7. Abstract

Historical Tank Content Estimate of the Southeast Quadrant provides historical evaluations on a tank by tank basis of the radioactive mixed wastes stored in the underground double-shell tanks of the Hanford 200 East and West Areas. This report summarizes historical information such as waste history, temperature profiles, psychrometric data, tank integrity, inventory estimates and tank level history on a tank by tank basis. Tank Farm aerial photos and in-tank photos of each tank are provided. A brief description of instrumentation methods used for waste tank surveillance are included. Components of the data management effort, such as Waste Status and Transaction Record Summary, Tank Layer Model, Supernatant Mixing Model, Defined Waste Types, and Inventory Estimates which generate these tank content estimates, are also given in this report.

1.0 Introduction

1.1 Purpose

The purpose of this historical characterization document is to present the synthesized summaries and evaluations of the historical records concerning the physical, radiological, and chemical composition of mixed wastes stored in underground double-shell tanks and the physical conditions of these tanks. The double-shell tanks are located on the Department of Energy Hanford Site, approximately 25 miles northwest of Richland, Washington. The document will be used to assist in characterizing the waste in the tanks after the current program of sampling and analyzing the tank wastes is completed. A historical review of the tanks may reveal anomalies or unusual contents that could be critical to characterization and post characterization activities.

This report was developed by reviewing the operating plant process histories, waste transfer data, and available physical and chemical data from numerous resources. These resources were generated by numerous contractors from 1945 to the present.

Waste characterization, the process of describing the character or quality of a waste, is required by Federal law (Resource Conservation and Recovery Act) and state law (Washington Administrative Code (WAC) 173-303, Dangerous Waste Regulations). Characterizing the waste is necessary for determining methods to safely retrieve, transport, and/or treat the wastes.

This document is not intended to be used as a total design basis document. Further field investigations of the information may be required before using this data for design purposes or safety analysis.

1.2 Scope

The scope of this document covers available information about the wastes contained in the double-shell tanks in the AZ Tank Farm. Waste transfer and level data, tank physical information, temperature data, and sampling data have been compiled for this report. A summary of this information is contained in the "Historical Tank Content Estimate for the Southeast Quadrant of the Hanford 200 Areas" (WHC-SD-WM-ER-350). The southeast quadrant document contains all six of the double-shell tank farms. Five tank farms, AN, AP, AW, AY, and AZ, are located in the 200-East Area and are shown on the map in Figure 1. SY Tank Farm, located in the 200-West Area shown in Figure 2, was included in the southeast quadrant because of its double-shell tank construction.

The six tank farms in the southeast quadrant contain 28 tanks: AN Tank Farm (seven 1,160,000-gallon tanks), AP Tank Farm (eight 1,160,000-gallon tanks), AW Tank Farm (six 1,160,000-gallon tanks), AY Tank Farm (two 1,000,000-gallon tanks), AZ Tank Farm (two 1,000,000-gallon tanks), and SY Tank Farm (three 1,160,000-gallon tanks). Double-shell tanks are constructed of a primary carbon steel

cylinder and base inside a secondary carbon steel liner. The secondary liner is encased in a reinforced concrete shell and both liners are covered by a reinforced concrete dome. Depending on the farm, the tops of the tanks are buried between six and eight feet below grade.

1.3 Approach

This report was compiled from work performed by ICF Kaiser Hanford Company, Los Alamos National Laboratory, and Westinghouse Hanford Company.

ICF Kaiser Hanford Company reviewed the historical records of the tanks in each of the four quadrants and incorporated the inventory estimates and models of tank layers being developed by Los Alamos National Laboratory into the report.

1.3.1 Surveillance Techniques for the Hanford Mixed Waste Storage Tanks

Surveillance information (e.g., temperatures, waste surface levels, psychrometric data) is used to determine the physical condition of the tanks and the waste. Tank integrity (i.e., whether assumed as sound, assumed leaker, assumed re-leaker) is investigated by monitoring waste levels and the leak detection pits. Waste temperatures can be used to calculate the heat load of heat-generating radionuclides such as cesium 137 (^{137}Cs) and strontium 91 (^{91}Sr). The instrumentation and methods used for tank surveillance are described in the following sections.

■ Waste Surface Levels

Four types of liquid level devices are used to monitor liquid levels in the primary tank of a double-shell tank: a level indicating transmitter or Food Instrument Corporation gauge, a level indicator assembly or manual tape, a high-level detector (an FIC gauge in intrusion mode), and the ENRAF® 854 ATG liquid level indicator/transmitter. A level indicator assembly or manual tape is used to measure liquid levels in the annulus.

The Food Instrument Corporation gauge is used as the primary liquid level monitoring device with the manual tape as a backup in the primary tank. The high-level detector is used to detect intrusions (i.e., any unexplained addition to the tank like rainwater) within the primary tank. The Food Instrument Corporation gauge consists of an electrode and steel tape that detects liquid on contact. The instruments are scanned hourly on the computer automated surveillance system (CASS). Daily at 7:00 a.m., the automatic FIC reading is loaded on the Surveillance Automated Computer System (SACS). Manual FIC readings are taken at any time of day and are manually entered into the SACS.

The manual tape flake boxes are used as an access point for measuring liquid levels manually if the automatic system fails or does not exist in the primary tank. A hand crank on the flake box is used to lower the tape probe until liquid is contacted and a liquid level measurement can be obtained (this is similar to the FIC gauge). The flake boxes located over the annulus can be used to lower manual tapes into the annulus to measure any liquid (condensate or leakage from the primary tank) if present.

The ENRAF® 854 Liquid Level Indicator/Transmitter has been installed on several tanks and will eventually replace the old level measurement devices. The ENRAF® 854 ATG is a microprocessor controlled surface level gauge. Level detection is based on the principle of buoyancy of a non-floating polyethylene displacer. The displacer is attached to a stainless steel measuring wire. The measuring wire is attached to a measuring drum which is fixed to a riser of known elevation. The weight of the displacer is entered into the memory of a force transducer. A second weight of about 10-15 grams less than the actual weight of the displacer is entered into the transducer as the control point. An electronic servomechanism turns the measuring drum causing the displacer to move. As the displacer is put in contact with the surface in question, the displacer will exert a smaller force on the transducer due to buoyancy. The displacer is continually lowered until the force exerted on the transducer is equal to the control point. By knowing the elevations of the riser and tank bottom, and the distance from the riser to the surface of the waste, the surface level of the waste can be determined. If the surface level changes, the displacer will be raised or lowered by the measuring drum depending on the force exerted on the transducer relative to the control point. The measurements are recorded by the Tank Monitoring and Control System (TMACS). Daily at 12:00 a.m., the ENRAF® reading is loaded on the SACS.

Sludge levels are determined with a sludge measurement device which consists of a "doughnut" shaped weight attached to a steel tape. The sludge measurement device is lowered into the tank until it stops. Several risers are used to determine the approximate levels of the sludge below the liquid waste.

■ Interstitial Liquid Level (Liquid Observation Wells)

The interstitial liquid is the liquid within and underneath the solid waste. Wells to monitor the levels of interstitial liquid were installed only in Tanks 241-SY-102 and 241-AW-103. Gamma, neutron, and acoustic probes may be lowered into the wells to determine the interstitial liquid levels.

■ Temperatures

The temperatures of the double-shell tanks are monitored with thermocouples. A typical double-shell tank contains approximately 100 thermocouples at a variety of locations including the structural concrete of the tank foundation, walls, and dome; the tank knuckle region; the insulating concrete in the base; the primary steel liner; and the tank waste and vapor space. The aging waste tanks (AY and AZ Tank Farms) have thermocouples in their airlift circulators.

Thermocouples in the waste are attached to a fabricated assembly called a thermocouple tree. The number of thermocouples on a tree varies between tanks with 18 being the most prevalent. The thermocouples are spaced along the tree so that a temperature profile can be developed. Recently, multi-functional instrument trees (MIT) have been installed into a few of the watch list tanks (Tanks 241-SY-101 and 241-SY-103). These trees measure other properties, such as gas pressure and hydrogen concentration in the vapor space, in addition to the temperature. An MIT contains 22 thermocouples. Details on the status of the thermocouples as of April 1993 can be found in the "Thermocouple Status, Single Shell and Double Shell Waste Tanks" (Tran 1993).

The temperatures are recorded either manually on data sheets using a portable potentiometer or by one of several computer-automated systems. These systems include the computer automated surveillance system (CASS), the tank monitor and control system (TMACS), and the data acquisition and control system (DACS). These systems record other data besides temperatures. The surveillance analysis computer system (SACS) is the primary database for storing tank temperature data. The CASS and TMACS record temperatures on some single-shell tanks and double-shell tanks. The DACS only records temperatures in Tank 241-SY-101. In the past, the CASS has recorded temperatures of all double-shell tanks, but it presently records temperatures for the AP Tank farm only. The CASS stores temperature data on magnetic tape. The TMACS presently records temperatures for the AN and SY Tank Farms, but it is planned to operate for all tank farms by September 1996. The TMACS transfers its daily temperature readings to the SACS. Operators manually record temperatures on data sheets for the AP, AW, AY, and AZ Tank Farms. For the AP and AW Tank Farms, the temperatures from data sheets are manually entered into the SACS. The SACS database does not presently store temperature data for the AY and AZ Tank Farms.

■ Annulus

The double-shell tanks are designed so that if a leak develops in the primary tank shell, the leak can be detected in the annulus, the space between the steel liners. The annulus monitoring equipment includes a conductivity probe to detect the presence of liquids, a continuous air monitor (CAM) to monitor the level of radiation, and thermocouples to detect an increase in temperature. Either the conductivity probe or the CAM can be inoperable for up to ten days. There is a forced ventilation system for each annulus to aid in heat transfer from the primary tank and containment of waste should a leak in the primary tank occur. A grid of drain channels in the basal concrete collect any leakage and direct it to the leak detection pit. Photographs were taken inside the annulus for inspection purposes.

■ Leak Detection Pits

Leak detection pits are located next to the tank. Three instruments are used in these pits: a liquid level detector, a thermocouple, and a radiation monitor. The liquid level detector used is a specific gravity dip tube. The dip tubes need to be checked for accuracy periodically; therefore, a 6-inch water level is maintained in the bottom of the 24-inch leak detection pit to allow

for continuous checking. A thermocouple is placed at the bottom of the pit to detect an increase in temperature from any leaking heat generating radionuclides. A drywell next to the leak detection pit contains a radiation monitoring device to determine background radiation levels and detect leaks.

■ Ventilation

The ventilation for the primary tank and the annulus is filtered through high-efficiency particulate air (HEPA) filters and monitored continuously for anomalies. All the double-shell tanks are actively ventilated to prevent radioactive releases to the environment. Because the ventilation creates negative pressure in the primary tank, the negative pressure is monitored in the primary tank to prevent the tank bottom from buckling. The annulus vacuum or negative pressure is also monitored for changes that indicate a tank leak or system problems.

Since differential pressure is related to air flow in the tank, differential pressure readings are taken at the exhaust fans, filters, and deentrainers. The vapor space and atmospheric pressures are monitored and compared. High differential pressures are caused by filter plugging or wet filters, while low differential pressure can be caused by filter seal problems or tank pressurization. Continuous monitoring exists for radiation levels at various locations along the ventilation system.

■ Interior Tank Pressures

The double shell tanks have certain limiting factors to maintain each tank for its full design life. One limiting factor is tank pressure. The safety limits for pressures vary with the design of the tank, but all double-shell tanks have an operating pressure between -4 and 0 inches of water gauge (-0.14 psig or -1 kPa gauge and 0 psig or 0 kPa gauge). The pressure is recorded on continuous strip charts. Refer to the occurrence sections on tank farms and tanks in this document for details on the frequency and duration of the tanks pressurizing.

■ Evaporation Rate (Psychrometrics)

Psychrometric data are collected on all the double-shell tanks and high-heat load single-shell tanks. The data are obtained from air moving through the inside of each tank and the annulus. The schedule for obtaining psychrometric data is determined by Westinghouse Hanford Company Process Engineering. Presently, data are recorded about once a month.

The main reason for recording psychrometric data is to determine the rate of evaporation in the tanks. The evaporation rates can be used to account for loss of liquid from the tanks. The data collected in the annulus are used to quantify the moisture content of the air in the annulus. The psychrometric data can also be used to estimate the instantaneous rate of heat transfer into the ventilation systems of the tank and the annulus.

Five pieces of information are required to calculate the evaporation rates and heat exchange in the tank: the wet-bulb and

dry-bulb temperatures of air entering the tank, the wet-bulb and dry-bulb temperatures of air leaving the tank, and the volumetric flow rate of air moving through the tank.

Dry-bulb temperatures are obtained using a standard thermometer. Wet-bulb temperatures are measured by a thermometer having the bulb covered by a cotton wick saturated with water. When the wet wick is placed in the air stream, some of the water in the wick is evaporated. As a result, the temperature of the water decreases. The heat loss from the water by evaporation equals the heat gain from the air, and the water temperature stabilizes. This stabilized temperature is the wet-bulb temperature.

Once the wet-bulb and dry-bulb temperatures are known, the properties (enthalpy, relative humidity, specific volume, and humidity ratio) of air at the tank entrance and exit can be determined. By comparing the properties of air at these points, the amount of water added and heat transferred to or from the air stream can be determined.

The raw data have always been measured and recorded in the field. However, methods of calculating the evaporation rate and heat transfer rate have differed. Evaporation rates and heat transfer rates were calculated using a program on a Hewlett Packard Calculator from the time data were first recorded (1977) to 1989. From 1989 until the present, the raw data were entered into a computer spreadsheet (Microsoft® Excel) and the evaporation rate and heat transfer rate were automatically calculated. The program was modified to represent more accurately the calculations made by the American Society of Heating, Refrigerating and Air-Conditioning Engineers, Inc. The main difference is that the density of water is now fit to a curve as a function of temperature to approximate a mass to volume conversion. These calculations have been documented and checked (Wood 1993).

■ In-Tank Photography

In-tank photography is another method used to determine the volume of waste. Photographs are used to resolve anomalous measurements inside the tanks and to assist in determining tank integrity. Photographs can also be used to determine sludge and liquid levels, provide a degree of corroboration with other waste monitoring techniques, and be a source of information about foreign objects contained in the tanks. The photographs can be compared to see if wastes in tanks with similar histories have similar characteristics. Currently, photographs are not used to determine waste levels in double-shell tanks because none are leaking.

1.3.2 Approach and Development of Supporting Information Contained in the Historical Tank Content Estimate and Supporting Documents

Extensive historical information was gathered for each tank. This document contains a comprehensive data set on each tank. The data are summarized in the Historical Tank Content Estimate.

■ Tank Level Histories

The tank level histories graphically represent waste levels over the lifetime of a tank. They include information such as waste types, in-tank photograph dates, transfer data, and physical data. Information was gathered from various documents and the resulting data, commentary, and dates were delineated on each drawing.

The liquid and solids levels on the tank level history graphs are based on waste volumes. The levels are calculated from the volumes and depicted in height above the bottom of the tank (see Appendix C). The sources of waste volume information include the "Tank Farm Surveillance and Waste Status Summary Reports" (Hanlon 1989 to 1993) and "A History of the 200 Areas Tank Farms" (Anderson 1990). The following formula was used to convert the waste volumes (total gallons) to the respective waste surface levels (total inches) for all tanks in the double-shell tank farms:

FORMULA

$$\frac{\text{Total Gallons}}{2750 \frac{\text{Gallons}}{\text{Inch}}} = \text{Total Inches} \quad (1)$$

■ Temperature Data

The sources of the historical temperatures presented here are the computer automated surveillance system (CASS), the surveillance analysis computer system (SACS), and manually recorded data sheets. The data from these sources span from July 1981 to June 1995 for all double-shell tanks. The CASS stored daily temperature readings for all double-shell tank farms on magnetic tapes. This system stored temperatures for most tank thermocouples (e.g., those in the foundation, walls, primary liner, etc.); however, only data from thermocouples inside the tank are presented in this report. The CASS occasionally stored an error code in place of a daily temperature for any errors that the system was programmed to recognize. These codes were removed from the data set before any data were processed. The SACS stored internal temperature readings for all farms except the AY and AZ Tank Farms. This system stored temperature readings for some subset of the internal thermocouples for a given double-shell tank. The temperature data from the SACS are available through the PC SACS software on the Hanford Local Area Network. Daily temperature readings for the AZ Tank Farm were obtained from data sheets in late 1989 and early 1990.

The data from the CASS, the SACS, and the data sheets were imported into Microsoft® Excel spreadsheets, then reviewed for suspect data points. Each data set was divided for this review into subsets of suspect and non-suspect temperatures. Because the full temperature data set was extremely large for each tank farm, each non-suspect subset was further reduced by extracting the weekly maximum temperature from the set. However, the full data set was presented for the two tanks in the AZ Tank Farm due to the large

temperature fluctuations measured in these tanks. The integration of the weekly maximum temperature set and the suspect temperature set is tabulated in Appendix D. For thermocouples with large amounts of suspect data, weekly temperatures were extracted in the same manner. Temperature history plots were developed for most of the thermocouples. A plot was not created for a thermocouple with five or less data points available. A discontinuity in the temperature plot represents a hiatus of greater than three years between two sequential data points. A straight line is used to connect sequential data points spanning less than three years. Linear regressions were performed on the temperature plots within Microsoft® Excel to quantify the temperature trend within an individual tank. Other statistics such as the mean, maximum, and minimum temperatures were also determined for each tank (see individual tank sections). The statistics are a function of the non-suspect temperature subset before being reduced to a set of weekly maximums.

The naming convention used for the thermocouples in this report follows that used by the thermocouple status report (Tran 1993). For example, according to Tran, the name of the topmost thermocouple on the tree in Tank 241-AP-101 is TE-101-AP-36. The computer automated surveillance system (CASS) generally uses this naming convention. The CASS excludes the name of the tank farm from the thermocouple name (e.g., TE-101-36) for some tank farms. The surveillance analysis computer system (SACS) uses a positive integer to identify the in-tank thermocouples (typically, 1 through 18 for an 18-element thermocouple tree). Tran also identifies thermocouples with a positive integer (e.g., TE-101-AP-36 is thermocouple 1). Using the two sets of thermocouple names provided by Tran, the data from the CASS were matched with the data from the SACS for each thermocouple.

■ Surface Level Plots

The data recorded from January 1, 1991 to June 30, 1995 for the waste surface levels were obtained from the Westinghouse Hanford Company surveillance analysis computer system (SACS). PC SACS is the user interface to the SACS database on a personal computer. The information was parsed in a spreadsheet (Microsoft® Excel) and graphed to show waste level versus time. There is a separate graph for the data from each type of measuring instrument. However, data from the manual FIC and automatic FIC gauges are shown together on the graphs with the heading FIC. Current information on the waste surface levels is in Appendix E.

■ Tank Profiles and Other Drawings

The drawings in this report were compiled from several sources including as-built drawings and the "Double-Shell Underground Waste Storage Tanks Riser Survey" (Anderson 1992). The risers and other penetrations through the tank dome serve several purposes including points of access for monitoring equipment and sampling the waste.

■ Photographs

The latest tank interior and tank farm aerial photographs were obtained from Pacific Northwest Laboratory and are in Appendix I. The tank farm aerial photographs were labeled to indicate the relative position of each tank in the farm. Larger equipment was

labeled in the photographs. Photographs of tank interiors have been arranged to show the contents of each tank. The auxiliary equipment shown on each photographic montage was identified if possible and labeled.

■ Historical Sample Analysis Data

The sampling data were obtained from the Westinghouse Hanford Company Tank Waste and Retrieval Group. Tables of analytical data were made for samples taken prior to September 1989. The information was compiled in the Microsoft® Excel computer program to present the data as similarly as possible. The tables include physical data, chemical analysis data by component, and radiological analysis data by component. Other data included with the sample references are summarized as text. Tank historical sample analysis data are in Appendix H.

■ Psychrometric Plots

The psychrometric data were obtained from both the manually recorded and electronic records of the Westinghouse Hanford Company Tank Farm Surveillance Group. All the data were entered into computer spreadsheets (Microsoft® Excel) and the latest program (Wood 1993) was used to calculate evaporation rates and heat transfer rates. These quantities have been plotted against time on separate graphs (see Appendix F). Evaporation rate versus time was plotted in both gallons per week and inches per week for the tanks. Evaporation rate is used to show the amount of water removed from the tank. Heat transfer rates were plotted in Btu/hr.

The heat generated in the waste is dispersed into the environment through the ventilation systems of the tank and annulus, through the tank walls into the soil, and through other types of heat loss. The major portion of the heat exchanged with the environment occurs through the ventilation systems. By plotting the rate of heat exchange between the waste and the ventilation systems and reviewing the respective trends in conjunction with the flow rates and ambient temperatures, trends were calculated for the heat generation rate of the waste.

1.3.3 Approach and Development of the Process-Based Historical Tank Content Estimate

The historical characterization inventory estimates of tank contents using process-based historical data, presented in this report, were developed by Los Alamos National Laboratory (S.F. Agnew et al.). The historical estimates are the primary sources of data to characterize tank contents until the tank characterization reports are completed. These reports will incorporate the results of current core sampling and analyses with the historical inventory estimates to present the most current evaluation of waste constituents.

Generating tank content estimates based on historical information involves managing and evaluating large quantities of data. The system of generating the estimates is composed of several parts that are described in the following sections.

■ Waste Status and Transaction Record Summary

The waste status and transaction record summary (i.e., transaction summary) contains all known waste transfer records. Historically, when waste was pumped from plant (process) to tank or tank to tank, a record was kept of the volume and type of waste that was pumped. The transaction summary contains the recorded levels of the solids and supernatant.

The transaction summary is partitioned into four separate sections (i.e., quadrants). The development method of the database, the strategies of subsequent data sets, and the data for the southeast quadrant are in the "Waste Status and Transaction Record Summary for the Southeast Quadrant" (Agnew 1995).

■ Defined Waste Types

Early in the development of the historical tank content estimates, a need to compile the chemical compositions of all known waste types into one reference document was recognized. The information was compiled by Los Alamos National Laboratory. The Hanford defined wastes document was developed independently of the waste status and transaction record summary and the tank layer model. However, the Hanford defined waste list was used with the model to obtain the tank waste inventory estimates described below.

The Hanford defined wastes document contains the compositions and physical properties for all known types of Hanford waste that were sent to the double-shell and single-shell tanks. For more details on the methods used to develop these waste types, refer to "Hanford Defined Wastes: Chemical and Radionuclide Compositions" (Agnew 1994).

■ Tank Layer Model

The tank layer model is derived from the waste status and transaction record summary. The purpose of the model is to predict the waste types and solids volumes in each tank. The model is generated by reconciling the reported levels of solids from each tank in the transaction summary with the volume percent of solids expected for the primary additions of waste. The transaction summary contains records of the types of waste that entered each tank and the corresponding increase in the solids volume from each waste entry. Not all transactions that occurred were recorded in the transaction summary because records were lost and transfers were unrecorded or mis-recorded. However, the tank layer model is representative of the waste because two crucial pieces of information required for the inventory estimates are well represented; the primary waste additions and measurements of solids levels.

The tank layer model associates a solids volume percent with each waste type. The solids volume percent was derived by comparing the observed change in the solids volume with the primary additions recorded in the waste status and transaction record summary. In waste types that lacked an adequate number of solids measurements to develop a solids volume percent, a nominal value was assigned based on similarity to other waste types that had adequate data. If the predicted volume percent solids was different from the measured

volume, the difference was indicated as an unknown gain or loss of solids for the tank. The unknown losses and gains were designated unknown layers and were assigned to a best estimate defined waste type when possible for the composite inventory estimates. Layers that were not assigned a best estimate waste type were not included in the composite tank estimates. The unknown layers were depicted on the tank layer model graphs but the volume of the unknown layers was assigned to the supernatant volume and not included as a volume in the solids inventory estimate.

A layer "set" in the tank is assumed not to move or change volume. The layers are presented in chronological order from the bottom of the tank to the top. Lateral variations were not accounted for and only average layer thickness can be derived from the model.

There are two main sources for variations in the solids volume percent in a single waste type. First, there is an inherent variability in the process stream as the process evolves. Second, solids can be added to or removed from a tank by inadvertent entrainment during supernatant transfers. In addition to these sources of variation, there are a number of other minor sources of solids changes such as compaction, subsidence, and dissolution of soluble salts by later additions.

Diatomaceous earth and cement were added to immobilize residual supernatant in tanks where pumping the liquid was not feasible. The conversion factor in the tank layer model is 160 gal/ton for diatomaceous earth and 120 gal/ton for cement. Cement and diatomaceous earth are not included in the composite inventory estimates.

It was assumed that any solids that accumulated were saltcake or salt slurry from the time a tank became a "bottoms" receiver to the end of the evaporator campaign. Saltcake can be any one of seven different types depending on which evaporator campaign created it. For saltcake accumulation, it was assumed that all of the solids reported were saltcake. The results of the model are presented graphically with the inventory estimate in Appendix K.

■ Supernatant Mixing Model

Los Alamos National Laboratory developed the supernatant mixing model that describes a "supernatant" portion of each tank as a combination of Hanford defined waste supernatants that have been concentrated by some factor (see Appendix K). The following fundamental criteria were used for this model:

- 1) Ideal mixing of the total volume of each tank throughout its history was assumed (i.e., no excluded volume for remaining solids layers).
- 2) Transactions were added to the waste status and transaction record summary to resolve unknown transactions for each quarter according to a set of rules. Therefore, an updated transaction summary was used that will be published later.

3) Not all of the saltwell liquid sources for 1978 through 1995 are known. All unknown saltwell liquid is now assigned to water for this estimate.

■ Inventory Estimates

The end result of combining the information from the tank layer model, the supernatant mixing model, and the Hanford defined wastes document is the tank inventory estimate (see Figure 3). When the volumes and compositions of each waste type in a particular tank are determined from the various sources of information, the total chemical inventory in the tank is calculated.

Figure 3. Schematic of Inventory Estimate Strategy.

The tank inventories used data from the Tank Farm Surveillance and Waste Status Summary Reports (Hanlon 1993). The inventories represent the estimated contents of the tanks as of January 1, 1994. The results for individual tanks are presented in tabular form and tanks that have unassigned waste layers are indicated.

The inventory estimates developed by Los Alamos National Laboratory were checked for accuracy against existing data from current sample analyses, thermal and physical models, and historical records. When the checking process reveals discrepancies between the estimates and the existing data, the models may be reevaluated. Thus, the process of generating estimates will be iterated and the associated errors will be reduced over time as knowledge of the tank waste operations increases.

1.3.4 Assumptions

The quality of the historical information available for the tanks often requires assumptions and judgements on the applicability and validity of the data. Some assumptions were used to interpret the data.

■ Temperature Data

All the temperature data obtained by ICF Kaiser Hanford Company were reviewed for suspect data points. Data that deviated from expected trends were marked as suspect and comments added accordingly. Suspect data points satisfied one of the following criteria: 1) a temperature less than 20°F, 2) a large scatter in temperatures from one day to the next over a continuous period of time, 3) an individual temperature reading not following the trend of other temperatures recorded during the same period, 4) disagreement between an individual thermocouple reading and the reading of thermocouples located above and below it on the tree, or 5) disagreement between data recorded at the same time from the CASS, the SACS, and/or manually recorded data sheets. All temperatures less than 20°F were removed from the data set and do not appear in the tables in Appendix D. Temperatures that deviated more than 15 percent from the data trend were assumed to be suspect from criterion 3 above. A clear indication that the data acquisition system recording the temperatures was in error was that the suspect data points were repeated concurrently for other tanks in the same farm. This behavior occurred in data from the CASS.

The instrumentation allowing manual recording of temperatures on data sheets is assumed to be calibrated the same as the instrumentation used by the CASS and the tank monitor and control system.

■ Sampling Data

When the sampling data were compiled, a sample was considered to be a solids sample if it contained greater than 30% solids.

■ Psychrometric Plots

Psychrometric data are collected randomly once a month. The data from air entering the tank would not always be collected at the

same time as the data from air exiting the tank. Therefore, the calculated evaporation rate and heat transfer rates may not truly represent the monthly, weekly, or daily average. The data represent only one point per month. By combining all these points, a trend is assumed to exist for each tank.

The program used to calculate evaporation rates contains some assumptions. The liquid waste temperature is assumed to be the same temperature as the outlet dry-bulb temperature in order to convert the mass of liquid in the air stream into a volume equivalent (gallons/week). Standing liquid is assumed to exist in order to convert the volume equivalent evaporation rate into a liquid level evaporation rate (inches/week).

■ Inventory Estimates

The result of combining the information from the tank layer model, the supernatant mixing model, and the Hanford defined wastes document is the tank inventory estimate. Waste stream compositions (Hanford defined wastes) were based on process flowsheet information and previous analytical data. The assumptions for the other precursors to the inventory estimates are described below.

Tank Layer Model

The formation of solids in the wastes varied by type and was determined individually by examination of the historical fill records. The volume of solids determined must conform to physically attainable systems (e.g., waste volumes contained in the tanks do not exceed the tank capacity and negative void fractions are not possible).

The solids were assumed to be evenly distributed throughout the slurry during their transfer. In the tank layer model, the distribution of solids is chronological and volumetric, but does not attempt to predict the solids stratigraphy (configuration of layers). Localized mounding and pocketing in various areas of the tank may have occurred due to phenomena around the inlets and outlets (e.g., transfers through pumps removing or depositing sludge). These phenomena would have affected only a small fraction of the tank area and do not impact the overall results of this study. However, spatial variability within the physical configuration and process history is acknowledged. No method is currently available that would adequately model this discrepancy. An effort is underway to develop this concept further and incorporate it into the tank characterization process, but it is incomplete at this time.

Solids from a specifically designated waste type are assumed to be homogeneous. Variation and layering of the sludge due to differences in component concentration between batches, precipitate particle size, and particle density were quite likely. The effect of these factors on the distribution of components within the solids is unknown. However, the effect was assumed to be small and not detectable with the present sample collection and analysis process.

Solids were not assumed to be compacted; therefore, compaction was not accounted for in the study. Although compaction probably

occurred in the history of the tanks because additional layers of solids formed atop each other, the degree of compression is unknown and, therefore, was not incorporated.

Density and other physical characteristics of the solids were determined from individual waste types using available information (e.g., process flowsheets), or were based on approximate physical analogues.

The capacity of each tank was assumed to never have been exceeded during transfers. Tank capacity is dependent on fill status, fill order, and tank type.

Tank transfers were assumed to be normally free of particulates. Therefore, the majority of solids were confined to their initial receiver tanks and were not sent to cribs or transferred extensively between tanks. This assumption was based on the following assumptions. The pumping equipment typically was not designed to transfer substantial quantities of solids (except when sluicing or specifically transferring solids). Monitors on the crib discharge lines would have indicated significant solids contamination, and the tank farm operating procedures would have prevented discharging solids to the ground.

Supernatant Mixing Model

Los Alamos National Laboratory developed the supernatant mixing model that describes a "supernatant" portion of each tank as a combination of Hanford defined waste supernatants that have been concentrated by some factor (see Appendix K). The following assumptions were used for this model:

- 1) Ideal mixing of the total volume of each tank throughout its history was assumed (i.e., no excluded volume for remaining solids layers).
- 2) Transactions were added to the waste status and transaction record summary to resolve unknown transactions for each quarter according to a set of rules. Therefore, an updated transaction summary was used that will be published later.
- 3) Not all of the saltwell liquid sources for 1978 through 1995 are known. All unknown saltwell liquid is now assigned to water for this estimate.

1.4 Historical Information Quality

The quality of information compiled for this report varied greatly. Some data came from published documentation. Other data were retrieved electronically from various Westinghouse Hanford Company databases. The quality of data used in the estimates is described in the following section.

■ Waste (Level) Histories

The waste history narrative contains a general description of the waste types contained in a specific tank from receipt of the

first waste transferred to the present. The current status of the tank is also presented. The history is not designed to be a detailed summary of every waste type and transaction for a tank. The waste types are general and are usually given only for transactions of sufficient volume to significantly impact the total volume of the tank (e.g., a transaction that increased the waste volume by 3,000 gallons in a tank originally containing a waste volume of 6,000 gallons would be considered significant. The same amount added to a tank containing 600,000 gallons of waste would not be considered significant.). For a more complete record of transactions and types of wastes involved, refer to the "Waste Status and Transaction Record Summary for the Southeast Quadrant" (Agnew 1995).

The accuracy of the tank waste histories relies on the completeness of the Westinghouse Hanford Company document "A History of the 200 Area Tank Farms" (Anderson 1990); the monthly Westinghouse Hanford Company, Atlantic Richfield Hanford Company, and Rockwell Hanford Operations waste summary reports; and the "Waste Status and Transaction Record Summary for the Southeast Quadrant" (Agnew 1995).

Surface level readings may be affected by plummet (e.g., manual tape) error, flushing water accumulation, waste surface irregularities, and gas generation. Crystalline wastes (i.e., saltcake) can build up on the end of the plummet gradually and contact the waste which indicates a false surface level increase. Significant level discrepancies occur when the buildup breaks off or when the measuring instrument plummet is flushed to remove the saltcake buildups. Flushing the Food Instrument Corporation gauge, manual tapes, or any other equipment may cause accumulated wash water to collect under the plummet which indicates a false increase in the overall volume of waste within the tank. Surface level readings are often difficult to obtain from tanks with a relatively dry saltcake surface. Some tanks have crystalline buildup on internal tank equipment (i.e., pumps, thermocouples, and other protruding equipment). As the supernatant is pumped from the tanks, the crystalline structure may remain attached to the equipment and be suspended above the liquid. Therefore, an accurate surface level measurement would be difficult if the breakup of the crystalline structure was inconsistent and a nonuniform waste surface was created. Steel tapes that are bent or warped from operation or those discarded on the waste surface are other sources of altered surface level readings.

■ Temperature Data

The quality of data from the computer automated surveillance system (CASS), surveillance analysis computer system (SACS), and manually recorded data sheets has not been verified. One exception is the subset of data from the SACS that had been reviewed. Engineering judgement formed the basis of removing suspect data from the original data set to produce a set of non-suspect data.

In the temperature tables of Appendix D, suspect data are labeled S, transcribed data are labeled T, and good data are labeled G. This quality indicator is used by the custodians of the SACS. The labels S and G both indicate that a review has taken place

(either by the SACS custodians or during creation of this report). Only data already labeled transcribed (T) and good (G) were retrieved from SACS. If interpreted as suspect during the compilation of this report, the data from SACS that originally were labeled T or G were relabeled with an S or S (G in SACS), respectively. Otherwise, the data retained the original label. Data from the CASS or the data sheets were labeled with a T when retrieved for this report, assuming such data had never been reviewed previously. If interpreted as suspect during the compilation of this report, the data from the CASS and data sheets were relabeled with an S; otherwise, the label remained T.

■ Surface Level Data

Data from the surveillance analysis computer system (SACS) were obtained electronically from the Westinghouse Hanford Company surveillance group and were plotted. The data are actual surface levels recorded from the surveillance equipment. If the surveillance equipment in a particular tank riser was removed from service, the readings may show a level change when a new instrument and/or riser is used, especially if the waste surface shows severe heterogeneity.

The data used to produce the plots and the data obtained from the surveillance group have been verified as identical. However, errors in the data prior to the exchange of information could still exist. The SACS data were understood to be unverified prior to the exchange. Westinghouse Hanford Company qualified the data with G, S, T for good, suspect, and transcribed, respectively. The criteria for determining these qualities are unknown.

■ Riser Configuration

The riser configurations are based on the design drawings and engineering change notices dated before August 3, 1995. The riser configuration document (WHC-SD-RE-TI-093, Rev. 3) was used as a guide; however, the design drawings and engineering change notices take precedence. The tables in Appendix G contain a riser number, diameter, and description of each riser and nozzle. A brief explanation and date of the pertaining engineering change notice, if applicable, is in parentheses under the description and comments heading for each riser. Available risers are labeled spare and do not have any attached equipment; this includes observation ports.

■ Photographs

The photographic montages were made from the latest available photographs of the tank interiors and are in Appendix I. In some tanks, photographs have not been taken since the early 1970's. Some tanks had fogging problems in the vapor space which prevented use of the latest photographs. Sometimes, reviewing the older photographs was useful to determine changes in waste volume or equipment. Montages made from older photographs may not be indicative of current tank contents, especially if the tank had been pumped since the last time a photograph was taken.

■ Psychrometric Data

The psychrometric data obtained from Westinghouse Hanford Company came from sheets of manually recorded data before 1989 and

computer files after 1989. Agreement between the raw data obtained from Westinghouse Hanford Company and the psychrometric plots has been checked. However, errors in the data prior to the exchange of information may still exist.

The raw data could contain errors. The inlet (ambient) conditions could have been measured when the operators first entered the farm and not immediately before the outlet measurements of each tank were taken. The volumetric flow rate is measured using a pitot tube. As the flow rate decreases, the pitot tube measurements become less accurate. Minter (1994) demonstrated a high degree of uncertainty in determining changes in moisture content as air passed through a primary tank and annulus. Even though Minter (1994) discusses uncertainties with Tank 241-C-106 (a single-shell tank), some of the same principles and errors exist in the data obtained from the double-shell tanks. Dodd (1994) suggested that collecting psychrometric data should cease for tank annuli until more rigorous examinations determined whether collecting the data was worthwhile.

Other limitations, besides the fact that the calculated data represent only one recorded data point per month, should be considered before drawing any conclusions about the data. The heat transfer rate only expresses heat transferred to or from the air stream; it does not include other methods of heat transfer such as conduction through the soil or radiant heat transfer. Floating objects or a surface crust could exist in the tank which would change the surface area available for evaporation and possibly change the temperature of the liquid.

When the raw data varied from certain physical laws, the data were labeled suspect and were not included in the graphs. The data point was labeled suspect if the wet-bulb temperature was greater than the corresponding dry-bulb temperature or if the flow rate was extremely high compared to the rest of the data. A brief explanation of why the data point was labeled suspect is in the comment column of Appendix F. Data labeled as suspect may vary between the originally labeled data from Westinghouse Hanford Company and the data after review during the creation of the supporting documents.

■ Historical Sample Analysis Data

The historical sample analysis data refer only to information obtained before September 1989 (see Appendix H). The data (results from analyzing the samples and details about the samples) have not been validated by the characterization program. When validated, the data will be reissued in a later revision of the Historical Tank Content Estimate report and supporting documentation. The sample data often were retrieved from memoranda indicating the results of the sample analysis. The analytical methods, holding times, quality control information, and location at which the sample was taken were not provided. The scope of analysis frequently was quite narrow which limited the available data set. However, the data sets are the only available historical information on chemical characterization.

The data obtained from the sample analysis records vary widely in type, quality, and scope. The data range from a process control

analysis (e.g., checking the plutonium separation process by analyzing a grab sample for a few selected components) to a total characterization suite performed on a core sample. There are no specific criteria for determining quantitative data quality for the information incorporated into the Supporting Document. The information sources were assessed to determine if the samples were from the waste in the tank. The available data were assessed for suitability and consistency with this report and selected information was incorporated.

1.5 Southeast Quadrant Background

The double-shell tanks were built between 1968 and 1986 to provide interim storage for high-level nuclear wastes. Processes such as plutonium separation from spent nuclear fuel and uranium metal recovery generated the millions of gallons of mixed (radioactive and hazardous) waste stored within these tanks.

The most common waste stored in the tanks in the southeast quadrant is dilute waste. However, many tanks in the quadrant currently store wastes from the Plutonium Finishing Plant process and other onsite separation processes. Much of the waste is scheduled for concentration in the 242-A Evaporator.

1.5.1 Waste Generating Plants and Processes

Although not all of the processes listed below contributed waste directly to tanks in the southeast quadrant, the waste they generated could have been transferred indirectly tank-to-tank. The plants and processes that generated waste now contained in the single-shell and double-shell tanks are presented in chronological order. Typically, the name of the plant and the process are synonymous.

■ T Plant

T Plant was the first full-scale separations plant at Hanford. It was constructed between June 1943 and October 1944 and was used as a separations facility for irradiated production reactor fuel until 1956. T Plant was designed to separate plutonium from uranium and the bulk of fission products in irradiated fuel through the bismuth phosphate separations process. The 224 (Concentration) Building, adjacent to T Plant, was part of this process. Since 1957, T Plant has been used as a facility for repair and decontamination of equipment. The facility was modified in 1978 to store pressurized water reactor (PWR) core II fuel assemblies. T Plant facilities have been used for repairing, testing, shipping, decontaminating, decommissioning, and storing contaminated tools and equipment from locations both onsite and offsite.

The following wastes were sent to the tank farms: metal waste (MW), decontamination waste (DW), first-cycle decontamination waste (1C), second-cycle decontamination waste (2C), and 224 waste.

■ B Plant

B Plant was constructed between August 1943 and February 1945 and was used for the bismuth phosphate process until 1952. B Plant

was designed to use the same bismuth phosphate separations process that was used at T Plant. This process used both bismuth phosphate and lanthanum fluoride. The 224 (Concentration) Building, adjacent to B Plant, was part of this process. In 1968, B Plant became a waste fractionation plant after it was modified to remove ¹³⁷Cs and ⁹⁰Sr from PUREX acid waste, high-level supernatant, and sludge from self-boiling liquid wastes.

The following B Plant wastes were sent to the tanks: B Plant high-level waste (B), B Plant flush waste water (BFSH), B Plant low-level waste (BL), complexant concentrate (CC or CCPL), complexed waste (CPLX), fission product waste (FP), metal waste (MW), REDOX ion exchange waste processed at B Plant (RIX), ion exchange waste (IX), strontium sludge (SRS), cell 5 tank 6 waste (5-6), first-cycle decontamination waste (1C), second-cycle decontamination waste (2C), and 224 waste.

■ Bismuth Phosphate Process

B Plant and T Plant used the bismuth phosphate extraction process to remove plutonium from uranium fuel elements. The 224 Buildings were also part of this process. The waste that resulted was a metal waste (MW) that still contained 90% of the fission products and 99% of the original uranium. The MW was sent to specific tank cascades in the 200-East and 200-West Areas. First-cycle decontamination waste (1C), second-cycle decontamination waste (2C), and 224 waste were also stored in other underground waste tanks in the 200 Areas.

■ Plutonium Finishing Plant

The Plutonium Finishing Plant (PFP) or Z Plant, previously called Plutonium Recovery and Finishing Operations, began operating in late 1949 to process plutonium and prepare plutonium products. The PFP operations included plutonium handling, plutonium reclamation, plutonium conversion, decontamination, and decommissioning.

Waste from the Plutonium Reclamation Facility (near PFP) and Z waste from the remote mechanical "C" line process were sent to tanks.

■ Uranium Oxide Plant

The 224-U Building was completed in 1944 as part of the U Plant complex. The building was converted to a uranium oxide (UO₃) plant in 1951. The 224-UA Building was constructed in 1957 with six installed calciners. The UO₃ plant was capable of handling the uranyl nitrate hexahydrate (UNH) stream from REDOX, U Plant, and PUREX. The UO₃ plant was shut down in 1972 but restarted in 1984 with the feed lines from REDOX and the U Plant canyon disconnected. Since 1984, there have been 17 campaigns at the plant averaging eight days each. The plant can calcine UNH much faster than it is produced by the PUREX plant. Final deactivation was ordered for the plants in 1992. In April 1993, the UO₃ plant resumed operations to convert 200,000 gallons of remaining UNH to uranium oxide powder. A final deactivation plan for the facility was prepared in the summer of 1993 and will be carried out in the next few years.

■ REDOX

The Reduction and Oxidation extraction (REDOX) plant was built between May 1950 and August 1951 and operated until July 1967. Uranium and plutonium were extracted from solid uranium metal slugs that were irradiated in the Hanford reactors or piles. Uranium and plutonium were extracted with methyl isobutyl ketone (hexone) solvent in a continuous solvent extraction process. The REDOX process was the first at Hanford to recover both plutonium and uranium.

The following wastes were sent to the tank farms: REDOX process waste resulting from the dissolution of aluminum and zircaloy fuel element cladding, REDOX coating waste (CWR), REDOX waste (R), the supernatant portion of waste generated by the REDOX process, and REDOX supernatant (RSN). RSN is found above the sludge in the underground storage tanks that received waste from REDOX.

■ U Plant

U Plant (221-U) was built as one of three original bismuth phosphate process facilities, but it was not used for that purpose. U Plant was modified extensively and used for the uranium recovery process, operating from 1952 to 1958. The main canyon at U Plant currently stores failed equipment.

Uranium in waste from the BiPO_4 process initially was stored in the single-shell tanks. Later, the waste was sluiced, dissolved in nitric acid, and processed through a solvent extraction process to recover the uranium. The process yielded approximately 1.4 gallons of UR waste for every gallon of metal waste originally stored. The increase in waste volume made developing technology to reduce the volume of stored waste a priority. This need resulted in developing and implementing the ferrocyanide scavenging process.

The waste sent to the tanks from U Plant was called tributyl phosphate (TBP) even though it contained very little TBP. Therefore, to eliminate confusion, the waste will be referred to as uranium recovery (UR) waste in this report.

■ Strontium Semiworks

The Strontium or Hot Semiworks facility (i.e., C Plant) was built in 1949 as a hot pilot plant for the REDOX process but was converted to a pilot plant for the PUREX process. In 1960, the plant was reactivated and used as a process demonstration for the conversion of B Plant to a waste fractionation facility. The plant was used to recover ^{90}Sr , promethium 147 (^{147}Pm), and ^{144}Cs from PUREX waste. The building and the site have been decontaminated and decommissioned.

Waste sent from the Strontium Semiworks to the tank farms was known as hot semiworks (HS), strontium semiworks (SSW), and fission product waste (FP).

■ PUREX

The process used in the Plutonium Uranium Extraction (PUREX) plant (i.e., A Plant) was an advanced solvent extraction method using tributyl phosphate in a paraffin hydrocarbon solvent to recover

uranium and plutonium from nitric acid solutions of irradiated uranium. The PUREX plant, built between April 1953 and April 1955, operated until 1972 when it was closed for 11 years. Two thorium campaigns were conducted between 1966 and 1971. The irradiated waste was similar to the PUREX waste, but it contained thorium and uranium 233 rather than uranium and plutonium found in typical PUREX waste. The PUREX plant was restarted in November 1983 but was shut down in 1988 after a safety violation. It was shut down several times between 1988 and 1990 for various reasons. In October 1990, the plant was put on standby and was identified for closure in December 1992 by Secretary of Energy James Watkins.

The following PUREX wastes were sent to the tank farms: cladding (coating) waste (CW or CWP), organic wash waste (OWW), neutralized PUREX acid waste (P), low-level waste from PUREX (PL), PUREX sludge supernatant liquid (PSS), organic wash waste (CARB), cesium feed (CF), and inorganic wash waste (IWW).

1.5.2 Waste Management Operations

This section describes the different methods used to concentrate waste in the 200 Area. Evaporating, concentrating, and scavenging are all methods used to reduce liquid volumes or precipitate solids out of supernatant. The operations are presented in chronological order.

■ 242-T Evaporator

The 242-T Evaporator was built in the early 1950's to reclaim nonboiling waste storage capacity in existing tanks. The evaporator was shut down in the summer of 1955 and modified for tributyl phosphate scavenging, although scavenging was never performed in this evaporator. The evaporator was restarted in 1965 and operated until 1976. Tank 241-TX-118 was the feed tank for this evaporator.

The following wastes were sent from the 242-T Evaporator to the tanks: slurry product from the evaporator bottoms (EB), evaporator feed (EF), and terminal liquor (TL).

■ 242-B Evaporator

The 242-B Evaporator, south of the B Tank Farm, started operating in December 1951. It received feed waste until November 1954, was shutdown in September 1955, and was never reactivated. Tanks 241-B-106 and -105 were used as the feed tank and bottoms tank, respectively. The evaporator operated at atmospheric pressure.

■ Ferrocyanide Scavenging

Ferrocyanide scavenging was developed to reduce waste volumes. The ferrocyanide flowsheet was first tested in U Plant in October 1953, and in-farm scavenging was completed in March 1956 and December 1957 for the 200-West and 200-East Areas, respectively. The ferrocyanide scavenging program was designed to remove fission products such as ¹³⁷Cs (half life = 28.6 yr) and ⁹⁰Sr (half life = 30.2 yr) from the uranium recovery and 1C wastes as a precipitate. After the ¹³⁷Cs and ⁹⁰Sr precipitates settled, the clarified supernatant was sampled and disposed of in cribs.

■ In-Tank Solidification

The primary function of the in-tank solidification systems was to concentrate the nonboiling waste directly inside of specially designed tanks. These tanks produced a saltcake slurry. Each system included a heat exchanger for water evaporation and a series of bottoms tanks. The first in-tank solidification unit (ITS #1) operated with an airlift circulator through Tank 241-BY-102, and the second in-tank solidification unit (ITS #2) operated with a similar circulator through Tank 241-BY-112. Tank 241-BY-112 also contained a 4,000 kW electric immersion heater. Tank 241-BY-101 contained an in-tank solidification prototype that was used for demonstration purposes only. In-tank solidification units 1 and 2 began operating in 1965 and 1968, respectively. In 1971, ITS #1 became the cooler for ITS #2. Both units were shut down in 1974.

■ REDOX Concentrator

The REDOX concentrator was used to reduce the volume of dilute 200-West Area tank farm wastes by removing water. The concentrator received tank farm wastes from July 28, 1967 until June 30, 1972. Cell D in the REDOX process was the concentration and neutralization section of the plant.

■ 242-S Evaporator-Crystallizer

The 242-S Evaporator-Crystallizer began operating in November 1973 and was shut down in 1981. It was designed as a reduced pressure (i.e., partial vacuum) evaporator-crystallizer. Aqueous salt wastes were converted in the evaporator to salt crystals for storage in underground tanks in the S and SX Tank Farms.

The following waste types were sent to the tanks from the 242-S Evaporator: noncomplexed waste concentrated until the solution was nearly saturated with sodium aluminate known as double-shell slurry feed (DSSF), slurry product from the evaporator bottoms (EB), evaporator feed (EF), Hanford defense residual liquor (HDRL), partially neutralized feed waste (PNF), and terminal liquor (TL).

■ 242-A Evaporator-Crystallizer

The 242-A Evaporator-Crystallizer was constructed in 1976 and began operating in March 1977 with a design life of ten years. In 1987, design changes were developed to extend the facility's operating life by ten years. The evaporator was shut down in April 1989 because of regulatory issues, but was restarted in May 1994 after extensive modifications.

The following wastes were sent to the tanks: B Plant low-level evaporator bottoms (BLEB), double-shell slurry feed (DSSF), evaporator feed (EF or EVAP), evaporator bottoms (EB), and terminal liquor (TL).

1.5.3 Miscellaneous Waste Sources and Equipment

Wastes from various other sources on the Hanford Site have been added to the tanks. Some wastes are from the 300 Area, 100 Area production reactors, various laboratories, and catch tanks. Unique contents added to single-shell tanks included laboratory wastes;

diatomaceous earth; Portland cement; shroud tubes; ceramic balls; experimental fuel elements; and relatively small amounts of enriched uranium, plutonium, cobalt, and natural uranium.

The following wastes were added to the tanks: Hanford defense residual liquor (HDRL), Hanford laboratory operations waste (HLO), water (H₂O), N Reactor waste (N) from phosphate decontamination process, and noncomplexed waste (NCPL).

■ Critical Mass Lab

The critical mass lab was used to develop data on the factors necessary to make a criticality or self-sustained nuclear reaction occur. Because plutonium was the key radioactive element on the Hanford Site, the research was based on plutonium criticality safety in various fuel cycles. The facility was located next to the Strontium Semiworks and ran from the early 1950's to the early 1980's. The plutonium used in the lab was reprocessed in PUREX.

■ 244-AR, -BXR, and -CR Process Vaults

The three process vaults in the northeast quadrant are the 244-AR Vault, the 244-BXR Vault, and the 244-CR Vault. These vaults were composed of several process vessels or tanks used to prepare the waste for treatment or storage. Specific wastes from tanks can be pumped temporarily to the vaults and later sent directly to desired tanks or processing facilities.

The AR Vault was designed and constructed between 1964 and 1968 and is located next to the A and AX Tank Farms. The AR Vault has been on standby since 1978.

The 244-BXR Vault is located south of the BX Tank Farm and was constructed between 1950 and 1951. The BXR Vault began operating in 1952 and became inactive in 1956. The waste in the vault was difficult to handle, so the vault was jetted with high-pressure steam in 1976. The vault was interrimly isolated after 1976 and interrimly stabilized in March 1985. Tank BXR-004 was removed in 1963.

The 244-CR Vault was constructed in 1952 and is located next to the C Tank Farm. Saltwell waste from the C Tank Farm is interrimly stored in the CR Vault. The 244-BXR and -CR Vaults were originally constructed to aid in the recovery of uranium from bismuth phosphate metal waste. The CR Vault received waste from the Strontium Semiworks Plant en route to the C Tank Farm.

■ 204-AR and 204-S Railroad Car Facilities

The 204-AR rail car unloading facility was built in 1981 and replaced the 204-S rail car unloading facility. The facilities were built for unloading tank cars containing radioactive liquid waste. Liquids or slurries from the 1314-N Building in the 100 Area and the 340 Building in the 300 Area are unloaded at the 204-AR unloading facility.

1.5.4 Timelines

Timelines are presented on the following pages that represent the different events that occurred during the lifetime of major Hanford plants and tank farms in the 200-East and 200-West Areas. 1.6 Safety Issues

The safety issues that affect the tanks can be divided into two groups: watch list and non-watch list. The watch lists are a listing of all tanks that are believed to pose potential safety hazards to the environment and the public. Non-watch list issues are of concern because they may impact the environment.

1.6.1 Watch List Safety Issues

Safety issues for these tanks were identified as "issues/situations that contain most necessary conditions that could lead to worker (onsite) or offsite radiation exposure through an uncontrolled release of fission products" under Public Law 101-510, Section 3137, of the National Defense Authorization Act of Fiscal Year 1991 (i.e., the Wyden Amendment). As of November 1993, 45 single-shell tanks and 6 double-shell tanks are on a watch list. All 6 of the double-shell tanks are on the watch list for hydrogen or other flammable gas. The four watch list designations described in this report are ferrocyanide, hydrogen or other flammable gas, organic salts, and high-heat load. The following sections provide a general description and criteria of the different watch lists. For a more complete explanation, refer to the Hanford Site Tank Farm Facilities Interim Safety Basis (WHC 1993).

■ Ferrocyanide

A tank containing or believed to contain greater than 1,000 gram moles of ferrocyanide (dry basis) is on the ferrocyanide watch list. Tanks containing ferrocyanide are potentially explosive if ferrocyanide and nitrates combine.

■ Hydrogen or Other Flammable Gas

Tanks were placed on this watch list due to the potential of containing flammable gas rather than the verified presence of hazardous concentrations. Tanks on the watch list for hydrogen or other flammable gas have been identified as an unreviewed safety question due to the concern that burning flammable gas could result in a radiological release.

■ Organic Salts

Tanks containing or believed to contain more than the equivalent of 10% by weight of sodium acetate or 3 wt% total organic carbon (TOC) on a dry basis received a watch list designation as in the "Tank Farm Surveillance and Waste Status Summary Report" (Hanlon 1993). Tanks containing organic salts could release waste if an uncontrolled increase in temperature or pressure results from oxidation by nitrates and nitrites.

■ High-Heat Load

Tanks with a heat load greater than 40,000 Btu/hr are designated as high-heat load tanks. Tank 241-C-106 is the only high-heat load tank on the high-heat load watch list.

Any tank not listed on the high-heat load tank list or the high-heat load watch list with a heat load less than 40,000 Btu/hr is considered a low-heat load tank by default.

The following table lists the tanks in the southeast quadrant that appeared on the watch list as of June 1995. A current listing is published monthly in the "Tank Farm Surveillance and Waste Status Summary Report".

Southeast Quadrant Double-Shell Watch List Tanks

DST Tank	Category
241-AN-103	Hydrogen
241-AN-104	Hydrogen
241-AN-105	Hydrogen
241-AW-101	Hydrogen
241-SY-101	Hydrogen
241-SY-103	Hydrogen

1.6.2 Non-Watch List Safety Issues

Tank leaks are a safety hazard because of the potential to release chemicals and radioactive liquids to the ground. Corrosion is the main cause of tank leaks. Three other safety issues that do not require a watch list and continual monitoring under the Wyden Amendment include criticality, tank bumps, and toxic vapor releases.

■ Corrosion

Corrosion is a localized or general reduction in the thickness of the carbon steel liner. Localized reduction in the liner thickness is one of three types of corrosion: pitting corrosion, stress corrosion cracking, and crevice corrosion. General reduction in liner thickness may be uniform corrosion.

The tanks are equipped with corrosion (cathodic) protection. None of the double-shell tanks are assumed or confirmed leaking.

■ Criticality

Criticality is a self-sustained, nuclear chain reaction. Studies have concluded that a nuclear criticality accident in the tank farms is probably not an imminent risk. However, knowledge of the inventory of fissile material and its distribution within the tanks is incomplete. Therefore, criticality remains a safety issue. The key radionuclide on the Hanford Site that would be involved in a criticality accident is plutonium. To prevent a criticality, a maximum content of 125 kg of fissile material has been specified for the tanks. An unusual occurrence report involving nuclear criticality was filed in June 1991 for Tank 241-C-104. Later, an inventory of 56 kg was calculated which indicated a low probability

for criticality. Criticality is considered an unreviewed safety question, but is not affected by the Wyden Amendment according to the Hanford Site Tank Farm Facilities Interim Safety Basis (WHC 1993).

■ Tank Bumps

Tank bumps have been an issue at Hanford since 1953 with the last bump occurring in 1968. Tank bumps occur when heat from the hotter solid waste in the lower portion of the tank is suddenly transferred to a near boiling supernatant. Mixing can be achieved by "roll over" or sudden restart of airlift circulators which results in rapid fluid vaporization and a sudden internal tank pressurization that causes a bump. The three documented bumps that have occurred were due to airlift circulator failure followed by rapid startup of the airlift circulators which causes rapid mixing. Two key factors have been identified to control bumping: liquid and solid temperatures must be maintained as far away from the local boiling point as possible, and airlift circulators and ventilation systems must be operated as designed. A tank bump is extremely unlikely if airlift circulators and vent flowrates are maintained at 500 to 1,000 ft³/min per tank and 50 ft³/min to the airlift circulators according to the Hanford Site Tank Farm Facilities Interim Safety Basis (WHC 1993).

■ Toxic Vapor Releases

Toxic vapor releases are a recently analyzed safety concern at Hanford. Odors have been released from the C Tank Farm in the northeast quadrant and from Tank 241-SY-101 in the southeast quadrant. The entire issue of toxic gas releases at the tank farms has just begun to be understood according to the Hanford Site Tank Farm Facilities Interim Safety Basis (WHC 1993).

1.7 Occurrences

Over the years, unusual events that occurred at the Hanford Site have been documented by various reporting methods. Some of these reports include unusual occurrences reports, off normal reports, event fact sheets and occurrence reports. According to these reports, four unusual events affected all of the tank farms included in the southeastern quadrant. Occurrence reports RL--WHC-Tank Farm-1993-0072, RL--WHC-Tank Farm-1992-0028, RL--WHC-Tank Farm-1991-1031, and RL--WHC-Tank Farm-1991-1026 were written due to loss of power in the area. For more information on occurrences, refer to the Farm Information section for the specific tank.

2.0 AZ Tank Farm

2.0.1 AZ Tank Farm History

The AZ Tank Farm is located between Buffalo Avenue and Canton Avenue on the eastern side of the 200-East Area. The farm contains two 75-foot diameter, 1,000,000-gallon capacity (980,000-gallon operating limit) double-shell tanks. The tanks are described as double-shell because of their two steel liners. The tanks were constructed with a primary steel liner (stress-relieved carbon steel), a secondary steel liner, and a reinforced concrete shell with an insulating concrete foundation between the primary and secondary liners (see tank cross-section in Appendix G). These tanks were designed to hold aging waste from PUREX and B Plant (i.e., they contain additional airlift circulators, ventilation, and thermocouples). Maximum design temperatures in the tanks are 350°F for sludge, 220°F for vapor, and 260°F for liquid. The tanks are at the same elevation with no cascade lines between tanks.

A color aerial photograph taken in 1993 of the AZ Tank Farm shows the orientation of the tanks, leak detection pits, annulus ventilation equipment, instrument house, and the 241-AZ-152 diversion (sluice transfer) box (see Appendix I).

2.0.1.1 AZ Tank Farm Waste History

Both tanks in the AZ Tank Farm first received evaporator waste in 1976 and complexant concentrate waste in 1978. The tanks also received residual liquor, PUREX low-level waste, and non-complexed waste while active. The tanks presently receive only condensation from other aging waste tanks.

2.0.1.2 AZ Tank Farm Temperature History

The two tanks within the AZ Tank Farm each contain 37 thermocouples distributed in risers 13A, B, C, and D; risers 16A, B, and C; and in the 22 airlift circulators. These thermocouples were installed during construction of the tanks and the elevations are known. The four risers, 13A through 13D, are equally spaced around the tank near the edge. Each contains a profile thermocouple tree with three thermocouples. A profile thermocouple tree consists of three ¾-inch diameter schedule 40 carbon steel pipes. Each pipe extends into the tank to a different height above the bottom of the tank (four inches, 13.2 feet, and 25 feet). Each pipe terminates with a welded cap that houses one thermocouple. Risers 16A through 16C are closer to the center of the tank and each contains a single thermocouple for measuring sludge temperature. Each of these thermocouples is housed in a similar ¾-inch diameter capped pipe which extends to a point approximately four inches above the tank bottom. Each airlift circulator is equipped with one thermocouple, also housed in a ¾-inch diameter capped pipe. This pipe extends down along the airlift circulator to a point approximately three inches above the tank bottom.

All the profile and sludge thermocouples in Tank 241-AZ-101 are being replaced with sludge thermocouples under Project W-151. The new sludge thermocouples will be installed in 5½-inch pipe. Additionally, five new profile thermocouple trees will be added also using 5½-inch pipe. The larger pipe is designed to withstand the forces imposed by the new mixer pump being installed as part of Project W-151. The existing thermocouples in the airlift circulators will remain. Thermocouples in Tank 241-AZ-101 apparently have been replaced in the past, but it is unclear what the replacement history has been. Tank 241-AZ-102 still has the original temperature sensing equipment and no modifications are planned at this time. Thermocouple locations as originally constructed are identified in the temperature history plots in Appendix D. See Appendix G for the specific locations of the risers and the airlift circulators.

Recording temperatures daily is a requirement for both tanks in the AZ Tank Farm. Data from the tanks in this report were obtained from the computer automated surveillance system (CASS) and data sheets from manual recordings. The CASS is still recording temperatures in the AZ Tank Farm, but none of the temperatures are valid. Temperature data from these tanks are currently recorded manually on data sheets. There are plans to eventually store data from these sheets in the surveillance analysis computer system (SACS) database. Although not included here, there are data sheets for temperatures recorded from 1993 to the present that are stored at the Technical Service Center (Building 278-AW) in the 200-East Area. The data from data sheets presented in this report are from late 1989 to early 1990.

The CASS appears to have been recording valid temperature data for the AZ Tank Farm for various periods between July 1983 and March 1988. After March 1988, the data is suspect because only a small number of valid temperatures per thermocouple were recorded intermittently. Most daily readings by the CASS after March 1988 resulted in the storage of an error code in place of a temperature value. This sparsely populated temperature history after March 1988 is, therefore, questionable and, like other suspect data, has been excluded from the temperature history plots in Appendix D.

The CASS data fluctuated greatly from day to day over a very large temperature range for some thermocouples in the two tanks. Such data were also considered suspect. The entire data set for a thermocouple was bad in some cases while only a portion of the data set was bad in other cases. This behavior was most likely due to an instrumentation problem that the CASS was not programmed to recognize.

2.0.1.3 AZ Tank Farm Occurrences

Twenty-four unusual events occurred in the AZ Tank Farm with five events specific to Tank 241-AZ-101 and four events specific to Tank 241-AZ-102. Since 1975 when the tanks began operating, the following fifteen occurrences affected both tanks. Two occurrence reports pertain to equipment that was not in compliance with procedures (RL--WHC-Tank Farm-1993-0083 and RL--WHC-Tank

Farm-1992-0012). Occurrence report RL--WHC-Tank Farm-1993-0068 was written due to an unexpected waste transfer. Eight reports were written because failing equipment caused the tanks to pressurize (occurrence reports RL--WHC-Tank Farm-1993-0011, RL--WHC-Tank Farm-1991-1064, and RL--WHC-Tank Farm-1991-0043; off-normal reports 86-53, 86-22, 86-13, 86-10, and 85-39; and unusual occurrence report 84-81). Occurrence report RL--WHC-Tank Farm-1992-0016 concerned an electrical problem with the instrument panel. Unusual occurrence report 77-102 was written because radioactive material was found in the air sample filters of each tank annulus.

2.0.1.4 AZ Tank Farm Ventilation

Air enters each tank by infiltrating around the pit cover blocks, leaves the tank through riser 4, and is pulled through ducts which join and lead to the 702-A primary ventilation system (the same system used by AY Tank Farm). The tank system also shares the backup system with the AY Tank Farm. Refer to drawing H-2-35749 for more information.

Each tank is designed to have 2,000 ft³/min (CFM) of air travel through the annulus. Outside air passes through a heating coil, two prefilters, and a HEPA filter before the duct splits leading to each tank annulus. After traveling through each annulus, the air passes through two heaters, two HEPA filters, and a 7,040 CFM exhaust fan. The exhaust fan returns the air to the atmosphere after it is sampled. For more information, refer to drawing H-2-92964, sheets 1 and 2.

The tanks in AZ Tank Farm have a minimum and maximum safety limit pressure of -6 inches of water gauge (-0.22 psig or 1.49 kPa gauge) and 60 inches of water gauge (2.17 psig or 14.93 kPa gauge), respectively. The operating pressure is between -4 and 0 inches of water gauge (-0.14 psig or -1 kPa gauge and 0 psig or 0 kPa gauge). These pressure limits can be found in document WHC-SD-WM-OSR-004, Rev. 1B (Aquirre 1994).

The psychrometric data were prepared in two parts, the tank data and the annulus data. Positive numbers represent moisture and heat leaving the tank and annulus, and negative numbers represent moisture and heat entering the tank and annulus. Since only two psychrometric data points were recorded almost one year apart for each of the tanks, no plots were made for the tanks. Psychrometric data have been recorded for 14 years on the annuli. Two plots were made for each tank annulus: heat transfer rate to the ventilation system versus time and evaporation in gallons per week versus time. Evaporation in inches per week, though calculated, was not plotted because this data is significant only if standing water is present in the annulus. If there were insufficient raw data or the data point was labeled suspect, the point was not plotted on the graph. See Appendix F for the tables and plots.

2.0.1.5 AZ Tank Farm Historical Sample Analysis Data

The 241-AZ Tank Farm contains what is classified as aging waste [i.e., waste that generates high temperatures because of decaying (aging) radionuclides]. This waste is chemically comprised of mainly sodium, nitrate, nitrite, and hydroxide. The radiological constituents in the greatest concentration are cesium and strontium. The wastes within the two tanks are primarily clear, yellow liquids with traces of rust to brown colored solids. The tanks have acquired a solids layer on the bottom that has also been analyzed for content. See Appendix H and the individual tank sections for more information.

2.0.2 Current Status of AZ Tank Farm

Tanks 241-AZ-101 and -102 are both inactive, are actively ventilated, and are categorized as sound. Currently, the combined waste volume of both tanks is 1,872,000 gallons (Hanlon, June 1995).

2.0.2.1 Inventory Estimates for AZ Tank Farm

There are three inventory estimates for each tank in the AZ Tank Farm created by Los Alamos National Laboratory (see Appendix J). The supernatant mixing model (SMM) composite estimate is based on the output of the supernatant mixing model. The tank layer model (TLM) solids composite estimate is based on the output of the tank layer model. The total inventory estimate is a combined volume weighted average of the SMM composite and the TLM composite inventory estimates.

2.0.2.2 Waste Volume Approximations AZ Tank Farm

The waste volume in each tank was modeled using two programs developed by Los Alamos National Laboratory (LANL). One program, the supernatant mixing model (SMM), modeled the liquid (supernatant) portion of the tank. The other program, the tank layer model (TLM), modeled the solids portion of the tank. The models were run using data representing the estimated contents of each tank as of the inventory estimate date (January 1, 1994). Results from both models are in Appendix K.

The waste volume approximations have been modified in both programs and are presented on each level history sketch in Appendix C. There are two areas that have been modified. The first area concerns the concentrated supernatant solids (CS solids). The CS solids are determined by taking the difference between the measured solids volume and the solids volume predicted by the tank layer model. The concentrated supernatant solids are considered part of the total supernatant and not as a solid according to the tank layer model. The second area concerns the supernatant volume. The supernatant volume from LANL presented on the level history sketch was determined by taking the difference between the predicted supernatant mixing model volume and the CS solids volume. These modifications were necessary in order to reflect the actual supernatant and solids volumes that were measured within each tank.

2.0.2.3 AZ Tank Farm In-Tank Photographs

The AZ Tank Farm photographs usually were taken from an off-center riser. Panoramic pictures of the entire inside surface area were taken and the photographs were assembled into a montage (see Appendix I). Most photographic montages provide a good representation of present tank contents if no activity has occurred to affect the tank since the photographs were taken.

2.1 Tank 241-AZ-101

2.1.1 241-AZ-101 Tank History

2.1.1.1 Waste History of Tank 241-AZ-101

The history of the primary additions is derived from the "Waste Status and Transaction Record Summary for the Southeast Quadrant" (Agnew 1995). Tank 241-AZ-101 received PUREX low-level waste from the first quarter of 1981 until the third quarter of 1985. The tank had an unknown transaction during the first quarter of 1982. From the third quarter of 1982 until the first quarter of 1986, the tank received PUREX high-level waste. During the fourth quarter of 1982, the tank received B Plant low-level waste.

The history of the waste types is derived from "A History of the 200 Area Tank Farms" (Anderson 1990) and Tank Farm Surveillance and Waste Status Summary Reports for January 1980 through March 1994. Tank 241-AZ-101 began receiving evaporator waste in the fourth quarter of 1976 and continued to receive this waste until the fourth quarter of 1977. From the first quarter of 1978 until September 1980, the tank received complexed waste, double-shell slurry feed waste, non-complexed waste, water, evaporator waste, residual liquor, and complexant concentrate waste. From October 1980 until January 1984, the tank received non-complexed waste. The waste in the tank was designated as aging waste from February 1984 until March 1994.

The tank is considered an aging waste tank. It is currently an inactive concentrated waste holding tank that receives only condensate from aging waste tanks. Internal photographs were taken on the following dates: August 1983, April 1981, April 1980, and May 1979. Sketch ES-TKS-E173, a graphical representation of the Tank 241-AZ-101 level history, and the historical waste level data used to generate the graph are in Appendix C.

2.1.1.2 Temperature History of Tank 241-AZ-101

Temperatures from within Tank 241-AZ-101 are recorded by 37 thermocouples. Non-suspect temperature data recorded between July 1983 and March 1988 for 33 of the 37 thermocouples were obtained from the computer automated surveillance system (CASS). However, not all of the 33 thermocouples have data that encompass that entire period. Non-suspect temperature data recorded between October 1989 and April 1990 for 33 of the 37 thermocouples were available from the data sheets. Within the time span recorded by the CASS, there were several small breaks in the sequence of the temperature data. Within the time span of the manually recorded data, there were no significant breaks in the sequence of temperature data for most thermocouples. The average temperature during this period was 145°F with a minimum of 45°F, a maximum of 271°F, and a standard deviation of 36.4°F. Linear regressions were performed on the temperature data for 32 of the 37 thermocouples with a resulting average increasing slope of 0.0131°F/day. Each of the data sets of the five thermocouples excluded from the average slope was either entirely suspect or encompassed a limited period of time.

The temperature history plots for Tank 241-AZ-101 exhibit several large temperature peaks and valleys for most thermocouples between July 1983 and early 1985 and again in early 1988. It was during these periods that the majority of the data came from the CASS. Possible explanations for these anomalies are the operation of the airlift circulators or the tank's steam coil heater.

2.1.1.3 Occurrences of Tank 241-AZ-101

Five unusual events affected only Tank 241-AZ-101 between 1976 and 1995. Occurrence report RL--WHC-Tank Farm-1992-0085 was written due to procedural requirements not being met. TFS & O-EFS-88-007 and off-normal report 86-52 were written due to unexpected transfers of waste. Off-normal report 86-16 concerned the tank pressurizing from an equipment failure. Unusual occurrence report 84-17 was written because of equipment failure.

2.1.1.4 Psychrometrics of Tank 241-AZ-101

The trend in the rates of heat exchange through the annular ventilation showed an increase from October 1980 to November 1994. This suggests an increase in the rate of heat generation in Tank 241-AZ-101 (see Appendix F).

2.1.1.5 Historical Sample Analysis Data for Tank 241-AZ-101

Several samples were taken from Tank 241-AZ-101 and analyzed between April 26, 1978 and July 6, 1988. Samples were analyzed for concentrations of anions, cations, and radionuclides (see Appendix H). The first sample, analyzed on April 26, 1978, was used to determine evaporative conditions necessary for concentrating the waste. The sample was composed primarily of sodium nitrate and sodium hydroxide with cesium as the primary radionuclide.

Eight samples were drawn and tested on December 3, 1979. The samples mainly consisted of anions of nitrate, nitrite, and hydroxide with the aluminum cation. Cesium and strontium were the radionuclides in highest concentration. All of the samples contained approximately fifty percent water.

A sample of the sludge was analyzed on December 28, 1983. The sludge was tested for specific components. Nitrate was the most common anion with lesser concentrations of nitrite and hydroxide. Cesium was the most common radionuclide in the sludge sample.

On September 13, 1985, a composite sample was analyzed from the supernatant in the tank. The analysis revealed that the primary cations were sodium with some aluminum, while nitrates with additional nitrites and hydroxides were the primary anions. The radionuclides found in the highest quantity were cesium and rhodium.

A sample analyzed on April 8, 1986 was separated into supernatant, centrifuged solids, and total slurry portions. The supernatant portion contained primarily sodium, nitrate, and hydroxide with high amounts of cesium. The centrifuged solids also

contained sodium, but the only highly concentrated anion was nitrate. Several radionuclides were in the solids in high concentrations: cesium, strontium, rhodium, and cerium. The total slurry sample also contained primarily sodium, nitrate, and hydroxide with cesium, strontium, rhodium, and cerium as the principal radionuclides.

The final sample, taken on March 11, 1988 and analyzed on July 6, 1988, again contained sodium as the most concentrated cation with trace amounts of aluminum and other cations in both the supernatant and solid sample. However, the solid sample had a very high concentration of fluoride anion. The most abundant radionuclide in the supernatant was cesium. Strontium was the most abundant in the solid sample.

Information on sampling procedures and methods was not available.

2.1.2 Current Status of Tank 241-AZ-101

Tank 241-AZ-101 entered service in November 1976 and currently stores approximately 932,000 gallons of waste (Hanlon, June 1995). The waste surface level, measured with a manual tape, has fluctuated over the past five years between about 330 inches and 360 inches. The automatic FIC measurements are all suspect data points and were not plotted. See Appendix E for information on surface level plots and data. The increases and decreases are attributed to evaporation and flush water from miscellaneous sources. The tank is actively ventilated and categorized as sound. A plan view in Appendix G depicts the riser locations. Tank 241-AZ-101 has 117 risers. One 4-inch riser (no.5), one 16-inch riser (no.22A), and one 42-inch riser (no.7) are available for use. An ENRAF® 854 ATG surface level gauge was installed in the tank in June 1995.

2.1.2.1 Inventory Estimate of Tank 241-AZ-101

The inventory estimates created by Los Alamos National Laboratory predict the physical, chemical, and radionuclide constituents of the supernatant, the solids, and the total volume of waste for each tank. These estimates are presented in Appendix J.

2.1.2.2 Waste Volume Approximations for Tank 241-AZ-101

The summary of approximated waste volumes, as derived by Los Alamos National Laboratory's supernatant mixing model (SMM) and tank layer model (TLM), are presented in Appendix K. The modeled volumes are from the tank waste contents corresponding to the inventory estimate date of January 1, 1994. A tank cross-section that depicts the volume of waste on the inventory estimate date is in Appendix G. The total waste volume on the inventory estimate date was 931,000 gallons according to the "Tank Farm Surveillance and Waste Summary Report" (Hanlon 1993). The total waste volume was divided by the SMM and the TLM into the following subsets. The SMM predicted there were 902,000 gallons of supernatant. The TLM predicted there were 1,000 gallons of PUREX low-level waste (PL2), 1,000 gallons of B Plant low-level waste (BL), 6,000 gallons of unknown waste (UNK), and 27,000

gallons of PUREX high-level waste (P3). There is a discrepancy between the total volume of waste predicted by the models and the total volume of waste reported by Hanlon. The sum of the predicted solid volumes from the TLM and the supernatant volume from the SMM totals 937,000 gallons while Hanlon reports a total volume of 931,000 gallons. The difference in these volumes cannot be explained at this time.

2.1.2.3 In-Tank Photograph of Tank 241-AZ-101

The most recent montage for this tank is 11 years old and was assembled from photographs taken in August 1983 (see Appendix I). Since the waste type and level have changed since 1983, the waste surface will not appear the same now. These photographs do provide an accurate picture of equipment inside the tank. This tank has more instruments and auxiliary equipment than other waste storage tanks because it is one of the four double-shell tanks containing aging waste. Monitoring instruments identified in this picture include three temperature probes, four level probes, and three drywells.

2.2 Tank 241-AZ-102

2.2.1 241-AZ-102 Tank History

2.2.1.1 Waste History of Tank 241-AZ-102

The history of the primary additions is derived from the "Waste Status and Transaction Record Summary for the Southeast Quadrant" (Agnew 1995). Tank 241-AZ-102 received PUREX low-level waste from the third quarter of 1983 until the first quarter of 1991. During the third quarter of 1985, the tank received dilute non-complexed waste from the 200-East Area single-shell tanks. The tank received B Plant low-level waste during the fourth quarter of 1985. From the first quarter of 1986 until the first quarter of 1990, the tank received PUREX high-level waste. The tank had an unknown transaction during the third quarter of 1987.

The history of the waste types is derived from "A History of the 200 Area Tank Farms" (Anderson 1990) and Tank Farm Surveillance and Waste Status Summary Reports for January 1980 through March 1994. Tank 241-AZ-102 began receiving water in the second quarter of 1976 and was labeled as a spare. The tank received evaporator waste from the third quarter of 1976 until the second quarter of 1977. During the third and fourth quarters of 1977, the tank received residual liquor waste. From the first quarter of 1978 until November 1983, the tank received complexant concentrate waste. The tank received complexed waste during December 1983 and January 1984. From February 1984 until February 1986, the tank received non-complexed waste. From April 1986 until March 1994, the tank was designated as containing aging waste.

The tank is considered an aging waste tank. It is currently an inactive dilute receiver tank that receives only condensate from aging waste tanks. Photographs of the tank interior were taken on the following dates: October 1984, February 1984, April 1981, April 1980, March 1979, and October 1977. Sketch ES-TKS-E174, a graphical representation of the level history, and the historical waste level data used to generate the graph are in Appendix C.

2.2.1.2 Temperature History of Tank 241-AZ-102

Temperatures from within Tank 241-AZ-102 are recorded by 37 thermocouples. Non-suspect temperature data recorded between July 1983 and March 1988 for 28 of the 37 thermocouples were obtained from the computer automated surveillance system (CASS) (see Appendix D). However, not all of the 28 thermocouples have data encompassing the entire period. Non-suspect temperature data recorded between May 1990 and September 1990 for all 37 thermocouples were obtained from manually recorded data sheets. There were several small breaks in the sequence of the temperature data recorded by the CASS. There were no significant breaks in the sequence of temperature data recorded manually for most thermocouples. The average temperature during this period was 115°F with a minimum of 54°F, a maximum of 250°F, and a standard deviation of 43.6°F. Linear regressions were performed on the temperature data for 28 of the 37 thermocouples with

a resulting average increasing slope of 0.0197°F/day. Each of the data sets of the nine thermocouples excluded from the average slope was either entirely suspect or encompassed a limited period of time.

The temperature history plots for Tank 241-AZ-102 exhibit several large temperature peaks and valleys for most thermocouples in late 1983, early 1986, and early 1988. It was during these periods that the majority of the data came from the CASS. Possible explanations for these anomalies are the operation of the airlift circulators or the tank's steam coil heater.

2.2.1.3 Occurrences of Tank 241-AZ-102

Four unusual events affected only Tank 241-AZ-102 between 1975 and 1995. TFS & O-EFS-89-063 concerned a bent riser. Two reports were written due to equipment failures (TFS & O-EFS-88-18 and unusual occurrence report 76-143). Unusual occurrence report 84-21 was written due to an unexpected waste transfer.

2.2.1.4 Psychrometrics of Tank 241-AZ-102

The trend in the rates of heat exchange through the annular ventilation increases from October 1980 to November 1994. This suggests an increase in the rate of heat generation in Tank 241-AZ-102 (see Appendix F).

2.2.1.5 Historical Sample Analysis Data for Tank 241-AZ-102

Tank 241-AZ-102 was sampled several times between April 26, 1978 and March 11, 1988. Samples were analyzed for concentrations of anions, cations, and radionuclides (see Appendix H). The first sample from April 26, 1978 contained mostly sodium nitrate and sodium hydroxide with high concentrations of strontium and cesium.

Another sample was reported on August 19, 1983, though the sample was dated June 26, 1979. The analysis showed that the contents remained similar to the first sample with high concentrations of sodium cations, hydroxide and nitrate anions, and cesium and strontium radionuclides.

On February 4, 1985, two samples were taken, one from one foot above the bottom of the tank (R-3699) and the other from eighteen feet above the bottom (R-3700). Consistent with the earlier samples, both of these samples contained the same primary components of sodium, nitrate, and hydroxide. Also, cesium and strontium were again the main radionuclides in the waste.

A sample analyzed on May 6, 1986 was centrifuged and the resulting supernatant and solids were tested. The supernatant again contained largely sodium, nitrate, and hydroxide with cesium and strontium. However, the centrifuged solids contained sodium, phosphate, phosphorous, aluminum, and nitrate. The radionuclides were mostly cesium, strontium, and cerium.

The final sample, analyzed on March 11, 1988, showed more consistency of the supernatant with sodium, nitrate, and hydroxide dominating the composition with additional nitrite concentrations. Cesium was the main radionuclide in the sample.

Information on sampling procedures and methods was not available.

2.2.2 Current Status of Tank 241-AZ-102

Tank 241-AZ-102 entered service in November 1976 and currently stores approximately 940,000 gallons of waste (Hanlon, June 1995). The waste surface level, measured with a manual tape, has fluctuated over the past five years between 340 inches and 360 inches. All the FIC data read 0.0 inches and were labeled suspect until March 1994. See Appendix E for information on surface level plots and data. The increases and decreases are attributed to evaporation and flush water from miscellaneous sources. This tank is inactive and only receives condensate from aging waste tanks. The tank is actively ventilated and categorized as sound. A plan view in Appendix G depicts the riser locations. Tank 241-AZ-102 has 117 risers. One 4-inch riser (no.5), one 16-inch riser (no.22A), and one 42-inch riser (no.7) are available for use.

2.2.2.1 Inventory Estimate of Tank 241-AZ-102

The inventory estimates created by Los Alamos National Laboratory (LANL) predict the physical, chemical, and radionuclide constituents of the supernatant, the solids, and the total volume of waste for each tank. These estimates are presented in Appendix J.

2.2.2.2 Waste Volume Approximations for Tank 241-AZ-102

The summary of approximated waste volumes, as derived by Los Alamos National Laboratory from the supernatant mixing model (SMM) and the tank layer model (TLM), are in Appendix K. The modeled volume is from the tank waste contents corresponding to the inventory estimate date of January 1, 1994. A tank cross-section that depicts the waste volume on the inventory estimate date is in Appendix G. The total waste volume on that date was 974,000 gallons according to the "Tank Farm Surveillance and Waste Summary Report" (Hanlon 1993). The total waste volume was divided by the SMM and the TLM into the following subsets. The SMM predicted 931,000 gallons of supernatant. The TLM predicted 76,000 gallons of unknown waste (UNK), 3,000 gallons of PUREX low-level waste (PL2), 1,000 gallons of Z Plant waste (Z), and 13,000 gallons of PUREX high-level waste (P3). There is a discrepancy between the total volume of waste predicted by the models and the total volume of waste reported by Hanlon 1993. The sum of the predicted solid volumes from the TLM and the supernatant volume from the SMM totals 1,024,000 gallons while Hanlon reports a total volume of 974,000 gallons. The difference in these volumes cannot be explained at this time.

2.2.2.3 In-Tank Photograph of Tank 241-AZ-102

The most recent montage for this tank is ten years old; it was assembled from photographs taken in October 1984 (see Appendix I). Since the waste type and level have changed since 1984, the waste surface will not appear the same now. These photographs do provide an accurate picture of the equipment in the tank. This tank has more instruments and auxiliary equipment than other waste storage tanks because it is one of the four double-shell tanks containing aging waste. Monitoring instruments identified in this picture include five temperature probes, four level probes, and five drywells. The tank contains air lift circulators, heating coils, and some drains and nozzles.

7. Abstract

Historical Tank Content Estimate of the Southeast Quadrant provides historical evaluations on a tank by tank basis of the radioactive mixed wastes stored in the underground double-shell tanks of the Hanford 200 East and West Areas. This report summarizes historical information such as waste history, temperature profiles, psychrometric data, tank integrity, inventory estimates and tank level history on a tank by tank basis. Tank Farm aerial photos and in-tank photos of each tank are provided. A brief description of instrumentation methods used for waste tank surveillance are included. Components of the data management effort, such as Waste Status and Transaction Record Summary, Tank Layer Model, Supernatant Mixing Model, Defined Waste Types, and Inventory Estimates which generate these tank content estimates, are also given in this report.

The following table describes the column headings for the Tank Layer Model developed by Los Alamos National Laboratories and the column headings correspond with the tables presented in this appendix.

Column Heading	Description
Tank	tank number
Year	year of last primary addition and year of solid measurement
Qtr	quarter of last primary addition and quarter of solid measurement
Meas, solids	reported solids from Anderson-91 in kgal
Solids change	calculated solids based on primary fill record or difference between solids records
Pred layer	predicted layer now in tank in kgal
Layer type	Defined Waste Type for that layer
Waste volume	sumation of primary waste additions calculated for this period
Comments	various details of each calculation
