LONGITUDINAL FLIGHT CHARACTERISTICS
OF THE BELL X-5 RESEARCH AIRPLANE AT 59° SWEEPBACK
WITH MODIFIED WING ROOTS
By James A. Martin

SUMMARY

In an attempt to improve the longitudinal stability characteristics of the Bell X-5 research airplane at 59° sweepback, the wing-root leading edge was modified by replacing the original 52.5° sweptback leading-edge fillets with rounded leading-edge fillets. The data obtained show that the longitudinal stability characteristics, as well as the buffet and drag characteristics, were unaffected by the modification.

INTRODUCTION

The results of a wind-tunnel investigation reported in reference 1 indicated that modifications of the leading-edge fillets of a model similar to the Bell X-5 research airplane substantially improved the longitudinal stability characteristics at high lift conditions. In view of these results a fillet modification similar to one of those investigated in reference 1 has been evaluated in flight on the Bell X-5 airplane at 59° sweepback in an attempt to alleviate the reduction of longitudinal stability discussed in reference 2. This reduction of stability limited the usable range of normal-force coefficient available for performing precise flight maneuvers, although the pilot did not consider the reduction of stability to be dangerous at altitudes above 30,000 feet.

The results of a flight made with the modified leading-edge fillets compared with the results of a flight made with the original fillets are presented in this paper. The flights were made at the NACA High-Speed Flight Research Station, Edwards Air Force Base, Calif.
SYMBOLS

b  wing span, ft

$C_D$  drag coefficient, total drag/qS

$C_L$  lift coefficient, total lift/qS

$C_{m_{\frac{\pi}{4}}}$  pitching-moment coefficient about quarter chord of $c$

$C_{N_A}$  airplane normal-force coefficient, $nW/qS$

$C_{N_t}$  tail normal-force coefficient, $L_t/qS_t$

$C_{N_w}$  wing normal-force coefficient, $2L_w/qS$ (one wing)

c  chord at any section along span, ft

$\bar{c}$  mean aerodynamic chord, ft

$F_e$  elevator stick force (pull is positive), lb

g  acceleration due to gravity, $ft/sec^2$

$h_p$  pressure altitude, ft

$i_t$  horizontal-tail angle of incidence, deg

$L_t$  aerodynamic horizontal-tail load (up tail load positive), lb

$L_w$  aerodynamic load on one wing (up load positive), lb

M  Mach number

n  airplane normal acceleration, g units

$\rho$  dynamic pressure, $\rho V^2/2$, lb/sq ft
DESCRIPTION OF THE AIRPLANE

The Bell X-5 research airplane is a single-place, midwing, turbojet-powered airplane on which the sweepback may be varied in flight between $20^\circ$ and $59^\circ$. The data presented in this paper were obtained at a constant sweepback of $59^\circ$. The physical characteristics are presented as table I and a three-view drawing at $59^\circ$ sweepback is shown in figure 1. In this drawing the right wing is shown in the modified condition and the left wing in the original configuration. Figure 2 is a photograph of the airplane at $59^\circ$ sweepback. A photograph of the original and the modified fillets and a drawing of the two fillets with pertinent dimensions are presented as figures 3 and 4, respectively.

The wing chord parallel to the airplane center line and passing through the wing pivot point (27.72 inches from the plane of symmetry) was decreased 18.85 inches by the modification, with a reduction of 1.37 square feet in the total wing area outboard of this point. The airfoil thickness at the section through the pivot point was increased from 6.94 to 8.27 percent chord by the modification.
INSTRUMENTATION AND ACCURACY

During the tests reported in this paper standard NACA recording instruments were used to measure the following:

- Airspeed
- Altitude
- Normal, longitudinal, and transverse accelerations
- Elevator stick force
- Pitching angular velocity and acceleration
- Yawing angular velocity and acceleration
- Rolling angular velocity
- Control positions
- Sweepback
- Horizontal-tail shear and bending moment
- Wing shear and bending moment

The estimated errors are as follows:

- Mach number .................................................. ±0.01
- Airplane normal-force coefficient .......................... ±0.02
- Normal acceleration, g ........................................ ±0.02
- Measured tail loads, lb ...................................... ±75
- Measured wing loads, lb ...................................... ±100
- Airplane weight determination, lb .......................... ±100

TESTS, RESULTS, AND DISCUSSION

The original and modified wing-root configurations are compared in this paper on the basis of results obtained from stabilizer and elevator maneuvers into the region of reduced stability for both configurations. The tests were made at pressure altitudes from 28,000 to 40,000 feet and ranged in Mach number from that for the approach to an unaccelerated clean stall to a Mach number of 0.97. Figure 5 presents the boundary for the reduction of longitudinal stability through the Mach number range from 0.65 to 0.98 as presented in reference 2 but with points obtained with the modified configuration noted also. Figures 6 to 8 present typical plots of the variation of several parameters with angle of attack from which the points in figure 5 were ascertained. These particular figures are for stall approach, for \( M = 0.84 \), and for \( M = 0.97 \), respectively. The point of stability reduction is determined, primarily, from the variation of control deflection with angle of attack and corresponds to the point at which this variation abruptly changes to essentially zero. It may be noted that for several maneuvers this point is not readily apparent, particularly in figure 6. Consequently, the points
selected from figures 7 and 8 for inclusion in figure 5 are indicated. The comparison of the points for the modified and unmodified configurations in figure 5 indicate that there was no appreciable effect of the modification.

It is the opinion of the pilot who performed the flight tests that, in general agreement with figure 5, the modified fillets caused little apparent difference in the longitudinal stability characteristics. He did feel, however, that the reduction of stability seemed to occur at a slightly higher $C_{pA}$ for the modified fillets at Mach numbers near 0.94.

It may be observed in figures 6 to 8 that the maximum $C_{pA}$ obtained is about 0.1 lower at each of the three Mach numbers for the modified configuration than for the original configuration and the angle of attack for maximum $C_{pA}$ was from 2.6° to 4.95° lower for the modified wing root than for the original. The lower $C_{pA}$ and consequent lower angle of attack for the modified configuration can be attributed to the reduced pitching parameter $\frac{C}{\alpha} \frac{dC}{d\alpha}$ for the modified wing root due to decreased control deflection. Both maximum $C_{pA}$ and the angle of attack at which it occurred showed a tendency to decrease with increasing Mach number for the two configurations.

The variation of $C_{N_t}$ with $C_{pA}$ for both configurations at each of the test Mach numbers is shown in figure 9. The values of the slope of $C_{N_t}$ plotted against $C_{pA}$ as obtained from figure 9(a) show that the static longitudinal stability of the wing-fuselage combination is considerably different for both configurations in the approach to a clean stall. The slope $\frac{dC_{N_t}}{dC_{pA}}$ has a value of -0.215 for the original fillets and -0.30 for the modified fillets at lift coefficients below 0.45. For lift coefficients from 0.50 to 0.75 for the original wing root, $\frac{dC_{N_t}}{dC_{pA}}$ is equal to 0.195, whereas for the modified wing root, it is equal to 0.13.

For Mach numbers of 0.84 and 0.97 it may be observed from figures 9(b) and 9(c) that the variation of tail normal-force coefficient with airplane normal-force coefficient is similar for the original and modified configurations. The point of instability at $M = 0.84$ is at about the same lift as it is for the stall approach, whereas at $M = 0.97$, it occurs at a lower $C_{pA}$ for both configurations.
The scatter of data points apparent in figure 9(b) above $C_{NA}$ of 0.6 and in figure 9(c) above $C_{NA}$ of 0.5 is caused by the high pitching rates resulting from the reduction of longitudinal stability. Although the data have been corrected for pitching acceleration in these regions, the accuracy of these data is reduced.

Figure 10 presents wing normal-force coefficient as a function of airplane normal-force coefficient for both configurations at the test Mach numbers. It may be observed in figure 10 that the variation of wing normal-force coefficient with airplane normal-force coefficient is essentially the same at Mach numbers of 0.84 and 0.97. In the stall approach, however, there is a difference of 0.086 in the slope of the curve of $C_{NW}$ against $C_{NA}$ for the two configurations, with the modified wing-root configuration having the steeper slope, an indication that in this condition the wing carries a greater part of the airplane load.

Figure 11 presents the variations of wing pitching-moment coefficient with $C_{NA}$ for both wing-root configurations. It may be seen from this figure that at Mach numbers of 0.84 and 0.97 the wing pitching-moment coefficient is unaffected by the fillet modification. However, in the approach to a clean stall the modified configuration exhibits slightly greater stability, the slope $\frac{dC_m}{dC_{NA}}$ being equal to -0.22 for the original fillets and -0.29 for the modified fillets.

The drag polars for the two configurations are shown in figure 12. In the three polars there are only slight variations of drag coefficient with lift coefficient due to the wing-root modification.

Figure 13 presents sections of records from the three-component recording accelerometer which may be utilized to compare buffet intensities. The buffet intensity is directly proportional to the amplitude of the normal acceleration trace. For each of the test Mach numbers little, if any, difference can be observed between the buffet intensity of the original and modified wing-root configurations.

CONCLUDING REMARKS

A comparison has been made between two configurations of the Bell X-5 research airplane at 590 sweepback, one with the original wing-root fillets and the other with wing-root fillets shown by low-speed wind-tunnel investigation to eliminate the loss of stability at high lift coefficients. The data obtained from the flight investigation, however, show
that the longitudinal stability characteristics, as well as the buffet and drag characteristics, were essentially unaffected by the modification.
