Abstract

This paper presents the Local Area Network Distributed Supervisory Control and Programming Environment (LandScape) commands set that provides a Generic Device Subsystem Application Programmers Interface (API). These commands are implemented using the Common Object Request Broker Architecture (CORBA) specification with Orbix from Iona Technologies.

1.0 Introduction

LandScape commands are divided into “blocking and “non-blocking” commands. In addition, the following states as shown in Figure 1.1 are defined for the command set: *Idle*, *Unlocked*, *Locked*, and *Active*. Each LandScape command is valid and may be called while the machine or device is in the appropriate state. The commands are also divided into the following categories: client, server, digital I/O, return codes and parameter constants to better identify the capabilities and proper usage.

Figure 1.1 Command Transition Diagram

2.0 Client IDL

These are the event handlers for non-blocking commands on the server.

2.1 Non-blocking and State-independent

oneway clientAlarm (in string eventID, in sequence string data)

This is used for error or alarm conditions on the server. The server may at any time execute an Alarm. This alarm is Non-Blocking and requires no response or acknowledgment from the client.

oneway clientEvent (in string eventID, in sequence string data)

This is used for event conditions on the server. The server may execute an event after it has entered a busy/working state of a Non-Blocking command. This event is Non-Blocking and requires no response or acknowledgment from the client.

2.2 Blocking and State-independent

A disconnect handler routine will allow certain shutdown actions to be performed automatically any time a client disconnects with the subsystem (either intentionally or due to error conditions) The default behavior will be to issue a deactivate command and a release command.

retVal clientAlarmRSVP (in string eventID, inout sequence string data)

This is used for alarm conditions on the server. The server may execute an alarm at any time. This alarm is Blocking and requires a response (RSVP) from the client.

retVal clientEventRSVP (in string eventID, inout sequence string data)

This is used for event conditions on the server. The server may execute an event after it has entered a busy/working state of a Non-Blocking command. This event is Blocking and requires a response (RSVP) from the client.

3.0 Server IDL

This section describes the LandScape commands supported on the server.

3.1 Connect/Power and Single POC Commands

This section presents device connect and power on/off commands as well as single point of control (POC) commands.

3.1.1 Blocking and Unlocked State

These commands are only valid only from the *Unlocked State*.

retVal lock ()

Give the supervisor exclusive REMOTE control over the subsystem, *no parameters*.

3.1.2 Blocking and Locked State

These commands are only valid only from the *Locked State*.

Note: When a subsystem is booted, its default state is "Idle".

retVal release ()

Give the subsystem exclusive LOCAL control over itself, *no parameters*.

retVal activate ()

Place the transport device in an active state such that it can be physically commanded to move, *no parameters*.

3.1.3 Blocking and Active State

These commands are only valid only from the *Active State*.

retVal deactivate ()

Place the transport device in an inactive state such that it will NOT physically move if commanded to do so, *no parameters*.

3.2 Set Commands

This section presents device set-up and configuration commands.

3.2.1 Blocking and Locked State

retVal setSpeed (in double <speed>, in SpeedType <attribute>)

Set the absolute speed for the robot, *two parameters*:

<speed> converted to double and its meaning depends upon <attribute>.

<attribute> one of the following TYPEDEFF'ed keywords which defines the type of speed being set.

PERCENT_SPEED (percent of max speed applied globally to both joint and Cartesian moves).

LINEAR_SPEED (absolute linear speed applied to Cartesian moves and interpreted according to how the last SetUnits command specified the units, such as inches/second or meters/second).

ANGULAR_SPEED (absolute angular speed applied to Cartesian moves and interpreted according to how the last SetUnits command specified the units, such as degrees/second or radians/sec).

refVal setAcceleration (in double <accel>, in long <attribute>)

Set the absolute acceleration for the robot, *two parameters*:

<accel> converted to double and its meaning depends upon <attribute>

<attribute> one of the following enumerated keywords which defines the type of accel being set.

PERCENT_ACCEL (percent of max accel applied globally to both joint and Cartesian moves, constant rate).

LINEAR_ACCEL (absolute linear accel applied to Cartesian moves and interpreted according to how the last SetUnits command specified the units, such as inches/second² or meters/second²).

ANGULAR_ACCEL (absolute angular accel applied to Cartesian moves and interpreted according to how the last SetUnits command specified the units, such as degrees/second² or radians/sec²).

refVal setToolOffset (in double <offset_array[6]>)

Set the tool length offsets for the robot, *six parameters*:

<offset_array> defined as: <x>, <y>, <z>, <roll>, <pitch>, <yaw> converted to double, units depend upon last SetUnits command executed (inches, degrees, meters, radians, etc.).

refVal setWorldCartesianFrame (in double <x> <y> <z> <roll> <pitch> <yaw>)

Set the offsets from the robot's base frame to the world frame., *six parameters*:

double <x>, <y>, <z>, <roll>, <pitch>, <yaw>

3.3 Get Commands

This section presents information retrieval commands.

3.3.1 Blocking and State Neutral

retVal getUnits (out string linear_units, out string angular_units)

Returns the units that the machine is speaking in.

<linear_units> inches/feet/meters/centimeters/millimeters.

<angular_units> degrees/radians.

retVal getVelocities (out double percent_velocity, out double world_linear_velocity, out double world_angular_velocity Sequence double joint_velocities)

Returns current velocity settings for percentage of max velocity, world angular, world joint and individual joint velocities.

retVal getAccelerations (out double percent_accel, out double world_linear_accel, out double world_angular_accel, out Sequence double joint_accels)

Returns current velocity settings for percentage of max accelerations, world angular, world joint and individual joint accelerations.

retVal getMaxVelocities (out double max_world_linear_velocity, out double max_world_angular_velocity, out double Sequence double max_joint_velocities)

Returns maximum velocity settings for world angular, world linear, and world joint velocities.

retVal getMaxAccelerations (out double max_world_linear_accel, out double max_world_angular_accel, out double sequence double max_joint_accels)

Returns maximum acceleration settings for world angular, world linear, and world joint acceleration.

retVal getToolOffsets (out double offset_array[6])

Returns the 6 Cartesian offsets of the robot from it's Cartesian base frame to the tool tip.

retVal getRobotPosition (out sequence double current_joint_position, out double current_world_position[6])

<current_joint_position> is the sequence of doubles which represents the values of each joint starting with joint 1 and going to joint N.

<current_world_position[6]> is the double array of the current Cartesian position of the robot.

retVal getMotionControlState (out string motionControlState, out string controlMode)

<motionControlState> ASCII string which describes the current trajectory state of the robot. The suggested states are:

- running_trajectory
- robot_paused
- robot_stopped_on_error
- robot_stopped_on_command

<controlMode> string which describes the current state of the controller. The suggested states are:

- power_on
- power_off
- controller_error, etc.

retVal getTagId (out string pathName, out string tagID)

<pathName> string which holds the name of the current path.

<tagID> string which holds the last tag name that the robot got to.

3.4 Single Motion Commands

This section presents commands that perform a single device motion.

3.4.1 Non-Blocking and Active State

These commands are valid only in the *Active State*.

retVal moveRelative (in string pointName, in ReferenceFrame frame, in sequence double values)

Performs a relative move with the device.

<pointName> a string that uniquely identifies the path.

<frame> enumerated keyword (s) describing the type of move: JOINT_FRAME data is a list of values which specify relative destination in terms of joint values)
WORLD_CARTESIAN_FRAME data is a list of values which specify relative destination in terms of world-based Cartesian coordinates.

BASE_CARTESIAN_FRAME data is a list of values which specify relative destination in terms of robot-based Cartesian coordinates TOOL_FRAME (data is x,y,z,roll,pitch,yaw which specify a location relative to the tool frame).

<sequence> desired move converted to double if the function returns the return code CMD_STARTED_OK, then the supervisor should expect an event which tells the supervisor that it has completed or an alarm which indicates an error. If it returns CMD_EXECUTED_OK then the function completed and no event monitoring needs to be performed.

retVal moveAbsolute (in string pointName, in ReferenceFrame frame, in sequence double values)

Perform an absolute move with the device.

<pointName> string which names the point the robot is going towards. This name will be included in the event data.

<frame> enumerated keyword (s) describing the type of data: JOINT_FRAME data is a list of values which specify absolute destination in terms of joint values).

WORLD_CARTESIAN_FRAME data is a list of values which specify absolute destination in terms of world-based Cartesian coordinates.

BASE_CARTESIAN_FRAME data is a list of values which specify absolute destination in terms of robot-based Cartesian coordinates.

<j1>, <j2>, <j3>, <j4>, <j5>, <j6> ... joint values converted to double.

<speed> converted to double and is optional (specifies speed for this move only - always interpreted as a percent of max speed).

Return Code: If the function returns the return code CMD_STARTED_OK, then the supervisor should expect an event which tells the supervisor that it has completed or an alarm which indicates an error. If it returns CMD_EXECUTED_OK then the function completed and no event monitoring needs to be performed.

retVal moveArc (in string pointName, in ReferenceFrame frame, in OffsetType offset_type, in sequence double arcValue, in sequence double goalValue)

Perform a circular move with the robot to goalValue while arcing in a straight line through arcValue.

<pointName> string which names the point the robot is going towards. This name will be included in the event data.

<frame> enumerated keyword (s) describing the type of data: JOINT_FRAME data is a list of values which specify absolute destination in terms of joint values).

WORLD_CARTESIAN_FRAME data is a list of values which specify absolute destination in terms of world-based Cartesian coordinates.

BASE_CARTESIAN_FRAME data is a list of values which specify absolute destination in terms of robot-based Cartesian coordinates.

<offset_type> one of the following enumerated keywords to designate the type of motion embodied in the downloaded data: ABSOLUTE_DATA (position data is absolute destination points) RELATIVE_DATA (position data is relative offsets).

<arcValue> sequence of data representing the arc-through point.

<goalValue> sequence of data representing the arc-through point.

Return Code: If the function returns the return code CMD_STARTED_OK, then the supervisor should expect an event which tells the supervisor that it has completed or an alarm which indicates an error. If it returns CMD_EXECUTED_OK then the function completed and no event monitoring needs to be performed.

3.5 Path Motion Commands

This section presents commands that perform path-defined motions.

3.5.1 Blocking and Locked or Resting States

These blocking commands are valid in both the *Locked and Resting States*.

retVal pathLoad (in string pathName, in ReferenceFrame frame, in MotionType motion_type, in OffsetType offset_type, in int number_of_points, in sequence tag_struct tags)

Download a path segment which is appended to the current designated motion queue, *three or four parameters*.

<pathName> optional ASCII string which provides an ID for the segment being downloaded (this will be ignored for now, but later the capability will be provided to select and execute paths by name).

<frame> one of the following enumerated keywords to designate which reference frame the data is in WORLD_CARTESIAN_FRAME
BASE_CARTESIAN_FRAME JOINT_FRAME.

<motion_type> one of the following enumerated keywords to designate the type of motion embodied in the downloaded data: STRAIGHT_MOTION
JOINT_MOTION.

<offset_type> one of the following enumerated keywords to designate the type of motion embodied in the downloaded data: ABSOLUTE_DATA (position data is absolute destination points) RELATIVE_DATA (position data is relative offsets).

<number_of_points> integer value indicating the number of points for the segment being downloaded.

<tag_structs> tag structures containing path data. The tag structure is shown below:

```
typedef struct _tag_struct
{
    double x,y,z,roll,pitch,yaw;
    double jointvals[24];
    string tagName;
    short tagIndex;
    double timeDelay;
    double transitionSpeed;
    double speed;
    double accel;
    sequence string auxCommands;
}
```

Note: Each pathName will be maintained as a separate motion queue. Queues will be maintained simultaneously. For each path name, the first LoadPath command executed will establish a new path when the data is downloaded. Subsequent LoadPath commands will append data to this path until either the path name is cleared with a ClearPath command or an error condition occurs. When LoadPath is executed, a series of data message exchanges occurs between the supervisor and subsystem in order to download the path data.

Each path point will contain 3 major segments of information: the position data, speed control parameters, and auxiliary data. The position data will consist of 6 values (x, y, z, roll, pitch, yaw) if a Cartesian path segment is being downloaded. Otherwise it will contain one joint value for each degree of freedom. If ABSOLUTE_DATA is designated, each point should be an absolute destination, and if RELATIVE_DATA is specified, each point should consist of relative offsets. The units will be interpreted according to what was established by the last SetUnits command executed prior to this command. There are 3 speed control parameters, a transition speed (percent of max), relative speed (percent of max), and delay (time in seconds). The auxiliary data will be defined later.

retVal pathClearPath (in string PathName)>

Clear the selected motion queue, *one parameter*.

<PathName> Name of path to clear This function will delete the path
<PathName> from the list of maintained motion queues.

3.5.2 Non-Blocking and Active State

These non-blocking commands are valid only in the *Active State*.

retVal pathMove (in string pathName, in int number_of_cycles)

perform a path move in which a motion queue is built up using the LoadPath command, and then MoveAlongPath is executed.

The system will execute any digital IO or other commands specified in the auxiliary data.

<PathName> name of path to execute.

<number_of_cycles> integer value applicable only when the actual path move is being performed; it indicates how many times to repeat the given path move (a 0 implies dry run without aux data activation; if omitted, 1 is assumed).

If the function returns the return code CMD_STARTED_OK, then the supervisor should expect an event which tells the supervisor that it has completed or an alarm which indicates an error. If it returns CMD_EXECUTED_OK then the function completed and no event monitoring needs to be performed. As the function proceeds along a path, an event will be generated when the robot arrives at each individual tagpoint. The event will have the name of the tagpoint as part of its data.

3.6 Asynchronous Interruption Commands

This section presents commands that perform asynchronous interruption commands.

3.6.1 Blocking and Moving State

These blocking commands are valid only in the *Moving State*.

retVal stopMotion ()

Stop current motion gracefully by generating a deceleration profile which follows the original pre-planned path, *no parameters*.

3.6.2 Blocking and Paused or Locked State

These blocking commands are valid only in the *Paused or Locked State*.

retVal resumeMotion ()

resume current motion gracefully by generating a acceleration profile which follows the original pre-planned path, no parameters.

retVal abortMotion ()

aborts current motion stopped by stopMotion (), and clear the motion queue, no parameters.

3.7 Sensor Dependent Commands

This section presents commands that perform Sensor Dependent Commands.

3.7.1 Blocking Command

This blocking command is *State Independent*.

retVal getSensorReading (in string sensor_type, out sequence double current_data)

<sensor_type> ASCII string which is associated with the name of a particular sensor type, such as: "force_sensor", "laser_standoff_sensor", etc.

<current_data> is the sequence of double data which is associated with the current sensor reading.

3.7.2 Non-Blocking and Active State**retVal moveReact (in string SensorType, in double MotionOffsets[6], in double MotionVelocity, in double ComplianceVelocity, in double Thresholds[6])**

This non-blocking command is valid only in the *Resting State*.

It will perform a relative move until an activated sensor detects a threshold or event of some kind, *eight parameters + react parameters - thresholds, gains, sensor envelope*.

<x>, <y>, <z> values converted to double specifying maximum distance and direction to move relative to a tool or end effector frame defined at the tool tip by a previous SetToolLength command (will move this far if a sensor threshold is never reached).

<c_x>, <c_y>, <c_z> values converted to double specifying maximum compliance distance and direction to move which should be orthogonal to the regular motion vector just defined (this normally will be a zero vector for MoveReact, meaning no compliant motion, but rather just a "mov-til-touch" motion).

<speed> converted to double (specifies speed for this move only - always interpreted as a percent of max speed).

<c_speed> converted to double (specifies compliance speed for this move only - should be 0 for MoveReact).

<t1>, <t2>, <t3> thresholds for the active sensor (currently only one non-zero threshold should be specified, and if a sensor reading for this component exceeds it, motion stops).

<g1>, <g2>, <g3> gains which influence the responsiveness of the algorithm (currently only the first gain is utilized by the algorithm, the others are ignored).

<min1>, <min2>, <min3> define the lower bounds for an envelope placed around the sensor data to eliminate spikes (currently ignored).

<max1>, <max2>, <max3> define the upper bounds for an envelope placed around the sensor data to eliminate spikes (currently only the first value is used, and if a sensor reading exceeds this value, motion is terminated).

Note: These arguments may change or be interpreted differently in later releases based on our experience gained from testing various types of react motion using different sensors and different manipulators. If the function returns the return code CMD_STARTED_OK, then the supervisor should expect an event which tells the supervisor that it has completed or an alarm which indicates an error. If it returns CMD_EXECUTED_OK then the function completed and no event monitoring needs to be performed.

retVal comply (in string SensorType, in double Thresholds[6], in double MaxTimeout, in short PanicStopCode, in double MaxTravelDistances[6]), in double ProportionalGains[6], in double DifferentialGains[6])

This non-blocking command is valid in both the *Resting and Moving States*.

It will perform a relative move while maintaining a continuous sensor reading in the direction normal to motion; sensor readings are used to compute perturbations which are added to the originally specified move in order to maintain compliance; *eight parameters + compliance parameters - thresholds, gains, sensor envelope*:

<x>, <y>, <z> values converted to double specifying maximum distance and direction to move relative to a tool or end effector frame defined at the tool tip by a previous SetToolLength command.

<c_x>, <c_y>, <c_z> values converted to double specifying maximum compliance distance and direction to move which should be orthogonal to the regular motion vector just defined.

<speed> converted to double (specifies speed for this move only - always interpreted as a percent of max speed).

<c_speed> converted to double (specifies compliance speed for this call).

<min1>, <min2>, <min3> define the lower bounds for an envelope placed around the sensor data to eliminate spikes (currently ignored).

<max1>, <max2>, <max3> define the upper bounds for an envelope placed around the sensor data to eliminate spikes (currently only the first value is used, and if a sensor reading exceeds this value, motion is terminated).

Note: These arguments may change or be interpreted differently in later releases based on our experience gained from testing various types of compliant motion using different sensors and different manipulators. If the function returns the return code CMD_STARTED_OK, then the supervisor should expect an event which tells the supervisor that it has completed or an alarm which indicates an error. If it returns CMD_EXECUTED_OK then the function completed and no event monitoring needs to be performed.

3.7.3 Blocking and Locked State

These blocking commands are valid only in the *Locked State*.

retVal manualControl (in string type)

control the robot with some manual input device, *one parameter*.

<type> ASCII keyword specifying the type of manual control desired: teachpendant
spaceball off.

3.8 EndEffector Commands

This section presents commands that perform EndEffector Commands.

3.8.1 Blocking and State Independent

These blocking commands are state independent.

retVal getEndEffectorState (out string currentEE, in string EEState,.....,)

<currentEE,> the name of the tool.

<EEState> string which describes the state of the tool.

retVal getTool (in string tool_ID)

pick up a tool with the robot, *one parameter*:

<tool_ID>ASCII string identifying the desired tool

retVal putTool (in string tool_ID)

put away a tool with the robot, *one parameter*:

<tool_ID>ASCII string identifying the desired tool

retVal activateTool (in string tool_ID, in long BitField)

retVal deactivateTool (in string tool_ID, in long BitField)

4.0 DIGITAL_IO IDL

This section describes the DIGITAL_IO IDL command set. The digital I/O interface will work as follows: The set function will allow a user to set I/Os, the get function will allow the user to query the I/Os, and the signalDigitalIO will allow the user to set up a callback on the IO, which will get invoked when the specified bits have been set.

4.1 Blocking and State Independent

These blocking commands are state independent.

retVal setDigitalIO (in string type, in short unitID, in long bitsON, in long bitsOFF, in string description)

<type> string which describes the type of IO being performed.

<unitID> short which describes which IO to toggle.

<bitsON> long which is the BitField of I/Os to activate.

<bitsOFF> long which is the BitField of I/Os to deactivate.

<description> string which describes the operation.

retVal getDigitalIO (in string type, in short unitID, out long bitsON, in string description)

<type> string which describes the type of IO being performed.

<unitID> short which describes which IO to query.

<bitsON> long which is the BitField of I/Os which are active.

<description> string which describes the operation.

retVal signalDigitalIO (in string type, in short unitID, in long bitString, in short pollingTimeOut, in short pollingCycleTime, short callback_type)

<type> string which describes the type of IO being performed.

<unitID> short which describes which IO unit to monitor.

<bitString> long which is the BitField of I/Os to which are being monitored for change to a set state.

<callbackType> flag which specifies which function calls the client.

retVal sendCommand (in string input, out string result)

Vendor hook for custom commands.

```
typedef struct _retval
{
    short ret_code;
    string ret_msg;
} retVal;
```

5.0 Return Codes

This section describes the Return Codes. For coding convention, return codes greater than or equal to 0 denote success and return codes less than 0 denote errors.

0 CMD_EXEC_OK

This return code means that for blocking commands the command was executed and completed with no errors.

1 CMD_STARTED_OK

For non-blocking commands this means the command was understood and started execution successfully.

-1 CMD_ERR

Generic error return code.

-2 CMD_PARAM_ERR

Error parsing one of the parameters.

-3 CMD_PARAM_OUT_OF_RANGE_ERR

Parameter is out of range.

6.0 Parameter Constants

This section describes the LandScape Parameter Constants.

enum OffsetType { ABSOLUTE_DATA, RELATIVE_DATA};

**enum ReferenceFrame { JOINT_FRAME, BASE_CARTESIAN_FRAME,
 WORLD_CARTESIAN_FRAME, TOOL_FRAME};**
