RESEARCH MEMORANDUM

THE EFFECTS OF CENTRALLY MOUNTED WING-TIP TANKS
ON THE SUBSONIC AERODYNAMIC CHARACTERISTICS
OF A WING OF ASPECT RATIO 10 WITH 35°
OF SWEEPBACK

By Bruce E. Tinling and W. Richard Kolk
Ames Aeronautical Laboratory
Moffett Field, Calif.

CLASSIFICATION CANCELLED
The effects of three centrally mounted wing-tip tanks on the aerodynamic characteristics of a cambered wing having an aspect ratio of 10 and 35° of sweepback were investigated. The three tip tanks had equal volumes and fineness ratios of 10, 6.67, and 5. The Reynolds number was varied from 2,000,000 to 10,000,000 at a Mach number of 0.25, and the Mach number was varied from 0.25 to 0.90 at a Reynolds number of 2,000,000. Lift, drag, and pitching moment were measured. The tip tanks reduced the maximum lift-drag ratio approximately 10 percent at a Mach number of 0.25 and a Reynolds number of 10,000,000. The reduction in drag-divergence Mach number caused by the tip tanks was small, the maximum reduction being about 0.02. In general, the reduction in the drag-divergence Mach number and in the lift-drag ratio at high Mach numbers caused by the tip tank having a fineness ratio of 10 was less than that caused by the tip tanks having fineness ratios of 6.67 and 5. At Mach numbers less than the drag-divergence Mach number the tip tanks caused an increase in static longitudinal stability indicated by a change in pitching-moment-curve slope $\frac{\partial C_m}{\partial C_L}$ of about -0.08. At low speeds, a vane near the tank-wing juncture alleviated flow separation near the juncture at Reynolds numbers of 6,000,000 and 10,000,000.

INTRODUCTION

The use of auxiliary fuel tanks mounted on the wing tips has been successful in extending the range of airplanes with unswept wings. Results of wind-tunnel tests have indicated that properly designed wing-tip fuel tanks may be used with unswept wings with very little change in the pitching-moment characteristics. In some instances (reference 1), an improvement in the drag at high lift coefficients was attained due to the
increase in the effective aspect ratio resulting from the end-plate
effects of the tip tanks. Data concerning the effects of external
stores, including wing-tip tanks, on the aerodynamic characteristics of
a tailless airplane having a wing with an aspect ratio of 3.01 and 35°
of sweepback are presented in reference 2. The effects of bodies of
revolution mounted on the tips of a wing having an aspect ratio of 3.5
and 63° of sweepback are presented in reference 3.

The present investigation was conducted in the Ames 12-foot pressure
wind tunnel to evaluate the effects of centrally mounted wing-tip tanks
having fineness ratios of 10, 6.67, and 5 on the aerodynamic characteristics of a cambered wing having an aspect ratio of 10 and 35° of sweep-
back. The results of tests of the semispan model wing without tip tanks
have previously been reported in reference 4.

The tests were conducted over a range of Mach numbers from 0.25 to
0.90 at a Reynolds number of 2,000,000 and over a range of Reynolds num-
bers from 2,000,000 to 10,000,000 at a Mach number of 0.25.

MODELS

The semispan model wing had 35° of sweepback of the quarter-chord line, a taper ratio of 0.5, and represented a wing of aspect ratio 10. The streamwise wing sections were the NACA 641A312 with a modified $a = 0.8$ mean line. (See reference 5.) The coordinates of the section are tabulated in table I. The three tip tanks were bodies of revolution having equal volumes and having fineness ratios of 10, 6.67, and 5. For each of the tanks, the longitudinal section containing the axis was that of an NACA 65A-series airfoil. (See table II.) Each tank was equipped with a vane, the purpose of which was to prevent flow separation at the tank-wing juncture. Details of the wing and tanks, and the position of the vane are shown in figure 1. The model wing and the tip tanks were furnished by the Lockheed Aircraft Corporation.

The turntable upon which the model was mounted in the wind tunnel is directly connected to the force-measuring apparatus. The model was mounted with the root chord in the plane of the turntable and the
turntable-model juncture was sealed. A photograph of the model mounted in the wind tunnel and of a typical tip-tank installation is shown in figure 2.

TESTS

Two series of tests were conducted: one to evaluate the effects of compressibility at a constant Reynolds number, and one to evaluate the effects of Reynolds number at a low Mach number. Lift, drag, and pitching moment were measured over a range of angle of attack sufficient to obtain lift coefficients from less than zero to that for stall, except where the range was limited by the capacity of the force balance or by the strength of the model.

The tests to evaluate the effects of compressibility were conducted at Mach numbers from 0.25 to 0.90 and at a Reynolds number of 2,000,000. The tests to evaluate the effects of Reynolds number were conducted at a Mach number of 0.25 and at Reynolds numbers up to 10,000,000.

CORRECTIONS TO DATA

The data have been corrected for the effects of tunnel-wall interference, including constriction due to the presence of the tunnel walls, and approximately for model-support bare forces.

Corrections to the data for the effects of tunnel-wall interference originating from lift on the model have been evaluated by the methods of reference 6, using the theoretical span loading for incompressible flow calculated by the methods of reference 7. The corrections added to the drag and to the angle of attack were

$$\Delta \alpha = 0.295 \, C_L$$

$$\Delta C_D = 0.00472 \, C_L^2$$

Constriction effects due to the presence of the tunnel walls were computed by the methods of reference 8. These corrections have not been modified to allow for the effect of sweep. The magnitudes of the corrections to the Mach number and to the dynamic pressure are shown in the following table:
A correction to the drag data was made to allow for forces on the exposed surface of the turntable. This correction was determined from tests with the model removed from the tunnel. The following tare corrections were subtracted from the measured drag coefficients:

No attempt was made to evaluate tares due to interference between the model and the turntable or to compensate for the tunnel–floor boundary layer which, at the location of the model, had a displacement thickness of one-half inch.
RESULTS AND DISCUSSION

Effects of Reynolds Number

The results of tests conducted to evaluate the effects of changing Reynolds number on the aerodynamic characteristics of the wing alone and of the wing and tip tank combinations are presented in figure 3. As reported in reference 4, decreasing the Reynolds number resulted in a reduction of lift over the outer sections of the wing. This reduction of lift caused a large change in the aerodynamic characteristics of the wing alone. As would be anticipated from these results, the effects of Reynolds number on the wing and tip tank combinations were also large.

The lift-drag ratios computed from the data shown in figure 3 are presented in figure 4. Inspection of these data reveals that the decrement of the lift-drag ratio caused by the tip tanks was dependent upon the test Reynolds number. At lift coefficients near that for the maximum lift-drag ratio, the tip tanks caused a greater decrease in the lift-drag ratio at a Reynolds number of 2,000,000 than at a Reynolds number of 10,000,000. At higher lift coefficients, increasing the Reynolds number had the opposite effect, the tanks causing a greater decrease in lift-drag ratio at a Reynolds number of 10,000,000 than at a Reynolds number of 2,000,000.

Effects of Wing-Tip Tanks at Low Subsonic Speeds

Only the data obtained at a Reynolds number of 10,000,000 will be considered in discussing the effects of tip tanks on the low-speed aerodynamic characteristics since these data are the most nearly representative of full-scale conditions. The data obtained at a Reynolds number of 10,000,000 and a Mach number of 0.25 are presented in figure 5. The values of some pertinent aerodynamic parameters as obtained from the data of this figure are presented in the following table:
The design lift coefficient of the wing was approximately 0.25 (streamwise section design lift coefficient multiplied by the cosine of 35°).

At R = 6,000,000 (fig. 3).

The increase in lift-curve slope of 0.004 per degree due to the tip tanks was primarily due to an increase in the effective aspect ratio caused by end-plate effects. Computations based on the lift of an isolated body of fineness ratio 9.9 (reference 9) indicate that the lift forces on the tanks could not account for an increase in the lift-curve slope of more than about 0.0003 per degree. Previous studies of wing and centrally mounted wing and tip tank combinations have, in some instances (reference 1), indicated a reduction in the induced drag due to an increase in the effective aspect ratio, which, at large lift coefficients, was sufficient to compensate for the drag of the tanks. The variation of $C_D - C_{D_{\text{min}}}$ with lift coefficient squared, presented in figure 6, shows that the value of $C_D - C_{D_{\text{min}}}$ was, in general, greater for the wing and tip tank combinations than for the wing alone. This indicates that the decrease in induced drag resulting from an increase in effective aspect ratio due to the tip tanks in the present investigation was not sufficient to compensate for the increases with lift coefficient in the profile drag due to the tank.

The tip tanks caused an increase of static longitudinal stability as is indicated by a change in the pitching-moment-curve slope $\frac{\partial C_m}{\partial C_L}$. 

\begin{table}[h]
\centering

\hline
\end{tabular}
\end{table}
of about −0.08. It should be noted, however, that on swept wings the weight of tip tanks and tip tank fuel is destabilizing since the installation is aft of the normal center of gravity. The aerodynamic effects therefore tend to counterbalance the mass effects of tip tanks.

As the lift coefficient was increased above about 0.3, the static longitudinal stability of the wing alone gradually became less. The static longitudinal stability of the wing and tip tank combinations, however, showed a more definite discontinuity as the lift coefficient was increased beyond about 0.3. (See fig. 5.)

Effect of Wing-Tip Tanks at High Subsonic Mach Numbers

The data obtained at Mach numbers from 0.25 to 0.90 at a Reynolds number of 2,000,000 are presented in figure 7. The effects of Mach number on the wing alone have previously been reported in reference 4.

The drag coefficient as a function of Mach number is presented in figure 8 for several values of lift coefficient. The Mach numbers for drag divergence, defined as the Mach number for which $\frac{\partial C_D}{\partial M} = 0.1$, are presented in the following table:

</table>

In addition to having a higher drag–divergence Mach number than the other wing and tip tank combinations, the drag of the wing and tip tank of fineness ratio 10 was less than that of the other wing and tip tank combinations at the higher Mach numbers. The lower drag of the wing and tip tank having a fineness ratio of 10 is further illustrated in figure 9 where the variation of lift–drag ratio with lift coefficient is presented. Up to a Mach number of about 0.70, these data indicate no important differences between the lift–drag ratios of the three wing and tip tank combinations. At Mach numbers greater than 0.70, the lift–drag ratio was, in general, greater for the wing and tip tank combination with the tip tank having a fineness ratio of 10 and least for the combinations with the tip tank having a fineness ratio of 5.
The possible effect of Reynolds number must be considered when comparing the lift–drag ratios of the wing alone and the wing and tip tank combinations at high Mach numbers. The results of tests at a Mach number of 0.25 indicated a large effect of Reynolds number on the decrement in lift–drag ratio due to the tip tanks. If these effects prevail at the higher Mach numbers, the decrement in lift–drag ratio due to the tip tanks for lift coefficients near that for maximum lift–drag ratio will not be as great at full-scale Reynolds numbers as indicated by the data at a Reynolds number of 2,000,000. At greater lift coefficients, an increase in Reynolds number may cause an increase in the decrement in lift–drag ratio due to the tip tanks. (See fig. 4.)

The effects of tip tanks on the lift–curve slope and the pitching-moment–curve slope at high subsonic speeds are summarized in figure 10 for a lift coefficient of 0.25. For Mach numbers up to about that for drag divergence, the tip tanks increased the lift–curve slope by approximately 0.005 and caused the pitching–moment–curve slope $\frac{\partial C_m}{\partial C_L}$ to more negative by about 0.06, indicating an increase of static longitudinal stability. The tip tanks caused no significant change in the Mach number at which the abrupt decrease of lift–curve slope occurred. The tip tanks of fineness ratios 6.67 and 5, however, did decrease the Mach number at which a decrease of static longitudinal stability occurred.

Effectiveness of the Wing-Tip-Tank Vane

The aerodynamic characteristics of the wing and tip tank having a fineness ratio of 6.67 both with and without the tip–tank vane are presented in figures 11 and 12. The results at a Mach number of 0.25 and Reynolds numbers of 6,000,000 and 10,000,000 show that the vane alleviated the separation effects over the outer sections of the wing. This alleviation is evidenced by the larger negative value of pitching–moment coefficient, increased lift coefficients, and decreased drag coefficients at angles of attack greater than about 7° when the vane was in place. The effect of the vane at a Reynolds number of 2,000,000 at Mach numbers from 0.25 to 0.875 was small except at a Mach number of 0.70. At this Mach number, the lift coefficient at which a reduction of static longitudinal stability occurred was increased from about 0.5 to 0.7 by the vane.

CONCLUSIONS

The results of wind–tunnel tests to evaluate the effects of centrally mounted wing–tip tanks on the aerodynamic characteristics of a
cambered wing having an aspect ratio of 10 with 35° of sweepback have been presented. These results indicated that:

1. The reduction in maximum lift-drag ratio due to the tip tanks was about 10 percent at a Reynolds number of 10,000,000 and a Mach number of 0.25. The decrement in the lift-drag ratio due to the tip tanks was dependent on the test Reynolds number.

2. The reduction in the drag-divergence Mach number due to the tip tanks was small, the greatest reduction observed being approximately 0.02. The reduction in the Mach number for drag divergence and in the lift-drag ratio at high Mach numbers was less for the tip tank having a fineness ratio of 10 than for those having fineness ratios of 6.67 and 5.

3. The tip tanks caused the pitching-moment-curve slope $\frac{\partial C_m}{\partial C_L}$ to be changed by about -0.08 at Mach numbers up to approximately the Mach number of drag divergence.

4. At low speeds and Reynolds numbers of 6,000,000 and 10,000,000 the vane near the tip tank and wing juncture alleviated the local separation.
