk}^g G_{nij}^g, \quad (48)$$

where the transformed expansion functions, G_n^g , are defined

$$G_{lij}^g = H_{lij}^g / s_1^g, \quad (49)$$

$$G_{nij}^g = (H_{nij}^g / s_n^g) - (H_{lij}^g / s_1^g), \quad n = 2 \dots N. \quad (50)$$

s_n^g is a scaling factor used to change the normalization. At each axial mesh interval and in each group this transformation has the effect of: (1) renormalizing whichever expansion function has been designated $n = 1$ (Eq. (49)), and (2) renormalizing and differencing the other functions with respect to the first (Eq. (50)). This differencing scheme is a sort of poor man's orthogonalization.

The relationships between the original and transformed combining coefficients are

$$b_1^g = s_1^g a_1^g + \sum_{n=2}^N b_n^g \quad (51)$$

$$b_n^g = s_n^g a_n^g, \quad n = 2 \dots N, \quad (52)$$

$$a_1^g = (b_1^g - \sum_{n=2}^N b_n^g) / s_1^g, \quad (53)$$

$$a_n^g = b_n^g / s_n^g, \quad n = 2 \dots N. \quad (54)$$

The transformation of the matrices in Eq. (37) is governed by

$$\sum_{g=1}^G \sum_{n=1}^N A_{mn}^{g'g} a_n^g = \sum_{g=1}^G \sum_{n=1}^N B_{mn}^{g'g} b_n^g \quad (55)$$

where A represents any of the matrices (A^- , A^+ or A^0) operating on the combining coefficients and B represents a transformed matrix. The relationships between A and B are

$$B_{m1}^{g'g} = A_{m1}^{g'g} / s_1^g, \quad (56)$$

$$B_{mn}^{g'g} = (A_{mn}^{g'g} / s_n^g) - (A_{m1}^{g'g} / s_1^g), \quad n = 2 \dots N, \quad (57)$$

$$A_{m1}^{g'g} = s_1^g B_{m1}^{g'g}, \quad (58)$$

$$A_{mn}^{g'g} = s_n^g (B_{mn}^{g'g} + (A_{m1}^{g'g} / s_1^g)), \quad n = 2 \dots N. \quad (59)$$

The scaling factors, s_n^g , used were taken from the set of axial leakage integrals, Eq. (25).

$$s_n^g = D_{m'mk} \quad (60)$$

where m' is the composite index for the appropriate group and "first" weighting function, H_1^{*g} , and m is the composite index for the same group and n 'th function. This choice was made because (1) the integrals $D_{m'mk}$ were available and (2) the elements of the transformed matrices in the synthesis equations were on the order of unity.

E. Other Calculations

Multichannel Synthesis

Multichannel synthesis is an extension of the single-channel approximation in which different combining coefficients are assigned to an expansion function in separate regions of the x-y plane.¹⁵ The multichannel trial function can be written,

$$\phi_{ijk}^g = \sum_{n=1}^N \sum_{c=1}^C a_{nck}^g f_{ncij}^g H_{nij}^g. \quad (61)$$

Equation (61) differs from Eq. (11) by the additional summation over the index c (for "channel") and the multichannel basis functions f_{nc}^g . Note that Eq. (61) permits the number and definitions of the sets of basis functions to differ from one expansion function to another.

Two constraints should be placed on the choice of basis functions. The first is that the expression on the right in Eq. (61) must be single-valued for each (i, j) . The second is the spatial analog to the restriction placed on the group-collapsing matrix (Eq. (15)). Because it is desirable that the planar flux shape of each expansion function, H_n^g , be recoverable from the synthesis trial function for the three-dimensional flux, ϕ^g ,

$$\sum_{c=1}^{C_n} f_{ncij}^g = \text{the same value for all } g, i \text{ and } j. \quad (62)$$

Our original intention was to offer multichannel synthesis as an option in SYN3D. After some experience with small test problems and large, fast-critical models we concluded that the advantage of improved accuracy was outweighed by the disadvantage of longer running times and more complex trial functions, and SYN3D was not carried beyond the single-channel stage. For experimental purposes and for special applications it is possible to perform multichannel calculations with SYN3D by factoring in the multichannel basis functions outside the code,

$$H_{nij}^g \rightarrow f_{ncij}^g H_{nij}^g, \quad c = 1 \dots C_n, \quad (63)$$

and treating each product, $f_{nc}^g H_n^g$, as a separate expansion function.

Perturbation Theory

The derivation of a perturbation theory expression for the change in an eigenvalue due to a change in the model, carried out within the framework of single-channel flux synthesis, leads to the same result one obtains with derivations based on the original difference equations. Therefore, any perturbation theory code which is based on the finite-difference equations in Eq. (1) can be used with fluxes and adjoints calculated with SYN3D. It is important to remember, however, that a different interpretation must be given the results. A perturbation theory calculation based on synthesis fluxes and adjoints answers the question "what happens to the synthesis calculation when one perturbs the model?" and not necessarily "what happens to the finite-difference calculation?"

III. USER CONSIDERATIONS

This section is a discussion of the mechanics of running SYN3D from a user's standpoint. It is mostly directed towards the ARC System SYN3D (as opposed to the stand-alone version available through the Argonne Code Center). Users who have the Code Center version should read Section V before Section III.

A. CCCC Standards and the ARC System

A number of features of SYN3D will seem strange unless one is aware of the ground rules under which the code was written. In recent years

code development supported by the Division of Reactor Research and Development of ERDA has been subject to a set of standards defined by the Committee on Computer Code Coordination (CCCC).²⁴ A major part of these standards is a set of definitions of a number of binary files, called standard interface files, which contain most of the data required for neutronics calculations. The ARC System of reactor analysis codes developed at Argonne has its own set of standard binary files.²⁵ SYN3D was written to conform to the CCCC standards but, at the same time, to be compatible with ARC System modules required in synthesis calculations at Argonne.

Table III-I lists both the ARC System and CCCC input files used by SYN3D. The ARC System SYN3D user should be aware of both sets of interface files; users of the Code Center version of SYN3D need only be concerned with the CCCC files.

The ARC System SYN3D is really the Code Center SYN3D prefaced by a translator (TRANSL) which reads ARC System files and writes the corresponding CCCC standard interface files. Output files generated by both versions of SYN3D are all in the CCCC formats.

B. Basic Input Requirements

Expansion Functions

The expansion functions, N^B , in Eq. (11), used in each synthesis calculation must be calculated in separate jobs; SYN3D does not compute expansion functions. Some suggestions of guidelines for choosing expansion functions based on Argonne's experience with LMFBR calculations are given in Section III-H.

The ARC System SYN3D user supplies a number of expansion functions in either ARC System form (FR.D1, FR.D2, FA.D1 and/or FA.D2), CCCC form (RTFLUX and/or ATFLUX) or a mix of the two. The several functions are differentiated by the CCCC device of a file version number. The current ARC System Standard Path for SYN3D (STP018) permits up to 10 flux files in the ARC System format (FR.D1, etc.). The ARC System SYN3D and Standard Path does not distinguish between flux and adjoint files (e.g. FR.D2 vs. FA.D2). The Code Center SYN3D permits 10 flux (RTFLUX) files and five adjoint (ATFLUX) files.

The user controls the version number of the expansion and weighting functions by his assignment of each file to a logical unit number. In the SYN3D input (SYNFI1) he/she refers to a particular expansion or weighting function by its CCCC designation (e.g. RTFLUX, version number five), even though he/she may have supplied the file in an ARC System format (FR.D2, version number five).

Cross Sections

SYN3D follows the practice of most ARC System neutronics calculations of permitting cross section input in either microscopic or macroscopic form. Microscopic cross sections in the ARC System Standard Path STP018 are in XS.180 files, and the compositions are defined by the type 13 and 14 cards of the BCD file A.NIP.²⁶

TABLE III-1. ARC System and OCCC Input Files for SYN3D. These are not all required; some are generated by SYN3D or its ARC System Standard Path, and others may never be needed at all

<u>ARC System BCD</u>	<u>ARC System Binary</u>	<u>OCCC Binary</u>	<u>Contents</u>
A.NIP	GEOM	GEODST	Model Geometry
	BC		
	B.HOMOC	NIXSRF ZNATON	Composition Definitions
	XS.ISO	ISOTXS	Microscopic Cross Sections
	XS.C.MIN COMPXS*	COMPXS*	Macroscopic Cross Sections
SYNFIL	SYNOON*	SYNOON*	SYN3D Control Data
	FR.D1 FR.D2	RTFLUX	Flux Files
	FA.D1 FA.D2	ATFLUX	Adjoint Flux Files

*COMPXS and SYNOON are code-dependent, binary files which are not officially part of either the ARC or OCCC Systems.

STP018 uses the module HOMOG to create the macroscopic cross section file XS.C.MIN, and the ARC System-to-CCCC translator in SYN3D, TRANSL, converts XS.C.MIN to COMPXS. Either XS.C.MIN or COMPXS can be input directly, in which case the preceding steps in the cross section generation procedure will be skipped. COMPXS can accommodate directional diffusion coefficients and "power" cross sections; otherwise it is similar to XS.C.MIN.

The Code Center version of SYN3D can run either from the CCCC microscopic cross section and composition files ISOTXS, NDXSRF and ZNATDN or from the macroscopic cross section file COMPXS. In the first case the SYN3D overlay HMG4C will create a COMPXS file.

Geometry

SYN3D builds up a three-dimensional model of a reactor by stacking user-supplied two-dimensional planes. This approach was chosen for two reasons:

- (1) At the time SYN3D was started, Argonne had no user-oriented, three-dimensional geometry input processor. We did have a well established, one- and two-dimensional input processor in the ARC System module GNIP.²⁶
- (2) The user was going to have to set up two-dimensional geometries for the expansion function calculations anyway, and it would be convenient if he/she could simply reuse that data without changes.

The ARC System input procedure is particularly suited to generating a series of two-dimensional geometry descriptions. STP018 looks for a BLOCK-GEOM card. If it finds one it expects there to be an A.NIP data set specified for a plane. GNIP processes the A.NIP data to a pair of GEOM and BC files (version number 1) and TRANSL converts them to a GEODST file (again, version number 1). STP018 then looks for another BLOCK-GEOM and a corresponding A.NIP for the next planar geometry description (this time producing a GEODST, version number 2). This procedure continues until all the BLOCK-GEOM data blocks are processed. What makes this scheme convenient is that while the first BLOCK-GEOM must contain a complete A.NIP (DATASET=A.NIP), subsequent blocks need only contain the type 15 cards unique to that plane (MODIFY=A.NIP). The manner in which the two-dimensional planes are stacked to form a three-dimensional model is specified in the SYN3D BCD input file SYNFIL.

It is possible to input a three-dimensional GEODST instead of several two-dimensional files. If the SYN3D BCD file SYNFIL does not specify an axial mesh or a stacking of planes (card types 4 and 5) the code interprets the version 1 GEODST to be a description of the full model and breaks it up into a number of two-dimensional GEODST's (version numbers 2, 3, etc.). This will only work when the expansion functions are also input in CCCC formats (RTFLUX and ATFLUX). This restriction is due to the translator TRANSL, and this mode of input only works when there is no geometry or flux file translation required.

In describing the geometry input we have been using the example of three-dimensional models. The same input procedure works for two-dimensional models built up from one-dimensional "planes".

Code Dependent Input - SYNFIL

The special BCD input required by SYN3D is defined by the BCD file SYNFIL. Appendix D is a file description for SYNFIL. SYNFIL must be included in the ARC System input in a data block BLOCK=SYN3D.

C. Running the ARC System SYN3D - ARCP018

The catalogued procedure for SYN3D on the Argonne 370/195 is ARCP018. The procedure is listed in Appendix C. ARCP018 executes the synthesis Standard Path STP018, which is listed in Appendix B and discussed briefly in Section IV.

Input and Output Data Sets

Table III-2 lists all the input and output data sets that are of interest to users. Besides the files already mentioned in Section III-B the list includes the direct and adjoint combining coefficient files DCCOEF and ACCOEF, the pointwise power density PWDINT, the composition-averaged flux file RZFLUX and the synthesis integral library files INTTOC, VOLINT and DIFINT. Scratch data sets are discussed in Section IV.

File descriptions for the data sets listed in Table III-2 can be found in one of three places:

For the following ARC System Files see ANL-7711 (Ref. 25)
GEOM, BC, FR.D1, FR.D2, FA.D1, FA.D2, XS.C.MIN, A.NIP,
XS.ISO

For the following CCCC Standard Interface Files see Appendix I.
GEODST, RTFLUX, ATFLUX, PWDINT, RZFLUX

For the following code-dependent files see Appendices D and E.
SYNFIL, COMPS, INTTOC, VOLINT, DIFINT, DCCOEF, ACCOEF

Job Control and Symbolic Parameters

The SYN3D catalogued procedure ARCP018 (see Appendix C for listing) is designed for the convenience of users operating from ARC System data sets. Table III-2 lists the symbolic parameters available and their default values.

Sample Input

Figure III-1 is a listing of an input deck. The problem it represents is Sample Problem 3 of the Code Center SYN3D package (see Section V-E), a three-dimensional model with control rods. There are six BLOCK=GEOM data blocks defining rodded and unrodded core, blanket and reflector planes. The four expansion functions are in the FR.D2 format, and the cross sections are generated from an XS.ISO file.

D. Multiple Problems and Restarts

For most problems the most expensive part of a SYN3D calculation is generating the integrals (Eqs. (24) and (25)) which form the coefficients of the synthesis equations. If the same integrals can be used for a number of synthesis calculations the user can save a significant amount of time.

Multiple Problems

The simplest way to reuse integrals is to run several problems in a single job. The ARC System SYN3D does this automatically by looping on BLOCK=SYN3D data blocks. A problem defined by a second BLOCK=SYN3D uses integrals generated under the first BLOCK=SYN3D, calculating additional integrals if required. The output flux file from each loop can be saved by specifying different version numbers for the output RTFLUX (see SYNFIL card type 16). Only the last set of combining coefficients can be saved, however, since SYN3D always writes them to DCCOEF version number 1.

This multiple pass feature is not available in the Code Center SYN3D. Code Center SYN3D users will have to use the more formal restart procedure described in the next paragraph.

Restarts - INTTOC, VOLINT and DIFINT

The integrals SYN3D calculates are stored in a library consisting of three files: INTTOC, VOLINT and DIFINT. SYN3D always writes these files with a version number of 2. If these files are input with a version number of 1 the code will merge the old integrals with whatever integrals it still must calculate before writing the output libraries. The version 1 files are not changed.

File descriptions for the library files are in Appendix E. INTTOC is a short file containing the table of contents for VOLINT and DIFINT as well as the general problem data. DIFINT contains the integrals associated with the axial leakage, $D_{m'nk}$ (Eq. (25)). VOLINT contains four types of integrals which are referred to in the coding and in the SYN3D output as REM, FIS, POW and FLUX. REM and FIS are, respectively, the removal and fission components of $R_{m'nk}$ (see Eqs. (24) and (36)). POW is the planar power integral,

$$POW_{nk}^b = \sum_{g=1}^G u_{gb} \sum_{i=1}^I \sum_{j=1}^J \Delta x_i \Delta y_j p_{ijk}^g H_{nij}^g \quad (64)$$

where p_{ijk}^g is a "power" cross section supplied in the COMPS file. Eq. (64) is written for an x-y plane; one can obtain the expression for other geometries by replacing $\Delta x_i \Delta y_j$ by the appropriate volume element. The FLUX integral is, as one might guess,

$$FLUX_n^b = \sum_{g=1}^G u_{gb} \sum_{i=1}^I \sum_{j=1}^J \Delta x_i \Delta y_j H_{nij}^g \quad (65)$$

The index b refers to a collapsed group. Recall that when group collapsing is not used u^{gb} is the Kronecker delta ($u^{gb} = 1$ when $g = b$, $= 0$ otherwise).

One can restart SYN3D to do another synthesis calculation or simply to obtain further edits for a problem run previously. In the latter case DCCOEF and/or ACCOEF must be among the input data sets.

SYN3D cannot be restarted in the middle of the synthesis integral calculation or the middle of the solution routine. If the job terminates before completing one of those two stages, that particular stage must be repeated.

E. Edits and Output Options

SYN3D has some standard edits, over which the user has no control, and some optional edits. Appendix H contains output from the sample problems in the Code Center package (Section V-E).

Standard Output

SYN3D always lists the SYNFIL input data and two pages describing the model and synthesis trial function (in terms of CCCC files). When logarithmic boundary conditions are used the constants C_1 and C_2 listed in the edits refer to Eq. (2) in Section II.

$$C_1^g D^g \hat{n} \cdot \nabla \phi^g + C_2^g \phi^g = 0. \quad (2)$$

In addition, SYN3D edits the integral tables of contents, the eigenvalue and the combining coefficients (a_{hk}^g).

The standard output files are:

INTTOC, 2	
DIFINT, 2	
VOLINT, 2	
DCCOEF, 1	(for a direct solution)
ACCOEF, 1	(for an adjoint solution)

Optional Output

SYNFIL card type 16 through 21 specify output options. Flux and adjoint edits may be specified by group and plane. Pointwise power density edits may be requested by plane. SYN3D will also edit the composition-averaged group fluxes (the contents of the RZFLUX file) and the perturbation theory denominator,

$$\sum_{g=1}^G \sum_{g'=1}^G \sum_{i=1}^I \sum_{j=1}^J \sum_{k=1}^K a_{ijk}^g x^g v_{fj}^{g'} \phi_{ijk}^{g'} v_{ijk} \quad (66)$$

where the symbols were defined for Eqs. (1) and (6).

The optional output files are:

RTFLUX, N	(N specified by user)
ATFLUX, N	(N specified by user)
PWDINT, N	(N specified by user)
RZFLUX, N	(N specified by user)
GEODST, N	(N specified by user)

The output, three-dimensional (or two-dimensional) GEODST file may be useful when the input geometry has been specified by a set of two-dimensional (or one-dimensional) GEODST files.

Combining Coefficient Plots

SYN3D will edit printer plots of the axial power distribution,

$$(\text{power})_k = \sum_{n=1}^N \sum_{b=1}^{G'} \text{POW}_{nk}^b a_{nk}^b, \quad (67)$$

and the axial group fluxes (after group collapsing)

$$(\text{flux})_k^b = \sum_{n=1}^N \text{FLUX}_n^b a_{nk}^b. \quad (68)$$

POW_{nk}^b and FLUX_n^b are defined by Eqs. (64) and (65). The plots show the totals (Eqs. (67) and (68)) as well as the nodal components (for each n). The output from Sample Problem 3 in Appendix H shows one of these plots.

F. Error Messages

Errors caught by SYN3D during execution are identified by subroutine name and an error number. Appendix F is a complete list. Non-fatal errors (positive error numbers) are flagged but never cause the termination of a run; they are frequently anomalies in the input which suggest user errors. Fatal errors will not cause the job to terminate immediately; SYN3D will continue as far as it can before forcing an abnormal termination through subroutine ERROR.

G. Storage Requirements and Running times

Data storage during a SYN3D calculation is managed dynamically through the BPOINTER routines (see Section IV-C for a description of BPOINTER). The BPOINTER storage container size required on input card type 3 of data set SYNFI1 should be set as large as practical for models of any significant size. SYN3D keeps in-core as much data as it can in order to minimize I/O time and makes use of all the container it is given. A very rough guess at the minimum size required is the largest of the three expressions given below:

$$5000 + 70 \cdot G + 7 \cdot G^2, \quad 2 \cdot I \cdot J,$$

$$\text{or } 5000 + 7 \cdot (N \cdot G)^2 . \quad (69)$$

G is the number of groups, I is the number of first-dimension mesh intervals, J is the number of second-dimension mesh intervals, and N is the maximum number of expansion functions used simultaneously at any one axial mesh interval. Users of the CDC version of the Code Center SYN3D may run into trouble at about $N \cdot G = 50$. Some coding changes are suggested in Section V-F which will alleviate the problem.

Running time can vary dramatically, depending on the complexity of the model and the synthesis scheme used. The time required to do the integrals is proportional to the square of the number of groups (before group collapsing), the number of planar mesh points, the number of different axial zones, and the square of the number of expansion functions. The time for the solution of the synthesis equations is proportional to the number of iterations, the number of axial mesh intervals, the cube of the number of groups (after group collapsing) and the cube of the number of expansion functions.

Table III-3 shows running times for two fast critical assembly models.

H. Applications of Synthesis

Choosing Expansion Functions

The choice of expansion functions is very important to the success of the synthesis approximation, but we will touch on that subject only very briefly in this report. The experiences of many users can be found in the Refs. 7, 9, 16, 19, 20, 27-30. We will summarize here some of Argonne's recent experience with SYN3D calculations of fast critical assemblies.²⁷⁻²⁹

We have settled on different prescriptions for high-reactivity (core) and low-reactivity (blanket and reflector) planes of a model. For high-reactivity planes the best choices are critically buckled, eigenvalue calculations. It is not necessary to fine-tune the buckling to force the two-dimensional eigenvalue to be exactly that expected for the three-dimensional model; 1% or 2% differences are probably close enough. We have tried expansion functions which are calculated with group- and region-dependent bucklings determined from an r-z model; synthesis calculations based on these expansion functions give better results than calculations based on uniformly buckled expansion functions, but the advantages are probably outweighed by the nuisance of setting up the extra r-z model. Our current practice is to choose a single, constant buckling,

$$B^2 = (\pi/L)^2 , \quad (70)$$

based on an effective unreflected core height, L, which is within 10 cm. of the value that would be required to get the expected critical eigenvalue.

TABLE III-3. ARC System SYN3D Running Times and Storage Requirements
for Two Fast Critical Assembly Models on the IBM 370/195.
The GCFR Model was Run at Two Different Container Sizes

<u>Model</u>	<u>GCFR</u>		<u>ZPPR3</u>
Groups	11		28
Spatial Mesh (x-y-z)	25 x 27 x 18		54 x 25 x 22
Axial Zones	4		3
Expansion Functions	2		3
Iterations	5		4
BPOINTER Container	40,000 8,000*		60,000
REGION Size (K-bytes)	650 375		800
CP Time (min)	0.9	0.9	8.9
WAIT Time (min)	1.7	2.4	3.3
Total Time (min)	2.6	3.3	12.2

* This was the minimum container size, rounded to the next 1000 words,
for which the GCFR model would run.

For low-reactivity planes such as a blanket zone, or no-reactivity planes like a reflector, an eigenvalue calculation is a poor (or even impossible) way to generate characteristic planar shapes. Our current practice is to obtain expansion functions from inhomogeneous calculations in which the fixed source is the product of the diffusion coefficient in the zone of interest times the expansion function characteristic of the adjacent, higher-reactivity plane. The philosophy behind this choice is that the most important source of neutrons in a low-reactivity plane is the leakage from a high-reactivity plane, and that leakage source is roughly proportional to:

- (1) the neutron distribution in the high-reactivity plane, and
- (2) the ability of neutrons to diffuse into the low-reactivity plane.

We have applied this prescription almost entirely to axial blankets; we are not usually so interested in reflector zones that it is necessary to supply a reflector expansion function.

Blanket Functions - STP016, AJC10 and ARCSP016

An ARC System Catalogued Procedure, ARCSP016, and Standard Path, STP016, have been written to set up a fixed source for a subsequent DIF1D or DIF2D calculation of a low-reactivity expansion function. ARCSP016 is listed in Appendix J, and STP016 is listed in Appendix K. Basically, STP016 calls the usual ARC System geometry and cross section processing modules to generate GEOM and XS.C.MIN files and then calls the module AJC010. AJC010 multiplies an input flux distribution (FR.D1 or FR.D2) by the local diffusion coefficients and writes a fixed source file (ES.D1D or ES.D2D). The symbolic parameters for ARCSP016 are listed in Appendix J.

An ARCSP016 job step is usually followed immediately by an ARCSP001 (DIF1D) or ARCSP003 (DIF2D) job step. Figure III-2 shows an input deck for calculating a blanket function for the sample problems described in Section V-E. Quirks in the DIF2D Standard Path make it necessary to include a type 19 card in A.NIP (even though the data on that card is not used) and to include DATASET=ES.D2SH in the DIF2D BLOCK=OLD (even though no such data set exists). Note that the A.NIP created in the first step is passed to the second.

IV. CODE STRUCTURE AND PROGRAMMING CONSIDERATIONS

This section describes the structure of SYN3D from a programmer's standpoint. It is a survey of the several distinct code blocks making up SYN3D and is intended as an aid to users who wish to make changes to the code or who wish to understand the flow of the calculation.

A. The ARC System SYN3D

The differences between the Code Center SYN3D and the ARC System SYN3D are in operating environment; the bulk of the coding (specifically,

the overlays CARDS, INTEG, SOLVE and EDITS) is identical. The ARC System synthesis Standard Path, STP018, calls a number of modules (among them SYN3D) in performing a synthesis calculation; the Standard Path and associated, additional ARC System modules have not been included in the Code Center SYN3D package.

STP018

Appendix B is a listing of the ARC System synthesis Standard Path, STP018. In addition to the SYN3D module, which is designated NU0012 in the ARC System, STP018 may execute one or more of the following modules:

NU1001	The cross section homogenization input processor.
NU0001	Cross section homogenization.
NU1004	Triangular mesh geometry input processor.
NU1002	General geometry input processor.

File Definitions

The ARC System SYN3D uses ARC System files, Version III CCCC files and a number of scratch files. The ARC System and CCCC files are discussed in Section III of this report. The official definitions of the required Version III CCCC files are given in Appendix I along with a discussion of the one instance (in a triangular mesh GEODST file) where the SYN3D requirements and the official definitions differ. Scratch files are defined in Appendix E.

B. Overlay Structure

Figure IV-1 is a diagram of the SYN3D module indicating the calling sequences of the overlays and subroutines. The Code Center version of the code does not include the TRANSL branch. The ARC System SYN3D does not contain the HMC4C branch. The functions of the main driver and each of the six primary overlays are discussed below. Table IV-1 lists each subroutine and common block and includes a brief description of functions performed.

Main Driver

The main drivers of the Code Center and ARC System versions of SYN3D differ somewhat in form but are similar in function. Each is a short routine which sets the values of a number of code dependent parameters and then calls the primary overlays which perform the synthesis calculation. In the Code Center version the main driver handles the SEEK initialization; in the ARC System this function is accomplished in the Standard Path.

TRANSL

TRANSL is a code block required in the ARC System SYN3D as an interface between ARC System files and the CCCC files that SYN3D works with.

FIGURE IV-1. SYND PROGRAM STRUCTURE SHOWING SUBROUTINE CALLING SEQUENCES. TRANSL IS USED ONLY IN THE ABC SYND, HQC IS USED ONLY IN THE CODE CENTER VERSION. ROUTINES CALLED BY SEVERAL SUBROUTINES IN A BRANCH ARE LISTED UNDER THE BRANCH NAME. FOR EXAMPLE, SEEK IS USED THROUGHOUT THE CODE, QUIT IS CALLED BY SEVERAL SUBROUTINES IN HQC, ETC.

TABLE IV-1. SYMID SUBROUTINES AND COMMON BLOCKS.

ROUTINES USED THROUGHOUT SYMID.

BULK	B-POINTER ROUTINE, INITIALIZES BULK STORAGE (LCM).
CLEAR	B-POINTER ROUTINE, ZEROES ZBARY.
ERR00	ERROR ROUTINE.
FREE	B-POINTER ROUTINE, RELEASES B-POINTER CONTAINER.
IP02	B-POINTER ROUTINE, RETURNS POINTER FOR SUBARRAY.
IP0PR0	B-POINTER ROUTINE, RETURNS NUMBER OF B-POINTER ERRORS.
IP0T	B-POINTER ROUTINE, RETURN POINTER FOR ARRAY.
LINES	DATA HEADINGS.
POINTR	B-POINTER ROUTINE, INITIALIZATION.
PT00P	B-POINTER ROUTINE, SHIFTS ARRAY STORAGE TO SQUEEZE OUT BLANKS.
PUT0	B-POINTER ROUTINE, RESERVES STORAGE FOR ARRAY.
PPDEFN	B-POINTER ROUTINE, CHANGES STORAGE FOR ARRAY.
READT0C	READS INTT0C FILE.
TEP0	READS BINARY FILES.
TYPE	WRITES BINARY FILES.
ZEK	CCCC FILE MANAGER.
TIME0	RETURNS TIME, DATE, ETC.
ZIP0UT	B-POINTER ROUTINE, RELEASES STORAGE FOR ARRAY.

COMMON BLOCKS.

ARRAY	REFERENCE POINT FOR B-POINTER CONTAINER.
INDEXTR	B-POINTER POINTERS FOR HNGAC.
NO00N	IO PARAMETERS.
LINE	DATA FOR LINES.
LOCATE	B-POINTER PARAMETERS.
MAST00	CENTRAL SYMID DATA.
OUTPUT	IO PARAMETER.
POINT	B-POINTER POINTERS FOR INTEG.
POINTC	B-POINTER POINTERS FOR CARDS.
POINTS	B-POINTER POINTERS FOR EDITS.
POINT0	B-POINTER POINTERS FOR SOLVE.
REF	GENERAL HNGAC DATA.
SCAT	SCATTERING CROSS SECTION PARAMETERS FOR HNGAC.
TRAN	DATA FOR TRAN0.

TABLE IV-1. SYN3D SUBROUTINES AND COMMON BLOCKS. CONTINUED.

TRANSL - APC TO CCCC CONVERSION (ARC SYSTEM ONLY).

RTPLUX	READS PR.D1, PR.D2, PA.D1, PA.D2, WRITES RTPLUX.
TRGE01	READS GEOM AND BC, WRITES GEODST.
TRGE02	TRANSLATES BOUNDARY CONDITIONS.
TRISCH	READS 2-FILE XS.C.MIN, WRITES COMPIX.

CAPDS - PROCESSES CODE-DEPENDENT, BCD DATA.

BRKUP	REPAKS 3D MODEL GEOMETRY INTO SEVERAL 2D GEODST FILES.
RPADCD	READS BCD CARD INPUT.
PITSYN	WRITES SYNCON FILE.

HMG4C - CREATES MACROSCOPIC CROSS SECTION FILE, COMPIX (CODE CENTER SYN3D ONLY).

ATDNT	READS ZONE ATOM DENSITIES.
DNLSPT	MOVES DOUBLE-PRECISION DATA.
EDTISO	EDITS RECORDS 2 AND 3 OF ISOTXS FILE.
EDTXS1	EDITS RECORDS 1 AND 2 OF COMPIX.
EDTXS2	EDITS RECORDS 3 AND 4 OF COMPIX FOR A SINGLE COMPOSITION.
FARSTT	REVERSES OPDPR AND MOVE SINGLE-PRECISION DATA.
PISPEC	COMPUTES PROMPT FISSION SPECTRUM.
INTSET	MOVES INTEGSR DATA.
ISOR14	READS RECORDS 1-4 OF ISOTXS FILE.
ISOR58	READS ISOTOPE-DEPENDENT ISOTXS RECORDS.
OV11	DRIVER FOR INITIAL CROSS SECTION INPUT PROCESSING.
OV12	DRIVER FOR MICROSCOPIC DATA PROCESSING.
OVL3	WRITES COMPIX FILE.
OVL4	EDITS COMPIX FILE.
QUIT	FATAL ERROR MESSAGE.
RDNDV	READS NDKSRP FILE.
RDATDN	READS ZNATDN FILE.
SINSET	MOVES SINGLE-PRECISION DATA.
SVSCAT	SCATTERING CROSS SECTION PROCESSING.
SVXS	PICKS UP MACROSCOPIC DATA.
TYM	COMMUNICATION WITH THE REST OF SYN3D.
UPDATP	BUILDS UP MACROSCOPIC DATA.
WPC1	WRITES RECORD TYPE 1 OF COMPIX FILE.
WPC2	WRITES RECORD TYPE 2 OF COMPIX FILE.
WPC3	WRITES RECORD TYPE 3 OF COMPIX FILE.
WPC4	WRITES RECORD TYPE 4 OF COMPIX FILE.

TABLE IV-1. SYN3D SUBROUTINES AND COMMON BLOCKS. CONTINUED.

 INTEG - CALCULATES SYNTHESIS INTEGRALS.

DECIDE	CHOOSES INTEGRALS TO BE DONE ON EACH PASS THROUGH INTEG.
EDMOD	EDITS MODEL DESCRIPTION.
EDTOC	EDITS INTEGRAL TABLE OF CONTENTS.
INPRO1	PROCESSES CODE-DEPENDENT INPUT FROM SYNCON.
INPRO2	DETERMINES WHAT INTEGRALS MUST BE CALCULATED.
INPRO4	MAKES DATA MANAGEMENT DECISIONS.
INTRIT	WRITES RECORDS OF OUTPUT INTEGRAL FILE.
INT1	CALCULATION OF SCATTERING, ABSORPTION AND FISSION INTEGRALS.
INT11	CALCULATION OF SCATTERING, ABSORPTION AND FISSION INTEGRALS.
INT2	CALCULATION OF PLANAR LEAKAGE INTEGRALS.
INT21	CALCULATION OF PLANAR LEAKAGE INTEGRALS.
INT3	CALCULATION OF AXIAL LEAKAGE INTEGRALS.
INT31	CALCULATION OF AXIAL LEAKAGE INTEGRALS.
INT32	CALCULATION OF AXIAL LEAKAGE INTEGRALS.
INT4	CALCULATION OF FLUX AND POWER INTEGRALS.
NXTPLC	RETURNS DATA REWRITE PARAMETERS.
PLACE	STORES INTEGRALS IN OUTPUT ARRAYS.
REWRIT	REWRITES FLUXES, GEOMETRY DATA AND CROSS SECTIONS.
RITTOC	WRITES INTTOC FILE.
SFOTOP	OPENS OUTPUT INTEGRAL FILES.
WRITXS	PROCESSES CROSS SECTIONS FOR REWRIT.

 SOLVE - SETS UP AND SOLVES SYNTHESIS EQUATIONS.

ARITH	MATRIX ARITHMETIC.
CALPOW	CALCULATES TOTAL POWER.
DIVVY	MAKES DATA MANAGEMENT DECISIONS.
FILLUP	BUILD EQUATION COEFFICIENT MATRICES FROM INTGLS FILE.
INVPRT	MATRIX INVERSION.
KI2IG	RETURNS AXIAL MESH DATA.
ORTH	CHANGE OF VARIABLE TRANSFORMATION OF SYNTHESIS EQUATIONS.
OUTPRO	EDITS, WRITES COMBINING COEFFICIENT FILE.
SHUFFL	SHIFTS INTEGRALS IN EQUATION COEFFICIENT MATRICES.
SPORR	DIRECTS SOLUTION OF SOURCE PROBLEM.
WINTGL	REWRITES INTEGRALS TO INTGLS FILE.

 EDITS - EDIT PACKAGE.

PLUX3D	RTFLUX, ATFLUX, FWDINT AND RZFLUX EDITS AND OUTPUT FILES.
PDENOM	PERTURBATION DENOMINATOR.
PGPLOT	PPINTER PLOTTER.
PLOTS	SETS UP COMBINING COEFFICIENT PLOTS.
REDED	INPUT PROCESSOR FOR EDITS.
RITGEO	WRITES GEODST.
TWOOPR	TABLE EDITS.

When there are input GEOM and BC files TRANSL translates the data into corresponding GEODST files. When there are input FR.D2 (or FR.D1) files TRANSL creates the corresponding RTFLUX files. It distinguishes between FR.D2 and FR.D1 by checking the dimensionality of the GEODST files. Finally, TRANSL rewrites the data in an input XS.C.MIN file into the COMPTS format.

CARDS

The main purpose of CARDS is to read BCD data and write the binary file SYNCON. The value of the integer variable IWHERE (defined in the main driver and transmitted to CARDS through the common block HOWIN) identifies the operating environment (ARC System or Code Center) and determines where the BCD data comes from.

In the Code Center version (IWHERE = 1) the SYN3D input, starting with the cards-per-card-type data (see section V of this report), is read from the card input file. The logical unit number of the card input file, NFLIN, is set in the main driver and transmitted to CARDS through the common block HOWIN. In the ARC System SYN3D (IWHERE = 2) the BCD input is contained in the ARC System BCD file SYNFIL. In this case the logical unit number is determined through a call to SEEK.

The subroutine READCD reads and stores all the BCD data. The subroutine RITSYN writes the SYNCON file, which is essentially a binary version of SYNFIL (see Appendix E). The first record contains a single number, the largest card type number. The second record contains the number of input cards for each card type. Each subsequent record contains the data on an input card, with the card type number (columns 1-2) omitted.

If the user wishes to install some other input procedure, CARDS can be eliminated entirely, just so long as it is replaced with some other method of generating SYNCON.

CARDS performs one other function. SYN3D normally operates with separate GEODST files for each of the planes of a model plus additional data in SYNCON specifying how the planes are to be stacked together. When a single GEODST file is input, and the "stacking" instructions (card types 4 and 5) are omitted, subroutine BRKUP converts the single input GEODST to a number of GEODST files of lower dimensionality and constructs the necessary card type 4 and 5 data before writing SYNCON.

HMG4C

HMG4C is used in the Code Center version of SYN3D to create macroscopic cross sections from input microscopic data; in the ARC System environment this calculation is performed outside the SYN3D module by the ARC System modules NUI001 and NUC001, and HMG4C is not used. HMG4C reads the three CCCC files NDXSRF, ZNATDN and ISOTXS and writes the macroscopic cross section file COMPTS (see Appendix E). When a COMPTS file is input to the code, the main driver recognizes the fact and omits the call to HMG4C.

After reading ZNATDN, NDXSRF and the isotope independent data of ISOTXS, into core HMG4C attempts to hold all the macroscopic arrays which

are to be computed in the remaining BPOINTER container space. If this is possible a single pass is made through the ISOTXS file and the contribution of each isotope is added to each macroscopic cross section of each composition containing that isotope. If all the macroscopic data will not fit in the available core, the code determines the maximum number of compositions which will fit in a single pass. As many passes through ISOTXS are then made as are required to process all the data. The results of each pass are written to a scratch file (HFILE) for temporary storage before being written to the output COMPTS.

The COMPTS file has provision for directional diffusion coefficient data. HMG4C only supplies default values for this data - unity for the multipliers and zero for the additive terms (see Appendix E). To use directional diffusion coefficients in SYN3D the user must supply an appropriate COMPTS file from outside the code.

INTEG

The integrals required for the synthesis equations (see Section II of this report) are calculated by the INTEG overlay. These integrals are written into the library files VOLINT and DIFINT, with a table of contents and supporting data for the model written to the INTTOC file (see Appendix E).

Subroutine INPRO1 reads input data from SYNCON and checks it for errors. Subroutines INPRO2 and INPRO4 inspect the model, determine what integrals are required and make data management decisions for the calculation of the integrals.

REWRIT rewrites the expansion and weighting function fluxes and the planar geometry descriptions into the REQFLX file (see Appendix E) and rewrites the required macroscopic cross sections into REQXST (see Appendix E). All the point group fluxes and mesh interval data associated with a number of adjacent rows of mesh intervals are combined into each record of REQFLX. The size of the records and, therefore, the number of rows represented in each record are determined at run time and depend on the available BPOINTER container space. The macroscopic cross sections are rewritten with the diffusion coefficients segregated (in separate records) from the removal and fission data. Again, the REQXST record size is determined at run time. Each record of removal/fission data contains cross sections for all groups for as many compositions as the record size allows. Each record of diffusion coefficient data contains coefficients for all compositions for as many groups as the record size allows.

The integrals are calculated inside a nest of loops over records of REQFLX and REQXST. Space is reserved for as many output records of integral library files (VOLINT and DIFINT) as can fit in core with one record of REQFLX and one record of REQXST. The integrals to be saved in those output records are built up during loops over REQFLX records (the inner loop) and REQXST records (the outer loop). The order in which the integrals are to be done is determined in subroutine DECIDE; in an effort to minimize arithmetic, integrals requiring the same two functions are done simultaneously.

The manner in which the input fluxes, geometries and cross section data are rewritten for a particular job is described in the SYN3D output under the heading "DATA MANAGEMENT PARAMETERS FOR INTEGRAL CALCULATION". The table of contents of the output DIFINT and VOLINT files is also edited.

Although the exact size of each VOLINT and DIFINT record depends on the integrals contained, a maximum record size, LENINT, is set in the main driver. The current value of LENINT has been arbitrarily set at 2000 words (REAL*8 words on IBM machines).

SOLVE

Overlay SOLVE sets up and solves the synthesis eigenvalue problem. In a series of calls to subroutine FILLUP the code determines the order in which integrals are going to be needed during the sweep through the axial mesh (see section II-D for the solution algorithm). Whenever possible, integrals required to set up equations at one mesh interval are saved and reused at the next. The required integrals from VOLINT and DIFINT are rewritten to a scratch file INTGLS in the order in which they are to be needed. Data management decisions required to set up the integral rewriting and later solution are made in subroutine DIVVY. The integrals are rewritten in WINTGL.

The inhomogeneous problem solution which is the basis of the eigenvalue calculation (see Section II-D) is carried out in subroutine SPROB. SPROB sets up the synthesis equations with the aid of subroutine FILLUP, now operating in a mode in which it retrieves integrals from the INTGLS file, and subroutine SHUFFL, which rearranges elements of the equation matrices in order to reuse integrals during the sweep of the axial mesh. During the forward-elimination part of the sweep the H matrices (see Eqs. 42 and 43) are stored in the file HFILE.

After the eigenvalue iterations subroutine OUTPRO edits the combining coefficients and writes the combining coefficient files, DCCOEF and ACCOEF.

EDITS

The EDITS overlay handles all the optional output edits and files.

C. BPOINTER, A Dynamic Storage Allocation Subprogram Package

BPOINTER is a general, FORTRAN subprogram package which was developed to alleviate bookkeeping chores associated with the use of dynamic storage allocation techniques.²⁵

Programs which use BPOINTER tend to be structured in subroutine form. A control routine is used to define one or two large blocks of storage (called the container array) and to make the appropriate calls to BPOINTER to control the allocation of storage within the block(s). Calls to calculational subroutines transmit pointers corresponding to appropriate array locations through the calling sequences. All BPOINTER capabilities are accessed through an appropriate call to an entry point, subroutine or function subprogram. The following capabilities are available in the BPOINTER system:

- (a) Storage of data in and retrieval of data from the container array, via user defined variable arrays.
- (b) Purge of variable arrays stored in the container array.
- (c) Automatic "cleanup" of the container array when more storage is required.
- (d) Re-definition of array sizes without loss of data already stored in the array.
- (e) Array dump of selected integer, floating point or BCD arrays in a prescribed format.
- (f) Trace dumps of BPOINTER activities.
- (g) Status reports of the BPOINTER tables.

Detailed program documentation including flow charts, common block information and subprogram descriptions is available in Ref. 25. This section is intended to provide a brief description of how the program package operates. The major differences between the IBM and CDC stand-alone versions of the program package are also noted.

The short example listed in Fig. IV-2 is intended to illustrate the structure of a program using the BPOINTER package. This example shows the manner in which a container is allocated, pointers defined and used, and the container released.

Brief descriptions of all the BPOINTER entry points, subroutines and functions are given in Table IV-2.

All dynamically allocated arrays are addressed relative to the common block /ARRAY/ which contains a single array element, BLK(1). In the IBM version of the code the element must be declared DOUBLE PRECISION. In some versions of the CDC BPOINTER (not the version accompanying the Code Center SYN3D, which does not use LCM) a second common block /ARRAY2/ is used to address arrays allocated to a large core memory container. In versions of BPOINTER which use LCM this common block also contains a single array element, BLKECS(1), which must be declared a LEVEL 2 variable. In the SYN3D BPOINTER package BLKECS appears in the coding but is equivalenced with BLK. The equivalent of the large core memory container on IBM equipment is a second container which may be given a Hierarchy 1 location but is addressed in precisely the same manner as the first (SCM) container. The one word assigned to the container by the source language program provides a reference address. At execution time machine language routines (ALLOC1, ALLOC2 on IBM, MEMGET1, MEMGET2 on CDC) are used to obtain the addresses of core which are available to the program for the allocation of data arrays. These blocks of core are allocated in the following manner:

FIGURE IV-2. EXAMPLE OF BPOINTER USE.

TABLE IV-2. BPOINTER Subprogram Descriptions

POINTR	Initializes tables of dynamic allocation program package and calls ALLOC1 and ALLOC2 to allocate container(s) for variably dimensioned arrays.
PUTPNT/PUTBLK	Dummy routine calls PUTM to allocate array storage.
BULK	Sets number of words of BULK(LCM) core to be allocated.
FREE	Calls FREE1 and FREE2 to release container allocated by calls from subroutine POINTR.
WIPOUT/CLEAR	Deletes a named array from BPOINTER tables; zeroes all locations assigned to a named array.
GETPNT/GETN/DUMP	Returns pointer for a named array; returns index in BPOINTER tables of a named array; controls printing of a named array.
IGET	Returns pointer for a named array.
IPT2	Returns pointer to a sub-array relative to a single precision word length container.
PUTM/PUTB	Enters named arrays into fast and BULK(LCM) containers respectively.
IPTErr/NNAMSF	Returns number of BPOINTER errors, returns number of named arrays in BPOINTER tables.
ILAST/ILASTB	Returns word number of first available word in SCM/LCM container.
REDEF	Dummy routine calls REDEFM to redefine size and/or location of named array.
REDEFM/REDEFB	Redefine the size and/or location of named array within BPOINTER tables and containers.
PURGE/PURGB	Sift storage in SCM/LCM containers to eliminate unused blocks created by WIPOUT calls.
STATUS	Edits status of BPOINTER tables.
PRTI1	Prints half word integer array from SCM container.
PRTI1E	Prints half word integer array from LCM container.
PRTI2	Prints full word integer array from SCM container.
PRTI2E	Prints full word integer array from LCM container.
PRTR1/PRTA1	Prints full word real array from SCM container.
PRTR1E/PRTA1E	Prints full word real array from LCM container.
PRTR2/PRTA2	Prints double word real array from SCM container.
PRTR2E/PRTA2E	Prints double word real array from LCM container.

IBM Allocation

The standard IBM macro instructions GETMAIN and FREEMAIN are used to allocate and free consecutive words of core which are available to the program. The designations subpool 1 and 2 are assigned to the bulk (LCM) and fast (SCM) containers, respectively. Since allocations are performed in units of 256 (eight byte) words, it is most efficient to request blocks of core in such multiples.

CDC Allocation

The COMPASS routine MEMGET uses the standard CDC macro instruction MEMORY to determine the job's SCM and LCM field lengths. The top of the user's SCM field length is used for the BPOINTER SCM container. The user is responsible for providing enough SCM memory to accommodate both the program and the BPOINTER container; there is currently no effective check to make sure that data stored in the BPOINTER container does not overlap code. It is assumed by the CDC version of BPOINTER that the level 2 common block /ARRAY2/ is addressed as the first word of LCM and the entire LCM field length is assumed to be available to BPOINTER for its LCM container.

The letters M and B are used as neumonics within BPOINTER to designate routines which operate on the SCM and LCM containers, respectively. Thus PUTM allocates an array in the SCM container while PUTB (which is not used in SYN3D) allocates an array which must be referenced on CDC equipment as a LEVEL 2 array. On IBM equipment without HIARCHY support (e.g. 370/195) the two containers are equivalent. The distinctions noted above between the two dynamic containers are important on CDC equipment where the containers are addressed quite differently and on IBM equipment with HIARCHY support where access to the BULK container (HIARCHY 1, subpool 1) is significantly slower than access to the MAIN core container (HIARCHY 0, subpool 2).

V. THE ARGONNE CODE CENTER VERSIONS OF SYN3D

SYN3D is available on magnetic tape through the Argonne Code Center for both IBM and CDC machines. This section describes the contents of the tapes and outlines the steps necessary to implement the code in stand-alone form (without understanding very much about synthesis or the code itself). The Code Center package includes several test problems; this section also contains descriptions and the solutions of these test problems.

A. The SYN3D Package

The Code Center SYN3D package consists of this memo and a magnetic tape containing four BCD files. There are separate tapes for IBM and CDC versions; Table V-1 describes the format of each tape and the contents and length of each BCD file.

TABLE V-1. Description of SYN3D Tapes and the BCD Files they Contain

	<u>IBM Tape</u>	<u>CDC Tape</u>
Type	9 trk.	7 trk.
Density	800 bpi	556 bpi
Character Code	EBCDIC (029 keypunch)	BCD (026 keypunch)

In both cases there are no internal labels, there are 80 characters per card image and the blocking is 3200 (Forty cards per block).

<u>File Number</u>	<u>Contents</u>	<u>Number of Card Images</u>	
		<u>IBM Tape</u>	<u>CDC Tape</u>
1	SYN3D FORTRAN source code	19163	19163
2	Additional BPOINTER routines	501	130
3	CDFILE FORTRAN source code	665	665
5	Interface files in CDFILE format	1418	1418

TABLE V-2. SYN3D Segments

<u>Overlay Name</u>	<u>Card Numbers</u>
MAIN	1-2154
CARDS	2155-2971
HMG4C	2972-6278
INTEG	6279-12981
SOLVE	12982-16363
EDITS	16364-19163

SYN3D

The first two files combine to form the SYN3D code. The first file is SYN3D proper. The IBM and CDC versions are derived from the same source code. Statements that are unique to IBM computers (e.g. REAL*8) are surrounded by pairs of comment cards starting with the characters "CIBM" in columns 1-4 and are commented out in the CDC version. Statements that are unique to CDC computers (e.g. OVERLAY) are surrounded by "CDC*" comment cards and are commented out in the IBM version.

The card number (columns 73-80) of a particular FORTRAN instruction in the IBM version is the same in the CDC version. This was done to avoid the nuisance of maintaining entirely separate versions of the code. Future corrections to the code will be specified in terms of this numbering system.

ADDITIONAL BPOINTER ROUTINES

BPOINTER is a set of dynamic storage allocation subroutines used in SYN3D to manage fast memory. The bulk of the coding is in FORTRAN, is common to both IBM and CDC versions of SYN3D, and is included in the SYN3D source file (cards 902-2154).

A few of the BPOINTER routines, however, are machine dependent, and these are included in file 2 of the Code Center tape. For the IBM version these additional routines are all in assembler language. For the CDC version they are partly FORTRAN (the first 108 cards of file 2) and partly COMPASS (the last 22 cards).

The additional BPOINTER routines can be assembled (and for the CDC version compiled) separately and included in the main overlay of SYN3D (cards 1-2154 of file 1) at load time.

CDFILE

CDFILE (file 3) is a short, stand-alone, FORTRAN code which provides a crude way of generating CCCC binary interface files from BCD card input. File 4 contains the CDFILE BCD input file needed to produce binary interface files for a number of sample problems. If the user has other means of writing CCCC interface files he/she may choose to ignore files 3 and 4.

B. Code Structure

The discussion of the structure of SYN3D included here will just cover those aspects which affect the linking and execution of the code in a straightforward, stand-alone form. The functions of the several overlays of the program are covered in more detail in Section IV.

The simplest overlay scheme (other than none at all) is a division into a main overlay and five primary overlays. The names of the overlays and the corresponding card numbers in the source coding (file 1 of the Code Center tape), are given in Table V-2. The additional BPOINTER routines (file 2) should be included in the main overlay.

The CDC version of SYN3D includes OVERLAY cards at the beginning of each of the segments listed in Table V-2 and, therefore, can be compiled directly from tape to a load file. For those compilers which permit a mix of FORTRAN and assembler language it may be convenient to splice the additional BPOINTER routines (file 2 on the Code Center tape) into the SYN3D source file after card 2154. Alternatively, one can compile SYN3D and the additional BPOINTER routines separately and merge the two either by inserting the additional BPOINTER relocatable object code at the proper place in the SYN3D load file or, for loaders that permit it, by providing the additional routines through a user library.

The IBM version of SYN3D has been run at Argonne by compiling the segments listed in Table V-2 and assembling the additional BPOINTER routines to a partitioned data set and then overlaying at load time.

C. File Number Assignments

All binary files (input and output interface files and scratch files) used by SYN3D are handled through the CCCC standard subroutines SEEK, REED and RITE. The assignment of file numbers to file names and the initialization of the SEEK tables is done from the SYN3D driver routine (cards 1-170 of the source code).

The file assignments in the Code Center version of SYN3D are listed in Table V-3. Multiple versions of some files are required. Printer output is written to file 6; BCD input (if required) is read from file 5. File assignments can be easily rearranged by changing the coding in the main driver; no other routines need be modified.

All files are written sequentially. All but one file (HFILE) is read sequentially. At different stages of the calculation HFILE is read both forwards and backwards. SYN3D does not require direct access files.

D. Running the Code Center SYN3D as a Stand-alone Program

The Code Center version of SYN3D is set up to execute in environments that may never have heard of the CCCC standards. Most of the input data are contained in CCCC standard interface binary files, and a small program, CDFILE, is provided (file 4 of the Code Center tape) to convert input from BCD cards or a card image file to the necessary binary files. Those installations which already can write CCCC files can ignore CDFILE. A small amount of data specifying input binary file numbers and additional, code-dependent data are read from cards. Even these BCD data can be eliminated if desired (see section V-F).

CDFILE

This utility program was written largely as a crude input processor for the Code Center version of SYN3D. It only processes the six CCCC files RTFLUX, ATFLUX, GEODST, ISOTXS, NDXSRF and ZMATDN.

CDFILE operates in two modes. In the first (MODE=1) it will read a number of CCCC binary files (those types listed above) and write the data in BCD card image form to a single BCD file. In the second (MODE=2) it

TABLE V-3. Files Required by the Code Center Version of SYN3D
(GEODST through ZNATIN are CCCC files. The
rest may be treated as scratch files.)

File Name	File Version Nos.	Use	Logical Unit No.*
GEODST	1-10	These are the several two-dimensional GEODST files required to describe a three-dimensional model. GEODST,1 can be a three-dimensional file, in which case the code will write two-dimensional files GEODST,2...GEODST,N.	11-21
RTFLUX	1-11	RTFLUX files containing expansion and/or weighting functions.	21-31
ATFLUX	1-5	ATFLUX files containing expansion and/or weighting functions.	32-36
PWDINT	1	Output power density, by mesh volume.	37
RZFLUX	1	Zone average fluxes.	38
ISOTXS	1	Input microscopic cross sections.	39
NDXSRF	1	Cross-section reference.	40
ZNATIN	1	Zone atom densities.	41
INTTOC	1	Input synthesis integral table of contents (optional).	42
INTTOC	2	Output synthesis integral table of contents.	43
VOLINT	1	Input synthesis VOLINT integrals (optional).	44
VOLINT	2	Output synthesis VOLINT integrals.	45
DIFINT	1	Input synthesis DIFINT integrals (optional).	46
DIFINT	2	Output synthesis DIFINT integrals.	47
DCCOEF	1	Direct synthesis combining coefficients.	48
ACCOEF	1	Adjoint synthesis combining coefficients.	49
COMPXS	1	Macroscopic cross sections.	50

TABLE V-3. Contd.

File Name	File Version Nos.	Use	Logical Unit No.
REQFLX	1	Rewritten fluxes.	51
REQXST	1	Rewritten macroscopic cross sections.	52
INTGLS	1	Rewritten synthesis integrals.	53
HFILE	1	Scratch file used during solution. (Also used by ING4C if multipass mode is used.	54
SYNCON	1	The input data in binary form.	55
SYNFIL	1	The input data in BCD card images (used with ARC System input routines).	56

* These are the file number assignments made in the main overlay of the Code Center version of SYN3D by the initialization call to SEEK. Since the rest of the code always uses SEEK to determine file numbers, it is a relatively simple job to assign entirely different file numbers by defining new SEEK tables.

will read BCD card images from a single BCD file and write a number of binary files. File 4 of the Code Center tape is a BCD file written by CDFILE in the first mode and represents the binary files necessary for several test calculations. Section V-E describes these test calculations run by first executing CDFILE with MODE=2 and file 4 of the Code Center tape as input and then executing SYN3D with the resulting binary files as input. Table V-4 describes the contents of the two input cards, and Table V-5 shows examples of the modes in which CDFILE can be run.

CDFILE can process any number of files. The BCD file (LUNBCD) contains blocks (decks) of card images stacked in the order indicated by (LUN(I),I=1,NFILES). There is no form of separator between blocks.

Installations with any sort of a network of reactor analysis codes can find a more efficient procedure for generating CCCC binary interface files than the CDFILE program. We will not encourage the general use of CDFILE by listing in this report the card image formats for those CCCC files the code can handle. Users who have no other way to generate interface files are referred to the CCCC standard file descriptions (see Appendix I) and to the FORTRAN source coding of CDFILE. It suffices to say that the program sweeps sequentially through a binary file reading and writing integer and floating point data as they are encountered.

It is suggested that CDFILE and the test problems supplied in the Code Center SYN3D package be used as a preliminary check of the code when it is initially implemented at any installation. Examples of the use of CDFILE on the ANL IBM-370 and the Lawrence Berkeley Laboratory CDC 7600 are included later in this section.

SEEK Table Initialization

SYN3D determines file numbers for all files (except card input and printer output) by calls to the CCCC standard subroutine SEEK. Among its several functions SEEK returns an "existence flag" which specifies whether or not a file "exists" (i.e. has been previously written). Files can exist because they are input to the code or because SYN3D writes them itself. There must be some mechanism, therefore, to flag an input file as "existing" in the tables kept by SEEK.

The Code Center version of SYN3D does this with a single input card, read by the main driver (at card number 134 in the SYN3D source code). Each column of this card represents a logical unit number, and a non-zero integer in a particular column means that the corresponding file is an existing, input file. SYN3D then sets the existence flag for that file through a call to SEEK with an operation code of 1. This SEEK initialization card is the first card read by SEEK.

The SYN3D BCD Control Data

Obviously, there is input required by SYN3D that cannot be accommodated by the CCCC standard interface files alone. The Code Center version of SYN3D is set up to read a certain amount of data from cards placed after the SEEK initialization card.

TABLE V-4. CDFILE Input Data

<u>Card</u>	<u>Contents</u>	<u>Format</u>
1	NFILES, LUNBCD, MODE	3I3
2	(LUN(I),I=1,NFILES)	24I3

NFILES = The number of CCCC binary interface files to be processed.

LUNBCD = The logical unit number of the BCD file to which BCD card images are to be written (MODE=1) or from which BCD card images are to be read (MODE=2).

MODE = 1, data from binary files is written to the BCD card image file (file number LUNBCD). 2, data from the BCD card image file is written to binary files.

LUN(I) = The logical unit number of the CCCC binary interface file from which (MODE=1) or to which (MODE=2) the Ith block of data on the BCD file number LUNBCD is to be transferred.

TABLE V-5. Examples of CDFILE Modes of Operation. These Examples Assume File 5 is Card Input, File 6 is Printer Output and File 7 is Punch Output

<u>Mode</u>	<u>LUNBCD</u>	<u>CDFILE Function</u>
1	6	Reads binary files and prints contents.
1	7	Reads binary files and punches contents.
2	5	Reads cards punched by a previous CDFILE run (MODE=1, LUNBCD=7) and writes binary files. The card deck should be placed immediately after the two cards described in Table V-4.
2	10	Reads card images from the file on logical unit 10 (e.g. the fourth file on the Code Center tape) and writes binary files.

These data are provided on cards which have numbers in columns 1-2 which identify a particular card type. In many cases several cards of the same type may be required. The cards must be arranged in order of ascending card type number. Immediately after the SEEK initialization card, and before the first numbered card, a card must be provided which defines (with format 24I3) the number of cards included for each card type. The number of type 1 cards is punched in columns 1-3, the number of type 2 cards in columns 4-6, etc.

The contents and formats of the numbered cards are given in the file description of the BCD file SYNFIL (see Appendix D). The user is also referred to the sample problem input shown later in this section.

Examples of Input Decks with Control Cards

Figures V-1 and V-2 show input decks set up to execute CDFILE and SYN3D. Figure V-1 is a job run on Argonne's IBM 370/195 which link edits SYN3D from a partitioned data set (C116.B21006.EXPORT.SEGLIB) containing the segments listed in Table V-2 and BPOINTER. The member ASSEM contains the additional BPOINTER routines. Figure V-2 is a job run on Berkeley's CDC 7600 which loads SYN3D from a load file (PROG) compiled by FTN4.5.

BPOINTER

Storage for almost all the dimensioned arrays used in SYN3D is managed through the dynamic storage allocation routine BPOINTER. At run time BPOINTER reserves a section of memory, called the "container", the length of which is specified in the input (card type 2). On the IBM 370/195 BPOINTER actually requests space from the system, and if the REGION size is too small to hold both the program and the container an error message is printed. On CDC systems error messages may not occur when there is insufficient field length for the container until the code tries to store data outside the designated field length for the job.

The version of BPOINTER included in the CDC package can be used to allocate storage only in SCM; at present SYN3D only uses SCM.

E. Sample Problems

Model Descriptions

The test calculations included in the Code Center SYN3D package are based on the three-dimensional, simplified LMFBR model shown in Fig. V-3. A set of three-energy group cross sections is supplied, as are geometry and expansion function files required for several SYN3D calculations. The model includes rods which are banked at the midplane. The cross section data files contain microscopic cross sections for seven isotopes and number densities for seven compositions. Table V-6 defines the compositions.

File 4 of the Code Center Tape

The card images supplied in file 4 of the Code Center tape represent the CDFILE input "deck" required to generate 17 separate binary interface files. A description of each file is given in Table V-7. The "sequence

in File 4 of the Code Center Tape

Sequence Number	Interface File Name	File Description
1	RTFLUX	A 2D flux solution in the unrodded core plane of the model. A buckled (transverse distance = 120 cm.) eigenvalue calculation ($k = .99596$).
2	RTFLUX	A 2D flux solution in the rodded core plane. A buckled (transverse height = 150 cm.) eigenvalue calculation ($k = 1.00914$).
3	RTFLUX	A 2D flux solution in the unrodded, axial blanket plane. An inhomogeneous calculation.
4	RTFLUX	A 2D flux solution in the rodded, axial blanket plane. An inhomogeneous calculation.
5	ATFLUX	A 2D adjoint solution in the unrodded core plane.
6	ATFLUX	A 2D adjoint solution in the rodded core plane.
7	GEODST	A 3D geometry description of the model.
8	GEODST	A 2D geometry description of the unrodded reflector plane.
9	GEODST	A 2D geometry description of the unrodded axial blanket plane.
10	GEODST	A 2D geometry description of the unrodded core plane.
11	GEODST	A 2D geometry description of the rodded core plane.
12	GEODST	A 2D geometry description of the rodded axial blanket plane.
13	GEODST	A 2D geometry description of the rodded reflector plane.
14	GEODST	A 2D geometry description of a 12 x 12 mesh, uniform plane with zero-current boundary conditions.
15	NDXSRF	Cross section reference data.
16	ZNATDN	Atom density data.
17	ISOTXS	Microscopic cross sections.

number" indicates the order in which the card image blocks for each binary file are arranged in the card image file.

Sample Problem 1

The first sample problem is a fundamental mode calculation for the infinite medium eigenvalue and spectrum for composition 1, the material in the inner core of the model (see Table V-6). One of the GEODST files (sequence number 14 in Table V-7) represents a homogeneous, reflected plane containing composition 1. The synthesis calculation uses this GEODST file, a flat expansion function (1.0 everywhere in space and energy) and zero-current axial boundary conditions.

This first sample problem requires four input interface files: the uniform plane GEODST mentioned above, NDXSRF, ZNATDN and ISOTXS. The GEODST file is used only in this calculation; the other three files define the compositions and cross sections and are used in all four sample problems. The SYN3D BCD input for the job is shown in Fig. V-4.

Appendix H-1 is the complete output (16 pages) from sample problem 1. In this one case the macroscopic cross section edits (card type 2) have been turned on to provide a printed record of their values. The infinite medium fundamental eigenvalue for composition 1 is 1.3017, and the eigenvector (from the synthesis combining coefficient edits) is

1.000, 1.400, 0.04585

Sample Problem 2

One of the RTFLUX files in file 5 of the Code Center tape (sequence number 1 in Table V-7) was generated from a buckled, 2D diffusion theory calculation in the unrodded core plane of the 3D model. The buckling corresponded to a transverse slab thickness of 120 cm., and the 2D eigenvalue was .99596. Sample problem 2 is a synthesis calculation of a 3D model which is axially uniform and is described in the plane by the 2D GEODST file defining the unrodded core plane (sequence number 10 in Table V-7). The model is 60 cm. high and has zero current and zero flux boundary conditions on the first and second z boundary planes, respectively.

The unrodded core RTFLUX file is provided as the only expansion function, and the flat (UNIT) weighting option is used. Since the expansion function is "perfect" for the problem, and the flat weighting reduces the synthesis equations to the balance satisfied by the original 2D calculation, SYN3D should reproduce the 2D eigenvalue and yield combining coefficients which are cosine shaped and equal in magnitude in all three groups. Figure V-5 lists the input interface files and shows the BCD input.

Appendix H-2 shows the complete output (6 pages) from this sample problem. The eigenvalue is .99600 and the combining coefficients are essentially equal in all groups. The output shown in Appendix H-2 comes from a job run on an IBM 370/195; the same job run on a CDC 7600 gave an eigenvalue of .99599. Small deviations are to be expected because of the finite axial mesh and the fact that on IBM machines the cross sections are stored in SYN3D in REAL*4 words.

```

While of little practical interest, this sort of calculation is useful as a debug tool and as a consistency check between SYN3D and whatever diffusion theory code is used to generate expansion functions. Significant discrepancies might indicate that the two codes are based on different finite-difference formulations.

Sample Problem 3

This is a calculation of the full, three-dimensional model shown in Fig. V-3. The approach used illustrates the way SYN3D has been used to calculate a variety of fast reactor models. The three-dimensional model is described in terms of the six, unique axial zones (reflector, blanket and core planes, each of which may be either rodged or unrodged). The six input GEODST files are sequence numbers 8-13 of Table V-7. Four expansion functions (sequence numbers 1-4) are provided. Two are buckled, eigenvalue calculations in the unrodged and rodged core planes. Two are from inhomogeneous calculations in the axial blankets in which the fixed source is the product of the expansion function associated with the adjacent core zone and the blanket diffusion coefficient distribution. Typically, the solution in the reflector is of little interest, and reflector expansion functions are not included.

Figure V-6 lists the input interface files and shows the BCD input. The core expansion functions are used everywhere, but each blanket function is used only over 40% of the height of the model. It is unlikely that a rodged (top) blanket function could contribute significantly to the unrodged (bottom) axial blanket. Economies of this sort can significantly reduce running times with little sacrifice of accuracy.

Appendix H-3 shows selected pages of the output for this job. The eigenvalue is .97506 (v. .97532 for a 3D finite-difference calculation). Samples of the flux, power density and zone average flux edits are included, as is a sample printer-plot of the contributions from each expansion function to the axial flux distribution (i.e. the 3D flux integrated over the x and y dimensions). Selective use of these plots can help identify poor choices of expansion functions and anomalous solutions.

Sample Problem 4

This last calculation is intended to illustrate some of the other options available in SYN3D. Figure V-7 lists the input interface files and shows the BCD input. The model geometry is the same as that of sample problem 3, but now there is a single, three-dimensional input GEODST file (sequence number 7 in Table V-7). At the top and bottom boundaries the boundary conditions are now logarithmic. The same four expansion functions used in problem 3 are used in problem 4, but each blanket function is used over half the height of the core, and the group 3 flux of each blanket function is not used at all. Two of the four weighting functions are now adjoint fluxes (sequence numbers 5 and 6 in Table V-7), and both direct and adjoint synthesis problems are solved. Sample problem 4 is intended as an illustration of some of the more exotic options in the code and should not be taken as a recommendation. Sample problem 3 is a more typical example of an application of SYN3D.

Appendix H-4 shows selected pages of output for this job. The eigenvalue is .97520 (vs. .97532 for a 3D finite-difference calculation). The input decks shown in Figs. V-1 and V-2 are set up to run this sample problem.

F. Suggested Modifications to the Code

TIMER

TIMER is a CCCC subroutine with a variety of options for returning elapsed and clock time, job identification, data, etc. Every computer installation has its own set of FORTRAN callable system routines for providing some or all of this information, and so no universal TIMER can offer all options. The version of TIMER included in both IBM and CDC versions of the Code Center package returns elapsed CP time; in addition the IBM version returns the date and wall clock time. SYN3D uses TIMER to determine the time spent in the several parts of the calculation and to provide the date and clock time for file identification and page headers.

SEEK Initialization

Those installations which have their own SEEK and an established SEEK initialization procedure will want to make some changes in the main driver of SYN3D. In the Code Center SYN3D the correspondence between file name and logical unit number is set by the DATA statements defining the elements of the arrays DSNAME and NREF. The file named DSNAME(N) is assigned to logical unit number NREF(N).

On the first call to SEEK (with an operation code of 3) the entire DSNAME array (up to the \$), as well as the NREF array, is transferred to a table in the subroutine. Files with the same names are assigned version numbers in ascending order. Blank file names are ignored. Existence flags are initialized to 0 (the file has not been written).

The main driver then reads the SEEK initialization card and looks for columns which contain a number greater than zero. It interprets column numbers as logical unit numbers and for a non-zero entry in a column requests the corresponding file name from SEEK (with an operation code of 5). When it has the file name and version number it calls SEEK with an operation code of 1 to set the existence flag.

Changes to any part or all of this initialization procedure can be made by recoding the main driver and SEEK. No other routines are affected.

Eliminating BCD Input Data

Some installations may prefer to run SYN3D in a mode that completely eliminates direct BCD card input. LASL, for example, uses a general input processor which converts BCD cards to binary interface files; ANL has the ARC System input processors SCAN and STUFF which convert BCD cards to BCD files.

The first overlay in SYN3D, CARDS, reads BCD data either from the BCD card input file or the BCD disk file SYNFIL, depending on the value of the

sentinel IWHERE set in the main driver. CARDS then rewrites the input data to the binary file SYNCON (see the Appendix E for the file description). SYNCON is a binary version of the BCD card input; the data on each card is rewritten to an unformatted record. The user can write SYNCON outside of SYN3D and drop the call to CARDS from the main driver. The rest of the code is unaffected.

CARDS provides one function which is lost if the overlay is eliminated. For historical reasons, SYN3D was set up to build 3D (or 2D) geometries from 2D (or 1D) GEODST files. After the code was written an option was added to permit an input 3D (or 2D) file. CARDS was coded to break up an input 3D (or 2D) GEODST into the required number of 2D (or 1D) files and to create the additional, required BCD input data (cards types 4 and 5) before writing SYNCON. If CARDS is eliminated the user must specify 3D (or 2D) models in terms of 2D (or 1D) GEODST files.

Matrix Inversion and Multiplication Subroutines

The matrix inversion routine INVERT and matrix arithmetic routine ARITH which are supplied with the Code Center SYN3D are coded to minimize running time for large problems (many groups and/or expansion functions) when the code is compiled under the IBM FORTRAN H Extended compiler and run on the 370/195. There may be more efficient routines available for other computers.

Restrictions on Problem Size in SOLVE

It is unlikely that the problem size limitations (see Section III-G) will affect users who have large IBM computers; more than enough fast core should be available. CDC users (with a 50K core limitation), however, may reach the problem size limit when the number of energy groups (after group collapsing) times the number of expansion functions used concurrently at any one axial mesh interval is about 50.

The difficulty is with the solution overlay SOLVE. As it is currently written SOLVE must have enough storage to keep six matrices in-core at the same time. These matrices are A_k^- , A_k^0 , A_k^+ , H_k , REM and FIS (see Eqs. (38), (39), (41), (42), (43) and Section III-D). With a modest investment in programming some or most of these matrices could be kept in LCM.

APPENDIX A

Code Abstract

1. Name or Designation - SYN3D
2. Computer for which Program is Designed and Others upon which it is Operable - IBM 370/195, CDC 7600.
3. Description of Problem or Function - SYN3D solves the direct and adjoint, diffusion theory, static eigenvalue equations in two and three dimensions. The geometries available are x-y, r-z, x-y-z and triangular-z.
4. Method and Solution - SYN3D uses single-channel spatial flux synthesis to calculate approximate solutions to the three-dimensional (or two-dimensional) diffusion theory difference equations. Synthesis expansion functions must be supplied by the user from two-dimensional (or one-dimensional) finite-difference calculations performed by some other code. SYN3D sets up the synthesis equations and solves them by power iteration with Wielandt acceleration. Each iteration is an exact inversion of the block-tridiagonal synthesis equations by forward-elimination, backward-substitution.
5. Restrictions on the Complexity of the Problem - For the most part, SYN3D uses variably dimensioned arrays and disk scratch files to manage data for any size problem in the available fast core. The only serious limitation is on the product of the number of groups and the maximum number of expansion functions used at any particular axial elevation; for CDC users (with a 64K machine) this product is limited to about 50.
6. Typical Running Time - Exclusive of the time required to generate expansion functions SYN3D will solve an 11-group, 12,000 mesh point model with two expansion functions in .9 minutes (CPU). A 28-group, 30,000 mesh point model with three expansion functions requires 8.9 minutes (CPU). These times are for jobs run on an IBM 370/195. For large problems the PP time is less than the CPU time.
7. Unusual Features of the Program - The difference equations SYN3D solves are the mesh-interval-centered type. Expansion functions should be generated using diffusion theory codes solving the same equations (e.g. 2DB, CITATION, VENTURE). The code is designed with restart capabilities which reduce, on the average, the running times for individual problems when a series of similar problems is to be run. SYN3D requires input cross sections, expansion functions and geometry descriptions in the Version III formats defined by the Committee on Computer Code Coordination (CCCC). Special options include group collapsing and the use of different expansion functions in different axial zones of the model.

8. **Related and Auxiliary Programs** - SYN3D requires binary input files containing cross sections, expansion functions and geometry descriptions. Although a small program is provided with the code to read these data from cards, the user may wish to use other programs which generate CCCC files. A finite-difference, diffusion theory program is required to generate expansion functions.
9. **Status** -
10. **References** - C. H. Adams, "SYN3D - A Single-Channel, Spatial Flux Synthesis Code for Diffusion Theory Calculations", ANL 76-21, Argonne National Laboratory (1976).
11. **Machine Requirements** - The code requires at least a 35 K full-word core to execute small problems and runs more efficiently with larger storage. SYN3D does not use BULK (IBM) or LCM (CDC) storage. Depending on the complexity of the problem, SYN3D may require up to 45 logical units.
12. **Programming Language Used** - FORTRAN IV. Both IBM and CDC version of SYN3D contain a few routines written in assembler language.
13. **Operating System or Monitor under which Program is Executed** - The IBM version of SYN3D has been compiled and executed under OS-370 with the FORTRAN H Extended compiler. The CDC SYN3D has been compiled and executed at Berkeley Laboratory under the COKE System with the FORTRAN FTN4.5 compiler.
14. **Any Other Programming or Operating Information or Restrictions** -
15. **Name and Establishment of Author** -

C. H. Adams
Applied Physics Division
Argonne National Laboratory
Argonne, Illinois 60439
16. **Material Available** - Separate tapes are available for the IBM and CDC versions of SYN3D. The SYN3D package includes:

Source decks for SYN3D and auxiliary input program,
Input for sample problems,
Reference report.
17. **Category** - C

Keywords - two-dimensional, three-dimensional, diffusion equations, synthesis, x-y, r-z, x-y-z, triangular-z.

APPENDIX B. STP018 - THE ARC SYSTEM STANDARD PATH FOR SYN3D.

APPENDIX D. INPUT DATA SET SYNFIL.

```

C*****
C
C          PREPARED 09/19/74 AT ANL
C
C          SYNFIL
C          BCD INPUT FOR SYNTHESIS CALCULATIONS
C
C          THIS IS A USPR SUPPLIED BCD DATA SET.
C          THE LIST FOR EACH PECOPD IS GIVEN IN TERMS
C          OF THE BCD FORMAT OF THAT DATA CARD.
C          COLUMNS 1-2 CONTAIN THE CARD TYPE NUMBER.
C          BLANK FIELDS PRODUCE THE DEFAULT VALUES.
C
C          CARD TYPES 01 THROUGH 06 CONTAIN THE MODEL
C          GEOMETRY SPECIFICATIONS. CARD TYPES 07
C          THROUGH 21 DESCRIBE THE SYNTHESIS SCHEME.

APPENDIX D. INPUT DATA SET SYNFILE. (CONTD.)

CD	13-18	NCALC, CALCULATION OPTIONS.	-
CD		0...DO NOT SOLVE SYNTHESIS EQUATIONS, ONLY UPDATE	-
CD		INTEGRALS TO INCLUDE WHAT IS NEEDED FOR FLUX AND	-
CD		POWER EDITS AND GO TO EDITS. IF THERE ARE ANY	-
CD		CARDS OF TYPES 16 THRU 21 A COMBINING COEFFICIENT	-
CD		FILE (DCCOEF OR ACCOEF) MUST BE AVAILABLE	-
CD		(DEFAULT).	-
CD		1...UPDATE INTEGRALS AND SOLVE A DIRECT EIGENVALUE	-
CD		PROBLEM.	-
CD		2...UPDATE INTEGRALS AND SOLVE BOTH A DIRECT AND	-
CD		ADJOINT EIGENVALUE PROBLEM.	-
CD		3...UPDATE INTEGRALS AND SOLVE AN ADJOINT EIGENVALUE	-
CD		PROBLEM.	-
CD			-
CD	19-24	MAXITR, MAXIMUM NUMBER OF EIGENVALUE ITERATIONS	-
CD		ALLOWED (DEFAULT=10).	-
CD			-
CD	25-30	IBCXL, BOUNDARY CONDITION FOR THE LOWER "X" BOUNDARY	-
CD		(X=0.) OF THE THREE-DIMENSIONAL MODEL.	-
CD			-
CD	31-36	IBCXU, BOUNDARY CONDITION FOR THE UPPER "X" BOUNDARY	-
CD		OF THE THREE-DIMENSIONAL MODEL.	-
CD			-
CD	37-42	IBCYL, BOUNDARY CONDITION FOR THE LOWER "Y" BOUNDARY	-
CD		OF THE THREE-DIMENSIONAL MODEL.	-
CD			-
CD	43-48	IBCYU, BOUNDARY CONDITION FOR THE UPPER "Y" BOUNDARY	-
CD		OF THE THREE-DIMENSIONAL MODEL.	-
CD			-
CD	49-54	IRCZL, BOUNDARY CONDITION FOR THE LOWER "Z" BOUNDARY	-
CD		OF THE THREE-DIMENSIONAL MODEL.	-
CD			-
CD	55-60	IRCZU, BOUNDARY CONDITION FOR THE UPPER "Z" BOUNDARY	-
CD		OF THE THREE-DIMENSIONAL MODEL.	-
CD			-
CD		THE POSSIBLE BOUNDARY CONDITIONS ARE:	-
CD		1...ZERO FLUX.	-
CD		2...REFLECTIVE.	-
CD		3...EXTRAPOLATED ($C \cdot D \cdot \Delta \Phi + \Phi = 0$).	-
CD		THE CONSTANTS C FOR THE EXTRAPOLATED BOUNDARY	-
CD		CONDITION ARE SPECIFIED ON CARD TYPE 06.	-
CD		4...PERIODIC WITH OPPOSITE BOUNDARY.	-
CD		5...PERIODIC WITH NEXT BOUNDARY GOING IN THE ORDER	-
CD		LOWER X, UPPER Y, UPPER X, LOWER Y.	-
CD		6...PERIODIC WITH NEXT BOUNDARY GOING IN THE ORDER	-
CD		LOWER X, UPPER Y, UPPER X, LOWER Y.	-
CD		CLOCKWISE.	-
CD		7...PERIODIC, INVERTED ALONG THE SAME BOUNDARY.	-
CD			-
CD		PERIODIC CONDITIONS (CONDITIONS 4 THROUGH 7) CAN ONLY	-
CD		APPLY TO "X" AND "Y" BOUNDARIES.	-

APPENDIX D. INPUT DATA SET SYNFILE. (CONTD.)

CD 61-66 LGROUP, THE NUMBER OF ENERGY GROUPS AFTER GROUP
 CD COLLAPSING. THIS NUMBER MUST BE PROVIDED WHEN A GENERAL
 CD GROUP COLLAPSING SCHEME IS EMPLOYED (CARD TYPES 11 AND
 CD 12 PRESENT IN INPUT), OTHERWISE, MAY BE IGNORED.
 CD
 CD 67-72 IEDT, EDIT OPTIONS FOR HMG4C OVERLAY. IGNORED IN THE
 CD ARC SYSTEM SYN3D.
 CD
 CD 0...NO EDIT DESIRED.
 CD 1...NORMAL EDIT SHOWING CORE USED AND ELAPSED TIME.
 CD 2...EDIT 1 PLUS COMPLETE EDIT OF MACROSCOPIC CROSS
 CD SECTION FILE WRITTEN BY HMG4C (COMPTS).
 CD 3...EDIT 2 PLUS RUNNING EDIT OF ISOTXS (I.E. ONLY THAT
 CD DATA FROM ISOTXS WHICH IS ACTUALLY USED IS EDITED).
 CD 4...EDIT 3 PLUS BPOINTER TRACE PRINTS.
 C
 CN WHEN THERE IS NO INPUT INTTOC FILE THE "X" AND "Y"
 CN BOUNDARY CONDITIONS ARE PICKED UP FROM THE FIRST
 CN GEODST FILE ON THE TYPE 05 CARD. WHEN THERE IS AN
 CN INPUT INTTOC FILE THE OLD BOUNDARY CONDITIONS ARE
 CN ASSUMED. THE DEFAULT "Z" BOUNDARY CONDITIONS ARE
 CN ZERO CURRENT.
 C
 CN IF THE "X" AND "Y" BOUNDARY CONDITIONS ARE EXTRAPOLATED
 CN THE CODE DOES NOT PICK UP THE CONSTANTS FROM THE
 CN GEODST FILE - CARD TYPE 06 IS REQUIRED.
 C
 CN FOR TWO-DIMENSIONAL (XY OR PZ) PROBLEMS THE SECOND
 CN DIMENSION IS TREATED AS THE "Z" DIMENSION. THE
 CN SECOND DIMENSION BOUNDARY CONDITIONS GO IN COLS.
 CN 49-54 AND 55-60.
 C
 C-----

C-----

APPENDIX F. SYN3D ERROR MESSAGES. ERRORS ARE IDENTIFIED BY SUBROUTINE NAME AND ERROR NUMBER.

SUBR.	NUMBER	DESCRIPTION
BRKUP	10	THE CODE CANNOT HANDLE THE GEOMETRY TYPE SPECIFIED IN THE INPUT GEODST FILE.
BRKUP	152	AN OUTPUT GEODST FILE CANNOT BE WRITTEN.
CARDS	12	THERE IS NO INPUT SYNFI1 FILE.
CARDS	14	THERE ARE NO INPUT CARDS.
CARDS	222	THERE ARE NEITHER TYPE 4 AND 5 CARDS NOR AN INPUT GEODST FILE.
CARDS	410	AN OUTPUT SYNCON FILE CANNOT BE WRITTEN.
DECIDE	50	CODE BUG. THE OUTPUT INTEGRALS FOR A SINGLE COMBINATION ARE TOO BIG FOR THE SPECIFIED RECORD LENGTH. INCREASE LENINT.
DECIDE	52	CODE BUG.
DECIDE	130	SAME AS 50.
DECIDE	134	CODE BUG.
DECIDE	232	CODE BUG.
DIVVY	48	THERE IS NOT ENOUGH SPACE IN THE BPOINTER CONTAINER TO HOLD THE MATRICES GENERATED IN THE SOLUTION ROUTINE.
DIVVY	110	CODE BUG.
EDITS	16	NO COMBINING COEFFICIENT DATASETS EXIST.
EDITS	20	THERE IS NO INTEGRAL DATASET AVAILABLE.
EDITS	26	THERE IS NO INTPOC DATASET AVAILABLE.
EDITS	60	TO CALCULATE THE PERTURBATION DENOMINATOR BOTH ECCOEF AND ACCOEF FILES MUST BE AVAILABLE. SUCH IS NOT THE CASE.
EDITS	82	THE BPOINTER CONTAINER IS NOT LARGE ENOUGH TO HOLD ALL THE DATA REQUIRED TO CONSTRUCT AN OUTPUT FLUX INTEGRAL FILE.
EDITS	102	THE BPOINTER CONTAINER IS NOT LARGE ENOUGH TO HOLD ALL THE DATA REQUIRED TO CONSTRUCT AN OUTPUT POWER FILE.
FILLUP	40	CODE BUG. MISSING DIFINT INTEGRAL.
FILLUP	130	CODE BUG. MISSING DIFINT INTEGRAL.
FILLUP	160	CODE BUG. MISSING DIFINT INTEGRAL.
FILLUP	220	CODE BUG. MISSING VOLINT INTEGRAL.
FILLUP	260	CODE BUG. MISSING VOLINT INTEGRAL.
FILLUP	340	CODE BUG. MISSING DIFINT INTEGRAL.
FLUX3D	10	AN OUTPUT FILE CANNOT BE WRITTEN.
FLUX3D	12	THE CROSS SECTION FILE XSCHN IS NOT AVAILABLE.
FLUX3D	62	A REQUIRED EXPANSION FUNCTION FILE IS NOT AVAILABLE.
HMG4C	1	A FATAL ERROR HAS BEEN ENCOUNTERED DURING THE CROSS SECTION PROCESSING.
INPRO1	10	THERE IS A SYNFI1 CARD TYPE NUMBER GREATER THAN THE LARGEST DEFINED.

APPENDIX F. SYN3D ERROR MESSAGES. CONTINUED.

INPRO1	28	THERE ARE MORE THAN ONE TYPE 2 CARDS. ALL BUT THE FIRST ARE IGNORED.
INPRO1	34	THE BOUNDARY CONDITIONS HAVE BEEN CHANGED SINCE THE INPUT INTEGRALS WERE CALCULATED. SOME OF THE INTEGRALS MAY NO LONGER BE CORRECT.
INPRO1	44	THERE ARE MORE THAN ONE TYPE 3 SYNFILE CARDS. ALL BUT THE FIRST ARE IGNORED.
INPRO1	62	THERE IS NO TYPE 5 SYNFILE CARD. IT IS REQUIRED.
INPRO1	68	A REQUIRED GEOMETRY FILE IS MISSING.
INPRO1	72	A REQUIRED GEOMETRY FILE IS MISSING.
INPRO1	74	THE LABEL ON A GEOMETRY FILE DOES NOT MATCH THE LABEL ON THE FILE WHEN THE INPUT INTEGRALS WERE CALCULATED. IF THE GEODST FILE HAS BEEN RECONSTRUCTED ARE YOU SURE NO CHANGES HAVE BEEN MADE IN THE CONTENT.
INPRO1	76	THE LOWER X BOUNDARY CONDITION READ FROM AN INPUT GEODST FILE IS NOT ALLOWED OR, IN THE CASE OF PERIODIC CONDITIONS, IS INCONSISTENT.
INPRO1	78	THE UPPER X BOUNDARY CONDITION READ FROM AN INPUT GEODST FILE IS NOT ALLOWED OR, IN THE CASE OF PERIODIC CONDITIONS, IS INCONSISTENT.
INPRO1	80	THE LOWER Y BOUNDARY CONDITION READ FROM AN INPUT GEODST FILE IS NOT ALLOWED OR, IN THE CASE OF PERIODIC CONDITIONS, IS INCONSISTENT.
INPRO1	82	THE UPPER Y BOUNDARY CONDITION READ FROM AN INPUT GEODST FILE IS NOT ALLOWED OR, IN THE CASE OF PERIODIC CONDITIONS, IS INCONSISTENT.
INPRO1	104	THE BOUNDARY SYMBOL ON A TYPE 6 SYNFILE CARD IS UNRECOGNIZABLE.
INPRO1	108	THE GROUP NUMBERS ON A TYPE 6 SYNFILE CARD ARE EITHER OUT OF SEQUENCE OR EXCEED THE TOTAL NUMBER OF GROUPS.
INPRO1	140	THERE IS NO FUNCTION NAME ON THE FIRST SYNFILE TYPE 7 CARD.
INPRO1	148	A REQUIRED EXPANSION FUNCTION FLUX FILE IS MISSING.
INPRO1	154	A REQUIRED EXPANSION FUNCTION FLUX FILE IS MISSING.
INPRO1	160	THE LABEL ON A FLUX FILE DOES NOT MATCH THE LABEL ON THE FILE WHEN THE INPUT INTEGRALS WERE CALCULATED. IF THE RTFLUX FILE HAS BEEN RECONSTRUCTED ARE YOU SURE NO CHANGES HAVE BEEN MADE IN THE CONTENT.
INPRO1	182	THERE IS NO FUNCTION NAME ON THE FIRST SYNFILE TYPE 8 CARD.
INPRO1	188	A REQUIRED WEIGHTING FUNCTION FLUX FILE IS MISSING.
INPRO1	194	A REQUIRED WEIGHTING FUNCTION FLUX FILE IS MISSING.
INPRO1	200	THE LABEL ON A FLUX FILE DOES NOT MATCH THE LABEL ON THE FILE WHEN THE INPUT INTEGRALS WERE CALCULATED. IF THE RTFLUX FILE HAS BEEN RECONSTRUCTED ARE YOU SURE NO CHANGES HAVE BEEN MADE IN THE CONTENT.

APPENDIX P. SYM3D ERROR MESSAGES. CONTINUED.

INPRO1	243	PLANAR GEOMETRY FILPS HAVE NOT BEEN DEFINED FOR ALL AXIAL MESH INTERVALS.
INPRO1	256	WHEN THERE ARE INPUT INTEGRALS THE OLD GROUP COLLAPSING SCHEME IS AUTOMATICALLY USED. SYM3D MUST CONTAIN NO CARDS OF TYPE 9-12.
INPRO1	262	WHEN THERE ARE NO TYPE 9 CARDS THERE CANNOT BE ANY TYPE 10 CARDS.
INPRO1	278	THE GROUP NUMBERS ON A TYPE 9 CARD ARE EITHER OUT OF SEQUENCE OR EXCEED THE TOTAL NUMBER OF GROUPS.
INPRO1	294	SAME AS 278, BUT FOR A TYPE 10 CARD.
INPRO1	298	THE NUMBER OF COLLAPSED GROUPS IS DIFFERENT FOR EXPANSION AND WEIGHTING FUNCTIONS.
INPRO1	302	MORE THAN ONE TYPE OF GROUP COLLAPSING IS SPECIFIED. IT CAN BE SPECIAL OR GENERAL, BUT NOT BOTH.
INPRO1	308	A TYPE 2 CARD MUST BE PROVIDED WITH THE PARAMETER 1 GROUP SPECIFIED.
INPRO1	312	THERE IS A WRONG AMOUNT OF DATA ON A TYPE 11 CARD.
INPRO1	328	GENERAL GROUP COLLAPSING IS SPECIFIED FOR THE WEIGHTING FUNCTIONS BUT NOT FOR THE EXPANSION FUNCTIONS.
INPRO1	334	THERE IS A WRONG AMOUNT OF DATA ON A TYPE 12 CARD.
INPRO1	346	THE FUNCTION NAME ON A SYM3D TYPE 13 CARD DOES NOT MATCH ANY FUNCTION SPECIFIED ON CARD TYPES 7 AND 8.
INPRO1	354	THE GROUP NUMBERS ON A TYPE 13 CARD ARE ENTERED INCORRECTLY.
INPRO1	392	THERE ARE INPUT INTEGRALS, AND SCALING IS SPECIFIED ON TYPE 14 AND/OR 15 CARDS. MAKE SURE THE SCALING IS THE SAME AS WHEN THE INPUT INTEGRALS WERE CALCULATED.
INPRO1	384	THE FUNCTION NAME ON A TYPE 14 OR 15 CARD DOES NOT MATCH ANY FUNCTIONS SPECIFIED ON CARD TYPES 7 AND 8.
INPRO1	388	SCALING IS SPECIFIED FOR FUNCTIONS ASSOCIATED WITH THE INPUT INTEGRALS. THE ORIGINAL SCALING FACTORS WILL BE USED IF MORE INTEGRALS ARE DONE.
INPRO1	392	A GROUP NUMBER IS OUT OF RANGE ON A TYPE 14 OR 15 CARD.
INPRO1	610	THE SCATTERING BANDWIDTH HAS CHANGED SINCE THE INPUT INTEGRALS WERE CALCULATED. THEY CANNOT BE USED.
INPRO4	62	A REQUIRED FLUX FILE IS NOT AVAILABLE.
INPRO4	64	A REQUIRED GEOMETRY FILE IS NOT AVAILABLE.
INPRO4	90	THERE IS NOT ENOUGH CONTAINER STORAGE TO HOLD AN INPUT FLUX FILE.

APPENDIX F. SYM3D ERROR MESSAGES. CONTINUED.

INTEG	12	THERE IS NEITHER AN INPUT INTCC DATASET NOR A SYNFIL DATASET.
INTEG	14	THERE IS NO MACROSCOPIC CROSS SECTION DATASET.
INTEG	34	THE INITIAL STORAGE ALLOCATIONS ASSIGNED BY THE CODE TO SEVERAL ARRAYS ARE FAR TOO SMALL. THIS IS UNUSUAL. CHECK YOUR INPUT.
INTPG	116	NOT ENOUGH STORAGE IS AVAILABLE TO DO THE INTEGRATION.
INVERT	10100	A MATRIX IS SINGULAR. POSSIBLE LINEAR DEPENDENCE PROBLEM.
INT1	110	THE CODE CANNOT YET HANDLE THIS PARTICULAR GEOMETRY TYPE.
INT1	142	CODE BUG.
INT1	148	CODE BUG.
INT1	180	CODE BUG.
INT2	21	CODE BUG.
INT2	24	CODE BUG.
INT2	30	CODE BUG.
INT21	1	THE CODE CANNOT YET HANDLE THIS PARTICULAR GEOMETRY TYPE.
INT21	14	CODE BUG. THERE ARE MISSING COMPOSITIONS IN THE MATERIAL MAP.
INT21	40	SAME AS 14.
INT21	90	SAME AS 14.
INT21	106	SAME AS 14.
INT21	132	SAME AS 14.
INT21	148	SAME AS 14.
INT21	166	SAME AS 14.
INT21	180	SAME AS 14.
INT21	198	SAME AS 14.
INT3	110	THE CODE CANNOT YET HANDLE THIS PARTICULAR GEOMETRY TYPE.
INT3	142	CODE BUG.
INT3	148	CODE BUG.
INT3	180	CODE BUG.
INT3	194	CODE BUG.
INT4	14	CODE BUG.
INT4	104	CODE BUG.
ORTH	110	NO FUNCTIONS HAVE BEEN SPECIFIED FOR ONE OF THE ENERGY GROUPS AT SOME MESH POINT.
OUTPRO	10	A COMBINING COEFFICIENT FILE (ACCOFF OR DCCOFF) CANNOT BE WRITTEN.
PDENOM	64	A REQUIRED INTEGRAL IS NOT AVAILABLE.
READCD	34	THE CARDS-PER-CARD-TYPE DATA IS WRONG.
REDPD	16	A DIRECT COMBINING COEFFICIENT PLOT IS REQUESTED FOR A GROUP NUMBER LARGER THAN THE TOTAL NUMBER OF GROUPS (AFTER COLLAPSING).
REDSD	26	AN ADJOINT COMBINING COEFFICIENT PLOT IS REQUESTED FOR A GROUP NUMBER LARGER THAN THE TOTAL NUMBER OF GROUPS (AFTER COLLAPSING).
REPWRIT	9	THE REOPFX FILE CANNOT BE WRITTEN.
REPWRIT	224	CODE BUG.
REPWRIT	222	CODE BUG. LENXST, THE RECORD LENGTH FOR REPXST, IS TOO SMALL.
REPWRIT	110	THE REPXST FILE CANNOT BE WRITTEN.

APPENDIX F. SYN3D ERROR MESSAGES. CONTINUED.

RITGEO	10	A REQUIRED, INPUT GEODST FILE CANNOT BE FOUND.
RITGEO	40	THE CODE CANNOT HANDLE THE GEOMETRY TYPE SPECIFIED IN AN INPUT GEODST FILE.
RITGEO	96	SAME AS 10.
RITGEO	100	TWO INPUT GEODST FILES ARE INCOMPATIBLE.
RITGEO	102	THE OUTPUT GEODST FILE CANNOT BE WRITTEN.
SETUP	10	THE VOLINT,2 FILE CANNOT BE WRITTEN.
SPINTP	14	THE DIPINT,2 FILE CANNOT BE WRITTEN.
SPINTP	20	THE VOLINT,1 FILE CANNOT BE FOUND.
SETUP	30	THE DIPINT,1 FILE CANNOT BE FOUND.
SHUFFL	26	CODE BUG.
SHUFFL	56	CODE BUG.
SHUFFL	114	CODE BUG.
SHUFFL	126	CODE BUG.
SOLVE	10	THE INTTOC,2 FILE CANNOT BE READ.
SOLVE	66	CODE BUG. IDIV.NP.1 AFTER DIVVY.
SOLVE	72	THE INTGLS FILE CANNOT BE WRITTEN.
SOLVE	74	THE VOLINT,2 FILE CANNOT BE READ.
SOLVE	76	THE DIPINT,2 FILE CANNOT BE READ.
SOLVE	86	THE HFILE FILE CANNOT BE WRITTEN.
TRANSI	1	A GEODST FILE CANNOT BE WRITTEN.
TRFLUX	1	AN RTFLUX FILE CANNOT BE WRITTEN.
TRGEO1	14	THE TRANSLATOR CANNOT YET HANDLE THIS TYPE OF GEOMETRY.
TRGEO1	60	THE TRANSLATOR CANNOT HANDLE THE PLANAR BOUNDARY CONDITIONS.
TRGEO1	70	SAME AS 60.
TRXSCH	12	THE XS.C.MIN FILE CANNOT BE FOUND.
WINTGL	18	CODE BUG.
WINTGL	110	CODE BUG. MULTICHANNEL SYNTHESIS NOT AVAILABLE.
WINTGL	126	NO FUNCTIONS HAVE BEEN SPECIFIED FOR ONE OF THE ENERGY GROUPS AT SOME MESH POINT.
WPTXS	20	THERE IS SOMETHING WRONG WITH THE XSCHN DATASET. THE CODE EXPECTED TO FIND THE GROUP NUMBER IN THE RECORD BEING READ.

APPENDIX G. FORTRAN VARIABLE GLOSSARY.

$((A(I,K), I=1, KDIM(IZ)), K=1, KMAX)$ = IN OVERLAY SOLVE, EITHER THE DIRECT OR ADJOINT COMBINING COEFFICIENTS. IZ IS THE SYNTHESIS ZONE ASSOCIATED WITH MESH INTERVAL K.
 $((ACCOEF(I,K), I=1, KDIM(IZ)), K=1, KMAX)$ = ADJOINT COMBINING COEFFICIENTS. IZ IS THE SYNTHESIS ZONE ASSOCIATED WITH MESH INTERVAL K.
 $((AMINUS(I,J), I=1, KDIM(IZ)), J=1, KDIM(IZM))$ = THE SUBBLOCK (FOR THE CURRENT AXIAL MESH INTERVAL) BELOW THE DIAGONAL OF THE BLOCK-TRIDIAGONAL SYSTEM OF SYNTHESIS EQUATIONS. IZ IS THE SYNTHESIS ZONE ASSOCIATED WITH THE CURRENT MESH INTERVAL. IZM IS THE SYNTHESIS ZONE ASSOCIATED WITH THE PREVIOUS AXIAL MESH INTERVAL.
 $((APLUS(I,J), I=1, KDIM(IZ)), J=1, KDIM(IZP))$ = THE SUBBLOCK (FOR THE CURRENT AXIAL MESH INTERVAL) ABOVE THE DIAGONAL OF THE BLOCK-TRIDIAGONAL SYSTEM OF SYNTHESIS EQUATIONS. IZ IS THE SYNTHESIS ZONE ASSOCIATED WITH THE CURRENT MESH INTERVAL. IZP IS THE SYNTHESIS ZONE ASSOCIATED WITH THE NEXT AXIAL MESH INTERVAL.
 $(ARRAY(I), I=1, 36)$ = THE LIST OF NAMES OF DIMENSIONED VARIABLES DEFINED THROUGH BPOINTER.
 $((AZERO(I,J), I=1, KDIM(IZ)), J=1, KDIM(IZ))$ = THE SUBBLOCK (FOR THE CURRENT AXIAL MESH INTERVAL) ON THE DIAGONAL OF THE BLOCK-TRIDIAGONAL SYSTEM OF SYNTHESIS EQUATIONS. IZ IS THE SYNTHESIS ZONE ASSOCIATED WITH THE CURRENT MESH INTERVAL.
 $(BLK(I), I=1, MAXSZ)$ = THE BPOINTER CONTAINER.
 $((CARD(I,J), I=1, 11), J=1, NREC)$ = THE CONTENTS OF EACH INPUT CARD, EXCLUDING THE CARD TYPE NUMBER. NREC = THE NUMBER OF DATA CARDS.
 $((C1C(I,J,K), I=1, NGROUP), J=1, 6), K=1, 2)$ = THE BOUNDARY CONDITION CONSTANTS C1 AND C2 FOR EACH GROUP AND EACH OF THE 6 BOUNDARY PLANES.
CONVGR = EIGENVALUE CONVERGENCE CRITERION.
 $((DCOEF(I,K), I=1, KDIM(IZ)), K=1, KMAX)$ = DIRECT COMBINING COEFFICIENTS. IZ IS THE SYNTHESIS ZONE ASSOCIATED WITH MESH INTERVAL K.
 $(DLZCAT(I), I=1, LNMZ)$ = RATIO OF 2 ADJACENT AXIAL MESH INTERVALS. (LOWER/UPPER)
EIGEN = EIGENVALUE
EPS = A SMALL NUMBER USED IN TESTS FOR EQUALITY OF MESH INTERVALS.
 $((ESCAL(I,J), I=1, NGROUP), J=1, MAXFUN)$ = A USER SUPPLIED SCALING FACTOR FOR EACH GROUP OF FUNCTION J WHEN FUNCTION I IS USED AS A EXPANSION FUNCTION. IT CAN ONLY HAVE AN EFFECT WHEN GROUP COLLAPSING IS EMPLOYED.
 $((FIS(I,J), I=1, KDIM(IZ)), J=1, KDIM(IZ))$ = THE SUBBLOCK (FOR THE CURRENT AXIAL MESH INTERVAL) CONTAINING THE INTEGRALS OVER THE FISSION CROSS SECTIONS. IZ IS THE SYNTHESIS ZONE ASSOCIATED WITH THE CURRENT AXIAL MESH INTERVAL.
 $(FLUX(I), I=1, MAXFUN*NGROUP)$ = AN ARRAY CONTAINING FUNCTION INTEGRALS. THE INTEGRALS ARE STORED IN THE SAME WAY AS THE COMBINING COEFFICIENTS, WITH PLANKS OMITTED. POINTERS TO THE FIRST NONZERO GROUP ARE GIVEN IN THE ARRAY IPLTOC.

APPENDIX G. FORTRAN VARIABLE GLOSSARY. (CONTD.)

(FLUX1(I), I=1, LENFLX) = THE ARRAY INTO WHICH A RECORD OF REQFLX IS READ. FLUX2 AND FLUX3 SERVE THE SAME PURPOSE.
 ((PUNNAM(I,J), I=1,3), IVPUN(J)), J=1, MAXPUN) = FULL NAME OF FILE FOR FUNCTION J.
 GUESS = EIGENVALUE ESTIMATE.
 ((H(I,J), I=1, KDIM(IZ)), J=1, KDIM(IZP)) = THE MATRIX FORMED DURING THE FORWARD ELIMINATION OF THE SYNTHESIS EQUATIONS FOR THE CURRENT MESH INTERVAL. IZ IS THE SYNTHESIS ZONE ASSOCIATED WITH THE CURRENT AXIAL MESH INTERVAL, IZP IS THE ZONE FOR THE NEXT INTERVAL.
 IBAND = THE NUMBER OF COLUMNS OF FLUXES IN ONE RECORD OF THE REQFLX FILE.
 IBCXL = THE LOWER X BOUNDARY CONDITION.
     1 = ZERO FLUX
     2 = REFLECTIVE
     3 = EXTRAPOLATED $C \cdot D \cdot \Delta \Phi + \Phi = 0$
     4 = PERIODIC WITH OPPOSITE BOUNDARY
     5 = PERIODIC WITH NEXT BOUNDARY GOING CLOCKWISE
     6 = PERIODIC WITH NEXT BOUNDARY GOING COUNTERCLOCKWISE
     7 = PERIODIC, INVERTED ALONG SAME BOUNDARY.
 IBCXU = THE UPPER X BOUNDARY CONDITION.
 IBCYL = THE LOWER Y BOUNDARY CONDITION.
 IBCYU = THE UPPER Y BOUNDARY CONDITION.
 IBCZL = THE LOWER Z BOUNDARY CONDITION.
 IBCZU = THE UPPER Z BOUNDARY CONDITION.
 IBNDCH = LOWEST ENERGY GROUP (AFTER GROUP COLLAPSING) FOR WHICH THERE IS A NONZERO CHI.
 (IBNDPI(I), I=1, MAXPIN) = LOWEST ENERGY GROUP (AFTER GROUP COLLAPSING) FOR WHICH THERE IS A NONZERO FISSION CROSS SECTION FOR PLANE I. A ZERO MEANS NO FISSION.
 (IBNDS1(I), I=1, LGROUP) = THE POSITION IN COLUMN I OF THE GROUP COLLAPSED SCATTERING MATRIX OF THE TOPMOST, NONZERO ELEMENT. EQUIVALENT TO LCCSCT WHEN THERE IS NO GROUP COLLAPSING.
 (IBNDS2(I), I=1, LGROUP) = THE POSITION IN COLUMN I OF THE GROUP COLLAPSED SCATTERING MATRIX OF THE BOTTOM, NONZERO ELEMENT.
 ((IDIFTR(I,K), I=1,8), K=1, IDIFTB) = TABLE OF CONTENTS FOR DIF INTEGRALS IN DIFINT FILE.
     IDIFTR(1,K) = RECORD OF THE DIFINT FILE CONTAINING THE INTEGRALS.
     IDIFTR(2,K) = POINTER TO THE FIRST WORD OF THE INTEGRAL BLOCK WITHIN THAT RECORD.
     IDIFTR(3,K) = LOWER PLANAR GEOMETRY IDENTIFIER.
         =0 FOR THE BOTTOM BOUNDARY INTEGRAL.
     IDIFTR(4,K) = UPPER PLANAR GEOMETRY IDENTIFIER.
         =0 FOR THE TOP BOUNDARY INTEGRAL.
     IDIFTR(5,K) = POINTER TO A MESH INTERVAL RATIO IN THE OLZRAT ARRAY.
     IDIFTR(6,K) = WEIGHTING FUNCTION IDENTIFIER.
     IDIFTR(7,K) = EXPANSION FUNCTION IDENTIFIER.
     IDIFTR(8,K) = NUMBER OF RECORDS REQUIRED FOR ALL THE INTEGRALS OF THIS COMBINATION.

APPENDIX G. FORTRAN VARIABLE GLOSSARY. (CONTD.)

(IDIM(I), I=1, MAXFUN) = THE NUMBER OF COMBINING COEFFICIENTS (OR EQUATIONS) ASSOCIATED WITH AN EXPANSION FUNCTION (OR WEIGHTING FUNCTION).

((IPL(J,I), J=1, MAXKNM), I=1, NUMKZN) = THE EXPANSION FUNCTIONS USED IN ZONE I. IF THERE ARE FEWER THAN MAXKNM, THE OTHER ENTRIES FOR A PARTICULAR ZONE ARE ZERO.

(IFLTOC(I), I=1, MAXFUN) = POINTERS TO THE FIRST GROUP FLUX INTEGRAL FOR FUNCTION I IN THE ARRAY FLUX. A ZERO MEANS THAT THERE ARE NO INTEGRALS FOR A FUNCTION.

IGEOM = PLANAR GEOMETRY TYPE SENTINEL.

((IGPUSE(N,J), N=1, LGROUP), J=1, MAXFUN) = A PROJECTION MATRIX (ELEMENTS ARE 0 OR 1) SHOWING WHICH GROUP FLUXES OF EACH FUNCTION ARE TO BE USED (1) OR OMITTED (0).

IMAX = THE NUMBER OF MESH INTERVALS IN THE X DIRECTION.

(INTGLS(I), I=1, NCONRC*MAXINT) = STORAGE USED FOR RECORDS OF THE INTGLS FILE. DURING THE SOLUTION NCONRC=1.

(IPLACC(I), I=1, NPLACC) = THE GROUP FOR WHICH THE ADJOINT COMBINING COEFFICIENTS ARE TO BE PLOTTED.

(IPLDCC(I), I=1, NPLDCC) = THE GROUP FOR WHICH THE DIRECT COMBINING COEFFICIENTS ARE TO BE PLOTTED.

((IPRATF(I,J), I=1,2), J=1, NPRATF) = GROUP NUMBERS (I=1) AND AXIAL MESH INTERVALS (I=2) FOR WHICH THE PLANAR ADJOINT IS TO BE EDITED. FOR TWO DIMENSIONAL MODELS J=1 WILL EDIT ALL FLUXES.

IPRINT = BPOINTER BEING EDIT SENTINEL.

(IPRPWD(I), I=1, NPRPWD) = AXIAL MESH INTERVALS FOR WHICH THE PLANAR POWER IS TO BE EDITED. FOR TWO DIMENSIONAL MODELS I=1 WILL EDIT ALL POWERS.

((IPRRTF(I,J), I=1,2), J=1, NPRRTF) = GROUP NUMBERS (I=1) AND AXIAL MESH INTERVALS (I=2) FOR WHICH THE PLANAR FLUX IS TO BE EDITED. FOR TWO DIMENSIONAL MODELS J=1 WILL EDIT ALL FLUXES.

((IPT(I,J), I=1, LGROUP), J=1,2) = THE NUMBER OF ROWS OF THE REM MATRIX STORED IN THE OUTPUT INTEGRAL FILE FOR THE COLUMNS ASSOCIATED WITH COLLAPSED GROUP I. IT IS THE SUM OF THE NUMBERS OF CHANNELS ASSOCIATED WITH EACH COLLAPSED GROUP BETWEEN IBNDS1(I) AND IBNDS2(I). J=1 OR 2 DEPENDING ON WHETHER THE WEIGHTING/EXPANSION FLUX COMBINATION BEING CONSIDERED IS IN THE PROPER ORDER FOR THE OUTPUT INTEGRAL DESIRED OR IS TRANSPOSED.

((IPTOC(I,J), I=1, MAXFUN), J=1, MAXPLN) = POINTERS TO THE FIRST GROUP POWER INTEGRAL FOR FUNCTION I AND PLANE J IN THE ARRAY POW. A ZERO MEANS THAT THERE ARE NO INTEGRALS.

IRCDIP = DIPINT FILE RECORD COUNTER.

IRCIINT = INTGLS FILE RECORD COUNTER.

IRCIITC = INTTOC FILE RECORD COUNTER.

IRCVOL = VOLINT FILE RECORD COUNTER.

ISCHI = SET-WIDE PROMPT CH SENTINEL FROM XSCHIN FILE.

APPENDIX G. FORTRAN VARIABLE GLOSSARY. (CONTD.)

((IVOLTB(I,K),I=1,7),K=1,IVOLTB) = TABLE OF CONTENTS FOR REM AND FIS INTEGRALS IN THE VOLINT FILE.

IVOLTB(1,K) = 1 FOR A REM INTEGRAL, 2 FOR A FIS INTEGRAL, 3 FOR A POW INTEGRAL, 4 FOR A FLUX INTEGRAL.

IVOLTB(2,K) = THE RECORD OF THE VOLINT FILE CONTAINING THE INTEGRAL. =0 IF THE INTEGRAL COULD NOT BE DONE AND -1 IF THE INTEGRAL COULD HAVE BEEN DONE BUT FOR SOME REASON WAS NOT.

IVOLTB(3,K) = POINTER TO THE FIRST WORD OF THE INTEGRAL BLOCK WITHIN THAT RECORD.

IVOLTB(4,K) = PLANAR GEOMETRY IDENTIFIER.

IVOLTB(5,K) = WEIGHTING FUNCTION IDENTIFIER.

IVOLTB(6,K) = EXPANSION FUNCTION IDENTIFIER.

IVOLTB(7,K) = NUMBER OF RECORDS REQUIRED FOR ALL THE INTEGRALS OF THIS COMBINATION.

(IVRPUN(J),J=1,MAXFUN) = VERSION NUMBER OF FILE FOR FUNCTION J. SEE FUNNAM.

(IVRPLN(J),J=1,MAXPLN) = VERSION NUMBER OF FILE FOR PLANAR GEOMETRY J. SEE PLNNAM.

INHERE = 1 IF THE INPUT DATA IS TO BE READ DIRECTLY FROM CARDS.
= 2 IF THE CARD INPUT IS TO BE PROCESSED THRU THE ARC SYSTEM ROUTINES.

((IWT(J,I),J=1,MAXKNM),I=1,NUMKZN) = THE WEIGHTING FUNCTIONS USED IN ZONE I. IF THERE ARE FEWER THAN MAXKNM, THE OTHER ENTRIES FOR A PARTICULAR ZONE ARE ZERO.

(IWRARP(I),I=1,50) = THE WORD LENGTH PARAMETER FOR EACH DIMENSIONED VARIABLE DEFINED THROUGH BCOTNTR. THIS ARRAY IS OF DIFFERENT LENGTH IN EACH OVERLAY.

JBAND = THE NUMBER OF ROWS OF FLUXES IN ONE RECORD OF THE REQFLX FILE.

(JDIETB(I,K),I=1,7),K=1,JDIETB) = TABLE OF CONTENTS FOR DIP INTEGRALS IN THE INTCLS FILE. THE DEFINITIONS ARE THE SAME AS FOR IDIETB, EXCEPT THAT THE LAST ENTRY IS OMITTED.

(JDOCMP(I),I=1,NUMCMF) = THE LIST OF COMPOSITIONS REQUIRED TO CALCULATE THE INTEGRALS.

(JDOPFN(I),I=1,NUMFUN) = THE LIST OF FUNCTIONS REQUIRED TO CALCULATE THE INTEGRALS, IN THE ORDER IN WHICH THEY APPEAR IN THE PREFIX FILE. WHEN IT IS PRESENT, THE UNIT FUNCTION IS LAST IN THE LIST.

(JDOPLN(I),I=1,NUMPLN) = THE LIST OF PLANAR GEOMETRIES REQUIRED TO CALCULATE THE INTEGRALS.

JMAX = THE NUMBER OF MESH INTERVALS IN THE Y DIRECTION.

((JPT(I,J,K),I=1,IRNDCH),K=1,MAXPLN),J=1,2) = A POINTER IN A COLUMN OF THE GROUP COLLAPSED FIS INTEGRAL FOR PLANE K TO THE FIRST ELEMENT ASSOCIATED WITH WEIGHTING FUNCTION GROUP I. THE DIFFERENCE BETWEEN JPT(I,J,K) AND JPT(I+1,J,K) IS THE NUMBER OF CHANNELS ASSOCIATED WITH GROUP I OF THE WEIGHTING FUNCTION. J=1 OR 2 DEPENDING ON WHETHER THE WEIGHTING/EXPANSION FLUX COMBINATION BEING CONSIDERED IS IN THE PROPER ORDER FOR THE OUTPUT INTEGRAL DESIRED OR IS TRANSPOSED.

APPENDIX G. PORTMAN VARIABLE GLOSSARY. (CONTD.)

(JVOLT(I,K), I=1,6), K=1,4 VOLT(I)) = TABLE OF CONTENTS FOR REM & PIS INTEGRALS IN THE INTGLS FILE. THE DEFINITIONS ARE THE SAME AS FOR IVOLT(I), EXCEPT THAT THE LAST ENTRY IS OMITTED.

(KCHANG(I), I=1, NUMKZN) = THE TOPMOST MESH INTERVAL IN EACH ZONE. KCHANG(NUMKZN) = KMAX.

(KOTH(I), I=1, NUMKZN) = THE NUMBER OF UNKNOWN COEFFICIENTS (AND THEREFORE EQUATIONS) ASSOCIATED WITH ONE MESH INTERVAL IN ZONE I.

(KGEOM(I), I=1, NUMKZN) = THE GEOMETRY FOR MESH INTERVALS KCHANG(I-1) TO KCHANG(I). KCHANG(0) IS DEFINED TO BE 1. KMAX = NUMBER OF AXIAL MESH INTERVALS.

(KNUMPI(I), I=1, NUMKZN) = THE NUMBER OF FLUX FILES REFERENCED AS EXPANSION FUNCTIONS FOR ZONE I.

(KNUMWT(I), I=1, NUMKZN) = THE NUMBER OF FLUX FILES REFERENCED AS WEIGHTING FUNCTIONS FOR ZONE I.

((KPT(I,J,K), I=1, LGROUP), J=1, LGROUP), K=1,2) = A POINTER IN THE 1D ARRAY CONTAINING THE 2D, GROUP-COLLAPSED REM INTEGRAL TO THE FIRST STORED ELEMENT OF THE INTEGRALS ASSOCIATED WITH WEIGHTING FUNCTION GROUP I AND EXPANSION FUNCTION GROUP J. THE DIFFERENCE BETWEEN KPT(I,J,K) AND KPT(I+1,J,K) IS THE NUMBER OF CHANNELS FOR WEIGHTING FUNCTION GROUP I. K=1 OR 2 DEPENDING ON WHETHER THE WEIGHTING/EXPANSION FLUX COMBINATION BEING CONSIDERED IS IN THE PROPER ORDER FOR THE OUTPUT INTEGRAL DESIRED OR IS TRANSPOSED.

IDIFTB = NUMBER OF ENTRIES IN THE IDIFTB TABLE.

LENA = THE STORAGE REQUIRED FOR THE COMPUTING COEFFICIENTS.

(LENAPP(I), I=1, 50) = THE LENGTH OF EACH DIMENSIONED VARIABLE DEFINED THROUGH BPOINTER. THIS ARRAY IS OF DIFFERENT LENGTH IN EACH OVERLAY.

(LENCRD(I), I=1, NREC) = THE LENGTH (IN R*4 WORDS) OF EACH DATA RECORD OF SYNCON. NREC = THE NUMBER OF DATA RECORDS.

(LENDIP(I), I=1, NRC DIP) = LENGTH OF RECORD I OF DIPINT FILE.

LENDIZ = LENGTH OF DIZRAT ARRAY.

LENFLX = RECORD SIZE FOR REOFLX.

LENFL = LENGTH OF THE ARRAY FLUX IN OVERLAY SOLVE.

LENH = MAXIMUM RECORD SIZE FOR THE HFILE FILE.

LENINT = THE MAXIMUM RECORD LENGTH FOR VOLINT AND DIPINT INTEGRAL FILES.

LENIST = THE MAXIMUM LENGTH OF THE LIST OF INTEGRALS, LISTV.

LENOV = LENGTH OF THE ARRAY POI IN OVERLAY SOLVE.

(LENRCH(I), I=1, NRCH) = THE LENGTH OF EACH RECORD OF THE HFILE FILE.

(LENRCI(I), I=1, NRCINT) = THE LENGTH OF EACH RECORD OF THE INTGLS FILE.

(LENVOL(I), I=1, NRCVOL) = LENGTH OF RECORD I OF THE VOLINT FILE.

LENYST = RECORD SIZE FOR CROSS SECTION FILE REOYST.

LEN1 = IRAND*JBAND = THE MAXIMUM NUMBER OF MESH BLOCKS REPRESENTED IN EACH RECORD OF REOFLX.

LEN2 = LEN1*NRGROUP

LEN3 = LVST1.

LGROUP = NUMBER OF ENERGY GROUPS AFTER COLLAPSING.

(LISTV(I), I=1, LENIST) = A LIST OF ENTRIES IN VOLT(I) AND/OR IDIFTB DESIGNATING INTEGRALS TO BE DONE AND THE ORDER IN WHICH THEY ARE TO BE DONE. THE IVOLT(I) ENTRIES ARE LISTED FIRST, THEN THE IDIFTB ENTRIES. ALSO SEE NTRYV AND NTRYD.

APPENDIX G. FORTRAN VARIABLE GLOSSARY. (CONTD.)

(LOCSC(I), I=1, NGROUP) = THE POSITION IN COLUMN I OF THE SCATTERING MATRIX OF THE TOPMOST, NONZERO ELEMENT. EQUIVALENT TO IBNDS1 WHEN THERE IS NO GROUP COLLAPSING.

((LPT(I,J,K), J=1, LGROUP), K=1, MAXPLN), J=1, 2) = A POINTER IN THE 1D ARRAY CONTAINING THE 2D, GROUP-COLLAPSED PIS INTEGRAL FOR PLANE K TO THE TOP OF THE FIRST COLUMN ASSOCIATED WITH EXPANSION FUNCTION GROUP I. THE DIFFERENCE BETWEEN LPT(I,J,K) AND LPT(I+1,J,K) IS MPT(J,K) TIMES THE NUMBER OF CHANNELS ASSOCIATED WITH GROUP I OF THE EXPANSION FUNCTION. J=1 OR 2 DEPENDING ON WHETHER THE WEIGHTING/EXPANSION FLUX COMBINATION BEING CONSIDERED IS IN THE PROPER ORDER FOR THE OUTPUT INTEGRAL DESIRED OR IS TRANSPOSED.

REQP = NUMBER OF RECORDS IN THE REQFLX FILE.

REQX1 = NUMBER OF RECORD OF THE REQXST FILE EXCLUDING DIFFUSION COEFFICIENTS.

REQX2 = NUMBER OF RECORDS OF THE REQXST FILE CONTAINING ONLY DIFFUSION COEFFICIENTS.

IVOLT = NUMBER OF ENTRIES IN THE IVOLTB TABLE.

LXST1 = THE NUMBER OF CROSS SECTION DATA PER COMPOSITION, FOR RECORDS OF REQXST EXCLUDING DIFFUSION COEFFICIENTS.

LXST2 = THE NUMBER OF COMPOSITIONS PER RECORD OF REQXST, FOR RECORDS EXCLUDING DIFFUSION COEFFICIENTS.

LXST3 = THE NUMBER OF GROUPS PER RECORD FOR RECORDS CONTAINING ONLY DIFFUSION COEFFICIENTS.

MAXCHN = THE MAXIMUM NUMBER OF CHANNELS IN ANY CHANNEL STRUCTURE SCHEME. = THE LARGEST VALUE OF NUNCHN(I), I=1, NCHNST.

MAXCMP = THE NUMBER OF MATERIALS REPRESENTED IN THE INPUT CROSS SECTION FILE.

MAXDIM = THE LARGEST DIMENSION OF ANY MATRIX USED IN THE SOLUTION.

MAXDN = MAXIMUM NUMBER OF DOWNSCATTERING GROUPS.

MAXFUN = NUMBER OF FUNCTION FILE NAMES IN TOC.

MAXINT = THE MAXIMUM RECORD LENGTH FOR THE INTGLS INTEGRAL FILE.

MAXITER = MAXIMUM NUMBER OF ITERATIONS ALLOWED.

MAXKNN = THE MAXIMUM NUMBER OF WEIGHTING FUNCTIONS USED IN A SINGLE ZONE, OR THE MAXIMUM NUMBER OF EXPANSION FUNCTIONS, WHICHEVER IS LARGER. MAXKNN.LE.MAXUSE.

MAXND = THE LARGEST DIMENSION OF AN INPUT MATRIX (THE LARGEST NUMBER OF GROUP-CHANNEL COMBINATIONS FOR A SINGLE FUNCTION). MAXND**2 IS THE MINIMUM SPACE REQUIRED FOR A RECORD OF DEWRITTEN INTEGRALS.

MAXPLN = NUMBER OF PLANAR GEOMETRY FILE NAMES IN TOC.

MAXREG = THE MAXIMUM NUMBER OF REGIONS ASSOCIATED WITH ANY OF THE PLANAR GEOMETRIES.

MAXSZ = THE LENGTH OF THE RPOINTER CONTAINER ARRAY.

MAXTIT = MAXIMUM ALLOWED NUMBER OF INPUT TITLE CARDS.

MAXUP = MAXIMUM NUMBER OF UPSCATTERING GROUPS.

MAXUSE = MAXIMUM NUMBER OF INPUT FUNCTIONS USED ANYWHERE IN THE MODEL AS EXPANSION FUNCTIONS OR WEIGHTING FUNCTIONS, WHICHEVER IS LARGER. MAXUSE.LE.MAXFUN.

NDIET = NUMBER OF ENTRIES IN THE JDIETB TABLE.

(MPT(I), I=1, MAXFUN) = THE NUMBER OF COMBINING COEFFICIENTS (OR EQUATIONS) ASSOCIATED WITH FUNCTION I.

APPENDIX G. FORTRAN VARIABLE GLOSSARY. (CONTD.)

((MPT(I,J),I=1,MAXPLN),J=1,2) = THE NUMBER OF ROWS IN THE GROUP COLLAPSED FIS INTEGRAL FOR PLANE I. IT IS THE SUM OF THE NUMBER OF CHANNELS ASSOCIATED WITH EACH COLLAPSED GROUP DOWN TO THE LAST NONZERO CHI. I=1 OR 2 DEPENDING ON WHETHER THE WEIGHTING/EXPANSION FLUX COMBINATION BEING CONSIDERED IS IN THE PROPER ORDER FOR THE OUTPUT INTEGRAL DESIRED OR IS TRANSPOSED.

MMULT = THE WORD LENGTH PARAMETER FOR INPUT/OUTPUT.

MMOLTS = NUMBER OF ENTRIES IN THE JVOLTB TABLE.

MBUFFER = 0 FOR NO BUFFERING, 1 FOR BUFFERING IN READ/RITE.

MCALC = CALCULATION TYPE SENTINEL. SEE TYPE 2 CARD OF SYNFILE.

((MCHAN(N,J),N=1,IGROUP),J=1,MAXFUN) = CHANNEL SCHEME ASSIGNMENT FOR EACH GROUP-COLLAPSED GROUP FLUX.

MCMST = THE NUMBER OF CHANNEL STRUCTURE SCHEMES.

MCOLGP = 0 FOR GROUP DEPENDENT SYNTHESIS, 1 FOR GENERAL GROUP COLLAPSING, 2 FOR SPECIAL GROUP COLLAPSING.

MCONC = THE NUMBER OF CONCURRENT INTGLS RECORDS THAT CAN BE HELD IN CORE DURING THE INTEGRAL REWRITE.

MDEMOD = 0, DO NOT CALCULATE PERTURBATION DENOMINATOR.
1, CALCULATE PERTURBATION DENOMINATOR.

MFILEDIF = THE FILE NUMBER FOR THE DIFINT FILE.

MFILEFLX = REOFLX FILE NUMBER.
(MFILEFUN(I),I=1,MAXFUN) = THE FILE NUMBER FOR EACH FLUX FILE.

MFILEH = HFILE FILE NUMBER.

MFILEINT = INTGLS FILE NUMBER.

MFILEITC = THE FILE NUMBER FOR THE INITOC FILE.
(MFILEPLN(I),I=1,MAXPLN) = THE FILE NUMBER FOR EACH PLANAR GEOMETRY FILE.

MFILESYN = SYNCON FILE NUMBER.

MFILEUNI = A ROGUS FILE NUMBER FOR THE UNIT FLUX.

MFILEVOL = THE FILE NUMBER FOR THE VOLINT FILE.

MFILEXSC = XSCMIN FILE NUMBER.

MFILEYST = REOYST FILE NUMBER.

MFNOLD = THE NUMBER OF FUNCTIONS REPRESENTED IN INPUT INTEGRAL FILES.

MGEOST = 0, DO NOT CONSTRUCT AN OUTPUT GEOST FILE.
.GT. 0, THE VERSION NUMBER FOR THE OUTPUT GEOST FILE.

MGROUP = NUMBER OF ENERGY GROUPS BEFORE COLLAPSING.

MINT = PRINTED OUTPUT FILE NUMBER.

MPIACC = THE NUMBER OF ADJOINT COMBINING COEFFICIENT PLOTS.

MPIACC = THE NUMBER OF DIRECT COMBINING COEFFICIENT PLOTS.

MPIOLD = THE NUMBER OF PLANAR GEOMETRIES REPRESENTED IN INPUT INTEGRAL FILES.

MPPATE = THE NUMBER OF PLANAR ADJOINT GROUP FLUXES TO BE EDITED.

MPPPOD = THE NUMBER OF PLANAR POWER DISTRIBUTIONS TO BE EDITED.

MPPRIE = THE NUMBER OF PLANAR DIRECT GROUP FLUXES TO BE EDITED.

MPPRZF = 0, DO NOT EDIT THE AVERAGE FLUXES BY ZONE.
.GT. 0, EDIT THE AVERAGE FLUXES BY ZONE (NRZFLX MUST BE .GT. 0).

(MPTAB(I),I=1,36) = THE POINTER TO EACH DIMENSIONED VARIABLE DEFINED THROUGH RPOINTER.

APPENDIX G. FORTRAN VARIABLE GLOSSARY. (CONTD.)

(NPTOUT(I), I=1, 2*LENLST) = A SCRATCH ARRAY CONTAINING POINTERS WITHIN THE OUTPUT RECORDS FOR EACH ENTRY OF LISTV.

NPTXMS = A POINTER TO THE LOCATION JUST BEFORE THE START OF THE MESH INTERVAL DATA IN A RECORD OF REQFLX.

(NPTXST(I), I=1, LENLST) = A SCRATCH ARRAY USED TO STORE POINTERS TO COMPOSITIONS FOR EACH ENTRY IN LISTV.

NPWDNT = 0, DO NOT CONSTRUCT AN OUTPUT PWDINT FILE.
.GT. 0, THE VERSION NUMBER FOR THE OUTPUT PWDINT FILE.

NPCDIF = NUMBER OF RECORDS IN THE DIFINT FILE.

NRCH = THE NUMBER OF RECORDS IN THE HFILE FILE.

NRCINT = THE NUMBER OF RECORDS IN THE INTGIS FILE.

NRCVOL = NUMBER OF RECORDS IN THE VOLINT FILE.

NRECD = THE NUMBER OF RECORDS OF THE DIFINT FILE BEING CONSTRUCTED ON A PARTICULAR PASS THRU THE INTEGRATION LOOP.

NRECV = THE NUMBER OF RECORDS OF THE VOLINT FILE BEING CONSTRUCTED ON A PARTICULAR PASS THRU THE INTEGRATION LOOP.

NRZFLX = 0, DO NOT CONSTRUCT AN OUTPUT RZFLUX FILE.
.GT. 0, THE VERSION NUMBER FOR THE OUTPUT RZFLUX FILE.

NSCALP = 1 IF USER SUPPLIED SCALING FACTORS FSCALE AND USCALE ARE TO BE APPLIED, 0 IF NOT.

NSTDIF = FORMAT SENTINEL FOR DIFINT FILE.

NTITLE = THE NUMBER OF AS WORDS USED TO STORE THE TITLE.

NTRIAG = TRIANGULAR MESH SENTINEL.

NTRIPT = SECONDARY TRIANGULAR MESH SENTINEL.

NTRYD = THE NUMBER OF ENTRIES IN LISTV WHICH PERTAIN TO THE IDIPTB TABLE OF CONTENTS.

NTRYV = THE FIRST NTRYV ENTRIES IN LISTV PERTAIN TO THE IVOLTB TABLE OF CONTENTS.

NTYPES = MAXIMUM ALLOWED NUMBER OF INPUT CARD TYPES.

NUMREC = THE NUMBER OF OUTPUT INTEGRAL RECORDS THAT CAN BE CONTAINED IN CORE.

(NUMCHN(I), I=1, NCHNST) = NUMBER OF CHANNELS IN CHANNEL STRUCTURE SCHEME I.

NUMCMP = THE NUMBER OF MATERIALS FOR WHICH CROSS SECTIONS ARE REQUIRED WHEN THE INTEGRALS ARE CALCULATED (NUMCMP.LE.MAXCMP)

NUMFUN = THE NUMBER OF FUNCTIONS REQUIRED TO CALCULATE THE INTEGRALS. IF THE UNIT FUNCTION IS REQUIRED, IT IS INCLUDED IN NUMFUN, EVEN THOUGH NO SUCH FLUX FILE IS EVER WRITTEN (NUMFUN.LE.MAXFUN).

NUMK2N = THE NUMBER OF AXIAL ZONES IN THE MODEL. THERE IS AN NEW ZONE WHEN EITHER THE PLANAR GEOMETRY OF THE FUNCTION SPDS CHANGE.

NUMPLN = THE NUMBER OF PLANAR GEOMETRIES REQUIRED TO CALCULATE THE INTEGRALS. (NUMPLN.LE.MAXPLN)

N3DADJ = 0, DO NOT CONSTRUCT AN OUTPUT ATFLUX FILE.
.GT. 0, THE VERSION NUMBER FOR THE OUTPUT ATFLUX FILE.

N3DPLX = 0, DO NOT CONSTRUCT AN OUTPUT PTFLUX FILE.
.GT. 0, THE VERSION NUMBER FOR THE OUTPUT PTFLUX FILE.

((ORTHFC(I,J), I=1, MAXDIM), J=1, NUMK2N) = THE FACTORS FOR EACH SYNTHESIS ZONE USED IN THE NORMALIZATION/DIFFERENCING TRANSFORMATION APPLIED TO THE SYNTHESIS EQUATIONS. FOR EACH ZONE THE FACTORS ARE STORED IN THE SAME MANNER AS THE CORRESPONDING COMBINING COEFFICIENT.

APPENDIX G. FORTRAN VARIABLE GLOSSARY. (CONTD.)

((PLNNAM(I,J),I=1,3),IV*PLN(J)),J=1,MAXPLN) = FULL NAME OF
 FILE FOR PLANAR GEOMETRY J.
 (POW(I),I=1,MAXFUN*LGROUP*MAXPLN) = AN ARRAY CONTAINING POWER
 INTEGRALS FOR EACH FUNCTION AND PLANE. THE INTEGRALS ARE
 STORED IN THE SAME WAY AS THE COMBINING COEFFICIENTS, WITH
 BLANKS OMITTED. POINTERS TO THE FIRST NONZERO GROUP ARE
 GIVEN IN THE ARRAY IPVTOC.
 POWFIS = WATTS PER FISSION.
 (PP(I),I=1,IPN1) = A SCRATCH ARRAY USED IN CALCULATING THE
 INTEGRALS. FOR A MULTICHANNEL CALCULATION 3*LEN1 IS RESERVED.
 ((REM(I,J),I=1,KDIM(IZ)),J=1,KDIM(IZ)) = THE SUBBLOCK (FOR THE
 CURRENT AXIAL MESH INTERVAL) CONTAINING THE INTEGRALS OVER
 THE REMOVAL CROSS SECTIONS. IZ IS THE SYNTHESIS ZONE
 ASSOCIATED WITH THE CURRENT AXIAL MESH INTERVAL.
 ((RESULT(I,J),J=1,LENINT),J=1,NUMREC) = ARRAYS FOR OUTPUT
 INTEGRALS.
 (TIME(I),I=1,10) = THE ARRAY IN THE ARGUMENT OF SUBROUTINE TIMER.
 (TITLE(I),I=1,NTITLE) = USER INPUT TITLE.
 ((U(I,J,K),I=1,IGROUP),J=1,NGROUP),K=1,2) = GENERAL GROUP
 COLLAPSING MATRIX FOR THE EXPANSION FUNCTIONS (K=1) AND
 WEIGHTING FUNCTIONS (K=2).
 (VOL(I),I=1,IPN1) = A SCRATCH ARRAY FOR MESH BLOCK VOLUMES.
 ((USCALE(I,J),I=1,NGROUP),J=1,MAXFUN) = A USER SUPPLIED SCALING
 FACTOR FOR EACH GROUP OF FUNCTION J WHEN FUNCTION J IS USED
 AS A WEIGHTING FUNCTION. IT CAN ONLY HAVE AN EFFECT WHEN
 GROUP COLLAPSING IS EMPLOYED.
 XEBS = A SMALL NUMBER USED IN TESTS FOR ZERO CROSS SECTIONS.
 (XSECT1(I),I=1,LENXST) = THE ARRAY INTO WHICH A RECORD OF REQXST
 IS READ. XSECT2 SERVES THE SAME PURPOSE.
 (ZMESH(K),K=1,KMAX) = POSITION OF UPPER BOUNDARY OF AXIAL MESH
 INTERVAL K.

APPENDIX I

CCCC Version III Standard Interface Files

The CCCC Standard Interface Files used in SYN3D are defined by the specifications in Ref. 24 with the following two additions:

- (1) In the File Specification record of GEODST. The 23rd entry (one of the "Reserved" in Ref. 24) is used to specify the orientation of the (1,1) mesh triangle for triangular mesh geometries (IGOM=9 or 17) bounded, in the x-y plane, by rectangles (NTRIAG=2). In SYN3D that entry is designated "NTRIPT" and has the following definition.

NTRIPT = 1 - Triangle (1,1) points away from the first dimensions axis. i.e., no internal mesh line intersects the origin.

2 - Triangle (1,1) points towards the first dimension axis. i.e., an internal mesh line intersects the origin.

- (2) In the Mesh Interval Boundary record of GEODST. For triangular mesh geometries (IGOM=9 or 17) the length (L) of a side of a triangle is calculated from

$$L = 2 \frac{XMESH(2) - XMESH(1)}{IFINTS(1)}$$

The other entries in XMESH and YMESH are never used.

The rest of this appendix consists of listings of the following CCCC Standard Interface Files from Reference 24:

GEODST
ISOTXS
NDXSRF
ZNATDN
RTFLUX
ATFLUX
PWDINT
RZFLUX

ACKNOWLEDGMENTS

A number of people made significant contributions to the programming of SYN3D and to this report. R. P. Hosteny coded the HMG4C overlay; W. F. Miller was responsible for the planar leakage integral calculations in the overlay INTEG. Contributions to this report were made by R. P. Hosteny and H. Henryson, II. Users whose feedback uncovered bugs and helped shape the code include C. L. Beck, E. K. Fujita, G. L. Grasseschi, K. R. Krack, M. J. Lineberry, and D. C. Wade. A. R. Hinds made several programming suggestions which resulted in significant improvements in running times.
