ABSTRACT

Montana's Geothermal Resources

The Montana Bureau of Mines and Geology has updated its inventory of low- and moderate temperature resources for the state and has assisted the Oregon Institute of Technology - GeoHeat Center and the University of Utah Research Institute in prioritizing and collocating important geothermal resource areas.

The database compiled for this assessment contains information on location, flow, water chemistry, and estimated reservoir temperatures for 267 geothermal wells and springs in Montana. For this assessment, the minimum temperature for low-temperature resource is defined as 10° C above the mean annual air temperature at the surface. The maximum temperature for a moderate-temperature resource is defined as greater than 50° C. Approximately 12% of the wells and springs in the database have temperatures above 50° C, 17% are between 30° and 50°C, 29% are between 20° and 30°C, and 42% are between 10° and 20° C. Low- and moderate-temperature wells and springs can be found in nearly all areas of Montana, but most are in the western third of the state. Information sources for the current database include the MBMG Ground Water Information Center, the USGS statewide database, the USGS GEOTHERM database, and new information collected as part of this program.

Five areas of Montana were identified for consideration in future investigations of geothermal development. The areas identified are those near Bozeman, Ennis, Butte, Boulder, and Camas Prairie. These areas were chosen based on the potential of the resource and its proximity to population centers.

1.0 INTRODUCTION

Previous Geothermal Assessments

Two state-wide geothermal assessments have been conducted in the past. Allen (1980) collocated geothermal resources and cities for eight western states including Montana. Allen's study focused on resource temperatures greater than 50°C and did not include low-temperature resources. Sonderegger and others (1981) produced a 1:1,000,000-scale map and associated table of geothermal resource areas in Montana based on a compilation of various published reports and theses. Although the compilation included temperatures below 50°C, these data were not stored in a digital format because electronic databases were not available then for retrieval or storage. These reports, however, provided a good basis for updating information which has now been stored in a digital format.

Overview of Program

The Montana Bureau of Mines and Geology (MBMG) entered into a cooperative agreement with the Oregon Institute of Technology GeoHeat Center (OIT-GHC) and the University of Utah Research Institute (UURI) to conduct several tasks related to Montana's geothermal resources. These tasks included:

- ▶ preparation of a comprehensive digital geothermal-resources database containing temperature, location (latitude/longitude, Township/Range/Section/tract, and county) and chemistry (pH, TDS, and selected chemistry). The minimum temperature for a low-temperature resource was defined to be 10°C above the mean annual air temperature at the surface.
- ▶ preparation of a 1:1,000,000-scale map of occurrences within Montana. The map was compiled in a digital format.

- ▶ collecting samples from areas lacking information; analyses of the samples were conducted by UURI Earth Science Laboratory.
- ▶ a final summary report describing all tasks and their results.
- ▶ assisting OIT-GHC and UURI to prioritize low- and moderate-temperature resource areas.

Funding for this program was provided by the Department of Energy through a task agreement with OIT GHC and UURI. The tasks performed under this agreement may be considered Phase I of the Low-Temperature Geothermal Resources and Technology Transfer Program. Phase II, if funded, will include a detailed study of priority sites.

2.0 DATA SOURCES

References Used and Selection Criteria

Ground Water Information Center

The criteria for selecting sites that were to be included in the database depended on the source of the data. For the initial search of the Montana Bureau of Mines Ground Water Information Center (GWIC) database, a minimum temperature of 13° Celsius was used (10° degrees above the lowest mean annual temperature officially reported anywhere in Montana) to ensure that all low-temperature sites were included. This query produced approximately 600 records. Each record included any information that was available on location, site name, well depth, flow, temperature, and chemistry. These records were then transferred to a PARADOX database where more restrictive queries could be made that would eliminate records while allowing for a review of the eliminated records. For example, after sorting and separating the data into five geographic areas for which the mean annual air temperature was better defined and running a query based on that temperature, approximately 250 sites were eliminated, leaving approximately 350 sites to be considered further. Each of the remaining 350 sites was assigned a 3-digit identification number with a prefix of MGEOT. The rejected records were reviewed for other geothermal indicators such as high chloride, silica, and/or arsenic concentrations and close proximity to known geothermal areas.

GEO THERM

A digital version of the GEO THERM database was obtained from the Department of Energy Geothermal Division. These data had been compiled in an earlier, region-wide inventory (Reed and others, 1983). Although no new records were added to the MGEOT database, the GEO THERM records were compared to those in the MGEOT database for accuracy and completeness. Since there were few changes, it was not necessary to merge the databases; any necessary changes to the MGEOT database were made manually.

Published Data

The tables of geothermal wells and springs produced by Mariner and others (1976), Leonard and others (1978), and Sonderegger and others (1981), were also used to ensure the completeness and accuracy of the MGEOT database. Any additional sites or information from these reports were entered manually into the database. The same approach was taken with other published sources.

Twelve Master's theses were reviewed for additional information on geothermal resource areas. Many of the investigations focused on the geologic or geophysical aspects of a known geothermal area. Little chemistry data was gleaned from these reports; however, temperature and location of many sites were verified as a result of the review.

Error and Duplicate Records

The most common error encountered was high temperatures reported for wells and springs in areas where geothermal sources are known *not* to exist. The most probable cause for the high temperature is "warm-day" sampling or improper purging of shallow wells. These sites were eliminated based on the personal knowledge of the investigators or on data collected at that same site at another time. Another common error was in the units used for concentration data. Trace-metals such as boron, arsenic, and lithium were often in error as a result of converting between parts-per-billion ($\mu\text{g/L}$) and parts-per-million (mg/L). The original publication was used, if possible, to correct these. In other cases, a calculation of ionic balance was used to determine if a problem existed.

With some exceptions, duplicate records in the form of data for two or more samples from the same site were eliminated and the most recent, most complete data were used. The exceptions were the site that had been re-sampled as part of this inventory (Symes Hotel, MGEOT352) and sites where samples had been collected several years apart. The intent was to provide information on changes in temperature and chemistry over time. The other exception were those sites where

information was limited with respect to chemistry. In these cases, two data sets provided more useful information on the site. There is a total of 24 duplicate sites.

Reference/Bibliography

A reference is given for each record in the database. The reports published by Mariner and others (1976), Leonard and others (1978), and Sonderegger and others (1981) provided most of the information for previously identified geothermal areas. The GWIC database provided more recent data for previously identified sites. GWIC also provided information for areas near previously identified resource areas and for low-temperature sites in geothermal areas not previously identified.

The references/bibliography listed in Section 8.0 also includes the theses and other publications that pertain to geothermal resource areas in Montana. As noted in Section 2.0, some of these references provided confirmation of location and temperature. Rautio and Sonderegger (1980) also provided a bibliography of geothermal resources in Montana. This is reproduced in this report as a useful supplement to the bibliography.

3.0 DATA FORMAT

Organization of Tables

The data fields used in the database were recommended by program leaders at OIT-GHC and UURI, and agreed upon by state team members. The final version of the data was exported from the PARADOX database to a LOTUS-123 format. The spreadsheet enabled an evaluation of the distribution of sites, the calculation of reservoir temperature, and provided a means of graphical output.

State Geothermal Resource Map

The location (latitude/longitude), temperature, resource type (well or spring), and ID number of all sites in the database were imported from the spreadsheet to an ARC/INFO based Geographical Information System. The data were then plotted at 1:1,000,000 scale with county boundaries. Each data-point indicated the ID-number, the temperature range (by color), and resource type (well or spring, by symbol) as well as location. This initial plot was used to verify the accuracy of the location, to give an indication of the density of sites in a given area, and to identify any sites that were plotted in areas where geothermal resources are known not to exist. The final map uses the same format and presents each of the individual sites listed in the database. A listing of selected fields for all sites is presented in Appendix I. The large number of sites in the Camas-Lonepine area made it impractical to plot the ID number for each site; these are repeated in a separate table in Appendix I.

Procedures for using the data

The database listing in Appendix I is sorted by location (ascending latitude). This format is also used in the listing of maximum temperatures based on selected geothermometers in Appendix II. The information for each site is listed with reference to the ID number on the 1:1,000,000-scale map.

In the repetitive process of adding and deleting sites based on a multitude of criteria, it was found that maintaining the database in a PARADOX (or similar)

format was best. This format enables searches using the an ID-number or location from the map or general information, such as site name, and is contained in a single database-table. This single table can be separated into several tables as the need arises.

4.0 FLUID CHEMISTRY

Samples collected in this assessment

Eight water samples were collected from five areas in Montana; seven of these sample sites had not been sampled previously or had only limited information prior to this investigation. The eighth site was selected to provide a comparison of data collected approximately 10 years apart.

Figure 1 Eight samples were collected from three areas of Montana. Seven of the sites had little or no chemistry data.

Boulder Hot Springs, south of Boulder, MT

The Boulder Hot Springs resort is approximately 3 miles south of the town of Boulder within the Boulder Hot Springs KGRA. Previous owners of the resort would not grant access for sample collection during previous investigations. The

current owners, however, kindly allowed access, and each of the three springs near the resort were sampled (MGEOT349, MGEOT350, and MGEOT351). A fourth sample (MGEOT356) was collected from a well that had been intended as a drinking-water supply for the hotel, but produced "hot water" according to the owner.

Symes Hotel, Hot Springs, MT

The Symes Hotel uses a well for domestic water use. This well had been sampled in previous investigations, the sample date being 1980. The area has since undergone a moderate amount of development, and several additional wells have been completed in the area. Thus, this site (MGEOT352) was chosen to provide a comparison.

Koepling Well (MGEOT355) and Ostranger Well (MGEOT 354) , north of Hot Springs, MT

These wells are in the Little Bitterroot Valley 3 to 5 miles north of the town of Hot Springs. Although previously identified to be within a geothermal resource area, these wells had not been sampled in previous investigations.

Green Springs Area (MGEOT353), southwest of Camas Prairie, MT

Local residents identified 3 to 4 "hot" springs in the area south of the town of Camas Prairie. Nearby, Green Springs had been identified by Sonderegger and others (1981) as a geothermal area, but only limited data were available.

Sample collection/analytical methods

Water samples were collected from wells and springs in accordance with the Standard Operating Procedures provided by UURI (Kroneman, 1992). Each sample consisted of a 60-ml bottle filtered and preserved with 20% HNO₃, and 250-ml bottle filtered and preserved with 1% HCL, and a 500-ml bottle filtered with no

preservative. Upon collection of each sample, specific conductance, pH, water temperature and air temperature were obtained at the sample source. Spring samples were collected as close as possible to the source. Wells were sampled after pumping or bailing a minimum of three casing volumes and after field-parameters (pH, SC, Eh, and temperature) had stabilized to a range of less than 10%.

Samples were shipped within 48-hours of collection, via overnight delivery, to the UURI Analytical Laboratory in Salt Lake City, Utah. The samples were analyzed for major cations, major anions, and selected trace-metals.

Reservoir Temperatures

Several methods to estimate the reservoir temperature have been proposed; the most widely used are those using dissolved concentrations of silica (as SiO_2), Na-K-Ca, Na-K-Ca with a correction for Mg, and Na-K and are summarized by Fournier (1981). These methods represent empirical, equilibrium equations for which the water temperature at the reservoir is calculated. As noted by the authors of the methods, these calculations should be interpreted in consideration of the geologic and hydrogeologic setting.

Analytical Results

The analytical results for selected analytes are presented in Table 1. These sites are also included in the listing in Appendix I, in the listing of temperatures from geothermometers in Appendix II, and in the MGEOT database.

ND = Not Detected

Boulder Hot Springs

The Boulder Hot Springs area lies approximately 3 miles south of the town of Boulder near the Interstate 15 highway. The area lies within the Boulder Batholith about 4 miles from its eastern edge. Until this investigation, only limited chemistry data and field parameters were publicly available for this area (Robertson and others, 1976, published limited chemistry and a reservoir temperature, but the location of the sample was not made clear). Other hot-springs and warm-water wells are known to exist in the area around Boulder; however, access was not gained either because the owner denied access or could not be contacted.

The samples were collected from three springs that have been developed to supply the Boulder Hot Springs resort. At present, the primary use of the hot water is a naturally heated swimming pool. As renovation of the hotel continues, the water may also be used for space heating as was the case in the past. Samples were collected at the supply pipe at each spring-box. Water-flow, which was difficult to measure because of the structures, was measured at two of the

springs using a bucket and stopwatch; the flow of the middle springs could only be estimated. The combined flow of all three springs is on the order of 490 L/min.

The field-temperatures of the springs vary by 20°C; the upper spring had the lowest temperature (54°C) and the middle spring, which was not being used, had the highest temperature (74°C). The variance in temperature suggests that the water supplying the springs is undergoing mixing. Conversely, the chemistry of the waters from each of the three springs is similar (all are strongly a sodium-potassium type water) and the estimated reservoir temperature for each of the springs tend to agree regardless of the geothermometer used (Table 2). Thus, the variance in temperature may result from the way the spring was developed and fed to the spring boxes.

TABLE 2
Selected Geothermometer Temperatures*
Boulder Hot Springs

ID	Site Name	Na-K-Ca (corrected)	Na-K-Ca (uncorr.)	Qtz (no steam)	Qtz (steam)
MGEOT349	BOULDER (UPPER)	110°C	134°C	133°C	129°C
MGEOT351	BOULDER (LOWER)		158°C	131°C	128°C
MGEOT350	BOULDER (MIDDLE)	120°C	141°C	136°C	132°C
MGEOT356	BOULDER (WELL)		134°C	129°C	126°C

*Geothermometer temperatures for all sites are presented in Appendix II.

The well, with a depth of 37.5 meters and a static-water-level of 0.85 meters, is downhill from the resort and the springs. The chemistry of its water (Table 1) is similar to that of the springs; and the geothermometer temperatures (Table 2) are in good agreement with those calculated for the springs. The water temperature (34.5°C) was 20°C lower than the spring with the lowest temperature. A small pond near the well had a temperature of 21°C.

Hot Springs Area

Three water samples were collected from the Hot Springs area: two from wells north of Hot Springs and one from a well in Hot Springs. As noted previously, temperature and chemistry data were not available for three of these sites, and the fourth, the Symes Hotel, had a sample collected in 1972.

The Koepling well and the Ostranger well are completed in the Lonepine aquifer approximately 1.5 miles apart and approximately 5 miles northeast of Hot Springs. The Symes Hotel is located in Hot Springs.

Water temperature and the concentration of several of the dissolved constituents varies between the three wells (Table 1). The geothermometer temperatures (Table 3) also indicate a range of temperatures wider than would be expected for a system with little or no mixing. Donovan (1985) suggested that the chemistry (and geothermometers) reflected the relative position of the well in a deep-circulating flow system.

TABLE 3
Selected Geothermometer Temperatures*
Hot Springs Area

ID	Site Name	Na-K-Ca (corrected)	Na-K-Ca (uncorr.)	Qtz (no steam)	Qtz (steam)
MGEOT352	SYMES HOTEL	35°C	131°C	120°C	118°C
MGEOT355	KOEPLING (WELL 138)			48°C	55°C
MGEOT354	OSTRANGER (WELL 56)		126°C	88°C	90°C

*Geothermometer temperatures for all sites are presented in Appendix II.

A time-comparison of geothermometer temperatures for the Symes Hotel well (Table 3) suggests a 3 to 5°C drop in temperature, perhaps the result of continued development of ground-water resources in the area. None of this

development, however, has been of the geothermal resources. This area could easily provide for applications of heat-transfer technology.

Green Springs

Green Springs is approximately 12 miles south of Hot Springs and approximately 2.5 miles southwest of Camas Prairie. Green Springs consists of 3 to 4 thermal springs feeding a wetlands/pond area. Elsewhere in the area, several small springs have been described by local citizens. A sample was collected from the largest of the springs at its source (Table 1). Although the site was documented by Sonderegger and others (1981), only a few chemical parameters were measured. The new data enabled a calculation of geothermometer temperatures (Table 4).

TABLE 4
Selected Geothermometer Temperatures*
Green Springs Area

ID	Site Name	Na-K-Ca (corrected)	Na-K-Ca (uncorr.)	Qtz (no steam)	Qtz (steam)
MGEOT353	GREEN SPRINGS		140°C	107°C	107°C

*Geothermometer temperatures for all sites are presented in Appendix II.

The differences between geothermometer temperatures suggests that mixing may be occurring and the difference in surface temperature and the geothermometer temperatures suggests either a high heat transfer or a slow circulation rate for this area.

Observations From Other Database Entries

Incorporating low-temperature sites in the inventory produced a new perspective of geothermal resources in the state. Areas such as Butte became more important with respect to potential development. The same may be true for the area near the city of Great Falls in Cascade County where wells 128- to 366-meters deep in the Madison Group produce water that ranges from 15 to 19°C; the water is used for irrigation and public water supply. Wells 274- to 396-meters deep in southern Treasure County and northern Big Horn County produce water whose temperatures range from 16.5°C to nearly 20°C.

The lower temperatures used in the selection criteria also had the effect of enlarging some of the areas identified by Sonderegger and others (1981). An example of this is in southern Broadwater County and northwestern Gallatin County where wells and springs had been identified in previous investigations. Updating the database provided additional information that may indicate a larger area for potential development.

5.0 DISCUSSION

Resource Potential

There are 291 records in the current database; these represent 267 individual sites (wells and springs). Approximately 71% of these sites exhibit water temperatures between 10 and 30° Celsius (Figure 2).

Figure 2 About 77% of the geothermal sites in Montana have water temperatures less than 40° Celsius; 12% of the sites have temperatures greater than 50° Celsius.

Collocation of Resources and Users

Montana's population centers are generally small (< 50,000 people) and

Figure 3 The western third of the state has 153 sites. About a third of those (approximately 100) have temperatures greater than 30°C.

widely distributed. The western third of the state has more of the larger population centers and a slightly higher overall population than the eastern two-thirds.

The distribution of geothermal resources mimics, but does not correlate, to that of the population; 152 of the 267 sites occur in the mountainous area of the western third (generally west of 111° longitude) whereas 115 sites are in the plains area of the eastern two-thirds of the state. Similarly, the number of warm and hot springs is much higher in the west.

A comparison of the distribution within the western (Figure 3) and eastern (Figure 4) parts of the state shows that the western third has a larger number of sites with temperatures greater than 30°C.

Collocation of population centers, albeit small, and geothermal resources are most likely to occur in the western third of the state. It should be noted, however, that deep wells into the Madison Formation in the eastern part of Montana have the potential to produce low- to moderate-temperature water as demonstrated in Treasure County and northern Big Horn County.

Figure 4 Most of the sites in the eastern third of the state. About 20 sites have temperatures greater than 30°C.

6.0 SUMMARY

Each of the tasks outlined in the agreement between the Montana Bureau of Mines and Geology and the Oregon Institute of Technology / University of Utah Research Institute have been completed. The database described here represents the most current information on geothermal resources in the state of Montana. The database also contains the information collected from eight sites that lacked information prior to this inventory. A 1:1,000,000 scale map, which accompanies this report, shows the location, temperature group, distribution, and type of geothermal resources in the state.

The distribution of geothermal resources and population in Montana suggests a good potential for development of these resources. Although Montana has only a few large population centers, smaller cities and towns near the resources could benefit from development. Although the low temperature of the resources (most are less than 50°C) restricts the type of development, small-scale direct-heat or heat-pump applications, aquaculture, and other development may be economical in some areas.

Whereas the information presented in this report reflects the current knowledge and information on geothermal resources across the state, funding and time limitations would not permit an evaluation of each site. Individuals or groups with the intention of developing any of the sites or areas identified in this assessment should conduct a more thorough investigation and confirm the temperatures, chemistry, and flows.

7.0 RECOMMENDATIONS

Priority Areas for Phase II Studies

The dominant consideration in selecting areas in Montana for future studies is the proximity of the resource area to transportation and population centers. Although there are several resource areas with a relatively high potential for development, limited past and/or current use and low population in the area likely prohibit development. The areas that have the highest potential and are nearest population centers (Figure 5) and transportation routes are as follows:

Bozeman

The Gallatin valley near Bozeman has experienced a steady population growth over the last decade. Data for the Bozeman Hot Springs just west of the city of Bozeman indicates a surface temperature of approximately 55°C and an estimated reservoir temperature of 80°C. The springs are currently used to heat a swimming pool at a commercial campground. Although little resource development has occurred in the area over the last ten years, the Gallatin valley was identified by Sonderegger and others (1981) as an area expected to contain geothermal resources suitable for development. Geophysical exploration and deep drilling would better define the source and extent of this resource area.

Butte

The Butte Mining District was extensively mined over a period of nearly 100 years. At the cessation of underground mining in the early 1980's, dewatering of the bedrock was discontinued and water-levels were allowed to rise. Soon after the mines were shut down, the area was listed in the National Priorities List and is designated as a Superfund site. The rising water, which has a low pH and a high dissolved-metals content, is of much to concern to local, state, and federal agencies, and it has been recognized that water-levels will need to be controlled by pumping to prevent discharge into the Clark Fork River drainage.

With respect to geothermal development, the Butte area offers several avenues for low-to-moderate temperature resources. The underground workings were notoriously hot areas to work in while operating and recent data collected from the mines show water temperatures ranging from 13° to 33°C. Monitoring wells completed in the bedrock aquifer at depths less than 183 meters indicate temperatures of 10 to 18°C, and water quality is quite good (for example, see MGEOT341 and MGEOT342). Diamond drill holes with depths up to 610 meters and open mine shafts may provide access to the deeper, warmer waters. An evaluation of depth, temperature, and potential applications of heat-pump technology is needed.

Figure 5 Five areas have been selected as potential areas for additional studies relating to application of direct-use technology.

Ennis

Several studies of the geothermal resources near Ennis have been conducted in the past; however, a deep drilling project is needed to fully understand the nature of this resource area. Recently, one of the areas in which wells were completed was offered for sale to the county government. Application of the information derived from previous studies to an investigation of potential direct-heat applications may also be warranted.

Boulder Hot Springs

The Boulder Hot Springs is within a few miles of Interstate-highway 15 and the town of Boulder is only 1/2 mile from it. Larger cities, Butte to the south and Helena to the north, are within 30 miles. The surface temperatures at the three springs sampled range from 54 to 74°C, and flow is approximately 340 L/min. at the larger spring. The site is currently undergoing renovation. The likelihood of other geothermal resources in the area is high. An inventory of springs and wells throughout the valley and a deep drilling project is needed to better define this potential resource area.

Camas Prairie

There are several previously un-recorded springs in this area; one site was sampled recently (MGEOT353). Although the area is not near any of the larger population centers, there are some recreational facilities in the area. This particular area of Montana has been especially popular for cottage-industry development. A more complete well and spring inventory, coupled with a water-chemistry sampling program is needed to better define the occurrence and potential development in this area.
