### 2. GENERAL SYMBOLS

\[ W = mg \]

\[ g = 9.80665 \text{ m/s}^2 \text{ or } 32.1740 \text{ ft./sec}^2 \]

\[ n = \frac{W}{g} \]

\[ I = mk^2 \] (Indicate axis of radius of gyration \( k \) by proper subscript.)

\[ \mu = \text{Coefficient of viscosity} \]

\[ \nu = \text{Kinematic viscosity} \]

\[ \rho = \text{Density (mass per unit volume)} \]

\[ \rho = 0.12497 \text{ kg/m}^3 \text{ at } 15^\circ \text{C.} \]

\[ \rho = 0.002378 \text{ lb.-ft.}^{-4} \text{sec}^2 \]

\[ \rho = \text{Specific weight of "standard" air, 1.2255 kg/m}^3 \text{ or } 0.07661 \text{ lb./cu. ft.} \]

### 3. AERODYNAMIC SYMBOLS

\[ S = \text{Area} \]

\[ S_w = \text{Area of wing} \]

\[ \theta = \text{Gap} \]

\[ b = \text{Span} \]

\[ c = \text{Chord} \]

\[ b^2 = \text{Aspect ratio} \]

\[ \frac{\alpha}{S} = \text{True air speed} \]

\[ V = \frac{1}{2} \rho V^2 \]

\[ L = \text{Lift, absolute coefficient } C_L = \frac{L}{\frac{qS}{2}} \]

\[ D = \text{Drag, absolute coefficient } C_D = \frac{D}{\frac{qS}{2}} \]

\[ D_0 = \text{Profile drag, absolute coefficient } C_{D_0} = \frac{D_0}{\frac{qS}{2}} \]

\[ D_0 = \text{Induced drag, absolute coefficient } C_{D_0} = \frac{D_0}{\frac{qS}{2}} \]

\[ D_p = \text{Parasite drag, absolute coefficient } C_{D_p} = \frac{D_p}{\frac{qS}{2}} \]

\[ C = \text{Cross-wind force, absolute coefficient } C_C = \frac{C}{\frac{qS}{2}} \]

\[ R = \text{Resultant force} \]

\[ i_w = \text{Angle of setting of wings (relative to thrust line)} \]

\[ i_s = \text{Angle of stabilizer setting (relative to thrust line)} \]

\[ Q = \text{Resultant moment} \]

\[ \Omega = \text{Resultant angular velocity} \]

\[ \frac{Vl}{\mu} = \text{Reynolds Number, where } l \text{ is a linear dimension (e.g., for a model airfoil 3 in. chord, 100 m.p.h. normal pressure at } 15^\circ \text{C., the corresponding number is 234,000; or for a model of 10 cm chord, 40 m.p.s., the corresponding number is 274,000)} \]

\[ C_{p} = \text{Center-of-pressure coefficient (ratio of distance of c.p. from leading edge to chord length)} \]

\[ \alpha = \text{Angle of attack} \]

\[ \epsilon = \text{Angle of downwash} \]

\[ \alpha_0 = \text{Angle of attack, infinite aspect ratio} \]

\[ \alpha_i = \text{Angle of attack, induced} \]

\[ \alpha_a = \text{Angle of attack, absolute (measured from zero-lift position)} \]

\[ \gamma = \text{Flight-path angle} \]

SUMMARY

Factors derived from wing theory are presented. By means of these factors, the angle of zero lift, the lift-curve slope, the pitching moment, the aerodynamic-center position, and the induced drag of tapered wings with partial-span flaps may be calculated. The factors are given for wings of aspect ratios 6 and 10, of taper ratios from 0.25 to 1.00, and with flaps of various lengths.

An example is presented of the method of application of the factors. Fair agreement with experimental results is shown for two wings of different taper ratio having plain flaps of various spans.

INTRODUCTION

Because of the widespread use of tapered wings equipped with partial-span flaps, it is desirable to have means for computing their aerodynamic characteristics. Previous reports (references 1, 2, and 3) have presented theoretical factors for use in computing the aerodynamic characteristics of wings with linear and with arbitrary twist and for use in finding the load distribution of wings with partial-span flaps.

This report presents factors, based on airfoil theory, for use in calculating the induced drag, the angle of zero lift, the pitching moment, and the aerodynamic center of tapered wings with partial-span flaps of constant flap-chord ratio. The factors, when used with adequate section data, should apply to various types of flap and various amounts of flap deflection.

THEORETICAL RESULTS

The particular wing chord distributions for which the theoretical computations were specifically made are given in figure 1 where the wing quarter-chord line is shown as straight. Two aspect ratios \( A = 6 \) and \( A = 10 \) and four taper ratios \( \lambda = 1.00, 0.75, 0.50, \) and \( 0.25 \) were used. A list of the symbols used herein is given in appendix A. Inasmuch as the various characteristics for elliptical wings with partial-span flaps could be obtained relatively easily, they were sometimes computed in order to aid in determining the shape of the various computed curves for the tapered wings.

The span load distributions from which the aerodynamic characteristics were obtained are given in reference 2 where a slope of the section lift curve equal to 5.67 per radian was used. The computations apply only to those cases in which no aerodynamic twist is present before the flaps are deflected.

Although the ordinary lifting-line theory is applicable only to wings without sweepback, experimental evidence indicates that small amounts of sweepback have no appreciable effect on the span loading. The computations may thus be applied to wings with moderate sweepback as long as the chord distributions are similar to those indicated in figure 1.

The computed aerodynamic characteristics are given in terms of factors such as \( J, H, \) and \( G \). The method of calculating the factors is omitted because of its length, but the formulas for the factors are presented in appendix B. The physical significance of the factors and of the aerodynamic characteristics they represent, however, is explained in the following sections.

Angle of zero lift.—The change in the angle of zero lift of a finite wing accompanying a flap deflection depends upon several variables, such as flap span, flap deflection, flap chord, and flap type. The effect of the last three variables can be conveniently represented
by the section characteristic $\Delta c_t$, the increment of section lift coefficient obtained by deflecting the flap.

By this grouping of variables, the change in the angle of zero lift (in degrees) for a wing with partial-span flaps can be expressed by the equation

$$\Delta \alpha_{(L=0)} = -J \Delta c_t$$

In order to obtain the angle of zero lift for the wing, this increment must be added to the initial angle of zero lift, i.e., the angle before the flap is deflected.

If this initial angle is measured from the chord of the root section, as is usually the case, the angle of zero lift for the wing is given by

$$\alpha_{(L=0)} = \alpha_0 - J \Delta c_t$$

The computed variation of the factor $J$ with flap span is shown in figure 2 for various aspect ratios and taper ratios.

Although the values of $J$ given in figure 2 apply specifically to wings in which the flap-chord ratio, or $\Delta c_t$, is constant along the portion with flaps and in which the flaps begin either at the center or at the tips, the results may be used to predict the angle of zero lift for any starting point of the flaps and for any $\Delta c_t$ distribution as long as they are symmetrical about the wing center. For example, if flaps of uniform flap-chord ratio extend from $0.3b$ to $0.7b$, the proper value of the factor $J$ is the difference between the values for $0.3b$ and $0.7b$ as shown by $\Delta J$ in figure 2.

The extension to the case of a nonuniform symmetrical distribution of $\Delta c_t$ consists simply in considering the resulting $\Delta c_t$ distribution to be caused by a series of elemental flaps of various lengths and performing either a numerical or a graphical integration for the value of $J$.

(See procedure given in reference 3.) In cases where the variation of $\Delta c_t$ along the span is slight, however, the use of an average value of $\Delta c_t$ is justified.

Lift-curve slope.—The wing lift-curve slope, $a$, per degree may be found from the equation

$$a = f \frac{-a_0}{1 + \frac{57.3a_0}{\pi A}}$$

where

$A$ is wing aspect ratio, $b^2/S$.

$f$, a theoretical factor given in figure 3. This factor has been plotted from results given in reference 1.

$a_0$, the weighted average of the section lift-curve slopes.

An average slope, weighted according to chord length, must be used because the slope of the sections with flaps may be considerably different from the slope of the
sections without flaps. If the section lift-curve slopes are constant across the spans of the flapped and the unflapped parts of the wing, then \( a_0 \) may be found in terms of the fraction of the area of the wing equipped with flaps:

\[
a_0 = \frac{S_r}{S} a_{0r} + \left(1 - \frac{S_r}{S}\right) a_0
\]

where

- \( a_0 \) is the lift-curve slope of section without flaps, per degree.
- \( a_{0r} \) lift-curve slope of section with flaps, per degree.
- \( S \) area of wing.
- \( S_r \) area of part of wing equipped with flaps.

If \( a_0 \) and \( a_{0r} \) are not constant across the two parts of the wing, then \( a_0 \) may be found by integration.

For a wing with sweepforward, \( \Lambda \) is negative and the aerodynamic center of the wing is ahead of the aerodynamic center of the root section.

Values of \( H \) are shown in figure 5.
Pitching moment.—As shown in figure 4, the upward and the downward parts of the basic load form a couple having a magnitude that increases directly with the semispan length, the angle of sweepback, and the flap deflection, i. e., $\Delta c_t$. An equation for the pitching moment due to the basic load distribution can thus be written:

$$M_b = k \frac{b}{2} \Delta c_t \tan \Lambda g S$$

where $k$ accounts for variations with wing taper, aspect ratio, and flap span. Because the basic load distribution is zero with no flap and is also zero with a full-span flap, the factor $k$ would have a maximum value at an intermediate flap span.

Transforming the preceding equation into the coefficient form gives

$$C_{mb} = G \Delta c_t A \tan \Lambda$$

(7)

where values of $G$ are given in figure 6. For a wing with sweepback ($A$ positive), the sign of the pitching-moment coefficient due to the basic lift is positive if the flap deflection introduces an effective washout toward the tip (e. g., flaps at the center deflected downward or flaps at the tip deflected upward). For a wing with sweepforward, the sign of $C_{mb}$ is negative for the same flap deflections.

For wings with flaps, however, the value of the section pitching-moment coefficient $c_{ms,a}$ may be assumed to consist of two parts: One denoted by $c_{ms}$, the section coefficient with flaps neutral; and the other denoted by $\Delta c_m$, the increase in the section coefficient above $c_{ms}$ due to the flaps. If $c_{ms}$ is constant across the span and $\Delta c_m$ is constant across the span (i. e., the flap-chord ratio is constant), then the pitching-moment coefficient due to the sections can be given by

$$C_{ms} = E c_{ms} + E' \Delta c_m$$

(9)

Values of $E$ and $E'$ for these conditions are given in figure 7 for the tapered wings. These values have been determined from the relations

$$E = \frac{2b}{S} \int_0^{c_m} c_{ms} dy$$

$$E' = \frac{2b}{S'} \int_{c_{ms}}^{c_m} c_{ms} dy$$

If neither $c_{ms}$ nor $\Delta c_m$ were constant across the span, then it would be necessary to use equation (9) and to evaluate $C_{ms}$ by an integration, as will be illustrated.
later. The total wing pitching-moment coefficient is given by

\[ C_{m,t} = C_{m,0} + C_{m,b} \]  

(11)

The coefficient \( C_{m,t} \) is defined by the equation

\[ M = C_{m,t} \frac{S^2}{\theta} \]  

(12)

where \( M \) is the total pitching moment.

**Induced drag.**—For any wing with a twist that is symmetrical about the wing center line, the induced-drag coefficient may be given by the equation

\[ C_{D,I} = \frac{C_L^2}{\pi A} + C_L \Delta \theta + \Delta \theta w \]  

(13)

The factors \( u, v, \) and \( w \) for wings with partial-span flaps, i.e., for the case of an abrupt twist, are given in figure 8.

The first term on the right-hand side of equation (13) is the usual induced-drag coefficient of an untwisted wing and the other two terms result from the aerodynamic wing twist introduced by deflecting the flaps. It can be seen from figure 8 that, for certain taper ratios, the \( v \) and the \( w \) factors are of opposite sign and their contributions counteract each other. In fact, under certain conditions, the sum of the last two terms may be slightly negative; and, as a result, the elliptical wing induced-drag coefficient may be approached. This tendency exists when the flaps are so placed and deflected that an elliptical loading is approximated.

**EXPERIMENTAL RESULTS**

**APPARATUS AND TESTS**

In order to provide a check on the reliability of the theoretical factors that have been presented, two tapered wings with partial-span flaps were tested. In addition, tests were made of three rectangular wings with full-span flaps to provide section data for use in calculating the characteristics of the tapered wings. The wings were made of aluminum alloy and had an area of 150 square inches.

A list of the tapered wings and the different flap lengths used is given in table I, together with the taper ratio, the aspect ratio, and the airfoil sections of the root and the construction tip (the extreme tip). The tips were rounded as shown in figure 1. The N. A. C. A. 23012 tapered wing had a moderate sweepback (line through quarter-chord points) but the N. A. C. A. 5–10–16 tapered wing had no sweepback. In the construction of the wings, straight-line elements were used between corresponding points of the root and the construction tip sections. For the N. A. C. A. 23012 wing, the chords of all sections along the span were in one plane; whereas, for the N. A. C. A. 5–10–16 wing, the highest points of the upper surface of each section were in one plane. The ordinates of the N. A. C. A. 5–10–16 wing are given in reference 4.
The rectangular wings had N. A. C. A. 23009, 23012, and 23015 sections and were included to provide airfoil section characteristics to aid in calculating the characteristics of the tapered wings.

Plain 0.2c flaps deflected downward 20° were built into all the wings and were made to simulate flaps pivoted about the midpoint of the thickness at 0.8c. Fillets of small radii were used to join the flap to the wing and to seal the gap, as indicated at the top of figure 9.

All the wings were tested in the variable-density wind tunnel at a pressure of 20 atmospheres. The lift, the drag, and the pitching moment were measured at the usual high Reynolds Number and, in addition, the maximum lift was measured at a lower Reynolds Number to indicate the scale effect on \( C_{L_{\text{max}}} \). The method of making and correcting the tests and a description of the tunnel are given in reference 5.

The results of the tests are presented in the usual form as figures 9 to 17. The results of the tests of rectangular wings, plotted on the left side of figures 9 to 11, have been corrected to aspect ratio 6; whereas the results given on the right side have been corrected to airfoil section characteristics by the method explained in reference 6. The pitching-moment coefficients are given about the aerodynamic-center position with the flap neutral.

The results of the tests of the tapered wings are presented in the usual manner in figures 12 to 17. In addition to the usual characteristics, the lift-curve peaks are given for two values of the effective Reynolds Number to indicate the scale effect on \( C_{L_{\text{max}}} \). The Reynolds Number is based on the mean chord \( S/b \). On the right side of the figures, effective profile-drag coefficients are given. This coefficient is the total drag coefficient with the induced-drag coefficient for elliptical span loading deducted, that is, \( C_{D_p} = C_D - C_L^2/\pi A \). The values of \( C_{D_p} \) have been corrected to effective Reynolds Number \( R_e \) by subtracting an increment (0.0011) to allow for the reduction in skin-friction drag when extrapolating from test to effective Reynolds Number (reference 6). The pitching-moment coefficients given are based on the mean chord \( S/b \) so that \( C_m = M/gS(S/b) = Mb/gS^2 \). The coefficients for each wing-and-flap combination are given about an axis through the aerodynamic center determined by the method given in the appendix of reference 4. The location of the aerodynamic center given in the upper part of the right side of the figures is measured from the quarter-chord point of the root chord and is in terms of \( S/b \).

Figure 17.—The tapered N. A. C. A. 5-10-16 airfoil with 0.5b plain flap down 20°.
CALCULATED CHARACTERISTICS OF THE WINGS

The factors previously presented were applied to the calculation of the characteristics of the wings used in the tests and the results are summarized in table I. The calculations will be illustrated for the tapered N. A. C. A. 23012 wing with the 0.5b flap.

Angle of zero lift and lift-curve slope.—The angle of zero lift by equation (2) is:

\[ \alpha_{0(L=0)} = -1.2 - (6.07 \times 0.90) = -6.7^\circ \]

The value of \( \Delta c_l \) (0.90) was measured from figure 10 at approximately the average lift coefficient of the basic \( c_{1b} \) distribution of the flapped portion of the wing. The average lift coefficient was estimated from column 15 of table II.

The lift-curve slope was calculated from equation (3), the value of \( f \) being taken from figure 3:

\[ a = 0.999 \frac{0.091}{1 + \frac{57.3 \times 0.091}{\pi \times 6}} = 0.071 \]

The value of \( \tilde{a}_0 \) (equation (4)), values of \( a_0 \) and \( a_{0f} \) having been taken from figures 18 and 19, is

\[ \tilde{a}_0 = \frac{89.6}{150} \times 0.085 + (1 - \frac{89.6}{150}) \times 0.099 = 0.091 \]
Aerodynamic center and pitching moment.—The x position was found directly from equation (6):

\[ \frac{x_{cg}}{S/\theta} = HA \tan \Lambda = 0.214 \times 0.6 \times 0.1703 = 0.219 \]

The appropriate values of \( \Lambda \) and \( H \) (fig. 5) were used and the aerodynamic centers of the wing sections were considered to be at the quarter-chord points.

The pitching-moment coefficient \( C_{m_{cg}} \) due to the moments of the airfoil sections (equation (9)) was obtained, as shown in figure 20, from the area above the \( c_m_{a,c} \) curve. Figure 20 illustrates the general method that may be applied to any plan form and any distribution of \( c_m_{a,c} \) across the span. The values of the necessary pitching-moment coefficients were taken from figures 18 and 19 and are for a value of \( c_i \) of zero, in which case \( c_m_{a,c} = c_m_{(a,c)0} \). If \( c_m_{(a,c)0} \) varies appreciably with \( c_i \), it should be taken at the average value of \( c_i \) over the portion of the wing with flaps. In this example, \( C_{m_{cg}} \) could also have been calculated from the values of \( E \) and \( E' \) given in figure 7 because the increment, as well as the initial value of the pitching-moment coefficient, was substantially constant across both the flapped and the unflapped parts of the span.

The pitching-moment coefficient due to the basic lift distribution is given by formula (7)

\[ C_{m_{lb}} = GL_{c}A \tan \Lambda = 0.029 \times 0.77 \times 6 \times 0.1703 = 0.023 \]

The value of \( G \) was taken from figure 6 and the value of \( L_c \) was taken at an intermediate \( c_i \) (\( c_i = 1.0 \)) from figure 10 for the N. A. C. A. 23012 airfoil with flap. Although \( L_c \) varies with the \( c_i \) at which it is taken, the exact value used does not affect the value of \( C_{m_{lb}} \) appreciably unless the sweepback is large. When the quarter-chord points do not lie on a straight line so that the angle of sweepback cannot be measured, \( C_{m_{lb}} \) may be computed from formula (8). The total pitching-moment coefficient about the axis through the aerodynamic center is then

\[ C_{m_{a,c}} = C_{m_{cg}} + C_{m_{lb}} = -0.128 + 0.023 = -0.105 \]

Drag.—The induced drag was calculated from formula (13) using values of \( u, v, \) and \( w \) from figure 8 and a value of \( \Delta c_i \) at an intermediate value of \( c_i \) (\( c_i = 1.0 \)) for the N. A. C. A. 23012 airfoil with flap (fig. 10). Thus \( C_{D_i} \) for any value of \( C_L \) is

\[ C_{D_i} = \frac{C_L^2}{\pi A \times 0.986} + (-0.0010)0.77C_L + 0.0100(0.77)^2 \]

Values of \( C_{D_i} \) were calculated for a series of values of \( C_L \).

The profile-drag coefficient of the wings was calculated by an integration of the section profile drag along the semispan as given by

\[ C_{D_0} = \frac{b}{S} \int_0^l c_{d0} \frac{y}{b_S} \, dx \]

This integration has been graphically performed as shown in figure 21. The value of \( c_{d0} \) at any point will, of course, depend upon the airfoil section, the lift coefficient, and the Reynolds Number at that point. The calculations are illustrated in table II for a \( C_L \) of 0.8 and follow the method of reference 4.

### Figure 20
Graphical determination of \( C_{m_{lb}} \) for the N. A. C. A. 23012 airfoil with 0.58 plan flap.

\[ C_{m_{lb}} = \frac{b}{S} \int_0^l c_{m_{a,c}} \, dx \left( \frac{y}{b_S} \right) = -0.128 \]

### Figure 21
Graphical determination of \( C_{d0} \) for the N. A. C. A. 23012 tapered airfoil with 0.58 plan flap.

\[ C_{d0} = \frac{b}{S} \int_0^l c_{d0} \left( \frac{y}{b_S} \right) = 0.014 \]

Values of \( c_{d0} \) were calculated at intervals along the semispan using the known lift distributions. The values of \( (c_{d0}_{max})_{slant} \), \( (c_{d0}_{max})_{slant} \), \( c_{d0}_{min} \) and \( \Delta c_{max} \) that appear in the various columns of table II were obtained from figures 18, 19, and 22. Section data for other flap deflections may be found in references 6 and 7. The values of \( c_{d0}_{min} \) were extrapolated to the Reynolds Number of each point along the semispan by the method given in figure 23 of reference 4. Although the formula given in reference 4 was derived for sections with moderate camber, it should apply approximately to airfoils with flaps.

The \( c_i \) distribution for \( C_L = 0.8 \) was obtained from the equation

\[ c_i = C_{D_i} c_{i_{slant}} + c_{ib} \]

where

\[ c_{i_{slant}} = \frac{S}{c_b} L_s \]

and

\[ c_{ib} = \frac{\Delta c_i S}{c_b} L_b \]
The values of $L_a$ and $L_b$ at $b/b=0.5$ were obtained from reference 2 by cross-plotting against $b/b$. The value of $\Delta c_l$ at $c_l=1.0$ for the flapped section was obtained from figure 10.

The profile-drag coefficient is given by the equation

$$c_d = c_{d,\text{slip}} + \Delta c_d$$

where $\Delta c_d$ depends on the quantity in column 19 of table II. Values of $\Delta c_d$ were obtained from figure 23 for the sections without flaps (data taken from reference 6) and from figure 24 for the N. A. C. A. 23012 section with flap.

![Figure 22](image-url)  
**Figure 22.**—Scale-effect corrections for $c_{\text{max}}$. In order to obtain the section maximum lift coefficient at the desired Reynolds Number, apply to the standard-test value the increment indicated by the curve that corresponds to the scale-effect designation (types B, C, D, or E) of the airfoil. (See reference 6, p. 33 and table II.)

![Figure 23](image-url)  
**Figure 23.**—Generalized variation of $\Delta c_d$ for airfoil sections with flaps neutral.

![Figure 24](image-url)  
**Figure 24.**—Curves of $\Delta c_d$ for airfoil sections with 0.3c plain flaps down 20°.
The values of $c_{D_f}$ given in column 22 of table II were plotted in figure 21 and extrapolated to the flap end. From the area under the curve, $C_{D_0}$ was found to be 0.0184. The process was repeated for other lift coefficients and for other wing-and-flap combinations and the results are plotted in figures 12 to 17 as effective profile-drag coefficients

$$C_{D_e} = C_{D_0} + C_{D_1} - C_{D_2}/\pi A$$

![Figure 25](image)

**Figure 25.** Calculation of the $C_{D_e}$ at which the N. A. C. A. 23012 airfoil with 0.50 plain flap begins to stall.

Maximum lift coefficient.—The lift coefficients at which the wings should begin to stall were estimated by the method used in reference 1 except that, instead of plotting $c_{\lambda}$ for a series of values of $C_{\lambda}$, the point at which which a section lift coefficient reaches $c_{\lambda\max}$ ($c_{\lambda}$ curve becomes tangent to the $c_{\lambda\max}$ curve) was found more conveniently by first deducting $c_{\lambda b}$ from $c_{\lambda\max}$ as in figure 25. (See column 23, table II.) The point at which the $c_{\lambda b}$ curve ($c_{\lambda b}$ for $C_{\lambda} = 1.0$) would become tangent if expanded to other lift coefficients then determines the point where stalling is predicted to start.

This point is most easily found by calculating $c_{\lambda\max} - c_{\lambda b}$ at several points along the semispan. The minimum value gives the location of the predicted stalling point of the sections with small flap deflections. The pitching-moment coefficients are in good agreement except for the N. A. C. A. 5–10–16 wing with 0.56 flap.

The $C_{D_e}$ curves given in figures 13 to 17 are in best agreement in the region of $C_{D_{\text{min}}}$ for $n=1$. The divergence for higher and lower lift coefficients is more for these wings than for wings without flaps (reference 4).

Two values of $C_{D_e}$ are listed in table I, $C_{D_{\text{min}}}$ and $C_{D_e}$ at $C_{\lambda} = 0.7$. It is interesting to note that, for the N. A. C. A. 23012 wing, $C_{D_e}$ increases with flap length up to $b_f/b = 0.5$ but is then substantially the same at $b_f/b = 0.7$ as it is at 0.5. The reason for this variation is that the increase in profile drag with flap length is compensated by the reduction in induced drag beyond $b_f/b = 0.5$. If plain flaps at a moderate angle are used

and the value of $C_{\lambda\max}$ as indicated on figure 25. The dashed curve fairied through the flap end was used. The solid line, which passes through calculated values of $c_{\lambda\max} - c_{\lambda b}$, would have indicated stalling at the plain section just outboard of the flap end at a low $C_{\lambda\max}$. Observations of the action of tufts, however, indicate that stalling does not necessarily begin at this point. It appears to be preferable to fair $c_{\lambda\max} - c_{\lambda b}$ through the flap end, as shown. The calculated $C_{\lambda\max}$ value is then higher and in better agreement with the test value. Tuft observations of the wings with 0.3b and 0.7b flaps indicated that stalling began at a point other than the predicted point so that the method can be expected to give only a rough indication of $C_{\lambda\max}$.

**Comparison of the Calculated and the Experimental Results**

The calculated and the experimental results are compared in table I. The angles of zero lift and the lift-curve slopes are in good agreement. The $x$ positions of the aerodynamic center are in fair agreement although the experimental aerodynamic-center positions move more and more ahead of the calculated position as the flap length is increased, probably owing to the forward movement of the position of the aerodynamic center
for take-off, as long a flap span as possible is therefore indicated to obtain the lowest drag. The decrease in induced drag with flap length beyond \( b_{f}/b \) equal to about 0.36 is illustrated in figure 26. The curves are given for various taper ratios, two values of \( A \), and for \( C_{L} \) and \( \Delta c_{p} \) both equal to 1.0. A value of \( \Delta c_{p} = 1.0 \) corresponds to an airfoil of moderate thickness with a 0.2\( &c \) flap at an angle a little larger than 20°. The change of induced drag with lift coefficient is illustrated in figure 27 for a wing with half-span flap of aspect ratio 6 and for two values of \( \Delta c_{p} \). The calculated and the experimental \( C_{L_{opt}} \) values given in table I are in as good agreement as can be expected in view of the difficulty of determining \( c_{L_{opt}} \). The agreement of the \( C_{L_{max}} \) values is fair.

CONCLUDING REMARKS
Although test results and the comparison with calculated results have been given only for the case of a plain flap deflected 20°, other test results were available for the N. A. C. A. 23012 wing with a split flap 45° down and with the same flap spans as those used herein. Comparison of the test and the calculated results for the split flap showed agreement similar to that obtained for the plain flap deflected 20°. It thus appears that fair estimates of the characteristics of tapered wings with partial-span flaps deflected various amounts can be obtained from the factors and the method given.

APPENDIX A

SYMBOLS USED IN TEXT

cb, section lift coefficient.
Δcb, increment of section lift coefficient due to flap deflection.
cb0, section basic lift coefficient (C_L=0).
cb1, section additional lift coefficient.
cb2, section additional lift coefficient for C_L=1.0.
cm0, section profile-drag coefficient.
α(L=0), wing angle of attack for zero lift, measured from the root chord.
α0, angle of zero lift of root section.
b, wing span.
b_f, total flap span.
S, area of wing.
S_p, area of part of wing equipped with flaps.
A, wing aspect ratio, b^2/S.
λ, taper ratio, c_t/c_r.
q, dynamic pressure.
c, chord at any section along the span.
c_t, tip chord (for rounded tips, c_t is the fictitious chord obtained by extending the leading and the trailing edges to the extreme tip).
c_r, chord at root of wing or plane of symmetry.
Λ, angle of sweepback measured between the lateral axis and a line through the aerodynamic centers (approximately the quarter-chord points) of the wing sections.

δ_f, flap angle.
C_L, wing lift coefficient.
C_D, wing drag coefficient.
C_D0, wing profile-drag coefficient.
C_Dv, effective wing profile-drag coefficient.
C_Dv0, wing induced-drag coefficient.

C_mza, total wing pitching-moment coefficient due to basic-lift forces.
C_mzb, wing pitching-moment coefficient due to basic-lift forces.
C_mz, total wing pitching-moment coefficient about aerodynamic center.

C_mza, total section pitching-moment coefficient about section aerodynamic center.
C_mza, total section pitching-moment coefficient about aerodynamic-center position with flap neutral.
C_mz, section pitching-moment coefficient with flaps neutral.
Δcm, increase in section pitching-moment coefficient above cm due to flap deflection.
M_i, total wing pitching moment.
M_b, wing pitching moment due to basic-lift forces.
C_mz, wing pitching-moment coefficient due to basic-lift forces.
C_mz, wing pitching-moment coefficient due to the pitching moments of the wing sections.
C_mza, total wing pitching-moment coefficient about aerodynamic center.
a, wing lift-curve slope.
a_0, lift-curve slope of section without flap.
a_global, lift-curve slope of section with flap.
x, moment arm measured from the quarter-chord point of the root chord and parallel to it (positive rearward).
y, lateral distance.
y_p, lateral distance to inboard end of flap.
x_a, coordinate of wing aerodynamic center.
R, effective Reynolds Number.
L_a, additional load parameter.
L_b, basic load parameter.
J, factor of angle of zero lift.
H, factor of wing aerodynamic center.
G, factor of basic-lift pitching moment.
f, factor of wing lift-curve slope.
E and E', factors of section pitching moment.
u, v, w, factors of induced drag.
APPENDIX B

AERODYNAMIC FACTORS IN TERMS OF THE FOURIER COEFFICIENTS

The various aerodynamic factors were obtained from a Fourier analysis in which the circulation \( \Gamma \) was expressed (see reference 2) by

\[
\Gamma = \frac{c_r m_v V}{2} \sum A_r \sin n\theta
\]

where

- \( c_r \) is the chord at plane of symmetry.
- \( m_v \) slope of the section lift curve at the plane of symmetry, per radian.
- \( V \), wind velocity.

\[
\cos \theta = -\frac{y}{b/2}
\]

If the Fourier coefficients of the plain wing at an angle of attack of one radian are denoted by \( A_r \) and if the Fourier coefficients for the same wings with a constant angle of attack extending only over the center of the span are denoted by \( a_r \), the various aerodynamic factors (in terms of the Fourier coefficients) can be found from the following equations:

\[
J = \frac{a_1}{A_1 m_0}
\]

in which \( m_0 \) is the slope of the lift curve at any section, per radian.

\[
H = \frac{2}{\pi A_1} \left( \frac{A_1}{3} + \frac{A_3}{5} + \frac{A_5}{21} + \frac{A_7}{45} - \frac{A_9}{77} + \cdots \right)
\]

\[
G = \frac{c_r A}{2b} \left( \frac{a_2}{3} - \frac{a_4}{21} + \frac{a_6}{45} \pm \cdots \right) - \frac{a_1}{A_1 \left( \frac{A_3}{5} - \frac{A_5}{21} + \frac{A_7}{45} \cdots \right)}
\]

\[
u = \frac{c_r}{2b A_1} \sum a_r A_r \left( \frac{a_r - a_1}{A_1} A_r \right)
\]

\[
w = \frac{\pi A c_2^2}{16 b^2} \sum n \left( \frac{a_r - a_1}{A_1} A_r \right)^2
\]
