SEVENTEENTH QUARTERLY PROGRESS REPORT

OBJECTIVE

The objective of this work is to demonstrate the use of indigenous microbes as a method of profile control in waterfloods. It is expected that as the microbial population is induced to increase, that the expanded biomass will selectively block the more permeable zones of the reservoir thereby forcing injection water to flow through the less permeable zones which will result in improved sweep efficiency.

This increase in microbial population will be accomplished by injecting a nutrient solution into four injectors. Four other injectors will act as control wells. During Phase I, two wells will be cored through the zone of interest. The core will be subjected to special core analyses in order to arrive at the optimum nutrient formulation. During Phase II, nutrient injection will begin, the results monitored, and adjustments to the nutrient composition made, if necessary. Phase II also will include the drilling of three wells for post-mortem core analysis. Phase III will focus on technology transfer of the results. It should be pointed out that one expected outcome of this new technology will be a prolongation of economical waterflooded operations, i.e. economical oil recovery should continue for much longer periods in the producing wells subjected to this selective plugging technique. Results from work under DOE Contract No. DE-AC22-90BC14665 will be incorporated as appropriate.

SUMMARY OF TECHNICAL PROGRESS

Phase I. Planning and Analysis

The concepts for the new technology to be evaluated in this project are scientifically sound and have been proven to be effective in laboratory experiments. Nevertheless, it is necessary to perform laboratory tests on live cores from the reservoir of interest. Two wells will be drilled for this purpose and special core analyses will be conducted in order to fine tune the exact concentration of, and schedule for, additions of nutrients to the injection water.

While the main purpose for drilling the two wells is to obtain cores suitable for use in the laboratory work, a secondary purpose is to obtain production data which will indicate the sweep efficiency of the existing waterflood. At the conclusion of Phase I, a specific feeding regime will have been formulated for each of the injection wells. Since the injection wells all vary in terms of years of service, differences in channeling are anticipated and a different feeding regime may be needed for each well.

The work for Phase I of the project has been divided into seven tasks as described below.

Task 1.1: The Drilling of Two New Injection Wells for the Acquisition of Cores and Other Data.
Completed

Task 1.2: On-Site Handling of Cores
Completed.

Task 1.3: Core Analysis to Determine MEOR Requirements
Completed.

Task 1.4: Microbial Analyses of Cores
Completed.

Task 1.5: Laboratory Waterflood Test of Live Cores
Completed.
Task 1.6  Acquisition of Baseline Data

Acquisition of baseline data has been completed.

Task 1.7: Analysis of Baseline Data

The analysis of baseline data has been completed.

Phase II: Implementation

This phase involves initiation of nutrient injection and the analysis of results.

Task 2.1 Design of Field Demonstration

During the quarter, nutrient injection continued into ten injection wells and production response continued to be monitored in twenty producing wells. A significant response has recently been noted in the NBCU 34-2 No. 1. The response is believed to be the result of nutrient injection into the NBCU 34-7 No. 1 which began in July 1997.

Task 2.2 Drill Three Additional Wells

Completed

Task 2.3 Reservoir Characterization

Petrophysical studies of recovered core sample from the 3 newly drilled wells are still in progress.

Task 2.5 Analysis of Results

Monthly collection of produced fluids from the test and control wells in all patterns continued with the following tasks performed,

1. Aliphatic profile (Gas chromatographic analysis),
2. API gravity and absolute viscosity under reservoir temperature,
3. pH of produced water,
4. Surface tension (ST) of produced water (water-air),
5. Interfacial tension (IFT) for produced oil-water system,
6. Inorganic analyses (nitrate, phosphate, sulfate, sulfide, chloride, potassium, and hardness).

Production data on all wells in all patterns continues to be evaluated.

Gas samples are continuing to be collected from selected production wells and analyzed by gas chromatography using a Fisher Model No. 1200 Gas Partitioner. The results of analyses from two sets of samples are given in the accompanying tables.

PLANS FOR NEXT QUARTER

Monitoring of the influent of the injector wells and effluent from the production wells, including the three newly drilled wells, will continue.

Analyses of cores from newly drilled wells will continue and will include gas chromatographic analyses of residual oil for signs of microbial activity.

Analyses of gas from selected production wells will continue.
