TECHNICAL NOTE 2457

AIR FORCES AND MOMENTS ON TRIANGULAR AND RELATED WINGS WITH SUBSONIC LEADING EDGES OSCILLATING IN SUPersonic POTENTIAL FLOW

By Charles E. Watkins

Langley Aeronautical Laboratory
Langley Field, Va.

WASHINGTON
September 1951
This analysis treats the air forces and moments in supersonic potential flow on oscillating triangular wings and a series of swept-back and arrow wings with subsonic leading edges and supersonic trailing edges. For the wings undergoing sinusoidal torsional oscillations simultaneously with vertical translations, the linearized velocity potential is derived in the form of a power series in terms of a frequency parameter. This method can be useful for treatment of similar problems for other plan forms and for wings undergoing other sinusoidal motions. For triangular wings, as many terms of such a series expansion as may be desired can be determined; however, the terms after the first few become very cumbersome.

Closed expressions that include the reduced frequency to the third power, an order which is sufficient for a large class of practical applications, are given for the velocity potential and for the components of chordwise section force and moment coefficients.

These wings are found to exhibit the possibility of undamped torsional oscillations for certain ranges of Mach number and locations of the axis of rotation. The ranges of these parameters are delineated for triangular wings.

INTRODUCTION

This paper is concerned with the derivation of expressions for the velocity potential and associated forces and moments for oscillating triangular wings in supersonic flow. The boundary-value problem for the linearized velocity potential for an apex-forward triangular wing oscillating in a supersonic main stream may be classified, according to reference 1, as "purely supersonic" if the leading edges of the triangle...
are outside the Mach cone emanating from the apex of the triangle or "mixed supersonic" if the leading edges are inside this Mach cone.

In the purely supersonic case the principle of independence holds; that is, the flow on the upper surface of the wing is independent of the flow on the lower surface and vice versa. Garrick and Rubinow (reference 1) have shown that the boundary-value problem for the velocity potential in the purely supersonic case can be satisfied by simple distributions of sources with local strength proportional to the local prescribed normal velocity of the wing.

In the mixed supersonic case the principle of independence does not hold. Boundary-value problems for lift-producing wings in this case can be satisfied by distributions of doublets; the relation between doublet strength and normal velocity of the wing is, however, in general, not simple. The determination of this relation requires the solution of an integral equation that employs the potential of a time-dependent unit doublet as kernel and limits of integration that depend on Mach number and wing plan form.

For treatment of problems that involve boundary conditions that are independent of time, such as constant angle of attack, constant rate of pitching, and so forth, the doublet potential, employed as kernel of the integral equation, is considered independent of time and in these cases the integral equations for triangular wings can be solved by a straightforward process.

For treatment of problems of oscillating wings, however, it is necessary to employ, as the kernel of the integral equations, a doublet potential that varies harmonically with time and in this case the solution of the integral equation, generally, becomes very cumbersome. If the doublet potential or kernel is expanded in terms of the frequency of oscillation, however, use can be made of knowledge of solutions of integral equations for problems that are independent of time to obtain an expanded form of solution for a wing undergoing harmonic oscillations. Such a procedure was demonstrated in treatments of rectangular wings in references 2 and 3. (The derivation in reference 3 is based on an erroneous argument, regarding certain terms in the normal velocity; nevertheless, the final expression given for the velocity potential is correct.)

The purpose of the present paper is to make use of the expanded form of the velocity potential to obtain the forces and moments, based on the first few terms of this potential, for a rigid triangular wing performing vertical and pitching sinusoidal oscillations in mixed supersonic flow. Although as many terms of the expanded potential as may be desired can be obtained after the first few terms, the process becomes very cumbersome. The flow normal to the leading edge is subsonic but
the flow normal to the trailing edge is considered to be supersonic.
This latter consideration implies that the potential derived for trian-
gular plan forms may be used to calculate the aerodynamic forces and
moments for other plan forms that may be formed with the triangular wing
by cutting the trailing edges so that they lie ahead of the Mach cones
emanating from their foremost points.

Other approaches to the solution of the problem of oscillating
trianangular wings have been given by Robinson (reference 4), Haskind and
Falkovich (reference 5), and by Stewartson (reference 6). In both
references 4 and 5 formal solutions to the problem were obtained in terms
of special systems of curvilinear coordinates. Robinson's solution was
given in terms of a double summation of trilinear combinations of Bessel
functions of the first kind with Lamé functions of the first and second
kinds. Similarly, the solution of Haskind and Falkovich was given in
terms of summations of Bessel functions of the first kind combined with
elliptic integrals of the first and second kinds. In both references 4
and 5 the potentials were not reduced to useful forms for calculating
forces and moments.

In reference 6 Stewartson makes an interesting though specialized
use of the Laplace transformation to develop a method whereby terms of
the velocity potential for triangular plan forms, expanded as herein,
can be obtained. Stewartson gives formulas that, except for errors
presumably in printing, can be used to develop the potential to the
second power of the frequency but he omits many details in his derivation.

SYMBOLS

\[ \phi \] disturbance-velocity potential

\[ x, y, z \] rectangular coordinates attached to wing moving in
negative x-direction

\[ \xi, \eta \] rectangular coordinates used to represent space location
of doublets in xy-plane

\[ Z_m \] function defining mean ordinates of any chordwise section
of wing such as \( y = y_1 \) as shown in figure 1

\[ w(x, y_1, t) \] vertical velocity at surface of wing along chordwise
section at \( y = y_1 \)

\[ x_0 \] abscissa of axis of rotation of wing as shown in figure 1
t  

vertical displacement of axis of rotation

\( h_0 \)

amplitude of vertical displacement of axis of rotation, positive downward

\( \alpha \)

angle of attack

\( \alpha_0 \)

amplitude of angular displacement about axis of rotation, positive leading edge up

\( \dot{h}, \dot{\alpha} \)

time derivatives of \( h \) and \( \alpha \), respectively

\( V \)

velocity of main stream

\( c \)

velocity of sound

\( M \)

free-stream Mach number \( (V/c) \)

\( \beta = \sqrt{M^2 - 1} \)

\( \omega \)

frequency of oscillations

\( \bar{\omega} = \frac{M^2 \omega}{V \beta^2} \)

\( k \)

reduced frequency \( \left( \frac{\beta \omega}{V} \right) \)

\( \epsilon \)

half apex angle

\( C = \tan \epsilon \)

\( a_{nm} \)

represents functions of \( \bar{\omega}, x, \) and \( M \)

\( D_n, F_n \)

functions used to denote doublet distribution functions

\( d_n \)

constants associated with \( D_n \) depending on \( \beta C \)

\( A_j, \lambda_j \)

constants depending on \( \beta C \)

\( \sigma_k \)

constants depending on \( \beta C \) and \( M \)

2b

root chord of wing
**ANALYSIS**

**Boundary-Value Problem for the Velocity Potential**

Referred to a rectangular coordinate system moving forward at a uniform supersonic speed in the negative x-direction (see fig. 1) the differential equation for the propagation of small disturbances that must be satisfied by the velocity potential is

\[
\frac{1}{c^2} \frac{\partial}{\partial t} \left( \frac{\partial \phi}{\partial x} \right)^2 + \frac{\partial}{\partial x} \left( \frac{\partial \phi}{\partial x} \right) = \frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} + \frac{\partial^2 \phi}{\partial z^2}
\]

The main governing boundary condition to be satisfied by the velocity potential is that the flow be tangent to the surface of the wing, or

\[
\left. \frac{\partial \phi}{\partial z} \right|_{z \rightarrow 0} = w(x, y, t) = v \frac{\partial z_m}{\partial x} + \frac{\partial z_m}{\partial t}
\]

where \( z_m \) is the vertical displacement of any point of the wing. For the particular case of a wing independently performing small sinusoidal
pitching oscillations of amplitude $\alpha_0$ about some spanwise axis $x_0$ and small sinusoidal vertical translations of amplitude $h_0$, the quantity $Z_m$ in equation (2) is

$$Z_m = e^{i\omega t} \left[ \alpha_0(x - x_0) + h_0 \right] = \alpha(x - x_0) + h$$

(3)

(See fig. 1(b) for sketch showing instantaneous displacement of section $y = y_1$.) For convenience, the frequency of oscillation of both pitching and translatory motion is denoted by $\omega$. Considering these motions to occur at separate frequencies would add no difficulties to the derivation.

Substituting the expression for $Z_m$ (equation (3)) into equation (2) gives

$$w(x, y, t) = \nu \alpha + \dot{\alpha}(x - x_0) + \dot{h}$$

(4)

Equation (4) implies that the velocity potential may be expressed as the sum of separate effects due to position and motion of the wing associated with individual terms of this equation, namely

$$\phi = \phi_\alpha + \phi_\dot{\alpha} + \phi_\dot{h}$$

(5)

Derivation of $\phi$

In order to obtain the analytical expression for the potential $\phi$, it is necessary to derive only one of the subsidiary potentials appearing in equation (5), say $\phi_\alpha$. The other subsidiary potentials $\phi_\dot{\alpha}$ and $\phi_\dot{h}$ can then be obtained from the derived expression for $\phi_\alpha$ by simple comparison.

In order to satisfy the boundary-value problem for $\phi_\alpha$, a convenient procedure is to start with the expanded form of the potential of a uniform distribution of doublets. Then, for a given power of the frequency of oscillation of this potential, as will be shown in the following analysis, can be modified so that, when integration is made over the appropriate region, the results satisfy the differential equation (1) to the given power of the frequency and satisfy the condition of tangential flow exactly. The type of doublet required is that with its axis normal to the plane of the wing. The potential of such a doublet may be obtained
from the potential of a source, located in the plane of the wing, by partial differentiation with respect to the direction normal to the plane of the wing. Similarly, the potential of a distribution of the required type of doublets can be obtained from a distribution of sources located in the plane of the wing.

The potential at \((x,y,z)\) due to sources located at points \((\xi,\eta,0)\) in region \(r\) (illustrated in fig. 2) of the \(xy\)-plane which satisfies the differential equation (1) may be written as

\[
\phi_s = \frac{V_0}{\pi} \int \int \frac{e^{-i\bar{m}(x-\xi)}}{R} \cos \left( \frac{\bar{m}}{M} R \right) \, d\xi \, d\eta
\]  

(6)

where

\[
\bar{m} = \frac{M_0}{C\beta^2} = \frac{M_0^2}{V\beta^2}
\]

and

\[
R = \sqrt{(x - \xi)^2 - \beta^2(y - \eta)^2 - \beta^2z^2}
\]

Expanding the integrand of equation (6) into a power series in \(\bar{m}\), collecting terms with respect to \(\xi\), and differentiating the resulting integral with respect to \(z\) gives the expanded form of the potential of a uniform distribution of doublets, namely

\[
\phi_D = \frac{V_0}{\pi} \frac{\partial}{\partial z} \int \int \left[ a_{01} \frac{1}{R} + a_{02}R + \ldots + a_{0m}R^{2m-3} + \ldots + \right.

\xi \left( a_{11} \frac{1}{R} + a_{12}R + \ldots + a_{1m}R^{2m-3} + \ldots \right) + \ldots +

\xi^n \left( a_{n1} \frac{1}{R} + a_{n2}R + \ldots + a_{nm}R^{2m-3} + \ldots \right) \right] \, d\xi \, d\eta
\]  

(7)
For convenience in the succeeding discussion and analysis equation (7) may be written in the following form:

\[
\phi_D = \frac{V_0}{\pi} \frac{\partial}{\partial z} \sum_{n=0}^{\infty} \left[ a_{n1} \int_r \int \frac{\xi_n}{R} d\xi d\eta + \left( \sum_{m=2}^{\infty} \frac{(-1)^{m-1} (\alpha/M)^{2m-2}}{(2m-2)!} a_{n1} \int_r \int \xi_n^n R^{2m-3} d\xi d\eta \right) \right]
\]

An interesting and significant property of equation (10) is that the coefficient of each power of \( \xi \) satisfies the differential equation (1) and has the form of a source potential with strength proportional to \((i\alpha/n!)^n e^{-i\xi} \). This property may be shown by writing the coefficient of \( \xi^n \) as follows:

\[
\frac{a_{n1}}{R} \left[ 1 + \sum_{m=2}^{\infty} \frac{(-1)^{m-1} (\alpha/R)^{2m-2}}{(2m-2)!} (\alpha/R) \right] = \frac{a_{n1}}{R} \cos \left( \frac{\alpha}{M} \right)
\]

\[
= \left( \frac{i\alpha}{n!} \right)^n \left[ \frac{e^{-i\xi(x-\xi)} \cos \left( \frac{\alpha}{M} \right)}{R} \right]
\]
A more general solution to equation (1) may thus be obtained by introducing properly chosen weight or distribution functions (denoted by $D_n(\xi, \eta)$) into the coefficients of $\xi^n$ in equation (10). Let this solution be denoted by $\phi_1$; then it can be written as

$$
\phi_1 = \frac{V\alpha}{\pi} \frac{\partial}{\partial z} \sum_{n=0}^{\infty} \left[ a_{nl} \int_{\gamma} \int_{r} D_n(\xi, \eta) \frac{\xi^{n+1}}{R} d\xi d\eta + \right]
$$

$$
\sum_{m=2}^{\infty} \frac{(-1)^{m-1}}{(2m-2)!} \left( \frac{\alpha}{M} \right)^{2m-2} a_{nl} \int_{\gamma} \int_{r} D_n(\xi, \eta) \xi^{n+1} \frac{2m-3}{R} d\xi d\eta \right] \quad (12)
$$

Examination of equation (12) shows that, at the surface $z = 0$, the potential $\phi_1$ is determined by the first integral expression but that both integral expressions may give rise to normal velocity. In succeeding steps in this analysis it is shown that the distribution functions $D_n(\xi, \eta)$ in equation (12) can be determined so that the first integral expression taken alone will exactly satisfy the boundary condition of tangential flow for $\phi_\alpha$; that is $\frac{\partial \phi_\alpha}{\partial z}_{z=0} = V\alpha$. Also, any additional normal velocity that arises from the second integral expression can be canceled, to the required order, by consideration of additional doublet solutions to equation (1). The problem of satisfying the boundary-value problem for the velocity potential $\phi_\alpha$ may thus be reduced to that of determining the appropriate distribution functions and additional solutions to equation (1).

In order to show that the first integral expression in equation (12) can be made to satisfy the boundary condition for $\phi_\alpha$, the coefficient $V\alpha a_{nl}$ appearing in this equation is first considered. If the analytical expression for the coefficient $a_{nl}$ (equation (8)) is multiplied by $x^n$ and summed with respect to $n$, the result is identically $V\alpha$. This result may be shown as follows:

$$
V\alpha \sum_{n=0}^{\infty} x^n a_{nl} = V\alpha \sum_{n=0}^{\infty} \frac{(\frac{i\alpha x}{n})^n}{n!} e^{-i\alpha x} = V\alpha e^{i\alpha x} e^{-i\alpha x} \equiv V\alpha \quad (13)
$$
It is significant that this identity holds if only terms in \( \frac{\partial}{\partial x} \) to any given power are considered. For example, retaining only terms including \( \frac{\partial}{\partial x} \) to the third power gives

\[
\frac{V_0}{\pi} \left[ \left( 1 - i \omega x - \frac{\omega^2 x^2}{2} \right) + x \left( i \omega + \frac{\omega^2 x}{2} - \frac{i \omega^3 x^2}{6} \right) \right] - \ \nonumber \\
x^2 \left( \frac{\omega^2}{2} - \frac{i \omega^3 x}{2} \right) - x^3 \frac{i \omega^3}{6} \nonumber = \frac{V_0}{\pi} 
\]

(14)

Next consider the normal velocity at \( z = 0 \) associated with \( \phi_1 \), namely

\[
V_1 = \left( \frac{\partial \phi_1}{\partial z} \right) \bigg|_{z=0} = \frac{V_0}{\pi} \lim_{\text{a} \to 0} \sum_{r=0}^{\infty} \left[ a_{n1} \int_r \int D_n(\xi, \eta) \frac{\xi^{n+1}}{R} \, d\xi \, d\eta + \right. \nonumber \\
+ \sum_{m=2}^{\infty} \left( \frac{-1}{(2m-2)!} \frac{n^{2m-2}}{M} \right) a_{n1} \int_r \int D_n(\xi, \eta) \frac{\xi^{n+1}}{R} (2m-3) \, d\xi \, d\eta \right] 
\]

(15)

Examination of this equation and equation (13) reveals that the first integral expression on the right of equation (15) yields \( V_0 \) exactly, provided the distribution functions are determined so that the following integral equation is satisfied:

\[
\frac{V_0}{\pi} \lim_{\text{a} \to 0} \int_r \int D_n(\xi, \eta) \frac{\xi^{n+1}}{R} \, d\xi \, d\eta = V_0 a^{n+1} 
\]

(16)

The kernel of this integral equation has the form of a steady-state doublet potential. The problem of determining the distribution functions for this case is therefore analogous to determining distribution functions for certain steady-state problems. The distribution functions for steady-state problems, at least for those involving conical flow, can be determined by a straightforward process, the main details of which are given in the appendix. In this appendix a method of solving equation (16) for a triangular wing is derived and the distribution functions required to
derive the velocity potential for this wing to the third power of \( \bar{\omega} \) are given. It is to be noted that the method derived for solving equation (16) for a triangular wing may be generalized to apply to various plan forms and to problems of satisfying the boundary conditions for various velocity distributions.

From this point on, the analysis is restricted to the derivation of terms of the expanded potential involving \( \bar{\omega} \) to the third power. The method for deriving these first few terms is quite general and can be used to obtain as many additional terms of the expanded potential as may be desired. As previously pointed out, however, terms of the potential after the first few become very unwieldy.

If the appropriate distribution functions are known for terms involving \( \bar{\omega} \) to the third power, equation (15) may be written as follows:

\[
w_1 = v_x + w_2
\]

where

\[
w_2 = \frac{v_x}{\pi} \lim_{z \to 0} \frac{\partial^2}{\partial z^2} \frac{\bar{\omega}^2}{2M^2} \int d\xi d\eta \left[ (1 - i\bar{\omega}x) D_0 R + i\bar{\omega} R D_1 R \right]
\]

is the additional vertical velocity arising from the second integral expression in equation (12) involving \( \bar{\omega} \) to the third power. In order to maintain the boundary condition for \( \phi_x \), this additional velocity \( w_2 \) must be canceled. As previously pointed out this canceling, to a required order, can be achieved by considering other doublet solutions to equation (1). For this particular case consider a relation \( \phi_1 \) similar to \( \phi_1 \) (equation (12)) having the following form:

\[
\phi_1 = \frac{v_x}{\pi} \frac{\partial}{\partial z} \frac{\bar{\omega}^2}{2M^2} \sum_{n=0}^{\infty} \left[ a_{n1} \int d\xi d\eta \bar{D}_n(\xi, \eta) R^{n+3} \right] d\xi d\eta + \\
\sum_{m=2}^{\infty} \frac{(-1)^{m-1}}{(2m-2)!} \frac{n!}{m!} \sum_{n=0}^{\infty} \left[ a_{n1} \int d\xi d\eta \bar{D}_n(\xi, \eta) R^{n+3} \right] d\xi d\eta
\]
The vertical velocity $\bar{w}_1$, to the third power of $\bar{a}$, arising from this expression is

$$\bar{w}_1 = \frac{V_0}{2\pi z} \lim_{z \to 0} \frac{\partial^2}{\partial z^2} \left( \frac{\bar{a}}{M} \right)^2 \int_R \int \left( 1 - i\alpha x \right) \bar{D}_0 \frac{\xi^3}{R} + i\alpha \bar{D}_1 \frac{\eta^4}{R} \right) d\xi d\eta \quad (20)$$

In this equation the distribution functions $\bar{D}_0$ and $\bar{D}_1$ can be determined, as discussed subsequently, by the method given in the appendix so that $\bar{w}_1$ is identically equal in value but opposite in sign to $\bar{w}_2$.

When these functions are determined, the boundary condition for $\phi_\alpha$ is satisfied by $\bar{w}_1 + \bar{w}_2 = V_0$, which implies that the potential $\phi_\alpha$ to the third power of $\bar{a}$ is given by the sum

$$\phi_\alpha = \phi_1 + \bar{\phi}_1 \quad (21)$$

to this power of $\bar{a}$.

Expressions for $\bar{D}_0$ and $\bar{D}_1$ are given together with expressions for other distribution functions $D_0$, $D_1$, $D_2$, and $D_3$ in the appendix.

In regard to the determination of $\bar{D}_0$ and $\bar{D}_1$, as well as other orders for $\bar{D}_n$ in more extended treatments, it may appear necessary, in order to formulate integral equations for these functions, to perform the generally unwieldy integrations of the type

$$\lim_{z \to 0} \frac{\partial^2}{\partial z^2} \int_R \int D_n(\xi, \eta) \xi^{n+1} \eta^{2m-3} d\xi d\eta \quad (22)$$

appearing in equation (15). In general, however, the information necessary for the determination of the functions $\bar{D}_n$ can be obtained, as is done in the derivation of the functions $D_n$ in the appendix, by examining the values of these integrals and their derivatives with regard to the parameter $\theta = \frac{y}{x}$ at some particular value of $\theta$.

Returning to equation (21) and introducing into this equation the expression for $\bar{\phi}_1$ (equation (12)) and the expression for $\bar{\phi}_1$.
(equation (19)), each to the third power of $\bar{m}$, gives for the potential $\phi_\alpha$ to this power of $\bar{m}$ the following result:

$$
\phi_\alpha = v_\alpha \frac{\partial}{\partial z} \int \int \left[ \xi D_0 \left( 1 - i \bar{m} x - \frac{\bar{m}^2}{2} x^2 + \frac{i \bar{m}^3}{6} x^3 \right) \frac{1}{R} - \left( \frac{\bar{m}^2}{2M^2} - \frac{i \bar{m}^3}{2M^2} x \right) R \right] + \\
\xi^2 D_1 \left[ \left( \frac{i \bar{m} + \bar{m}^2 x - \frac{i \bar{m}^3}{2} x^2}{2} \right) \frac{1}{R} - \frac{i \bar{m}^3}{2M^2} R \right] - \xi^3 D_2 \left( \frac{\bar{m}^2}{2} - \frac{i \bar{m}^3}{3} x \right) \frac{1}{R} - \\
\xi^4 D_3 \frac{i \bar{m}^3}{6} \frac{1}{R} + \xi^3 D_0 \left( \frac{\bar{m}^2}{2M^2} - \frac{i \bar{m}^3}{2M^2} x \right) \frac{1}{R} + \xi^4 D_1 \frac{i \bar{m}^3}{2M^2} \frac{1}{R} \right] d\xi d\eta \tag{23}
$$

Since it may be shown, as in reference 7, for example, that

$$
\frac{V_\alpha}{\pi} \lim_{z \to 0} \frac{\partial}{\partial z} \int \int D_{n+1} d\xi d\eta = V_{\alpha x} D_{n+1}(x,y)
$$

equation (23) reduces, at $z = 0$, to

$$
\phi_\alpha = v_\alpha \left[ 1 - i \bar{m} x - \frac{\bar{m}^2}{2} x^2 + \frac{i \bar{m}^3}{6} x^3 \right] D_0(x,y) + \\
x \left( i \bar{m} + \bar{m}^2 x - \frac{i \bar{m}^3 x^2}{2} \right) D_1(x,y) - x^2 \left( \frac{\bar{m}^2}{2} - \frac{i \bar{m}^3}{3} x \right) D_2(x,y) - \\
x^3 \frac{i \bar{m}^3}{6} D_3(x,y) + x^2 \left( \frac{\bar{m}^2}{2M^2} - \frac{i \bar{m}^3}{2M^2} x \right) D_0(x,y) + x^3 \frac{i \bar{m}^3}{2M^2} D_1(x,y) \tag{24}
$$
which, after the expressions for the distribution functions given in the
appendix are substituted and the terms are regrouped, may be written in
the following simple form:

\[
\Phi_\alpha = \sqrt{c^2 x^2 - y^2} \left[ A_0 + (A_1 - A_0) i \tilde{m} x - \sigma_1 \tilde{m}^2 x^2 - \sigma_2 \tilde{w}^2 \beta^2 y^2 + \sigma_3 i \tilde{m}^3 x^3 + \sigma_4 i \tilde{m}^3 \beta^2 y^2 x \right]
\]  

(25)

The quantities \( A_0, A_1, \) and \( \sigma_1, \sigma_2, \sigma_3, \) and \( \sigma_4 \) in this equation are part of a group of quantities \( A_1, \lambda_j, \sigma_k \) which are defined in
the appendix; these quantities are suitable for writing the potential and expressions subsequently derived for forces and moments in simple form. The quantities \( A_1 \) and \( \lambda_j \) are functions only of the product \( \beta C \) (ratio of
tangent of the half apex angle of the triangle to the Mach angle) and
are shown plotted in figures 3 and 4, respectively. The quantities \( \sigma_k \)
are functions of Mach number \( M \) and the product \( \beta C \). These quantities
may be evaluated for particular values of \( M \) from the plots of \( \lambda_j \) in
figure 4.

The quantities \( A_0 \) and \( A_1 \) are the same, as should be expected,
as the parameters associated, respectively, with constant angle of attack
and constant pitching of triangular wings of references 8 and 9.

Expressions for the potentials \( \Phi_\alpha \) and \( \Phi_\lambda \) can be obtained by the
method discussed for obtaining \( \Phi_\alpha \), or they can be obtained to the third
order of \( \tilde{w} \) by comparison and synthesis from equation (23). After
simplification these expressions are

\[
\Phi_\alpha = k \sqrt{c^2 x^2 - y^2} \left[ A_1 x - 2 \lambda_1 i \tilde{m} x + A_3 \tilde{m}^2 \beta^2 y^2 - \sigma_2 \tilde{w}^2 x^2 + \sigma_4 \tilde{w}^2 \beta^2 y^2 x \right]
\]

(26)

\[
\Phi_\lambda = k \sqrt{c^2 x^2 - y^2} \left[ A_0 - 2 \lambda_1 \tilde{m} x - \sigma_1 \tilde{w}^2 x^2 - \sigma_2 \tilde{w}^2 \beta^2 y^2 \right]
\]

(27)
At $\beta C = 1$ or $C = \frac{1}{\beta}$, which is the condition at which the Mach lines from the apex of the triangle coincide with the leading edges of the triangle, equations (23), (26), and (27) reduce, respectively, to

$$\phi_\alpha = \frac{2V_\alpha}{\beta \pi} \sqrt{x^2 - \beta^2 y^2} \left(1 - \frac{16x}{3} - \frac{7M^2 + 5}{90M^2} \omega^2 x^2 - \frac{2M^2 - 5}{90M^2} \omega^2 \beta^2 y^2 + \frac{3M^2 + 7}{210M^2} \omega^3 x^3 + \frac{2M^2 - 7}{210M^2} \omega^3 \beta^2 y^2 x\right)$$

(28)

$$\phi_\ast = \frac{2h}{\beta \pi} \sqrt{x^2 - \beta^2 y^2} \left[\frac{2}{3} x - \frac{81x}{15} x^2 + \frac{24x}{15} \beta^2 y^2 - \frac{\omega^2 (11M^2 + 7)}{315M^2} x^3 + \frac{\omega^2 (2M^2 + 7)}{315M^2} \beta^2 y^2 x\right] - x_0 \left(1 - \frac{16x}{3} - \frac{7M^2 + 5}{90M^2} \omega^2 x^2 - \frac{2M^2 - 5}{90M^2} \omega^2 \beta^2 y^2\right)$$

(29)

$$\phi_h = \frac{2h}{\beta \pi} \sqrt{x^2 - \beta^2 y^2} \left(1 - \frac{16x}{3} - \frac{7M^2 + 5}{90M^2} \omega^2 x^2 - \frac{2M^2 - 5}{90M^2} \omega^2 \beta^2 y^2\right)$$

(30)

For $M = 1$ or for values of the product $\beta C$ such that $\beta^2 C^2 \ll 1$, equations (23), (26), and (27) reduce, respectively, to

$$\phi_\alpha = V_\alpha \sqrt{c^2 x^2 - y^2}$$

(31)

$$\phi_\ast = c \sqrt{c^2 x^2 - y^2} (x - x_0)$$

(32)
These expressions are the counterpart of the potential for vanishingly small triangular wings in steady flow (reference 10) and may thus be regarded as the potential of a small triangle oscillating in pitch and vertical translation in either subsonic or supersonic flow.

Forces and Moments

As pointed out in the introduction, the velocity potential for the triangular wing can be used to calculate the aerodynamic forces and moments for other plan forms that can be formed from the triangular wing by cutting the trailing edges so that they lie ahead of the Mach cones emanating from their foremost points. Sketches of different plan forms thus obtained are shown in figure 5.

The force and moment coefficients desirable for most flutter calculations are those that yield the spanwise variation in these quantities or chordwise force and moment coefficients. These coefficients are obtained by integrating the pressure difference along any chord for the forces and the pressure difference multiplied by a moment arm for the moments. A convenient procedure in deriving these quantities is to introduce the reduced-frequency parameter \( \frac{b_0}{V} = k \) and to employ the variables \( x, y, \) and \( x_0 \) in a new sense as nondimensional quantities obtained by dividing the old variables by the maximum chord \( 2b \) of the wing.

The pressure difference between the upper and lower surfaces of the wing is

\[
\Delta p = -2\rho \left( \frac{V}{2b} \frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial t} \right) \quad (34)
\]

The force, positive downward, at any section of any of the plan forms shown in figure 5 may be expressed as
\[ P = 2b \int_{y/c}^{x_1} \Delta \phi \, dx = -4\rho b \int_{y/c}^{x_1} \left( \frac{V}{2b} \frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial t} \right) \, dx \]
\[ = -2\rho V \left[ \phi \bigg|_{y/c}^{x_1} + 21k \int_{y/c}^{x_1} \phi \, dx \right] \] (35)

where \( x_1 \) has the following values with respect to the different configurations shown in figure 5:

In plan form A
\[ x_1 = 1 \] (36a)

In plan form B
\[ x_1 = 1 - \frac{y}{m} \] (36b)

In plan form C
\[ x_1 = 1 + \frac{y}{m} \] (36c)

In plan form D
\[ x_1 = \begin{cases} 1 + \frac{y}{m} & \text{for } 0 \leq y \leq m \left( \frac{s}{2bc} - 1 \right) \\ \frac{s}{2bc} & \text{for } m \left( \frac{s}{2bc} - 1 \right) < y \leq \frac{s}{2b} \end{cases} \] (36d)

After the expression for \( \phi \), given by the sum of equations (25), (26), and (27), is substituted into equation (35) and the integration is performed, the results may be reduced to the form

\[ P = -4\rho b \nu^{2} k^{2} e^{i\omega t} \left[ \frac{h_{0}}{b} (L_{1} + iL_{2}) + \alpha_{0}(L_{3} + iL_{4}) \right] \] (37)

where
\[ L_{1} = \frac{x_{1}^{2} - y^{2}}{b^{2}} \left( \frac{\beta^{2} - \lambda_{1}}{\lambda_{1} - \beta^{2} h_{0}} + \frac{A\nu^{2}}{c} \cosh^{-1} \frac{cx_{1}}{y} \right) \] (38a)
\[ L_2 = \sqrt{c^2 x_1^2 - y^2} \left[ \frac{A_0}{k} - \frac{4w^2 c^2 x_1^2}{3\beta^4} (3\beta^2 \sigma_1 - 2\beta^2 \lambda_1) - \frac{4w^2 c^2}{3\beta^2 c^2} (3\beta^2 \sigma_2 + 2\beta^2 \lambda_1) \right] \]

\[ L_3 = \sqrt{c^2 x_1^2 - y^2} \left[ \frac{A_0}{k^2} + \frac{4w^2 c^2 x_1^2}{3\beta^4} (6\beta^2 M^2 \sigma_2 - \beta^4 A_1 - 3\lambda^4 \sigma_1 + 2\beta^2 \lambda_1) + \frac{4w^2 c^2}{3\beta^2 c^2} [\beta^2 A_1 - 3\beta^2 M^2 c^2 A_3 - 3\lambda^4 \sigma_2 - 2\beta^2 \lambda_1] \right] - 2x_0 L_1 \]

\[ L_4 = \sqrt{c^2 x_1^2 - y^2} \left[ \frac{x_1}{3\beta^2 k} (2\beta^2 A_1 + \beta^2 A_0 - 4w^2 \lambda_1) + \frac{2w^2 c^2 x_1^3}{\beta^6} (2\beta^4 \lambda_2 - M^2 \beta^2 \sigma_1 + 4w^2 \sigma_3 - 4\beta^2 M^2 \sigma_5) - \frac{4w^2 c^2 A_3}{\beta^4 c^2} (4\beta^4 c^2 \sigma_3 + 2\beta^2 \lambda_2 - M^2 \sigma_1 + 4w^2 c^2 \sigma_4 - 8\beta^2 c^2 M^2 \sigma_6) \right] - \cosh^{-1} \frac{C x_1}{y} \left[ \frac{A_0 y^2}{k c} \right] - \frac{M^2 c^2 x_1^3}{\beta^4 c^3} \left[ (4w^2 c^2 A_3 - 2\beta^2 \lambda_2 + M^2 \sigma_1 + 4w^2 \beta^2 c^2 \sigma_2) \right] - 2x_0 L_2 \]

In a similar manner, the moment (positive leading edge up) about the axis \( x = x_0 \) is

\[ M_x = -h_0^2 \int_{y/c}^{x_1} (x - x_0) \Delta p \, dx = -4\rho V^2 k^2 c^2 \left[ \frac{h_0}{b} (M_1 - iM_2) + c_0 (M_3 + iM_4) \right] \]
where

\[ M_1 = \sqrt{c^2 x_1^2 - y^2} \left\{ \frac{4x_1^2}{3\beta^2} \left( 4M^2\lambda_1 - \beta^2\lambda_0 \right) + \frac{4y^2}{3\beta^2} \left( 2M^2\lambda_1 + \beta^2\lambda_0 \right) \right\} - 2x_0 I_1 \] (40a)

\[ M_2 = \sqrt{c^2 x_1^2 - y^2} \left[ \frac{A_0}{k} x_1 + \frac{2M^2 k x_1}{\beta^4} \left( 2\beta^2\lambda_1 - 3M^2\sigma_1 \right) - \frac{M^2 k x_1^2}{\beta^4} \left( 2\beta^2\lambda_1 + M^2\sigma_1 + 4M^2\lambda_1 \right) \right] \cosh^{-1} \frac{C x_1}{y} - 2x_0 I_2 \] (40b)

\[ M_3 = \sqrt{c^2 x_1^2 - y^2} \left[ \frac{A_0 x_1}{k^2} - \frac{2x_1^3}{\beta^4} \left( \beta^4 A_1 - 2M^2\beta^2\lambda_1 - 6M^2\beta^2\lambda_2 + 3M^4\sigma_1 \right) + \frac{x_1 y^2}{\beta^4} \left( \beta^4 A_1 - 4M^2\lambda_1 A_3 - 2\beta^2 M^2\lambda_1 + 2M^2\beta^2\lambda_2 - \beta^4 A_1 + 4M^4\beta^2\sigma_2 \right) \right] + \frac{A_0 y^2}{\beta^4} \left[ \frac{y^4}{\beta^4} \left( \beta^4 A_1 - 4M^2\beta^2\lambda_1 A_3 - 2M^2\beta^2\lambda_1 + 2M^2\beta^2\lambda_2 - \beta^4 A_1 + 4M^4\beta^2\sigma_2 \right) \right] \cosh^{-1} \frac{C x_1}{y} - 2x_0 \left( M_1 + I_3 + 2x_0 I_1 \right) \] (40c)
In equation (37), for example, the quantity \((L_1 + iL_2)\) is the lift-force coefficient associated with vertical motion of the wing. The real part \(L_1\) is in phase with the vertical position of the wing and the complex part \(L_2\) is 90° out of phase with this position. Similar definitions apply to the lift coefficient \((L_3 + iL_4)\) associated with pitching motion and to the moment coefficients \((M_1 + iM_2)\) and \((M_3 + iM_4)\). The complex or out-of-phase terms determine the aerodynamic damping associated with different wing motions.

Although the expressions for the components of lift-force and moment coefficients in equations (38) and (40), respectively, are lengthy, they may be quite easily evaluated with the aid of the graphs in figures 3 and 4.
DISCUSSION

Sample Calculations

In order to give some indication as to the general nature of the spanwise distribution of the different components of lift and moment coefficients, equations (38) and (40) have been evaluated at different spanwise positions \( y \) for plan form A (fig. 5(a)) for the following set of conditions: \( \beta c = 0.5, \ C = 1.0, \ x_0 = 0.6, \ M = 5/4, \) and \( k = 0.1. \)

These sample results are plotted as functions of spanwise position in figure 6. The spanwise variations of the different components of lift force are shown in figure 6(a) and the corresponding variations of moment coefficients in figure 6(b).

In figure 6 note that, for the particular set of conditions for this example, the maximum values of the components of moment coefficients \( M_1, M_2, \) and \( M_3 \) are positive and act near the tips of the wing, whereas the maximum value of the component \( M_4 \) is negative but also acts near the tips. It may also be noted that the integrated (in spanwise direction) values of the components of moment coefficient, or components of total moment coefficient, would in each case have the same sign as the maximum value of the corresponding component of section moment coefficient. This result is not necessarily true in general, because changing some of the parameters involved in the evaluation of the spanwise distribution of some components of both force and moment coefficients may change the distributions significantly from those shown in figure 6.

The fact that the total component of moment coefficient \( M_4 \) is negative in the example just discussed shows that, for the conditions of the example, this term would not contribute to the aerodynamic damping but, on the contrary, would act as a source of energy for the oscillating system. This circumstance is significant since it leads to the possibility of the single-degree-of-freedom torsional instability discussed in the following paragraphs.

Undamped Torsional Oscillations

The wing plan forms discussed herein, like two-dimensional and rectangular wings, exhibit the possibility of undamped torsional oscillations for certain ranges of Mach number \( M \) and location of axis of rotation \( x_0. \) This fact is borne out, as indicated in the preceding paragraph, by considering the integrated (spanwise) value of the component of damping moment \( M_4 \) associated with pitching or torsional
motions. The main results of this phenomenon can be obtained by considering very slow oscillations so that only terms in equation (40a) for $M_4$ involving the reduced frequency $k$ to the order $1/k$ need be retained. In this case,

$$M_4 = \frac{\sqrt{C_{x_1^2} - y^2}}{k} \left\{ \frac{4x_0^2}{\beta^2} \left[ (M^2 + 1)A_0 - A_1(4M^2 - 2) \right] + \frac{8(2M^2 - 1)}{3\beta^2c^2} \lambda_1y^2 + \frac{4x_0}{\beta^2} \left[ (A_0 - (2M^2 - 1)A_1)x_1 + \beta^2x_0A_0 \right] \right\} \quad (41)$$

For the triangular plan form (fig. 5(a)) the integrated value or total component of moment coefficient is

$$\overline{M}_4 = \frac{\pi c^2}{2\beta^2x} \left\{ -(2M^2 + 1)A_0 + 3(2M^2 - 1)A_1 + 4x_0 \left[ A_0 - (2M^2 - 1)A_1 \right] + \right\} \quad (42)$$

In general, the condition of torsional stability or instability depends on the sign and magnitude of $\overline{M}_4$ in equation (42). Positive values of $\overline{M}_4$ indicate stable conditions and negative values indicate the possibility of torsional instability. Between the stable and unstable conditions, that is when $\overline{M}_4$ vanishes, a borderline state of unstable equilibrium separating damped and undamped torsional oscillations exists.

The ranges of values of Mach number $M$ and location of axis of rotation $x_0$ for which $M_4$ vanishes for some selected values of $C = \tan \epsilon$ are shown plotted in figure 7. The regions inside the curve in this figure indicate instability. The dashed curve, on which some of the solid curves terminate, represents the locus of values of $M$ and $x_0$ for which $\overline{M}_4$ vanishes for the whole class of triangular wings with supersonic leading edges, that is, for triangular wings where $\beta c \geq 1$. It will be noted that $M_4$ vanishes for values of $x_0$ ahead of the root $\frac{3}{4}$-chord position. It will also be noted that, as the vertex
angle $\epsilon = \tan^{-1} C$ decreases to $30^\circ$, the range of values of Mach number for which $\tilde{M}_h$ vanishes decreases sharply.

In conclusion, investigation of equation (42) shows that, for a given value of the reduced frequency $k$, Mach number $M$, and location of the axis of rotation $x_0$, the magnitude of the damping coefficient $\tilde{M}_h$ decreases as $C$ decreases and, consequently, torsional instability is less likely to occur with slender triangles than with wider triangles.

APPENDIX

METHOD FOR DETERMINING DISTRIBUTION FUNCTIONS

In this appendix a method of obtaining the distribution functions is developed in detail. Expressions for the distribution functions required to derive the velocity potential to the third power of the frequency of oscillations and a set of functions useful in writing the expression for the potential in concise form are given.

As indicated in references 8 and 9, where the triangular wing is treated for constant angle of attack and for constant rolling and pitching motions, a convenient form of the velocity potential corresponding to a distribution of vertical velocity proportional to \( x^n \) is

\[
\phi_n = \frac{1}{\pi} \frac{\partial}{\partial z} \int_C F_n(\sigma) \, d\sigma \int_0^{\xi_1} \frac{\xi^{n+2} \, d\xi}{\sqrt{(x - \xi)^2 - \beta^2(y - \sigma\xi)^2 - \beta^2z^2}} \tag{A1}
\]

where \( \sigma \) is the slope of a ray passing through the vertex of the wing \( (\eta = \sigma\xi) \), \( \xi_1 \) is the least value of \( \xi \) that causes the denominator \( R \) in the integrand to vanish, and \( F_n(\sigma) = \frac{1}{\xi} D_n(\xi, \eta) \) is the distribution function that is to be determined so that

\[
(\phi_n)_{z=0} = \left. \left( \frac{\partial \phi_n}{\partial z} \right) \right|_{z=0} = x^n \tag{A2}
\]

In equation (A1), the integrand is noted to be singular at the limit \( \xi = \xi_1 \). A form of the integrand which avoids this difficulty is obtained by making the following change of variables:

\[
\begin{align*}
q &= \frac{x}{1 - \beta^2\sigma^2} \left( 1 - \beta^2\sigma^2 \right) \\
N &= \frac{\beta}{1 - \beta^2\sigma^2} \sqrt{(\theta - \sigma)^2 + \frac{z^2}{x^2} (1 - \beta^2\sigma^2)} \\
\theta &= \frac{N}{x} \\
\tau &= \cosh^{-1} \frac{q - \xi}{N}
\end{align*} \tag{A3}
\]
where \( \tau \) is the new variable of integration. With these substitutions equation (A1) becomes

\[
\phi_n = \frac{1}{\pi} \int_{-C}^{C} \frac{F_n(\sigma)}{\sqrt{1 - \beta^2 \sigma^2}} \int_0^{\cosh^{-1} \frac{q}{N}} (q - N \cosh \tau)^{n+2} \, d\tau
\]

and the corresponding expression for \( w_n = \left( \frac{\partial \phi_n}{\partial z} \right)_{z=0} \), which is an integral equation for \( F_n(\sigma) \), is

\[
w_n = \frac{1}{\pi} \lim_{z \to 0} \left\{ -\beta^2 (n+2) \int_{-C}^{C} \frac{F_n(\sigma)}{(1 - \beta^2 \sigma^2)^{3/2}} \int_0^{\cosh^{-1} \frac{q}{N}} N^{n-2} \left( \frac{q}{N} - \cosh \tau \right)^{n+1} \cosh \tau \, d\tau + \right\}
\]

\[
\beta^4 \sigma^2 (n+2) \int_{-C}^{C} \frac{F_n(\sigma) \, d\sigma}{(1 - \beta^2 \sigma^2)^{5/2}} \int_0^{\cosh^{-1} \frac{q}{N}} N^{n-2} \left( \frac{q}{N} - \cosh \tau \right)^{n+1} \left( \frac{q}{N} + \frac{n \cosh \tau}{N} \right) \cosh \tau \, d\tau
\]

\[
= x^n
\]

In this equation the value of \( w_n \) obtained by performing the indicated integrations and then going to the limit \( z = 0 \) is the same as the value that would be obtained by first going to the limit and then performing the integration but neglecting singularities, pointed out subsequently, that arise when the value of \( \sigma \) approaches the value of \( \sigma \). Making use of this fact reduces the calculations involved and simplifies the integral equation for \( F_n \). Thus passing to the limit gives for equation (A5)
\[
\begin{align*}
\frac{d^K w_n}{d\theta^K} &= -\frac{\beta^2(n+2)}{\pi} \int C \frac{F_n(\sigma)}{(1 - \beta^2 \sigma^2)^{3/2}} \int_0^{\cosh^{-1} \frac{q}{N_0}} \frac{q}{N_0} \left( \frac{\beta x}{1 - \beta^2 \sigma^2} \right)^K (q) - \\
N_0 \cosh \tau \frac{\cosh \tau}{N_0} \phi(\tau) \, d\tau &= 0 
\end{align*}
\]

where \( N_0 \) is the value of \( N \) at \( z = 0 \). The requirement that the normal velocity be proportional to \( x^n \) and independent of \( y \) implies that all derivatives of equation (A6) with respect to \( y \) or \( \theta \) must vanish, or that \( F_n(\sigma) \) must be so determined that the final value of the integral in this equation be independent of \( \theta \). The requirement that all derivatives of equation (A6) with respect to \( \phi \) vanish leads to other equations for \( F_n \), and, after \( n + 1 \) such differentiations, the equations acquire forms for which solutions are known. The value of \( F_n \) can then be determined from these known solutions by evaluating each of the derivatives \( \frac{d^K w_n}{d\theta^K} \) at any arbitrary value of \( \theta \) in the range \(-C < \theta < C\) as follows:

The Kth derivative of \( w_n \) with respect to \( \theta \) (equation (A6)) gives the following integral equation for \( F_n \):

\[
\begin{align*}
\frac{d^K w_n}{d\theta^K} &= -\frac{\beta^2(n+2)}{\pi} \int C \frac{F_n(\sigma)}{(1 - \beta^2 \sigma^2)^{3/2}} \int_0^{\cosh^{-1} \frac{q}{N_0}} \frac{q}{N_0} \left( \frac{\beta x}{1 - \beta^2 \sigma^2} \right)^K (q) - \\
N_0 \cosh \tau \frac{\cosh \tau}{N_0} \phi(\tau) \, d\tau &= 0 
\end{align*}
\]
where

\[
\phi(\tau) = \frac{(n + 1)!}{(n + 1 - K)!} \left( \frac{\beta \sigma \cosh \tau + q}{N_0 \cosh \tau - q} \right)^K - \\
\frac{K(n + 1)!}{(n + 2 - K)!} \left( \frac{\beta \sigma \cosh \tau}{N_0 \cosh \tau - q} \right)^{K-1} - \\
\frac{K(K - 1)(n + 1)!}{(n + 3 - K)!} \left( \frac{\beta \sigma \cosh \tau + q}{N_0 \cosh \tau - q} \right)^{K-2} N_0^{-2} + \ldots + (-1)^K K! N_0^{-K}
\]

When \( K = n + 1 \), the expression for \( \phi(\tau) \) may be recognized as being a binomial expression, namely

\[
\phi(\tau) = (n + 1)! \left( \frac{\beta \sigma \cosh \tau + q}{N_0 \cosh \tau - q} - \frac{1}{N_0} \right)^{n+1}
\]

\[
= \frac{(n + 1)! (\beta \sigma N_0 + q)^{n+1}}{(-N_0)^{n+1} (q - N_0 \cosh \tau)^{n+1}}
\]

\[
= \frac{(n + 1)! x^{n+1}}{(-N_0)^{n+1} (q - N_0 \cosh \tau)^{n+1}}
\]
Thus the integral equation corresponding to the $n + 1$ derivative of $w_n$ is

$$\frac{d^{n+1}w_n}{d\theta^{n+1}} = \frac{(-1)^{n+1}(n + 2)! \beta^{n+2} \xi^{2n+2}}{\pi} \int_{C} \frac{F_n(\sigma) \, d\sigma}{N_0^{n+2}(1 - \beta^2 \sigma^2)^{n+2}} \int_{0}^{\sinh^{-1} \frac{\sqrt{1-\beta^2 \sigma^2}}{N_0(1-\beta^2 \sigma^2)^2} \cosh \tau \, d\tau}

= \frac{(-1)^{n+1}(n + 2)! \xi^{n+1}}{\pi} \int_{C} \frac{F_n(\sigma)}{(\theta - \sigma)^{n+3}} \, d\sigma = 0 \quad (A9)$$

Further differentiation of $w_n$ leads to other equations involving integrals similar to that in equation (A9) and, as will be seen subsequently, is not necessary for the determination of $F_n$. The singularity at $\sigma = \theta$ in equation (A9) is a result of going to the limit $z = 0$ after equation (A5) and, as previously implied, is to be ignored.

Consider the following equation similar to equation (A9):

$$\int_{C} \frac{f_n(\sigma) \, d\sigma}{\theta - \sigma^{n+3}} = 0 \quad (A10)$$

It is known by analogy with problems in incompressible flow and may be shown by direct substitution and reduction that this equation is satisfied for any value of $n$ ($n = 0, 1, 2, \ldots$) by the function

$$f_0(\sigma) = \sqrt{c^2 - \sigma^2} \quad (A11)$$
This function also satisfies equation (A9) for any value of \( n \) and satisfies equation (A7) for all derivatives \( \frac{\partial^K \omega_n}{\partial \theta^K} \) beyond the \( n \)th derivative. A more general form of solution to equation (A10) may be shown to be

\[
f_m = \sigma^m \sqrt{c^2 - \sigma^2} \tag{A12}
\]

where \( m \) is an integer and \( m \leq n \). The validity of this solution follows, since

\[
\sigma^m = \left[ \theta - (\theta - \sigma) \right]^m = \sum_{r=0}^{m} \frac{m! \sigma^{m-r}}{(m-r)! r!} (\theta - \sigma)^r \tag{A13}
\]

and

\[
\frac{\sigma^m \sqrt{c^2 - \sigma^2}}{(\theta - \sigma)^{n+3}} = \sum_{r=0}^{m} \frac{m! \sigma^{m-r}}{(m-r)! r!} \frac{\sqrt{c^2 - \sigma^2}}{(\theta - \sigma)^{n-r+3}} \tag{A14}
\]

Each term of the summation in equation (A14) is found to have the form of the integrand in equation (A10), from which the function (A12) is concluded to satisfy equation (A10) and equation (A7) for all values of \( K > n \).

From the foregoing discussion and consideration the distribution function \( F_n(\sigma) \) may be uniquely determined in terms of expression (A12) as follows:

Consider the expression

\[
F_n(\sigma) = A_0 f_0 + A_1 f_1 + \ldots + A_n f_n \tag{A15}
\]

where the coefficients \( A_0, A_1, \ldots, A_n \) are constants that are to be determined.

Each term on the right of equation (A15) is noted to satisfy equation (A7) for all derivatives beyond the \( n \)th and a total of
n + 1 parameters is to be determined. If expression (A15) is introduced into equations (A6) and (A7) and the indicated integrations in equation (A6) and in equation (A7) for \( K = 1, 2, \ldots, n \) are performed, \( n + 1 \) linear equations are obtained in \( A_0, A_1, \ldots, A_n \) from which these constants may be determined.

The integrations with respect to \( \sigma \) in equations (A6) and (A7) are in general difficult and tedious to perform; however, as previously pointed out it is only necessary to perform the integrations for some particular value of \( \theta \) in the range \(-C < \theta < C\). The integrals have their simplest form when \( \theta = 0 \) and the integrations can be made for this value of \( \theta \) by reductions and use of formulas in reference 11.

The distribution functions \( F_0(\sigma), F_1(\sigma), F_2(\sigma), F_3(\sigma), F_0(\sigma), \) and \( F_1(\sigma) \) and functions \( D_n(\xi, \eta) \) calculated by the foregoing method are as follows:

\[
F_0 = A_0\sqrt{c^2 - \sigma^2} \quad D_0 = A_0\sqrt{c^2\xi^2 - \eta^2}
\]

\[
F_1 = A_1\sqrt{c^2 - \sigma^2} \quad D_1 = A_1\sqrt{c^2\xi^2 - \eta^2}
\]

\[
F_2 = (A_2 + A_3\beta^2\sigma^2)\sqrt{c^2 - \sigma^2} \quad D_2 = \left( A_2 + A_3\frac{\beta^2\eta^2}{\xi^2} \right)\sqrt{c^2\xi^2 - \eta^2}
\]

\[
F_3 = (A_4 + A_5\beta^2\sigma^2)\sqrt{c^2 - \sigma^2} \quad D_3 = \left( A_4 + \frac{A_5\beta^2\eta^2}{\xi^2} \right)\sqrt{c^2\xi^2 - \eta^2}
\]

\[
F_0 = (A_6 + A_7\beta^2\sigma^2)\sqrt{c^2 - \sigma^2} \quad D_0 = \left( A_6 + A_7\frac{\beta^2\eta^2}{\xi^2} \right)\sqrt{c^2\xi^2 - \eta^2}
\]

\[
F_1 = (A_8 + A_9\beta^2\sigma^2)\sqrt{c^2 - \sigma^2} \quad D_1 = \left( A_8 + A_9\frac{\beta^2\eta^2}{\xi^2} \right)\sqrt{c^2\xi^2 - \eta^2}
\]

where

\[
A_0 = \frac{1}{E'}
\]

\[
A_1 = \frac{1 - \beta^2\sigma^2}{\beta^2c^2E' + (1 - \beta^2\sigma^2)E'}
\]
\[ A_2 = \frac{2d_3}{2d_1 d_3 + \beta^2 c^2 d_2^2} \]

\[ A_3 = \frac{2d_2}{2d_1 d_3 + \beta^2 c^2 d_2^2} \]

\[ A_4 = \frac{6d_6}{6d_4 d_6 + \beta^2 c^2 d_5^2} \]

\[ A_5 = \frac{6d_5}{6d_4 d_6 + \beta^2 c^2 d_5^2} \]

\[ A_6 = \frac{2d_3 d_7 - \beta^2 c^2 a_2 d_8}{2d_1 d_3 + \beta^2 c^2 d_2^2} \]

\[ A_7 = \frac{2(d_1 d_8 + d_2 d_7)}{2d_1 d_3 + \beta^2 c^2 d_2^2} \]

\[ A_8 = \frac{6d_6 d_9 - \beta^2 c^2 a_2 d_5}{6d_4 d_6 + \beta^2 c^2 d_5^2} \]

\[ A_9 = \frac{6(d_2 d_4 + d_3 d_9)}{6d_4 d_6 + \beta^2 c^2 d_5^2} \]

The quantities \( a_n \) are defined as

\[ a_1 = \frac{5(\beta^2 c^2 - 3\beta^4 c^4)F' + (2 - 10\beta^2 c^2 + 6\beta^4 c^4)E'}{2(1 - \beta^2 c^2)^2} \]
\[ d_2 = \frac{2\beta^2 c^2 F' - (1 + \beta^2 c^2)E'}{(1 - \beta^2 c^2)^2} \]

\[ d_3 = \frac{(3\beta^2 c^2 - 5\beta^4 c^4)F' - (6 - 10\beta^2 c^2 + 2\beta^4 c^4)E'}{(1 - \beta^2 c^2)^2} \]

\[ d_4 = \frac{(27\beta^2 c^2 - 31\beta^4 c^4 + 12\beta^6 c^6)F' + (6 - 55\beta^2 c^2 + 65\beta^4 c^4 - 24\beta^6 c^6)E'}{6(1 - \beta^2 c^2)^3} \]

\[ d_5 = \frac{(9\beta^2 c^2 - \beta^4 c^4)F' - (3 + 7\beta^2 c^2 - 2\beta^4 c^4)E'}{(1 - \beta^2 c^2)^3} \]

\[ d_6 = \frac{(3\beta^2 c^2 - 9\beta^4 c^4 - 2\beta^6 c^6)F' - (6 - 15\beta^2 c^2 + 5\beta^4 c^4 - 4\beta^6 c^6)E'}{(1 - \beta^2 c^2)^3} \]

\[ d_7 = \frac{\beta^2 c^2 (E' - F')}{2(1 - \beta^2 c^2)} \]

\[ d_8 = \frac{\beta^2 c^2 F' - E'}{1 - \beta^2 c^2} \]

\[ d_9 = \frac{\beta^2 c^2 \left[(\beta^2 c^2 - 3)F' + (4 - 2\beta^2 c^2)E' \right]}{6(1 - \beta^2 c^2)^2} \]
Combinations of these functions useful for writing the potential in concise form are:

\[
\begin{align*}
\frac{A_0 - A_1}{2} &= \lambda_1 \\
\frac{A_1 - A_2}{2} &= \lambda_2 \\
\frac{A_2 - A_3}{2} &= \lambda_3 \\
\frac{2A_3 - A_4}{2} &= \lambda_4 \\
\lambda_1 - \lambda_2 &= \lambda_5 \\
\lambda_2 - \lambda_3 &= \lambda_6 \\
\lambda_5 - \lambda_6 &= \lambda_7 \\
\lambda_4 + \frac{A_3}{2} &= \lambda_8 \\
\frac{A_0A_6}{2} &= \lambda_9 \\
\frac{A_0A_7}{2} &= \lambda_{10} \\
\frac{A_1A_8}{2} &= \lambda_{11} \\
\frac{A_1A_9}{2} &= \lambda_{12} \\
\lambda_9 - \lambda_{11} &= \lambda_{13} \\
\lambda_{10} - \lambda_{12} &= \lambda_{14}
\end{align*}
\]

It will be noted that the quantities \( A_i \) \((i = 0, 1, \ldots, 9)\) and \( \lambda_j \) \((j = 1, 2, \ldots, 14)\) are functions only of the product \( \beta C \). They are shown plotted in figures 3 and 4, respectively. The quantities \( \sigma_k \) \((k = 1, 2, \ldots, 6)\) are functions of Mach number \( M \) and the product \( \beta C \) and can be evaluated for particular values of \( M \) from the plots of \( A_i \) and \( \lambda_j \).
