April 1945 as Memorandum Report L5D12a

TESTS OF 0.14-SCALE MODELS OF THE CONTROL SURFACES OF
ARMY PROJECT MX-511 IN ATTITUDES SIMULATING SPINS

By H. Page Hoggard, Jr. and John R. Hagerman

Langley Memorial Aeronautical Laboratory
Langley Field, Va.

NACA WARTIME REPORTS are reprints of papers originally issued to provide rapid distribution of advance research results to an authorized group requiring them for the war effort. They were previously held under a security status but are now unclassified. Some of these reports were not technically edited. All have been reproduced without change in order to expedite general distribution.

TESTS OF 0.14-SCALE MODELS OF THE CONTROL SURFACES OF

ARMY PROJECT MX-511 IN ATTITUDES SIMULATING SPINS

By H. Page Hoggard, Jr. and John R. Hagerman

SUMMARY

Tests of 0.14-scale models of the partial-span wing and the isolated tail of the Bell XP-83 airplane (Army Project MX-511) have been made in the Langley 4-by 6-foot tunnel to determine the aerodynamic characteristics in attitudes simulating spin conditions. The tests were made at a Mach number of about 0.095.

The slope of the curve of aileron hinge moment against angle of attack increases negatively as the angle of attack of the wing is increased. At the higher angles of attack the slope of the curve of aileron hinge moment against aileron deflection is more negative for small aileron deflections even though the aileron hinge-moment increment from 25° to -25° aileron deflections is practically constant over the angle-of-attack range. The data presented indicate that in spin attitudes the yawing moment produced by the aileron is practically as much as the rolling moment.

The elevator hinge-moment increment from 25° to -25° elevator deflections is practically constant over the angle-of-attack range and the slope of the curve of elevator hinge moment against angle of attack increases negatively as the angle of attack of the horizontal tail is increased. The elevator hinge-moment and lift-curve slopes of the isolated-tail model show close agreement with those of the complete model.

As the angle of attack is increased the drag produced by elevator deflection increases while the lift produced by elevator deflection decreases. The elevator deflection has large effects on rudder hinge moments at $a_t = 20.5°$ and angle of yaw and rudder deflection of like signs. No consistent effect of elevator deflection on rudder hinge moment is shown at $a_t = 50.4°$, except that negative elevator deflec-
tions usually gave the largest rudder hinge moments for the yawed conditions.

INTRODUCTION

In view of the results of spin tests of a model of the Bell XP-83 airplane (Army Project MX-511) conducted in the Langley 20-foot free-spinning tunnel, it was deemed necessary to determine the hinge-moment characteristics of the control surfaces of the 0.14-scale model of the Bell XP-83 airplane in attitudes simulating spins.

In order to obtain the necessary control-surface hinge-moment data, 0.14-scale models of the left wing panel and of the isolated tail unit were tested in the Langley 4-by-6-foot tunnel. The hinge-moment data obtained are presented herein, along with the lift and drag data obtained from the same tests. It is planned to use the data presented herein in the estimation of stick and pedal forces during the steady spin and for spin recovery. Complete ranges of aileron, elevator, and rudder deflection over wide ranges of angle of attack and yaw simulating spin conditions were investigated.

COEFFICIENTS AND SYMBOLS

The results of the tests are presented as standard non-dimensional FACA coefficients of forces and moments as follows:

\[
C_{Lu} \quad \text{uncorrected lift coefficient of test panel} \left( \frac{L_u}{qS_w} \right)
\]

\[
C_{Lw} \quad \text{corrected lift coefficient of test panel} \left( \frac{L_w}{qS_w} \right)
\]

\[
C_{Lt} \quad \text{horizontal tail lift coefficient} \left( \frac{L_t}{qS_t} \right)
\]

\[
C_{Du} \quad \text{uncorrected drag coefficient of test panel} \left( \frac{D_u}{qS_w} \right)
\]

\[
C_{Dw} \quad \text{corrected drag coefficient of test panel} \left( \frac{D_w}{qS_w} \right)
\]

\[
C_{Dt} \quad \text{horizontal tail drag coefficient} \left( \frac{D_t}{qS_t} \right)
\]
\( C_l \) rolling-moment coefficient of complete wing \( \left( \frac{L}{qS'b'} \right) \)

\( C_n \) yawing-moment coefficient of complete wing \( \left( \frac{N}{qS'b'} \right) \)

\( C_{ba} \) aileron hinge-moment coefficient \( \left( \frac{H_a}{qb_a c_a^2} \right) \)

\( C_{eL} \) left elevator hinge-moment coefficient \( \left( \frac{H_e l}{qb_e l c_e^2} \right) \)

\( C_{hr} \) rudder hinge-moment coefficient \( \left( \frac{H_r}{qb_r c_r^2} \right) \)

where

\( L_u \) uncorrected lift force on test panel

\( L_w \) corrected lift force on test panel

\( L_t \) lift force on horizontal tail

\( D_u \) uncorrected drag force on test panel

\( D_w \) corrected drag force on test panel

\( D_t \) drag force on tail

\( L \) rolling moment about the wind axis, positive when it tends to raise the left wing tip (ft-lb)

\( N \) yawing moment about the wind axis, positive when it tends to advance the left wing tip (ft-lb)

\( H_a \) aileron moment about the aileron hinge axis, positive when it tends to depress the aileron trailing edge (ft-lb)

\( H_e l \) left elevator moment about the elevator hinge axis, positive when it tends to depress the elevator trailing edge (ft-lb)

\( H_r \) rudder moment about the rudder hinge axis, positive when it tends to deflect the rudder trailing edge to the left (ft-lb)
dynamic pressure \((\text{lb/sq ft})\left(\frac{\rho v^2}{g}\right)\)

mass density of air \((\text{slugs/cu ft})\)

airspeed \((\text{ft/sec})\)

area of partial-span wing \((\text{sq ft})\)

area of horizontal tail \((\text{sq ft})\)

area of wing on complete model \((\text{sq ft})\)

span of wing on complete model \((\text{ft})\)

span of aileron along hinge axis \((\text{ft})\)

root-mean-square chord of aileron behind hinge axis \((\text{ft})\)

span of left elevator along hinge axis \((\text{ft})\)

root-mean-square chord of elevator behind hinge axis \((\text{ft})\)

span of rudder along hinge axis \((\text{ft})\)

root-mean-square chord of rudder behind hinge axis \((\text{ft})\)

angle of attack of test panel, referred to chord line at station 26.55 \((\text{degrees})\) (see fig. 1)

angle of attack of tail unit, referred to reference line of dummy fuselage \((\text{degrees})\) (see fig. 3)

angle of yaw, angle between model plane of symmetry and relative wind \((\text{degrees})\)

aileron deflection with respect to wing chord line, positive with trailing edge down \((\text{degrees})\)

elevator deflection with respect to stabilizer chord line, positive with trailing edge down \((\text{degrees})\)

rudder deflection with respect to chord line of fin, positive with trailing edge deflected to left \((\text{degrees})\)
\( \theta_t \)
angle of chord plane of stabilizer relative to reference line of fuselage \((\pm 2.66^\circ)\)

\( \Delta C_{L\delta_a} \)
one-half of the increment of uncorrected lift coefficient caused by deflection of the aileron on the model as tested (see note on page 6)

\( \Delta C_{D\delta_a} \)
one-half of the increment of uncorrected drag coefficient caused by deflection of the aileron on the model as tested (see note on page 6)

\( \Delta C_{L_t} \)
increment of tail lift coefficient for a given elevator deflection

\( \Delta C_h \)
increment of hinge-moment coefficient for a given surface deflection (with subscripts \(a, el,\) and \(r\) to denote aileron, left elevator, and rudder, respectively)

\[
C_{L_{\delta_a}} = \left( \frac{\delta C_{L,\delta_a}}{\delta \alpha_a} \right) \delta_a
\]

\[
C_{L_{\delta_e}} = \left( \frac{\delta C_{L,t}}{\delta \delta_e} \right) \delta_e
\]

\[
C_{L_{\delta_t}} = \left( \frac{\delta C_{L,t}}{\delta \delta_t} \right) \delta_t
\]

\[
C_{h_{\alpha_w}} = \left( \frac{\delta C_{h,\alpha}}{\delta \alpha_w} \right) \delta_a
\]

\[
C_{h_{\delta_e}} = \left( \frac{\delta C_{h,\delta_e}}{\delta \delta_e} \right) \alpha_w
\]

\[
C_{h_{\delta_t}} = \left( \frac{\delta C_{h,\delta_t}}{\delta \delta_t} \right) \delta_e
\]

where the subscripts outside the parentheses indicate the factors held constant during measurement of the parameters.
\[
\frac{\delta C_m}{\delta \delta_e} = \left( \frac{\delta C_m}{\delta \delta_e} \right)_{ct}
\]

change in pitching-moment coefficient of complete model of the airplane per degree change in stabilizer setting

\[
\frac{\delta C_m}{\delta \delta_e}
\]

change in pitching-moment coefficient of complete model of the airplane per degree change in elevator deflection

Note: Because the model of the wing panel was tested as a reflection-plane model, the deflection of one aileron will have the same aerodynamic effect on the model as the deflection of two ailerons in the same direction on a complete wing of the same plan form as the model plus its image. All increments of forces caused by aileron deflection are therefore twice those that would be obtained by deflecting only one aileron. This fact is noted on figures 7 and 8.

MODELS AND APPARATUS

The model of the partial-span left wing was composed of the tip and aileron assembly supplied by the Bell Aircraft Corporation for the investigation of the stability and control characteristics. A drawing of the model is presented in figure 1. The panel, from station 0 to the inboard end of the aileron, was made at the Langley Laboratory from templates supplied with the model, and was attached to the tip with steel straps. The complete model wing has a geometric twist of \(-2.1/4^\circ\). The partial-span model, for construction simplicity, was built with \(0^\circ\) twist between stations 0 and 17.850 (inboard end of aileron). This deviation in construction should have a negligible effect on the aileron characteristics above the stall. The aileron gap was sealed. Aileron hinge moments were read by means of an electrical strain gage. The location of the model in the Langley 4- by 6-foot wind tunnel is shown in figure 2. The geometric characteristics of the wing panel and aileron are presented in table I.

The model of the isolated tail unit was composed of the complete tail assembly supplied by the Bell Aircraft Corporation. The extended-span flat-sided rudder was used. A dummy fuselage, or fairing, was added by the Langley Laboratory, as shown in figure 3, to simulate a portion of the actual fuselage. The elevator and rudder gaps were not sealed. Elevator hinge moments were measured with an electrical strain gage on the left elevator only. Rudder hinge moments were also
read by means of an electrical strain gage. The position of the model in the Langley 4-by 6-foot wind tunnel is illustrated in figure 4. The strut supporting the fork and model was covered by a streamline fairing which was fastened to the tunnel wall. The strut itself was mounted on the balance system so that lift and drag forces could be read. The angle of attack of the model was changed by an electrical drive from outside the tunnel; the system was designed to give a range from 0° to 70°. The yaw tests were run by manually turning the outer end of the support strut while checking the angle with an inclinometer. A three-quarter top-view photograph is presented in figure 5. The geometric characteristics of the horizontal and vertical tails are presented in table 1.

When the model of the tail was received from the Langley 8-foot high-speed tunnel, it was found to have a transition strip of No. 60 carborundum grains glued to the stabilizer surface at the 0.17 chord station over the entire stabilizer span. The transition strip was not removed since it probably would have little, if any, effect at the attitudes being investigated.

TESTS AND RESULTS

Test conditions.- The tests of the partial-span left wing panel were made in the Langley 4-by 6-foot tunnel at a dynamic pressure of 13 pounds per square foot for angles of attack up to 35°, and at 10 pounds per square foot for angles of attack from 30° to 67°. The values of q of 13 and 10 pounds per square foot correspond to test Reynolds numbers of about 700,000 and 610,000, respectively, based on the average chord, for the wing panel tested, of 1.04 feet. Because of the turbulence factor of 1.93 for the 4-by 6-foot tunnel, the effective Reynolds numbers are 1,350,000 and 1,178,000, respectively.

The tests of the isolated tail were also made in the Langley 4-by 6-foot tunnel at a dynamic pressure of 13 pounds per square foot, which corresponds to a Mach number of about 0.095. Tests were run through a yaw range from -55° to 35° at constant angles of attack of the fuselage reference line of 20° and 50° with elevators and rudder at various deflections simulating their probable positions in a spin. The control surface tabs were neutral for all tests. Pitch tests were also run through an angle-of-attack range of 0° to 70°, with the elevator set at various deflections, and the rudder set at 0° for all tests. The horizontal-tail incidence was -2.66° with respect to the fuselage reference line for all tests. The test Reynolds number, based on the average chord of the horizontal tail of 0.563 feet, and a dynamic pressure of 13
pounds per square foot, is 370,000, and the effective Reynolds number is 714,000.

A dummy tail block (with tail surfaces removed) supplied by the Bell Aircraft Corporation was attached to the dummy fuselage, or fairing, and tested through a yaw range of \(-35^\circ\) to \(10^\circ\) at constant angles of attack of the fuselage reference line of \(20^\circ\) and \(50^\circ\). Also a pitch test was run through an angle-of-attack range of \(0^\circ\) to \(70^\circ\) at zero yaw.

Corrections.- The data on the partial-span wing have been corrected, by the method described in reference 1, for the influence of jet boundaries. The jet-boundary corrections for the partial-span wing were applied as follows:

\[
\Delta C_{L,w} = 1.193 \, C_{L,u}
\]
\[
\Delta C_{D,w} = -0.020 \, C_{L,u}
\]
\[
\Delta C_{D_{1w}} = 0.0158 \, C_{L,u}^2
\]
\[
\Delta C_{\alpha} = 0.00313 \, C_{L,u}
\]

These corrections were added to the partial-span wing test values.

The rolling and yawing moments for the deflection of one rileron on the wing of the complete model airplane were estimated by use of the following equations:

\[
C_l = 0.2265 \, \Delta C_{D_{\delta_a}^{1}}
\]

and

\[
C_n = -0.284 \, \Delta C_{D_{\delta_a}^{1}} + 0.003 \left( C_{L,u} \right) \delta_a = 0^\circ \, \Delta C_{D_{\delta_a}^{1}}
\]

If it is desired to convert the data of figures 7 and 8 to the plan form of the complete airplane, the increments of lift and drag caused by aileron deflection should be divided by 2, and all angles of attack should be corrected by adding the increment \(\Delta C_{L} = -0.400 \, C_{L,w}\).

The data for the isolated tail have been corrected for the influence of the jet boundaries. The jet-boundary correction was applied as follows:

\[
\Delta a_t = 0.9109 \, C_{L_t}
\]
This correction was added to the test values. The correction to the induced drag caused by the jet boundaries was found to be negligible. The lift and drag data for the tail surfaces alone were obtained by subtracting the values for the dummy fuselage alone (figs. 15 and 16) from the values obtained from tests of the dummy fuselage with tail surfaces. Thus, the lift and drag characteristics presented for the tail surfaces still include the fuselage-tail interference, but not the direct fuselage forces. The pressure difference between the inside of the strut fairing and the atmosphere outside the tunnel necessitated a correction to the lift data which was obtained by calibration. The corrections to the hinge moments of the rudder and elevator were found negligible and were not applied.

Test procedure.- The 0.14-scale partial-span wing model was mounted in the tunnel (fig. 2) with station 0 adjacent to the tunnel wall, which thereby acted as a reflection plane. The model was supported entirely by the balance frame with a small clearance at the tunnel wall so that all forces and moments acting on the model could be measured. Since the 0 station of the wing is not on the center line of the airplane, the lift and drag presented herein are for two ailerons deflected in the same direction on a wing of aspect ratio 5.69 having an area of 6.20 square feet, including the reflection image, instead of for one aileron on the complete model which has a wing of aspect ratio 6.52 with an area of 8.45 square feet. This difference in aspect ratio is thought to have a negligible effect on the aileron hinge moment, particularly at high angles of attack.

The electric angle-of-attack drive is designed to give a range of approximately 40°. For this reason it was necessary to run the tests from 0° to 35° for all aileron deflections, and then to repeat the tests for some aileron deflections with the angle-of-attack range shifted to give 30° to 67°. The accuracy of resetting the deflections is indicated by the double points on the curves at αw = 30° and 35° in figures 6, 7, and 8. The tests were run at constant aileron deflections, except for a slight strain-gage deflection, in 2° increments of angle of attack through the stall, and then in 5° increments up to 65°, the last step being 2° to reach 67°. The aileron deflection range was from neutral to ±25° in 5° increments.

The yaw tests for constant elevator deflections of -25° and 25° were run in 5° increments of yaw from 0° to +35° and from 0° to -35° while holding angle of attack and rudder deflections constant. The yaw tests run at a constant elevator deflection of 15° were made in 5° steps from 0° to 10° and from 0° to -25° while holding angle of attack and rudder deflections constant. The control-surface deflections varied slightly because of strain-gage deflection.
DISCUSSION

Partial-Span Wing Tests

The partial-span wing data presented in this paper are being used in estimating stick forces (to be published) on the ailerons at high angles of attack simulating spin conditions (fig. 6). Lift, drag, rolling-moment, and yawing-moment characteristics are also presented (figs. 7, 8, 9, and 10, respectively).

Aileron hinge moments. - The values of $C_{h\alpha_w}$ and $C_{h\delta_a}$, as read over a small range of $\alpha_w$ and $\delta_a$ at low angles of attack (fig. 6), are -0.0015 and -0.0036, respectively. Values of $C_{h\alpha_w}$ and $C_{h\delta_a}$, as determined from tests of the complete model in the Langley 7- by 10-foot wind tunnel (unpublished), are -0.0020 and -0.0040, respectively. The close agreement of the parameter values at low angles of attack for the complete model wing and the partial-span wing of slightly different aspect ratio indicates that the differences in aspect ratio, wind tunnel, and test procedures have little effect on the hinge-moment parameter values for this particular case.

The curves of figure 6 indicate that the slope, $C_{h\alpha_w}$, is increased from -0.0015 at low angles of attack to about -0.0070 at angles of attack between $40^\circ$ and $50^\circ$. The slope, $C_{h\delta_a}$, for small deflections is increased from -0.0036 at low angles of attack to about -0.0100 at high angles of attack. The total increment in $C_{h\delta_a}$ between deflections of ±25°, however, is fairly constant for the whole angle-of-attack range.

Wing lift and drag. - No plan-form corrections have been applied to the lift and drag data in figures 7 and 8, which therefore represent the deflection of two ailerons in the same direction on a wing of aspect ratio 5.69.

The slope of the lift curve, $C_{L\alpha_w}$, for the complete-model wing with fuselage and canopy was found to be 0.072 when read over a range of $\alpha_w = 16^\circ$ (unpublished). The slope of the lift curve for fuselage and canopy only is very low and therefore the value above may be considered as that for the wing alone. The partial-span wing data gave a $C_{L\alpha_w}$ value of 0.067 and application of the plan-form corrections given previously would increase this slope to about 0.069 which compares
favorably with the complete-wing value of 0.072.

Aileron rolling and yawing moments.—By means of the equations given previously, the uncorrected data used to compute the corrected data of figures 7 and 8 were also used to compute the rolling- and yawing-moment coefficients for the deflection of one aileron on a wing of aspect ratio 6.52, for comparison with the data from the complete model (unpublished). These rolling- and yawing-moment coefficients are plotted in figures 9 and 10 against aileron deflection.

A comparison of the rolling-moment characteristics of figure 9 with data from the complete model indicated fair agreement. The agreement shown is thought to be fairly good considering the mathematical manipulations involved in computing rolling-moment coefficients from the lift data of the present partial-span tests.

A similar estimation and comparison was made for the yawing-moment characteristics resulting from aileron deflection on the complete model (fig. 10). The agreement is fairly good for negative aileron deflections, but not for positive deflections. A lack of agreement might be expected because of the small increments of drag and the difficulty of determining the correct spanwise lever arm at which this small increment of drag may be considered to act.

Although the computed rolling and yawing moments cannot be considered very accurate, the data indicate that in spin attitudes the yawing moment produced by the aileron is as much as or more than the rolling moment produced.

Isolated Tail Tests

The isolated tail hinge-moment data presented in this paper (figs. 11 and 12) were obtained for use in estimating stick and pedal forces (to be published) at angles of attack and yaw simulating spin attitudes. Lift and drag characteristics were also obtained and are presented in figures 13 and 14.

Elevator hinge moments.—From tests of the complete model (unpublished), the value of $C_{h_{\alpha t}}$ is approximately 0.0020, and $\Delta C_{h_{\alpha t}}$ was found to be approximately -0.028 for $10^\circ$ elevator deflection. The values taken from the present data in the unstalled condition (fig. 11) were $C_{h_{\alpha t}} = 0.0020$ and $\Delta C_{h_{\alpha t}} = -0.030$ for $\delta_{e} = 15^\circ$. For the present tests transition was fixed while for the complete-model tests it was free.
The curves for $\delta_e = 0^\circ$ and $-25^\circ$, in figure 11, appear to fall together in the stalled range between $\alpha_t = 24^\circ$ and $32^\circ$. The value of $C_{h_{\alpha t}}$ at $\delta_e = 0^\circ$ changed from 0.0020 at $\alpha_t = 0^\circ$ to about -0.0120 at $\alpha_t = 50^\circ$. The elevator hinge-moment increment resulting from changing the deflection of the elevator from $-25^\circ$ to $25^\circ$ increased between $\alpha_t = 0^\circ$ and $15^\circ$, decreased from $15^\circ$ to about $30^\circ$ $\alpha_t$, and then increased again until at $\alpha_t = 60^\circ$ the increment was about equal to that at $\alpha_t = 0^\circ$.

For yaw tests at constant $\alpha_t$ (fig. 12) the left elevator hinge-moment curves generally have a negative slope with angle of yaw. This slope becomes fairly steep for negative angles of yaw with $\alpha_t = 50.4^\circ$. The negative slope of $C_{h_{\alpha t}}$ against $\Psi_t$ may be caused by the dihedral angle of the horizontal tail, which, at positive angles of yaw, gives the left horizontal tail a positive increment of $\alpha_t$; and, since $C_{h_{\alpha t}}$ is generally negative, the positive increment of $\alpha_t$ causes a negative increment of $C_{h_{\alpha t}}$.

Changing rudder deflection from minus to plus generally increased the negative value of $C_{h_{\alpha t}}$ for all the values of $\Psi_t$, $\alpha_t$, and $\delta_e$ tested.

**Rudder hinge moments.** At $\alpha_t = 20.5^\circ$ (fig. 12) the rudder hinge-moment curves generally have a negative slope with angle of yaw. With angle of yaw and rudder deflection of opposite sign, the elevator deflection has practically no effect on rudder hinge moments at $\alpha_t = 20.5^\circ$ for large angles of yaw. With like signs for $\Psi_t$ and $\delta_r$ the elevator deflection has a large effect on rudder hinge moments. A negative increment in $\delta_e$ generally produces a positive increment in $C_{h_r}$ for negative values of $\delta_r$ and a negative increment in $C_{h_r}$ for positive values of $\delta_r$. With $\alpha_t = 50.4^\circ$ no consistent effect of elevator deflection on rudder hinge moments.
is shown, except that negative elevator deflections usually result in slightly larger rudder hinge moments at high angles of yaw. No data are available for comparison of the rudder hinge-moment characteristics in yaw presented here with those of the rudder on the complete model, because the complete model data were obtained at angles of attack below the stall.

The curves, in general, show the large effect of the deflection of one control surface on the hinge moments of the others, especially the large effect of elevator deflection on rudder hinge moment.

**Tail lift and drag**—The lift and drag data are presented for the tail surfaces (including fuselage-tail interference) in figures 13 and 14.

The slope of the unstalled \((\alpha_t = 0^\circ \text{ to } 10^\circ)\) lift curve with elevator neutral was found to be 0.056 from the data shown in figure 13. An equal value of \(C_{L_{\alpha_t}}\) was obtained by calculation from the value \(\frac{\delta C_m}{\delta \delta_e} = -0.0243\) obtained in the complete model tests (assuming the \(q\) ratio at the tail equal to one). The complete model tests of reference 2 gave a value of \(\frac{\delta C_m}{\delta \delta_e} = -0.0155\) which by the method of calculation discussed above gives \(\frac{\delta C_{L_{t}}}{\delta \delta_e} = 0.036\). From the present data, the value of \(\Delta C_{L_{t}}\) for an elevator deflection of \(15^\circ\) is 0.45, which if the variation is assumed linear would give \(\frac{\delta C_{L_{t}}}{\delta \delta_e} = 0.030\).

From figure 13 the decreasing effect of elevator deflection on tail lift with increased angle of attack is obvious. The drag increment caused by elevator deflections, however, appears to increase with angle of attack.

The lift effectiveness of the elevator, \(C_{L_{\delta_e}}\), increases with angle of yaw when \(\alpha_t = 20.5^\circ\), while with \(\alpha_t = 50.4^\circ\) the lift effectiveness decreases with angle of yaw (fig. 14). Rudder deflection had comparatively little effect on the value of \(C_{L_{t}}\).
The drag at high angles of yaw and $\alpha_t = 20.5^\circ$ depends on both elevator and rudder deflections, and is smallest when both surfaces are deflected more nearly parallel to the relative wind. With $\alpha_t = 50.4^\circ$ the same tendency for lower drag with the surfaces deflected parallel to the relative wind exists, but is of smaller magnitude. At $\alpha_t = 20.5^\circ$ the drag, with surfaces at any combination of deflections, increased with angle of yaw, while at $\alpha_t = 50.4^\circ$ the drag remained nearly constant or decreased with angle of yaw.

**Fuselage lift and drag.** The lift and drag characteristics of the dummy fuselage without the tail surfaces are presented in figures 15 and 16. It is to be noted that the interference effect of the strut and fork are included in these values.

The curve of lift against angle of attack in figure 15 shows the usual low slope value for a plain isolated fuselage. The drag curves in figures 15 and 16 show the usual increase in drag with both angle of attack and yaw.

**CONCLUSIONS**

From the results of test of 0.15-scale models of the Bell XP-83 control surfaces in the Langley 4- by 6-foot tunnel at attitudes simulating spin conditions, the following conclusions may be drawn:

1. The slope of the curve of aileron hinge moment against angle of attack increases negatively as the angle of attack of the wing is increased. The aileron hinge-moment increment from $25^\circ$ to $-25^\circ$ aileron deflections is practically constant over the angle-of-attack range even though the slope of the curve of aileron hinge moment against aileron deflection is more negative for small aileron deflections at the higher angles of attack.

2. The data presented indicate that the aileron produces practically as much yawing moment as rolling moment when in spin attitudes.

3. The slope of the curve of elevator hinge moment against angle of attack increases negatively as the angle of attack of the horizontal tail is increased. The elevator hinge-moment increment from $25^\circ$ to $-25^\circ$ elevator deflections is practically constant over the angle-of-attack range tested.

4. The lift-curve slope and the elevator hinge-moment slopes for the isolated-tail model and the complete model show close agreement.
5. The data presented indicate that the drag produced by elevator deflection increases as the angle of attack is increased while the lift produced by elevator deflection decreases.

6. At $\alpha = 20.5^\circ$, and angle of yaw and rudder deflection of like signs, the elevator deflection has large effects on rudder hinge moments. At $\alpha = 50.4^\circ$ no consistent effect of elevator deflection on rudder hinge moment is shown, except that negative elevator deflections usually gave the largest rudder hinge moments for the yawed conditions.

### TABLE II

**GEOMETRIC CHARACTERISTICS OF 0.14-SCALE MODELS OF THE BELL XP-83 HORIZONTAL AND VERTICAL TAIL SURFACES**

#### Vertical tail:

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total area, sq ft</td>
<td>0.932</td>
</tr>
<tr>
<td>Span, ft</td>
<td>1.191</td>
</tr>
<tr>
<td>Aspect ratio</td>
<td>1.523</td>
</tr>
<tr>
<td>Angle of offset, degrees</td>
<td>0</td>
</tr>
</tbody>
</table>

#### Rudder:

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Area, sq ft</td>
<td>0.274</td>
</tr>
<tr>
<td>Span, ft</td>
<td>1.431</td>
</tr>
<tr>
<td>Root-mean-square chord, ft</td>

<tr>
<th>Characteristic</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Percent elevator balance</td>
<td>48</td>
</tr>
<tr>
<td>Area aft of hinge (one elevator), sq ft</td>
<td>0.195</td>
</tr>
<tr>
<td>Root-mean-square chord, ft</td>
<td>0.165</td>
</tr>
<tr>
<td>Maximum deflection, degrees</td>
<td>±25</td>
</tr>
<tr>
<td>Span along hinge axis (one elevator), ft</td>
<td>1.300</td>
</tr>
</tbody>
</table>
Figure 1: Details and dimensions of 0.14-scale model of the XP-83 airplane left wing panel as tested in the Langley 4-by 6-foot wind tunnel.
Figure 2. — Location of partial-span wing in the test section of the Langley 4-by 6-foot wind tunnel.
Figure 3.—Details and dimensions of 0.14-scale model of the XP-83 airplane tail unit tested in the Langley 4-by 6-foot wind tunnel.
Figure 4.–Location of tail surfaces and dummy fuselage in test section of the Langley 4-by 6-foot wind tunnel.
Figure 5.- Three-quarter top view of XP-83 tail surfaces with dummy fuselage as tested in Langley 4- by 6-foot tunnel. Model at positive angle of yaw and at high angle of attack, relative wind vertical in plane of picture.
Figure 6: Hinge-moment characteristics of aileron on left wing panel of 0.14-scale model of the XP-85 airplane.
NOTE: Increments of $C_{L_{a}}$ due to aileron deflection are equivalent to those obtained on a complete wing with both ailerons deflected the same direction.

Figure 7: Lift characteristics of aileron on left wing panel of 0.14-scale model of the XP-83 airplane.
Figure 18. Drag coefficients, \( C_{Dw} \):

- Drag characteristics of dihedral angle at 0°, 4°, 8°, 12°, 16°, 20°, 24°, 28°, 32°, 36°, 40°, 44°, 48°, 52°, 56°, 60°, 64°, 68°, 72°.

Note:

- Increments of \( C_{Dw} \) are equivalent to those obtained on a complete wing with both ailerons deflected in the same direction.

- The data points are plotted on a graph with the x-axis representing the dihedral angle and the y-axis representing the drag coefficient.
Figure 9 - Rolling-moment characteristics of complete wing of XP-83 airplane with only left aileron deflected, as estimated from left-wing-panel test data.
Figure 10: Yawing-moment characteristics of complete wing of XP-85 airplane with only left aileron deflected, as estimated from left-wing-panel test data.
Figure 11: Left elevator hinge-moment characteristics of 0.14-scale model of the XP-83 airplane tail surfaces as tested with dummy fuselage in the Langley 4-by-6-foot wind tunnel. $\delta_e = 0^\circ$, $\gamma = 0^\circ$. National Advisory Committee for Aeronautics
Figure 12 - Left elevator and rudder hinge-moment characteristics of 0.14-scale model of the XP-83 airplane tail surfaces as tested in the Langley 4-by-6-foot wind tunnel.
Figure 12.—(Continued)
Figure 13: Elevator lift and drag characteristics obtained from tests of 0.14-scale model of the XP-83 airplane tail surfaces (with fuselage interference) in the Langley 4-by-6-foot wind tunnel. $\delta_f=0^\circ$, $U=0^*$
Figure 14 - Lift and drag characteristics obtained from tests of 0.14-scale model of the XP-83 airplane tail surfaces (with fuselage interference) in the Langley 4-by 6-foot wind tunnel.
Figure 14 - (Continued)  (b) $\alpha_e = 50.4^\circ$
Figure 14. (Continued) (b) Continued
