1. Introduction

This document describes the `tcl` command and command types which are used to communicate with EPICS database servers. The application libraries upon which `et` is built include `tcl`, `tk`, `tcl-dp`, and `blt`. The reader of this document is assumed to be familiar with `tcl/tk`.

2. Running et

Start `et` by typing:

```
et_wish
```

In the extensions source directory of `et` (i.e. `extensions/src/tcl_et`) is a subdirectory `examples` containing examples using `et`. These examples together with the following descriptions of the `pv` command types should be used when learning to use `et`.

3. Command Syntax

The command syntax consists of three or more words, with the first three words having the same meaning in each command. The words after the first three words are dependent on the type of command issued. A command example follows:

```
pv link {ai1 ai2 ai3} {IOC:ai1 IOC:ai2 IOC:ai3}
```

- First word: the `tcl` `pv` command

MASTER

- Second word: the **command type** i.e. link. Command types which communicate with an EPICS database can be either synchronous (blocking) or asynchronous. A 'w' suffix (i.e. linkw) makes the command type blocking. The final word in blocking command types i.e. linkw, getw, and putw is a timeout value. The timeout value is optional and defaults to 10.0 sec.
- Third word: the **name or list of names of tcl variable(s)** i.e. ai1 or {ai1 ai2 ai3}
- Other words: **depend on the type** i.e. for type link the fourth word consists of a name or list of names of EPICS database process variables i.e. {BEAM:turnOn KLY:modAnode}

Examples of all supported types:

```
pv link {c0 ai1 ai2 ai3 ai4} {T:calc T:ai1 T:ai2 T:ai3 T:ai4}
pv get c0
pv getw ai1 11.1
pv put ai1
pv info {c0 ai1 ai2 ai3 ai4} {state status severity time units}
pv stat ai1
pv mon {c0 ai3 ai4} {puts "I can execute a script for you"}
<<<<start multi-element (vector) record oriented types>>>>>>>>>
pv link {wf wf1} {vong:xy566WaveformCh0 vong:xy566WaveformCh1}
pv vdef {wf wf1} {0 256 5}
pv vset wf
pv vdis wf $graph line1
```

4. pv Command Types

link

Syntax:

```
pv link(w) tclVars iocVars <optional timeout>
```

Description: Establish a link at run-time between tcl variables and process variables in existing IOC databases. The tcl variables are automatically created during the operation. For string and enum process variables the tcl type created will be a string.* For all other process variable types the tcl variable type created is a double. A tcl variable may be subsequently linked with a different process variable (i.e. relinked). When relinked the old link is completely removed.

Return:

- 0 successful
- 1 unsuccessful and error is described in tcl variable "errorCode"

Comments: The user must always check the state of the link after link and linkw type commands, using either the 'stat' or 'info' command types. The state must be 'OK' (see stat and info type commands) before further operations on the tcl or process variable(s) are made. When the link(w) is first issued 'state' is set to 'IO'. If a link to a database process variable is successful the state changes to 'OK'. If the link was unsuccessful the state will be something other than 'IO' or 'OK', i.e. NC (Never Connected), LC (Lost Connection), RD (No Read Access), WR (No Write Access). For blocking links, i.e. linkw, the state can be checked immediately after the linkw command is issued. For non-blocking links, i.e. link,

* For ENUM database process variables which DO NOT have strings defined, use of numbers is supported.

the state may still be in the 'IO' state after the link command is issued and subsequently (asynchronously) change to another state. For the non-blocking command it is up to the user code to wait until a 'state' transition or timeout has occurred. I recommend using blocking links because of their coding simplicity.

Examples of correct forms of link(w):

```
pv link a1l IOC:beamVoltage
pv linkw {a1l a0l b1l} {IOC:beamCurrent IOC:outputCurrent IOC:beamStatus}
set varList{a1l a0l b1l}

set iocList {IOC:beamCurrent IOC:outputCurrent IOC:beamStatus}
pv link $varList $iocList
pv linkw $varList $iocList
if { [pv linkw a1l IOC:beamVoltage] == 1 } puts stdout $errorCode
```

get

Syntax:

```
pv get(w) tclvars <optional timeout>
```

Description: Update the linked tcl variables to the current values stored in the IOC databases.

Return:

- 0 successful
- 1 unsuccessful and error is described in tcl variable "errorCode"

Comments: The user should always check state of the link after get and getw type commands using either the 'stat' or 'info' command types. The state must be 'OK'. Additionally the severity of the process variable should be checked to, at least, make sure that it is not INVALID. I recommend using the 'stat' command type for checking.

Examples of correct forms of get(w):

```
set varList {a1l a0l b1l}
set iocList {IOC:beamCurrent IOC:outputCurrent IOC:beamStatus}
pv link $varList $iocList

pv get $varList
pv getw $varList
pv get {a1l a0l}
pv getw {a0l b1l}
pv get b1l
pv getw b1l
```

put

Syntax:

```
pv put(w,q) tclvars <optional timeout>
```

Description: Update the current process variable values stored in the IOC databases to the linked tcl variable values. The put and putw types require notification from the IOC that record processing has completed for all the linked variables in the command. The putw blocks until all notifications have been received. The putq returns to the application as soon as the proper requests have been forwarded to the IOC. I recommend using the putq type unless there is a compelling reason for wanting to wait for record processing associated with a process variable to complete.

Return:

- 0 successful
- 1 unsuccessful and error is identified in tcl variable "errorCode"

Comments: User should always check state of the link after put, putw, and putq type commands. The state must be 'OK'. I recommend using the 'stat' command.

Examples of correct forms of put(w,q):

```
set varList {a11 a01 bil}
set iocList {IOC:beamCurrent IOC:outputCurrent IOC:beamStatus}
pv link $varList $iocList

pv put a01
pv putw a01
pv putq a01
pv put {a11 a01 bil}
pv putw {a11 a01 bil}
pv putq {a11 a01 bil}
pv put $varList
pv putw $varList
pv putq $varList
```

mon, cmon**Syntax:**

```
pv mon tclVars <optional script>
pv cmon tclVars
```

Description: Establish/Clear an EPICS database monitor for the linked tcl variable(s). The linked tcl variable is automatically updated whenever a monitored event is received. An optional tcl script, when defined in the command, will be executed whenever a monitored event is received from an IOC. Using the optional script, the user can implement a completely event driven application.

Return:

- 0 successful
- 1 unsuccessful and error is identified in tcl variable "errorCode"

Examples of correct forms of mon and cmon:

```
set varList {a11 a01 bil}
set iocList {IOC:beamCurrent IOC:outputCurrent IOC:beamStatus}
pv link $varList $iocList
pv link {c0 a11 ai2 ai3 ai4} {T:calc T:a11 T:ai2 T:ai3 T:ai4}

pv mon $varList
pv mon $varList {puts "Print this every event"}
pv mon $varList tclProcedureName
pv mon a11
pv mon a11 {puts "Print this every event"}
pv mon a11 tclProcedureName
pv mon {a11 bil}
pv mon {a11 bil} {puts "Print this every event"}
pv mon {a11 bil} tclProcedureName
pv cmon $varList
pv cmon a11
pv cmon {a11 bil}
```

info**Syntax:**

```
pv info tclVars requestedInfo
```

Description: Obtain information in the form of a list of lists about linked tcl variables stored in the interface. Any or all of the following information may be requested in any order. Information is available for:

- **state:** of the communication link*
- **severity:** as defined by EPICS
- **status:** as defined by EPICS
- **time:** from IOC process variable shown as 10/03/94 14:04:36.791566783
- **units:** as defined in EPICS record
- **name:** of linked IOC process variable
- **choices:** for enum types
- **hopr:** as defined by EPICS
- **lopr:** as defined by EPICS
- **hihi:** as defined by EPICS
- **hi:** as defined by EPICS
- **lolo:** as defined by EPICS
- **lo:** as defined by EPICS
- **precision:** as defined by EPICS
- **ioc:** what IOC the process variable came from
- **access:** read & write privileges
- **size:** number of elements

Return:

- 0 successful
- 1 unsuccessful and error is identified in tcl variable "errorCode"

Examples of correct forms of info:

```
set varList {a11 a01 b11}
set iocList {IOC:beamCurrent IOC:outputCurrent IOC:beamStatus}
pv link $varList $iocList
pv link {c0 a11 ai2 ai3 ai4} {T:calc T:a11 T:ai2 T:ai3 T:ai4}
pv getw $varList

pv info a11 state
pv info a11 {state ioc name units severity status}
pv info a11 {units state name ioc}
pv info $varList {state severity status time}
pv info $varList severity
pv info {a11 b11} {name choices hopr lopr precision units lo lolo ioc access}
```

stat

Syntax:

```
pv stat tclVar associative_array_name
```

Description: Obtain state, status, severity, and time information about a single process variable as elements (state, status, severity and time) of an tcl associative array named in command. The array is created if it doesn't exist.

* 'state' is a two-character string, whose possible values are:
 NC->NeverConnected, LC->LostConnection, RD->NoReadAccess,
 WR->NoWriteAccess, IO->I/OinProgress, OK->OK

Return:

- 0 successful
- 1 unsuccessful and error is identified in tcl variable "errorCode"

Comments: In tcl scripts 'stat' provides a more convenient command type than 'info'.

Examples of correct forms of stat:

```
set varList {a11 a01 b11}
set iocList {IOC:beamCurrent IOC:outputCurrent IOC:beamStatus}
pv link $varList $iocList
pv link {c0 a11 ai2 ai3 ai4} {T:calc T:a11 T:ai2 T:ai3 T:ai4}
pv getw $varList

pv stat a11 arrayName1
pv stat b11 arrayName2
pv stat a01 arrayName3

set arrayName1 (state)
set arrayName2 (severity)
set arrayName3 (status)
```

vdef, vset, vdis**Syntax:**

```
pv vdef tclVars {base size precision}
pv vset tclVars {list of values to be written to tclVars}
pv vdis tclVar graph graph_element
```

Description: All three of these command types are used to deal with multi-element and waveform records. For multi-element and single element records the link, get, put, and mon command types operate the same and transfer all the process variable elements into an internal et interface buffer. However, for multi-element process variables the linked tcl variable only reflects the value of the first element. The user reads/writes/displays multi-element data stored in the interface buffer using a "view" mechanism. A view is a defined subset of a multi-element record which will be subsequently used for accessing data from the record.

- **vdef** defines a view which specifies the base, size and number of significant digits. vdef can be defined for each linked tcl variable.
- **vset** is used either to return to tcl a list consisting of the values in the view with the number of significant digits defined by vset or to write into the interface the values defined by the final word (normally a list of values) to vset command type. The base and maximum number of values to be written are determined by the vset command type.
- **vdis** is used with the blt graph widget to display the process variable view as an "blt graph element" on a "blt graph".

Return:*

- 0 successful
- 1 unsuccessful and error is identified in tcl variable "errorCode"

Examples of correct forms of vdef, vset, and vdis:

```
set graph .g
blt_graph $graph -width 500
$graph element create line1 -symbol circle -bg red
```

*When a list of values to be written is not included as the final word of the vset command type, vset returns a list of values (defined by vdef).

```

pack append . .g {}
pv link {wf1 wf} {vong:xy566WaveformCh0 vong:xy566WaveformCh1}
pv get {wf1 wf}

pv vdef wf {0 256 5}
pv vdef wf1{100 50 2}
pv vset wf
pv vset wf1
pv vset wf1 {1 2 33 56.4 987.56 1.01}
pv vdef wf1 {150 50 5 }
pv vset wf1
pv vdis wf $graph line1

```

5. Usage

There are typically only three steps needed to communicate with an EPICS database:

- Establish a link between a `tcl` variable and a process variable (sometimes called channel) and check that the link has been established OK. This operation uses a `link` type and an `info` or `stat` type.
- Either **update the tcl variable** to reflect the current value of the process variable via a `get` type command or **update the process variable** to reflect the value of the `tcl` variable via a `put` type command and check that the update has completed OK. This operation uses a `get` or `put` type and a `stat` type.
- In the case of the `get` type operation, insure that the data received from the process variable is valid (i.e. not `INVALID`). This operation uses a `stat/info` type.

The user must keep in mind that command types `link`, `get`, and `put` involve transferring data over a network which means that the user must check that the network operation has successfully completed. The return result (either 0 or 1) of these command types together with the `stat/info` command type are used to insure that the operation was successful. In addition, when the command type is a `get` the user must insure that the data is valid (the network operation might have succeeded but the GPIB instrument timed out during a GPIB read). The `stat/info` command type is also used to check the validity of data.

The user must keep in mind that both the process variable in an IOC and the `tcl` linked variable can change at any time and are **only synchronized only during a get or put type command**.

Use of lists is encouraged in `link`, `get`, `put` and `mon` types to improve the efficiency of the network communications.

Use of `mon` types is encouraged for process variables which change infrequently (at least less frequently than referenced in script) and for applications which are designed to be event driven.

When checking the state, status, severity, and time in scripts, it is usually easier to use the `stat` command type. `Info` works well for interactive use.

The `put` and `putw` command types require notification from the IOC that the record has processed before completion. It is much better to rely on readback process variables to ensure that a `put` operation has successfully completed. With a readback available use of `putq` is preferred. The `putq` does not require IOC notification before completing.

When using asynchronous forms of `link`, `get` and `put`, the application must give the X-event loop time to process before each check on completion. The `tcl/tk` event loop processes whenever user code is not running, or whenever certain `tcl/tk` command are issued as described in the `tcl/tk` documentation. Otherwise, the application code will end up in an endless loop testing for something (state, status, severity, time) that never gets updated.

In the script associated with monitors, **THE SYNCHRONOUS COMMAND TYPES LINKW, PUTW and GETW SHOULD NOT BE USED** (this is a network software limitation related to code reentrancy).
