Abstract — Rare-earth-transition-metal thin films are successfully grown by magnetron sputtering onto single-crystal MgO substrates with epitaxial W buffer layers. The use of epitaxial W buffer layers allows oriented single-phase films to be grown. Sm-Co films grown onto W(100), have strong in-plane anisotropy and coercivities exceeding 5 T at 5 K whereas Fe-Sm films have strong perpendicular anisotropy and are magnetically soft.

I. Introduction

Growth of epitaxial transition-metal superlattices has proven essential in elucidating the role of crystal orientation and structure on magnetic properties such as giant magnetoresistance and interlayer coupling [1]. Extending these studies to the growth of epitaxial rare earth-transition metal (RE-TM) films and superlattices hold promise in further exploring and optimizing the properties of magnetic films and, in particular, those of hard-magnet films. For instance, Skomski and Coey predict that a giant energy product (120 MG Oe) is possible in multilayer structures consisting of aligned hard-magnet layers interleaved with soft-phase layers with high magnetization [2]. Experimental realization of such structures depends on the growth of epitaxial hard-magnet thin films. Epitaxial growth also allows the magnetic properties to be tailored by controlling the crystal orientation and the anisotropies of the magnetic layers and opens the possibility of synthesizing a range of RE-TM phases [3]. In the present work, we study the growth and magnetic properties of a variety of RE-TM thin films (RE=Sm, Nd, TM=Fe,Co) on epitaxial TM buffer layers.

II. Synthesis and Characterization

The 10-20 nm buffer layers (Cr or W) are deposited by magnetron sputtering onto single-crystal MgO(100) and (111) substrates at a substrate

temperature T_s of 600 °C. This results in (100) and (110) epitaxial growth onto MgO(100) and (111), respectively for both Cr and W [4]. In this paper we concentrate on the films grown onto W buffer layers. The RE-TM films are deposited by co-sputtering from elemental sources at a substrate temperature T_s = 400-800°C or depositing at T_s < 200°C and then annealing at higher temperatures. The relative deposition rates of the sources ($\approx$ 0.1nm/sec) were used to adjust the composition of the films. The total film thicknesses ranged from 6-500 nm. The film structure was studied by x-ray diffraction and atomic force microscopy (AFM). The magnetic properties were measured with both a Quantum Design d.c. magnetometer equipped with a 9 Tesla magnet, and by magnetic force microscopy (MFM).

Shown in Fig. 1(a) and (b) are the x-ray diffraction results for $\approx$ 400-nm thick Co-Sm films deposited simultaneously onto adjacent MgO(100) and MgO(110) substrates, respectively (T_s =600 °C; the Co and Sm sputtering sources are operated at 100 and 24 W, respectively). In Fig. 1a, in addition to the MgO and W a -axis diffraction peaks, a single Co-Sm diffraction peak is observed at $2\theta=35.52^\circ$ with higher-order reflections at $2\theta=75.2^\circ$ and 132.6° . No other crystalline phases or orientations are observed. Rocking curves about the Co-Sm peaks have a full width at half maximum $\Delta\theta = 1.3^\circ$ indicative of a high degree of crystalline orientation as in epitaxial growth. Figure 1b is for the film grown simultaneously onto a MgO(111) substrate with a W(110) buffer layer which results in a dramatic change in the diffraction pattern. A series of diffraction peaks are observed which corresponds to a periodicity of 0.819 nm. In this orientation, additional peaks indicate the presence of secondary phases. The rocking curve through the Co-Sm peak again shows a high degree of crystalline orientation ($\Delta\theta=1.4^\circ$). The oriented growth presently precludes a unique determination of the Co-Sm phase since a standard θ - 2θ x-ray diffraction scan only probes a single direction in the unit cell. However, from the lattice spacing determined from these scans, the phase can be inferred by assuming (i) that the same phase forms on the two substrate but with different crystallographic orientations, and (ii) that the films prefer to grow in low-index orientations. For the samples shown in Fig. 1, the diffraction peaks are best indexed to the SmCo_5 phase (see Fig. 1) which is a rhombohedral Be_3Nb -type structure with lattice parameters $a=0.5055$ nm and $c=2.457$ nm. The

lattice parameters for this phase calculated from Fig. 1 are 0.5052 and 2.459 nm, respectively. This phase identification as well as determining the epitaxial orientation of the film with respect to the substrate needs to be confirmed by transmission electron diffraction and in-plane x-ray diffraction. AFM images indicate a rough surface morphology with a rms roughness of ≈ 12 nm and typical in-plane grain size are ≈ 200 nm for both orientations.

Figure 1: Sm-Co films grown on (a) MgO(100) and (b) MgO(111) substrates with W (100) and (110) buffer layers, respectively. The Sm-Co peaks are indexed to the SmCo_5 phase.

Shown in Fig. 2 are the magnetic hysteresis loops for the Sm-Co film shown in Fig. 1a. The film has strong in-plane anisotropy requiring ≈ 10 T to saturate perpendicular to the film and coercive fields H_c much higher than those typical of sputtered Co-Sm films [5,6]. The in-plane coercive field is 3.1 T at room temperature which increases to 5.1 T at 5 K for the Co-Sm film on MgO(100). The H_c values depend on the in-plane orientation of the H with respect to the substrate orientation. For $H \parallel \text{MgO}[011] \parallel \text{W}[001]$ the maximum $H_c = 3.1$ T is observed. With $H \parallel \text{MgO}[001] \parallel \text{W}[011]$, lower H_c values of 2.3 T (3.6 T at 5 K) are observed. The magnetic properties reflect the four-fold symmetry of the substrate and W buffer layer. The room temperature H_c values of the Sm-Co film on MgO(111) is 1.6 T.

Figure 2: Room-temperature magnetic hysteresis loops for Sm-Co film shown in Fig. 1(a) with the field parallel (||) and perpendicular ($\perp$) to the film. The in-plane loop is measured with $H \parallel \text{MgO}[011]$.

Growth of Sm-Fe onto MgO(100)/W(100) results in highly-oriented ($\Delta\theta \approx 1.1^\circ$) single-phase films with a lattice spacing of 0.2402 nm. This spacing is well matched to the (002) reflection of SmFe_{12} (0.2403 nm) determined by Wang *et al.* [7]. AFM images show a smoother growth as compared to Co-Sm films (3-nm rms roughness for a 400-nm film). Growth onto MgO(111)/W(110) often results in significant contributions from epitaxial $\alpha\text{-Fe}(110)$.

Figure 3: Room-temperature magnetic hysteresis loops for a Sm-Fe film with the field parallel (||) and perpendicular ($\perp$) to the film. The film was grown onto a MgO(100) substrate.

Shown in Fig. 3 are the magnetization loops for a Sm-Fe film grown onto MgO(100). There is a strong perpendicular anisotropy. This indicated by

the sheared in-plane hysteresis loop and is consistent with the c -axis anisotropy of SmFe_{12} . The perpendicular anisotropy (estimated by the saturation field of the in-plane loop) is ≈ 10 T at room temperature and increases to ≈ 27 T at 5 K. Unlike the Sm-Co film, these films are soft with zero remanence in both orientations suggesting domain formation at low fields. The domain pattern, observed by MFM, is shown in Fig. 4. The magnetization of each contrasted region is either in or out of the plane of the film and the typical stripe width is ≈ 130 nm.

Figure 4: Room-temperature magnetic force microscope image for the Sm-Fe film shown in Fig. 3. The horizontal scale of the image is 2 μm .

The growth of Nd-Fe films onto W(100) and W(110) is similar to that of Sm-Co. Using the same indexing procedure outlined for Sm-Co films, the Nd-Fe diffraction peaks can be indexed to either the $\text{Nd}_2\text{Fe}_{17}$ or NdFe_7 (100) and (00 l) reflections for the W(100) and (110) buffer layers, respectively. This latter orientation is consistent with recent reports by Robaut *et al.* of growth of c -axis Y_2Co_{17} on W(011) by pulsed laser deposition [8]. The calculated lattice parameters are $a=0.8581$ nm and $c=1.2482$ nm as compared to the bulk $\text{Nd}_2\text{Fe}_{17}$ values of 0.8578 and 1.2462 nm, respectively.

In conclusion, a variety of oriented RE-TM films have been grown onto MgO(100) and (111) substrates with epitaxial W buffer layers. The use of epitaxial W buffer layers allows highly oriented single-phase films to be grown. For Sm-Co and Nd-Fe we find W(110) buffer layers initiate c -axis growth and W(100) buffer layers promote growth with the c -axis in-plane. When grown on W(100),

Sm-Co films have strong in-plane anisotropy and coercivities exceeding 5 T at 5 K. Sm-Fe films grown on MgO(100) exhibits perpendicular magnetic anisotropy and are magnetically soft.
