U. S. Crude Oil, Natural Gas, and Natural Gas Liquids Reserves Annual Report 1995

HOW TO OBTAIN EIA PRODUCTS AND SERVICES

For further information on any of the following services, or for answers to energy information questions, please contact EIA's National Energy Information Center:

National Energy Information Center (NEIC)	(202) 586-8800
Energy Information Administration	(202) 586-0727 (fax)
Forrestal Building, Room 1F-048	TTY: (202) 586-1181
Washington, DC 20585	E-mail: infoctr@eia.doe.gov

Electronic Products and Services

EIA's **Internet Site Services** offer nearly all EIA publications. Users can view and download selected pages or entire reports, search for information, download EIA data and analysis applications, and find out about new EIA information products and services.

World Wide Web: <http://www.eia.doe.gov>
Gopher: <gopher://gopher.eia.doe.gov>
FTP: <ftp://ftp.eia.doe.gov>

EIA also offers a listserve service for EIA press releases and other short documents. Sign up on the EIA World Wide Web site.

EIA's **CD-ROM, *Energy InfoDisc***, contains most EIA publications, several databases, and an energy forecasting model. The *Energy InfoDisc*, produced quarterly, is available for a fee from STAT-USA, Department of Commerce, 1-800-STAT-USA.

The **Comprehensive Oil and Gas Information Source (COGIS)**, a bulletin board service, contains data files from most of EIA's oil- and gas-related reports. It is available for a fee from STAT-USA, on 1-800-STAT-USA.

EIA's **Electronic Publishing System (EPUB)** bulletin board contains data files, directories, and forecasts from most EIA reports. It can be accessed free of charge by dialing (202) 586-2557.

Many of EIA's **data files and modeling programs** are available for sale on diskette, tape, or cartridge, through either the National Technical Information Service or the Office of Scientific and Technical Information, Department of Energy. Contact NEIC for information on specific products, sources, and media, and ordering instructions.

Printed Publications

EIA **directories** are available free of charge from NEIC. Recent **periodicals and one-time reports** are available from the Government Printing Office. Older reports are available from the National Technical Information Service:

Reserves Data on Diskette

Historical oil and gas reserves data are available on 3.5 or 5.25 inch high-density diskettes. These data cover the years 1977 through 1995, as published in the Energy Information Administration's *U.S. Crude Oil, Natural Gas, and Natural Gas Liquids Reserves*. Nineteen separate annual ASCII files are stored on a single diskette and each contains the following data tables:

- Crude Oil Proved Reserves, Reserves Changes, and Production
- Dry Natural Gas Proved Reserves, Reserves Changes, and Production
- Natural Gas Proved Reserves, Reserves Changes, and Production, Wet After Lease Separation
- Nonassociated Natural Gas Proved Reserves, Reserves Changes, and Production, Wet After Lease Separation
- Associated-Dissolved Natural Gas Proved Reserves, Reserves Changes, and Production, Wet After Lease Separation
- Natural Gas Liquids Proved Reserves, Reserves Changes, and Production
- Natural Gas Plant Liquids Proved Reserves and Production
- Lease Condensate Proved Reserves and Production.

This diskette, U.S. Crude Oil, Natural Gas, and Natural Gas Liquids Reserves, 1977-1995, is available from the Energy Information Administration. Contact Bob King 202-586-4787 Fax 202-586-1076 E-mail: rking@eia.doe.gov.

Preface

The *U.S. Crude Oil, Natural Gas, and Natural Gas Liquids Reserves 1995 Annual Report* is the 19th prepared by the Energy Information Administration (EIA) to fulfill its responsibility to gather and report annual proved reserves estimates. The EIA annual reserves report series is the only source of comprehensive domestic proved reserves estimates. This publication is used by the Congress, Federal and State agencies, industry, and other interested parties to obtain accurate estimates of the Nation's proved reserves of crude oil, natural gas, and natural gas liquids. These data are essential to the development, implementation, and evaluation of energy policy and legislation.

This report presents estimates of proved reserves of crude oil, natural gas, and natural gas liquids as of December 31, 1995, as well as production volumes for the United States and selected States and State subdivisions for the year 1995. Estimates are presented for the following four categories of natural gas: total gas (wet after lease separation), nonassociated gas and associated-dissolved gas (which are the two major types of wet natural gas), and total dry gas (wet gas adjusted for the removal of liquids at natural gas processing plants). In addition, reserve estimates for two types of natural gas liquids, lease condensate and natural gas plant liquids, are presented. The estimates are based upon data obtained from two annual EIA surveys: Form EIA-23, "Annual Survey of Domestic Oil and Gas Reserves" and Form EIA-64A, "Annual Report of the Origin of Natural Gas Liquids Production." Also included is information on indicated additional crude oil reserves and crude oil, natural gas, and lease condensate reserves in nonproducing reservoirs. A discussion of notable oil and gas exploration and development activities during 1995 is provided.

The appendices contain data by operator production size class for crude oil and natural gas reserves and production; the top 100 U.S. fields ranked within an

oil or gas proved reserves group for 1993; report Table 1 converted to metric units; historical State data; a summary of survey operations; a discussion of statistical considerations; methods used to develop the estimates provided in this report; maps of selected State subdivisions; and examples of the survey forms. A glossary of the terms used in this report and in survey Forms EIA-23 and EIA-64A is provided to assist readers in more fully understanding the data.

This annual reserves report was prepared by the Dallas Field Office staff of the Reserves and Natural Gas Division, Office of Oil and Gas, Energy Information Administration. General information regarding preparation of the report may be obtained from Kenneth A. Vagts, Director, Office of Oil and Gas; Joan E. Heinkel, Director, Reserves and Production Branch (202-586-6023); or John H. Wood, Director, Dallas Field Office (214-767-2200).

Address questions on specific sections of the publication to the following analyst/author:

- Chapter 2 and Chapter 3
Steven G. Grape 214-767-0874
Fax: 214-767-2204 or E-mail: sgrape@eia.doe.gov
- Chapter 4, Chapter 5, Appendices A, B, C, and G
Paul Chapman 214-767-0885
Fax 214-767-2204 or E-mail pchapman@eia.doe.gov
- Appendices D, E, F, H, and I
Rhonda S. Green 214-767-0886
Fax 214-767-2204 or E-mail rgreen@eia.doe.gov

The preparation of the report was supervised by John H. Wood. Significant contributions were made by Jack S. Sanders, David F. Morehouse, William L. Monroe, Rafi M. Zeinalpour and Robert F. King. Editorial support was provided by Ann C. Whitfield.

Other EIA Oil and Gas Publications

Other reports published by the Energy Information Administration (EIA) offer additional information and analysis related to domestic oil and gas supply. They may be obtained from the Government Printing Office in the same manner as this oil and gas reserves report.

*Natural Gas Productive Capacity for the Lower 48 States, DOE/EIA-0542,
December 1996*

This report describes an analysis of monthly natural gas wellhead productive capacity in the lower 48 States from 1985 through 1995, and projects this capacity through 1997. The impacts of drilling, oil and gas price assumptions, and demand on gas productive capacity are integrated into the capacity projections as low, base, and high cases.

*Natural Gas Annual 1995, DOE/EIA-0131(95), November 1996
Petroleum Supply Annual 1995, DOE/EIA-0340(95), May 1996*

These annual reports provide comprehensive statistics on supply, disposition, and prices of natural gas and petroleum in the United States.

Natural Gas 1996: Issues and Trends, DOE/EIA-0560(96), December 1996

This report focuses on the increasing choices and challenges in the natural gas industry, as regulatory requirements are increasingly removed from the sale and transport of natural gas.

Executive Summary

U.S. proved reserves of natural gas were up in 1995 for the second year in a row. A 1 percent 1995 gain marked the first back-to-back increases in 28 years. Proved oil reserves declined by half a percent, the smallest amount in 8 years. Large oil and gas discoveries in the Federal offshore—several in deep water—continued to play a major role. Successful exploratory gas well completions were up although development and total gas well completions were down, as were gas prices. For oil, both successful exploratory and total well completions were up, as were oil prices.

As of December 31, proved reserves were:

Dry Natural Gas (billion cubic feet)

1994	163,837
1995	165,146
Increase	+ 0.8%

Crude Oil (million barrels)

1994	22,457
1995	22,351
Decrease	- 0.5%

Natural Gas Liquids (million barrels)

1994	7,170
1995	7,399
Increase	+ 3.2%

Proved reserves are those quantities that geological and engineering data demonstrate with reasonable certainty to be recoverable in future years from known reservoirs under existing economic and operating conditions. Petroleum engineering and geological judgment are required in estimating proved reserves; therefore, the results are not precise measurements. This report of 1995 U.S. proved reserves of crude oil, natural gas, and natural gas liquids is the 19th in an annual series prepared by the Energy Information Administration.

Natural Gas

Reserve additions replaced 107 percent of gas production in 1995. *Revisions and adjustments* were up. *Total discoveries* were down from a high 1994 level, but still 14 percent higher than the prior 10-year average. With the successive increases, 1995 proved gas reserves were up 2,731 billion cubic feet from those of 1993.

Improved exploration and deepwater production technologies enhanced the ability to discover and develop offshore fields. For example, Shell Oil announced in September 1995 plans to install a tension leg platform (TLP) to develop its *Prospect Ursa*. It will set a new world record for TLP water depth at approximately 3,950 feet and is expected to be installed in early 1999.

Coalbed methane reserves resumed growing, more than replacing the decline of 1994 and accounting for over 6 percent of 1995 natural gas reserves. Coalbed methane production increased to over 5 percent of U.S. dry gas production in 1995. No federal tax incentives for new coalbed methane wells have been available for 3 years.

Wyoming, the Gulf of Mexico Federal Offshore, Texas, and Colorado each had 1995 proved reserves increases greater than 500 billion cubic feet, totaling 3,057 billion cubic feet.

U.S. *total discoveries* of dry gas reserves were 10,961 billion cubic feet in 1995, down 11 percent from 1994. Texas and the Gulf of Mexico Federal Offshore accounted for over two-thirds of them. *Total discoveries*, which equaled 61 percent of 1995 gas production, are those reserves attributable to field extensions, new field discoveries, and new reservoir discoveries in old fields. They result from drilling exploratory wells.

- *New field discoveries* were 1,666 billion cubic feet, down 12 percent from 1994, but 33 percent higher than the prior 10-year average.
- *Field extensions* were 6,843 billion cubic feet, down 1 percent from 1994.
- *New reservoir discoveries in old fields* were 2,452 billion cubic feet, down 30 percent from 1994, but still 14 percent higher than the prior 10-year average.

The net volume of *revisions and adjustments* to reserves played a large role in increasing U.S. natural gas proved reserves. It amounted to 8,314 billion cubic feet in 1995, up 12 percent over 1994. Texas, where proved gas reserves increased in 1995, had the largest increase in *revisions and adjustments*. Wyoming's proved reserves of natural gas grew by 1,287 billion cubic feet in 1995. Significant *revision*

increases reflected large additions of proved undeveloped methane reserves in deep Paleozoic formations in the Big Piney-Labarge Field. Since the gas in these formations is predominantly carbon dioxide, additional processing facilities will have to be brought on-line to produce these reserves.

Other 1995 natural gas events of note:

- Exploratory gas well completions increased again, reaching 814 in 1995.
- *Total discoveries* per exploratory gas well were down in 1995, but still more than twice that of the early 1980s.
- Total gas well completions decreased 17 percent in 1995, but still exceeded oil well completions.
- Natural gas prices at the wellhead dropped 18 percent to an annual average of \$1.55 per thousand cubic feet.

Crude Oil

Overall, reserve additions replaced 95 percent of 1995 oil production. Although proved reserves of crude oil declined for the eighth consecutive year, the half percent decline was the smallest since reserves last increased in 1987. Reserve additions from the Gulf of Mexico Federal Offshore almost single-handedly outweighed the combined proved reserves losses of Alaska, California, and Texas.

Lower-48 States crude oil proved reserves increased for the first time in a decade. Reserves rose by 81 million barrels.

Total discoveries of crude oil were 957 million barrels in 1995, of which the Gulf of Mexico Federal Offshore accounted for 60 percent, Texas for 16 percent, and Alaska for 8 percent. *Total discoveries* of crude oil in 1995 were the highest in a decade—67 percent higher than last year's.

- *New reservoir discoveries in old fields* were 343 million barrels. This more than tripled both the 1994 total and the prior 10-year average for the United States! The Gulf of Mexico Federal Offshore had 91 percent of the *new reservoir discoveries in old fields*.
- *New field discoveries* were 114 million barrels, up 78 percent from the 1994 level. The Gulf of Mexico Federal Offshore had 79 percent of the *new field discoveries*.

- *Field extensions* added 500 million barrels of proved oil reserves in 1995, 26 percent more than in 1994.

Revisions and adjustments were 1,150 million barrels in 1995, down 4 percent from 1994. They still were over half of the total reserve additions. Texas, Alaska, and California, the States with the largest oil reserves and large enhanced oil recovery projects, had the largest *revisions and adjustments*, accounting for 59 percent of them.

Other 1995 crude oil events of note:

- The annual average domestic first purchase price for crude oil increased to \$14.62 per barrel in 1995, and rose through the second half of the year.
- Oil well completions increased slightly to 6,796.

Indicated additional reserves of crude oil were 2,669 million barrels in 1995, a 15-percent decrease from 1994. These are crude oil volumes that may become economically recoverable from known reservoirs through the application of improved recovery techniques using current technology. The presence of large *indicated additional reserves* in the Alaskan North Slope, California, west Texas, and New Mexico implies that significant upward revisions to crude oil proved reserves could occur in the future.

Natural Gas Liquids

U.S. natural gas liquids proved reserves increased 3 percent to 7,399 million barrels in 1995. Natural gas liquids reserves are the sum of natural gas plant liquids and lease condensate reserves.

Total proved reserves of liquid hydrocarbons (crude oil plus natural gas liquids) were 29,750 million barrels in 1995, an increase of 123 million barrels from the 1994 level. Natural gas liquids grew to a quarter of total liquid hydrocarbon proved reserves in 1995.

Data

These estimates are based upon analysis of data from Form EIA-23, "Annual Survey of Domestic Oil and Gas Reserves," filed by 3,591 operators of oil and gas wells, and Form EIA-64A, "Annual Report of the Origin of Natural Gas Liquids Production," filed by operators of 718 active natural gas processing plants. The U.S. proved reserves estimates for crude oil and natural gas are associated with sampling errors of less than 1 percent at a 95 percent confidence level.

1. Introduction

Background

The principal focus of this report is to provide accurate annual estimates of U.S. proved reserves of crude oil, natural gas, and natural gas liquids. These estimates are essential to the development, implementation, and evaluation of national energy policy and legislation. In the past, the Government and the public relied upon industry estimates of proved reserves. However, the industry ceased publication of reserve estimates after its 1979 report.

In response to a recognized need for credible annual proved reserves estimates, Congress, in 1977, required the Department of Energy to prepare such estimates. To meet this requirement, the Energy Information Administration (EIA) developed a program that established a unified, verifiable, comprehensive, and continuing annual statistical series for proved reserves of crude oil and natural gas. It was expanded to include proved reserves of natural gas liquids for the 1979 and subsequent reports.

Survey Overview

EIA defines proved reserves, the major topic of this report, as those volumes of oil and gas that geological and engineering data demonstrate with reasonable certainty to be recoverable in future years from known reservoirs under existing economic and operating conditions. There are other categories of reserves, but by definition they are more speculative and less precise than proved reserves. Readers who are unfamiliar with the distinctions between types of reserves or with how reserves fit in the description of overall oil and gas resources should see Appendix G.

While the primary topic of this report is proved reserves, information is also presented on indicated additional crude oil reserves. Indicated additional crude oil reserves are not included in proved reserves because of their uncertain economic recoverability. When economic recoverability is demonstrated, these volumes will be reclassified and transferred to the proved reserves category as positive revisions.

This report provides proved reserves estimates for calendar year 1995. It is based on data filed by a sample

of operators of oil and gas wells on Form EIA-23, "Annual Survey of Domestic Oil and Gas Reserves," and by operators of all natural gas processing plants on Form EIA-64A, "Annual Report of the Origin of Natural Gas Liquids Production." The U.S. crude oil and natural gas proved reserves estimates are associated with sampling errors of less than 1 percent at a 95-percent confidence level.

Form EIA-23

On Form EIA-23, an operator is defined as an organization or person responsible for the management and day-to-day operation of oil and/or gas wells. This definition eliminates responses from royalty owners, working interest owners (unless they are also operators), and others not directly responsible for oil and gas production operations.

Operator size categories are based upon their annual production as indicated in various Federal, State, and commercial records. Large operators are those that produced at least 1.5 million barrels of crude oil or 15 billion cubic feet of natural gas, or both, during the report year. Intermediate operators produced less than large operators, but more than 400,000 barrels of crude oil or 2 billion cubic feet of natural gas, or both. Small operators are those that produced less than did intermediate operators. All data are reported on a total operated basis, encompassing all proved reserves and production associated with wells operated by an individual operator. This concept is also called the "gross operated" or "8/8ths" basis.

Large operators and most intermediate size operators report reserves balance data on Form EIA-23 to show how and why reserves components changed during the year on a field-by-field basis. Small operators and intermediate size operators who do not keep reserves data were not asked to provide estimates of reserves at the beginning of the year or annual changes to proved reserves by component of change; i.e., revisions, extensions, and new discoveries. These volumes were estimated by applying an algebraic allocation scheme that preserved the relative relationships between these items within each State or State subdivision, as reported by large and intermediate operators.

The published reserve estimates include an additional term, adjustments, calculated by the EIA; that preserves an exact annual reserves balance of the form:

Published Proved Reserves at End of Previous Report Year
+ Adjustments
+ Revision Increases
- Revision Decreases
+ Extensions
+ New Field Discoveries
+ New Reservoir Discoveries in Old Fields
- Report Year Production
= Published Proved Reserves at End of Report Year

Adjustments are the annual changes in the published reserve estimates that cannot be attributed to the estimates for other reserve change categories. They result from the survey and statistical estimation methods employed. For example, variations caused by changes in the operator frame, different random samples, changes in reserve estimates following ownership changes, incorrectly reported data, or imputations for missing or unreported reserve changes can contribute to adjustments.

Form EIA-64A

Form EIA-64A data were first collected for the 1979 survey year in order to develop estimates for total natural gas liquids reserves. Data on liquids recovered from natural gas, as reported by natural gas processing plant operators, are combined with lease condensate data collected on Form EIA-23 to provide the total natural gas liquids reserves estimates.

Data Collection Operations

An intensive effort is made each year to maintain an accurate and complete survey frame consisting of operators of oil and gas wells and of natural gas processing plants. The Form EIA-23 operator frame contained 22,695 probable active operators and the Form EIA-64A plant frame contained 759 probable active natural gas processing plants in the United States when the 1995 surveys were initiated. As usual, additional operators were added to the survey as it progressed, and many operators initially in the sample frame were found to be inactive in 1995.

For the report year 1995, the EIA mailed 3,865 EIA-23 forms to all known large and intermediate size oil and gas well operators and to a sample of smaller operators that were believed to be active during 1995. Of these, 282 were found to be nonoperators that did not have successor operators in 1995. Data were received from 3,591 operators, an overall response rate of 100 percent of the active operators in the Form EIA-23 survey. The EIA mailed 788 EIA-64A forms to natural gas processing plant operators. More than one form is received for a plant that has more than one operator during the year. Forms were received from 100 percent of the operators of the 718 unique active natural gas processing plants in the Form EIA-64A survey.

National estimates of the production volumes for crude oil, lease condensate, natural gas liquids, and dry natural gas based on Form EIA-23 and Form EIA-64A were compared with corresponding official production volumes published by the EIA, which are obtained from non-survey based State sources. For report year 1995, the Form EIA-23 National production estimates were 1.5 percent lower than the comparable *Petroleum Supply Annual 1995* volumes for crude oil and lease condensate combined, and were 3.4 percent lower than the comparable *Natural Gas Annual 1995* volume for 1995 dry natural gas. For report year 1995, the Form EIA-64A National estimates were 0.9 percent higher than the *Petroleum Supply Annual 1995* volume for natural gas plant liquids production.

2. Overview

National Summary

The United States had the following proved reserves as of December 31, 1995:

- Crude Oil—22,351 million barrels
- Dry Natural Gas—165,146 billion cubic feet
- Natural Gas Liquids—7,399 million barrels.

This Overview section summarizes the 1995 proved reserves balances of crude oil, dry natural gas, and natural gas liquids on a National level, and provides historical comparisons between 1995 and years past.

Table 1 lists the estimated annual reserve balances since 1985. In 1995, the proved reserves of dry natural gas increased by 1 percent over the 1994 proved reserves level. This is second consecutive year that gas reserves have increased. Crude oil proved reserves declined slightly in 1995—down 0.5 percent from 1994's level—the lowest recorded decline since 1987 (crude oil proved reserves increased in 1987.)

Crude Oil

Proved reserves of crude oil decreased by 106 million barrels in 1995. The largest decline was in Alaska, where reserves decreased 187 million barrels. The largest increase occurred in the Federal Offshore area in the Gulf of Mexico, where 391 million barrels of crude oil proved reserves were added to the National total. Figure 1 shows the crude oil proved reserves levels by major region and Figure 2 shows the components of reserves changes from 1985 through 1995.

Consistent with the trend in Figure 2, total reserve additions (the positive side of the scale) increased for the fifth year in a row, while production of crude oil (the negative side of Figure 2's scale) declined slightly for the fifth year in a row. However, in 1995 production still exceeded the amount of reserve additions, resulting in a small decline of U.S. crude oil proved reserves in 1995. Operators replaced 95 percent of their 1995 oil production with reserve additions.

Total discoveries are those reserves attributable to field extensions, new field discoveries, and new reservoir discoveries in old fields. There were 957 million barrels of

total discoveries of crude oil proved reserves in 1995. This is 67 percent more than in 1994.

Extensions added 500 million barrels of proved reserves. This is 26 percent more than in 1994 (397 million barrels) and 12 percent more than the average *extensions* in the prior 10 years (447 million barrels).

New field discoveries were 114 million barrels, up 78 percent from the 1994 level. This is 14 percent more than the average volume discovered in the prior 10 years (100 million barrels).

New reservoir discoveries in old fields added 343 million barrels of proved reserves. This more than tripled both the 1994 total and the prior 10-year average for the United States (111 million barrels).

Revisions and adjustments added 1,150 million barrels of proved reserves. This is 96 percent of 1994's volume (1,196 million barrels) and 83 percent of the average volume of the prior 10 years (1,380 million barrels).

Crude oil reserves have been primarily sustained by continuing upward *revisions and adjustments* to the reserves of older fields. During the 1985-1994 decade, *revisions and adjustments* accounted for an average of 68 percent of reserve additions. In 1995, *revisions and adjustments* accounted for 55 percent of reserve additions.

Production deducted an estimated 2,213 million barrels of proved reserves from the National total. Production was down 2 percent from 1994's level (2,268 million barrels) and at 84 percent of the prior 10-year average (2,637 million barrels).

The overall 1995 United States reduction of 106 million barrels of crude oil proved reserves is the smallest decline in crude oil proved reserves since 1987. In the 10 years prior to 1995, the United States had an average annual reduction of 599 million barrels of crude oil proved reserves. 1995's decline is only 18 percent of that average.

Natural Gas

U.S. proved reserves of dry natural gas increased for the second year in a row in 1995—up 1 percent from 1994's level to a total of 165,146 billion cubic feet. Dry natural

^cProved reserves = Col. 10 from prior year + Col. 4 + Col. 8 - Col. 9.

^dAn unusually large revision decrease to North Slope dry natural gas reserves was made in 1988. It recognizes some 24.6 trillion cubic feet of downward revisions reported during prior years by operators because of economic and market conditions. The Energy Information Administration (EIA) in previous years carried these reserves in the proved category.

Notes: Old means discovered in a prior year. New means discovered during the report year. The production estimates in this table are based on data reported on Form EIA-23, "Annual Survey of Domestic Oil and Gas Reserves" and Form EIA-64A, "Annual Report of the Origin of Natural Gas Liquids Production." They may differ from the official EIA production data for crude oil, natural gas, and natural gas liquids for 1995 contained in the *Petroleum Supply Annual 1995*, DOE/EIA-0340(95) and the *Natural Gas Annual 1995*, DOE/EIA-0131(95).

Sources: *U.S. Crude Oil, Natural Gas, and Natural Gas Liquids Reserves*, 1985 through 1995 annual reports, DOE/EIA-0216.(1-10)

Figure 1. U.S. Crude Oil Proved Reserves, 1985-1995

Figure 2. Components of Reserves Changes for Crude Oil, 1985-1995

Source: U.S. Crude Oil, Natural Gas, and Natural Gas Liquids Reserves, 1985-1994 annual reports, DOE/EIA-0216.{1-10}

gas reserves decreased by 236 billion cubic feet in Alaska, but dry natural gas reserves for the lower 48 States increased by 1,545 billion cubic feet. Figure 3 shows the dry natural gas proved reserves levels by major region and Figure 4 shows the components of reserves changes from 1985 through 1995.

Operators were able to replace all of 1995's dry gas production (estimated to be about 17,966 billion cubic feet) with reserve additions, and then add 1,309 billion cubic feet of dry natural gas to the proved reserves total.

For 1995, U.S. *total discoveries* of dry gas reserves were 10,961 billion cubic feet, down 11 percent from 1994. *Total discoveries* were 57 percent of all reserve additions in 1995, while *revisions and adjustments* provided the remaining 43 percent. Unlike crude oil, *total discoveries* of dry natural gas proved reserves usually exceed the *revisions and adjustments*.

Extensions added 6,843 billion cubic feet of proved reserves. This is 99 percent of 1994's *extensions* and 111 percent of the average of *extensions* over the prior 10 years (6,172 billion cubic feet).

New field discoveries added 1,666 billion cubic feet of proved reserves. This is 12 percent less than what was discovered in 1994, but 33 percent higher than the average volume discovered in the prior 10 years (1,257 billion cubic feet).

New reservoir discoveries in old fields added 2,452 billion cubic feet of proved reserves. This is 30 percent less than the volume discovered in 1994, but 14 percent higher than the prior 10-year average (2,147 billion cubic feet).

Revisions and adjustments added 8,314 billion cubic feet of proved reserves. This is 112 percent of 1994's *revisions and adjustments*.

Production deducted an estimated 17,966 billion cubic feet of proved reserves from the National total. Gas production decreased compared to 1994, the first decrease in production since 1991.

Coalbed methane gas production and reserves are included in the 1995 totals. However, EIA separately tracks these reserves in order to record the development and performance of this gas source. Coalbed methane gas reserves increased in 1995, more than replacing the small decline of 1994. Coalbed methane gas reserves account for over 6 percent of 1995 U.S. dry natural gas reserves, and coalbed methane production rose in 1995 to over 5 percent of U.S. dry gas production. No Federal

tax incentives for new coalbed methane wells have been available for 3 years.

Natural Gas Liquids

Proved reserves of natural gas liquids increased by 229 million barrels during 1995—more than 3 percent higher than 1994 levels. An increase of 5 million barrels occurred in Alaska, while the lower 48 States' reserves increased by 224 million barrels. Figure 5 shows the natural gas liquids proved reserves levels by major region and Figure 6 shows the components of reserves changes from 1985 through 1995.

Operators replaced 129 percent of their 1995 natural gas liquids production with reserve additions. *Total discoveries* accounted for 54 percent of all reserve additions, while *revisions and adjustments* accounted for the remaining 46 percent.

Total proved reserves of liquid hydrocarbons (crude oil plus natural gas liquids) were 29,750 million barrels in 1995—an increase of 123 million barrels from the 1994 level. Natural gas liquids represented 25 percent of total liquid hydrocarbon proved reserves in 1995, 1 percent higher than the 1994 level.

The 1995 contribution of natural gas liquids proved reserves to total liquid hydrocarbon reserves in the United States is a record-high percentage. In 1979, when EIA began reporting natural gas liquids proved reserves, they represented only 18 percent of total liquid hydrocarbon reserves.

Reserves Changes Since 1977

EIA has collected oil and gas reserves estimates annually since 1977. Table 2 lists the cumulative totals of the components of reserves changes for crude oil and dry natural gas from 1977 through 1995. Table 2 contains two sections, one for the lower 48 States, and another for the U.S. total (which includes Alaska's contribution). Annual averages of each component of reserves changes are also listed in Table 2, along with the percentage of that particular component's impact on the U.S. total of proved reserves. In this section, we compare these averages to the 1995 proved reserves estimates as a means of gauging the past year against history.

Source: U.S. Crude Oil, Natural Gas, and Natural Gas Liquids Reserves 1977-1994 annual reports, DOE/EIA-0216.(1-18)

Crude Oil: Since 1977, the Nation has:

- discovered an average of 785 million barrels per year of new reserves
- revised and adjusted proved reserves upwards by an average of 1,383 million barrels per year
- reduced proved reserves by an average 587 million barrels per year because reserve additions did not replace production.

Crude oil reserves have been primarily sustained by continuing upward *revisions and adjustments* to the reserves of older fields, not discoveries. The bulk of post-1976 crude oil reserves additions were the 26,274 million barrels of *revisions and adjustments*, which accounted for 64 percent of all crude oil reserves additions since 1977. The 14,909 million barrels of *total discoveries* accounted for the remaining 36 percent of reserve additions.

Compared to the average reserves changes since 1977, 1995 was a good year for crude oil discoveries, even though the U.S. reserves total declined. In 1995, *total discoveries* of crude oil exceeded the post-1976 U.S.

average by 22 percent, while *revisions and adjustments* were less than the post-1976 U.S. average.

Only one component of *total discoveries* exceeded the post-1976 averages—*new reservoir discoveries in old fields*. Since 1977, operators have found only an average of 139 million barrels of crude oil proved reserves per year from *new reservoir discoveries in old fields*. In 1995, operators discovered 343 million barrels of proved reserves—247 percent of the post-1976 average.

Dry Natural Gas: Since 1977, the Nation has:

- discovered an average of 11,851 billion cubic feet per year of new reserves
- revised and adjusted proved reserves upwards by an average 3,096 billion cubic feet per year
- reduced reserves by an average 2,533 billion cubic feet per year because reserve additions did not replace production.

Unlike crude oil reserves, natural gas reserves have been sustained primarily by *total discoveries*. *Revisions and adjustments* account for only 21 percent of all reserve

additions since 1977. However, since 1985, the contribution from *revisions and adjustments* has increased substantially (it was 43 percent in 1995).

Compared to the average reserves changes since 1977, 1995 was an excellent year for natural gas reserve additions from *net revisions and adjustments*. U.S. total dry natural gas reserves increased for the second year in a row. Operators reported 8,314 billion cubic feet of *net revisions and adjustments* to their dry natural gas proved reserves—169 percent higher than the post-1976 average (3,096 billion cubic feet). However, compared to the post-1976 U.S. average, *total discoveries* (and all of its components) were slightly lower.

Economics and Drilling

Economics: Table 3 lists the average annual domestic wellhead prices of crude oil and natural gas, as well as the average number of active rotary drilling rigs, from 1970 to 1995.

U.S. crude oil first purchase price started at an average of \$14.00 per barrel in January 1995, and rose to \$15.85 per barrel in May. Prices returned to the \$14 per barrel level in midyear 1995, then wavered up and down until December, when colder weather supported a price increase to \$15.02 per barrel. The average U.S. crude oil first purchase price rose from \$13.19 in 1994 to \$14.62 per barrel in 1995.

Table 3. U.S. Average Annual Domestic Wellhead Prices for Crude Oil and Natural Gas, and the Average Number of Active Rotary Drilling Rigs, 1970-1995

Year	Crude Oil		Natural Gas		Number of Rigs

R=Revised data.

Sources: Current dollars and Number of rigs: *Monthly Energy Review July 1996*, DOE/EIA-0035(96/07) and *Natural Gas Annual 1995*, Volume 1, November 1996, DOE/EIA-0131(95)/1. 1995 constant dollars: U.S. Department of Commerce, Bureau of Economic Analysis, Gross Domestic Product Implicit Price Deflators, June 1996.

Oil prices vary by region. In Texas the average price was \$16.38 per barrel, while in California it was \$14.00 per barrel, and only \$11.12 per barrel on the Alaskan North Slope.{19}

The average natural gas price at the wellhead decreased from \$1.88 in 1994 to \$1.55 per thousand cubic feet in 1995 (Table 3). Gas prices started higher than the annual average in January 1995, but dropped in February as expected colder weather failed to materialize. The price increased in late spring, declined in summer months, then increased again in the fall. In the last months of 1995, blizzard conditions blanketed

much of the eastern United States—resulting in the highest gas prices of the year at the wellhead.{20}

Drilling: From 1994 to 1995, the average active rig count decreased from 775 to 723 rigs (Table 3). The rig count remains well below the activity level of a decade ago (average 1,980 rigs in 1985).

Looking first at exploratory wells, there were 3,480 exploratory wells drilled in 1995 (Table 4). Of these, 21 percent were oil wells, 23 percent were gas wells, and 55 percent were dry holes. The total (which includes dry holes) was almost 3 percent less than in 1994. Although fewer exploratory wells were drilled, they were significantly more successful.

^aExcludes service wells and stratigraphic and core testing.

R=Revised data.

Notes: Estimates are based on well completions taken from American Petroleum Institute data tapes through June 1995. Due to the method of estimation, data shown are frequently revised. Data are no longer rounded to nearest 10 wells.

Sources: Years 1970-1972: Energy Information Administration, Office of Oil and Gas. Years 1973-1995: *Monthly Energy Review*, DOE/EIA-0035(96/07), July 1996.

The success rate for exploratory drilling increased from 38 percent in 1994 to 45 percent in 1995. The higher success rate led to the completion of 6 percent more exploratory gas wells (Figure 7) and 23 percent more exploratory oil wells (Figure 8) than in 1994. The 814 gas wells represent the highest level of successful exploratory gas well completions since 1985. Operators are using improved drilling, completion, and seismic exploration technology to increase their drilling success rate.

Figures 9 and 10 show the average volume of discoveries per exploratory well for dry natural gas and oil, respectively, since 1977. The average volume of new gas discoveries per exploratory well decreased for the second year in a row, but remains over 1.5 times the volume of dry gas discovered per well 10 years ago. The average volume of new oil discoveries per exploratory well is substantially higher than last year's level. The volume of oil discoveries per exploratory well in 1995 is the second highest since 1977.

There were an estimated 18,518 exploratory and development wells drilled in 1995. This is 12 percent fewer than in 1994 and is only 55 percent of the average number of wells drilled annually over the prior 10 years (33,618).

Operators completed more oil wells, but fewer gas wells in 1995 than in 1994. Oil well completions had been declining for 5 years—1995's increase halts that trend. However, the number of gas well completions has significantly dropped—a decline of 17 percent from 1994.

For the third year in a row, the number of gas well completions exceeded the number of oil well completions in both the exploratory and development categories.

Reserve-to-Production Ratios and Ultimate Recovery

R/P Ratios

The relationship between proved reserves and production levels, expressed as the ratio of reserves to production (R/P ratio) is often used in analyses. For a mature producing area, the R/P ratio tends to be reasonably stable, so that the proved reserves at the end of a year serve as a rough guide to the production level that can be maintained during the following year.

Operators report data which yield R/P ratios that vary widely by area depending upon:

- category of operator
- geology and economics
- number and size of new discoveries
- amount of drilling that has occurred.

R/P ratios are an indication of the state of development in an area and, over time, the ratios change. For example, when the Alaskan North Slope oil reserves were booked, the U.S. R/P ratio for crude oil increased because significant production from these reserves did not begin until 7 years after booking due to the need to first build the Trans Alaska pipeline. The U.S. R/P ratio for crude oil decreased from 11.1-to-1 to 9.4-to-1 between 1977 and 1982, as Alaskan North Slope oil production reached high levels.

U.S. crude oil proved reserves decreased in 1995, but oil production decreased by a larger amount—resulting in an increase in the National average R/P ratio.

Figure 11 shows the U.S. R/P ratio trend for crude oil since 1945. After World War II, increased drilling and discoveries led to a greater R/P ratio. Later, when drilling found fewer reserves than were produced, the ratio became smaller. R/P ratios also vary geographically. Less developed areas of the country, such as the Pacific offshore, have higher R/P ratios for crude oil than the 1995 National average of 10.1-to-1. Other areas with relatively high R/P ratios are the Permian Basin of Texas and New Mexico, and California, where enhanced oil recovery techniques such as carbon dioxide (CO₂) injection or steamflooding have improved recoverability of oil in old, mature fields. Areas that have the lowest R/P ratios usually have many older fields, like the Mid-Continent region. There, even use of new technologies such as horizontal drilling have so far only helped to add reserves equivalent to the annual production, keeping the regional reserves and R/P ratio for oil relatively stable.

Figure 12 shows the historical R/P ratio for wet natural gas since 1945. Prior to 1945, R/P ratios were very high, since the interstate pipeline infrastructure was not well developed. The market for and production of natural gas grew rapidly after World War II, lowering the R/P ratio. The U.S. average R/P ratio for natural gas increased in 1995, as reserves increased while production declined.

Different marketing, transportation, and production characteristics for gas are seen when looking at regional

Figure 7. U.S. Exploratory Gas Well Completions, 1977-1995

Source: Energy Information Administration, Office of Oil and Gas.

average R/P ratios, compared to the 1995 U.S. average R/P ratio of about 9.2-to-1. The areas with the higher range of R/P ratios are the less developed areas of the country, such as the Pacific offshore and the Rockies, and also include areas such as Alabama and Colorado, where considerable booking of coalbed methane reserves has recently occurred. Several major gas producing areas have R/P ratios below the National average—such as Texas, the Gulf of Mexico Federal Offshore, and Oklahoma. The R/P ratio of these three areas combined has increased from 6.9-to-1 in 1994 to 7.2-to-1 in 1995, but remains below the National 1995 average.

Ultimate Recovery

Figures 13 and 14 show successive estimates of ultimate recovery and its components, proved reserves and cumulative production, for crude oil plus lease condensate, and wet natural gas, from 1977 to 1995. They illustrate the continued growth of estimated ultimate recovery over time.

In 1977, U.S. crude oil and lease condensate proved reserves were 33,615 million barrels. Cumulative production for 1977 through 1995 was 52,611 million barrels. This cumulative production substantially exceeds the 1977 proved reserves, but at the end of 1995 there were still 23,548 million barrels of crude oil and lease condensate proved reserves. Therefore, the estimated ultimate recovery of crude oil significantly increased during this period due to the continuing development of old fields and *new field discoveries*.

Similarly, the 1977 wet natural gas proved reserves were 209,490 billion cubic feet, and cumulative wet gas production from 1977 through 1995 was 331,451 billion cubic feet. Cumulative wet gas production exceeded the 1977 reserves by 121,961 billion cubic feet, but at the end of 1995 there were still 173,476 billion cubic feet of wet natural gas proved reserves, for the same reasons.

International Perspective

International Reserves

The EIA estimates domestic oil and gas reserves but does not systematically estimate worldwide reserves. As shown in Table 5, international reserves estimates are presented in two widely circulated trade publications. The world's total reserves are estimated to

be roughly 1 trillion barrels of oil and 5 quadrillion cubic feet of gas.

The United States ranked 11th in the world for proved reserves of crude oil and 6th for natural gas in 1995, unchanged from 1994. A comparison of EIA's U.S. proved reserves estimates with worldwide estimates obtained from other sources shows that the United States had about 2 percent of the world's total crude oil proved reserves and over 3 percent of the world's total natural gas proved reserves at the end of 1995. There are sometimes substantial differences between the estimates from these sources. Condensate is often included in foreign oil reserve estimates.

The trade press did not agree on world trends in 1995. The *Oil & Gas Journal*{21} estimate for world oil reserves increased in 1995, while the *World Oil*{22} estimate declined. On world gas reserves, the *Oil & Gas Journal* reported a decline, while *World Oil* reported an increase.

Several foreign countries have oil reserves considerably larger than those of the United States. Saudi Arabian oil reserves are the largest in the world, dwarfing U.S. oil reserves. Iraqi oil reserves are more than 4 times U.S. reserves. Closer to home, Venezuela has almost 3 times and Mexico has just over twice the United States' oil reserves.

Oil reserve estimates for various countries differ widely. For example, *World Oil* reported oil reserves for the former Soviet Union (FSU) of about 190 billion barrels. This is more than 3 times the *Oil & Gas Journal's* estimate. However, *World Oil* has included more than proved reserves in its 1995 FSU estimate. EIA considers *World Oil's* FSU estimate comparable to proved reserves plus probable reserves classifications commonly used in the United States. The U.S. oil reserve estimates only include proved reserves.

Petroleum Consumption

The United States is the world's largest energy consumer. The EIA estimates energy consumption and publishes it in its *Annual Energy Review*. In 1995:

- The U.S. consumed 90,618,000,000,000 Btu of energy (90.618 quadrillion Btu).
- 63 percent of U.S. energy consumption was provided by petroleum and natural gas—crude oil and natural gas liquids combined (38 percent), and natural gas (25 percent).{25}

Note: The Energy Information Administration does not certify these international reserves data, but reproduces the information as a matter of convenience for the reader.

Sources: *Oil & Gas Journal*, December 25, 1995, pp. 44-45. *World Oil*, August, 1996, p. 34.

- U.S. petroleum consumption was about 18 million barrels of oil and natural gas liquids and 59 billion cubic feet of dry gas per day.

Dependence on Imports

The United States remains heavily dependent on imported oil and gas to satisfy its ever-increasing appetite for energy. In 1994, dependence on petroleum net imports reached a 17-year high of 45 percent of energy consumption. In 1995, it declined slightly to 44 percent.

Net gas imports rose 4 percent in 1995 to a total of 2.73 trillion cubic feet. Almost all of this gas (2.7 trillion cubic feet) was from Canada.

Price-competitive Canadian gas exports continue to capture an increasing share of the U.S. market. Venezuela, Saudi Arabia, Canada, Mexico, and Nigeria were the primary foreign suppliers of petroleum to the United States. {26}

List Of Appendices

Appendix A: Reserves by Operator Production Size Class - How much of the National total of proved reserves are operated by the large oil and gas corporations? Appendix A separates the large operators from the small and presents reserves data according to operator production size classes. The top 20 producing companies had 58 percent of U.S. natural gas proved reserves in 1995.

Appendix B: Top 100 Oil and Gas Fields - What fields have the most reserves and production in the United States? The top 100 fields for oil and natural gas out of the inventory of more than 45,000 oil and gas fields are listed in Appendix B. These fields hold two-thirds of U.S. crude oil proved reserves.

Appendix C: Conversion to the Metric System - To simplify international comparisons, a summary of U.S. Crude Oil, Natural Gas, and Natural Gas Liquids Reserves expressed in metric units is included as Appendix C.

Appendix D: Historical Reserves Statistics - Appendix D contains selected historical reserves data

presented at the State and National level. Readers interested in a historical look at one specific State or region can review these tables.

Appendix E: Summary of Data Collection Operations - This report is based on two EIA surveys. Proved reserves data is collected annually from U.S. oil and gas field operators on Form EIA-23. Natural gas liquids production data is collected annually from U.S. natural gas plant operators on Form EIA-64A. Appendix E describes survey designs, response statistics, reporting requirements, and how the sampling frames are maintained. Pending budget reductions at EIA may reduce the scope and coverage of these surveys in the near future.

Appendix F: Statistical Considerations - The EIA strives to maintain or improve the accuracy of its reports. Since complete coverage of all oil and gas operators is impractical, the EIA has adopted sound statistical methods to impute data for those operators not sampled and for those data elements that smaller operators are not required to file. These methods are described in Appendix F.

Appendix G: Discussion of Reserve Estimation Techniques - Reserves are not measured directly. Reserves are estimated on the basis of the best geological, engineering, and economic data available to the estimator. Appendix G describes reserve estimation techniques commonly used by oil and gas field operators and EIA personnel when in the field performing quality assurance checks. A discussion of the relationship of reserves to overall U.S. oil and gas resources is also included.

Appendix H: Maps of Selected State Subdivisions - Certain large producing States have been subdivided into smaller regions to allow more specific reporting of reserves data. Maps of these States identifying the smaller regions are provided in Appendix H.

Appendix I: Annual Survey Forms of Domestic Oil and Gas Reserves - Samples of Form EIA-23 and Form EIA-64A are presented in Appendix I.

Glossary - Contains definitions of many of the technical terms used in this report.

3. Crude Oil Statistics

The United States had 22,351 million barrels of crude oil proved reserves as of December 31, 1995. This is 0.5 percent (106 million barrels) less than in 1994 and it is the eighth consecutive year that crude oil proved reserves have declined. However, reserve additions of crude oil replaced 95 percent of 1995 oil production (Figure 15), the best replacement rate in 8 years.

Figure 15. Reserve Additions Nearly Replace U.S. Oil Production in 1995

Source: Energy Information Administration, Office of Oil and Gas.

The three States with the largest oil reserves, Texas, Alaska, and California, all reported reductions in crude oil proved reserves in 1995. However, because of continued exploration and development of prospects in the Gulf of Mexico Federal Offshore (which contains the nation's fourth largest reserves of crude oil), the total decline for the United States in 1995 was the smallest since 1987 (crude oil proved reserves increased in 1987). The Gulf of Mexico Federal Offshore reported an 18 percent increase (391 million barrels) in crude oil proved reserves, which almost single-handedly outweighed the combined proved reserves losses of Alaska, California, and Texas.

Lower-48 States crude oil proved reserves increased for the first time in a decade—a 0.5 percent increase (81 million barrels) in 1995. The lower 48 States total was dominated by the increase in the Gulf of Mexico Federal Offshore. The last time the lower 48 States crude oil proved reserves increased was in 1985, when they increased 2 percent (477 million barrels). Meanwhile, Alaska's oil reserves decreased 3 percent (187 million barrels) in 1995.

Over the past decade, U.S. crude oil proved reserves have generally been declining (Figure 1, Chapter 2). Oil reserves have declined an average of over 2 percent per year. The 1995 decline (0.5 percent) is less than a quarter of the previous 10-year average.

In addition to 1995's success in the Gulf of Mexico Federal Offshore, there were also significant revisions and extensions for oil fields in Alaska and Texas—although not enough to exceed 1995 production and prevent a net loss of proved reserves in these States.

Proved Reserves

Table 6 presents the U.S. proved reserves of crude oil as of December 31, 1995, by selected States and State subdivisions.

Figure 16 maps the U.S. 1995 crude oil proved reserves by State. The following four areas account for 77 percent of U.S. crude oil proved reserves:

Area	Percent of U.S. Oil Reserves
Texas	26
Alaska	25
California	15
Gulf of Mexico Federal Offshore	11
Total	77

Of these four areas, the top three all experienced a decline in crude oil proved reserves during 1995, while the Gulf of Mexico Federal Offshore had an increase.

Source: Energy Information Administration, Office of Oil and Gas.

Discussion of Reserves Changes

Figure 17 maps the change in crude oil proved reserves from 1994 to 1995 by area. Here's how the top four areas fared, compared to the total United States:

Area	Change in U.S. Oil Reserves (million barrels)
Texas	-104
Alaska	-187
California	-111
Gulf of Mexico Federal Offshore	+391
Area Subtotal	-11
U.S. Total	-106

Figure 2 in Chapter 2 shows the components of the changes in crude oil proved reserves for 1995 and the preceding 10 years. These components are discussed below.

Total Discoveries

Total discoveries are those new reserves attributable to *extensions* of existing fields, *new field discoveries*, and *new reservoir discoveries in old fields*. They result from the drilling of exploratory wells.

Total discoveries of crude oil were 957 million barrels in 1995, the highest in a decade, and 67 percent higher than in 1994. Only four areas had *total discoveries* exceeding 35 million barrels:

- The Gulf of Mexico Federal Offshore had 577 million barrels of *total discoveries*, 60 percent of the National total.
- Texas had 151 million barrels of *total discoveries*, 16 percent of the National total.
- Alaska had 76 million barrels of *total discoveries*, 8 percent of the National total.
- New Mexico had 40 million barrels of *total discoveries*, 4 percent of the National total.

The United States discovered an average of 657 million barrels of new crude oil proved reserves per year in the prior 10 years (1985 through 1994). *Total discoveries* in 1995 were 146 percent of that average.

Extensions: Operators reported 500 million barrels of *extensions* in 1995. The highest volume of *extensions* was reported for the Gulf of Mexico Federal Offshore (175 million barrels). Second, Texas reported 134 million barrels of *extensions*, and 53 percent of them (71 million of 134 million barrels total) were in west Texas (Texas Railroad Commission (RRC) Districts 8 and 8A). Alaska

was third with 66 million barrels of *extensions*, followed by New Mexico with 35 million barrels. Despite its large share of U.S. oil reserves, only 11 million barrels of *extensions* were reported in California, where production is dominated by large, old fields and exploration has been restricted by environmental concerns. Over half of California's 1995 *extensions* (6 million barrels) were from the San Joaquin Basin Onshore region.

In the prior 10 years, U.S. operators reported an average of 447 million barrels of *extensions* per year. The 1995 *extensions* were 112 percent of that average.

New Field Discoveries: There were 114 million barrels of *new field discoveries* reported in 1995. Only nine areas in the United States reported any *new field discoveries*. Of these, only four contributed more than 1 percent to the total:

- Gulf of Mexico Federal Offshore (79 percent)
- North Dakota (8 percent)
- Texas (6 percent)
- New Mexico (3 percent).

The Gulf of Mexico Federal Offshore's *new field discoveries* provided 90 million barrels of crude oil proved reserves in 1995. In the prior 10 years, U.S. operators reported an average of 100 million barrels of reserves from *new field discoveries* per year. Reserves from *new field discoveries* in 1995 were 114 percent of that average.

New Reservoir Discoveries in Old Fields: Operators in the United States reported 343 million barrels of crude oil reserves from *new reservoir discoveries in old fields* in 1995. This is the highest level of discoveries of this type since 1977, when EIA started estimating reserves. The previous EIA high for *new reservoir discoveries in old fields* was 193 million barrels—set in 1982.

As with *new field discoveries*, the most significant portion of the *new reservoir discoveries in old fields* came from the Gulf of Mexico Federal Offshore—312 million barrels or 91 percent. Texas reported 10 million barrels, and Alaska reported 10 million barrels (3 percent each). In the prior 10 years, U.S. operators reported an average of 111 million barrels of reserves from *new reservoir discoveries in old fields* per year. Reserves from *new reservoir discoveries in old fields* in 1995 were 309 percent of that average.

Revisions and Adjustments

Thousands of positive and negative *revisions* to proved reserves occur each year as infill wells are drilled, well performance is analyzed, new technology is applied, or economic conditions change. *Adjustments* are the annual changes in the published reserve estimates that cannot be directly attributed to the estimates for other reserve change categories because of the survey and statistical estimation methods employed.

There were 1,150 million barrels of net *revisions and adjustments* for crude oil in 1995, somewhat less than the 1994 total of 1,196 million barrels. Average *revisions and adjustments* for the prior 10 years were 1,380 million barrels, and those for 1995 were only 83 percent of this average.

Production

U.S. production of crude oil in 1995 was 2,213 million barrels. This was 2 percent lower than 1994's total of 2,268 million barrels. U.S. crude oil production has declined in 9 of the last 10 years.

Areas of Note: Large Discoveries and Reserve Additions

The following State and area discussions summarize notable activities during 1995 concerning expected new field reserves, development plans, and possible production rates as reported in various trade publications. The citations do not necessarily reflect EIA's concurrence, but are considered important enough to be brought to the reader's attention.

The following areas are the major success stories for crude oil reserves and production for 1995.

Gulf of Mexico Federal Offshore

Projects in the Gulf of Mexico Federal Offshore were the biggest success stories for oil exploration during 1995. Most of the United States' crude oil reserve additions from *new field discoveries* (79 percent), and 91 percent of the additions from *new reservoir discoveries in old fields*, came from this area. The net increase of crude oil proved reserves in the region was 391 million barrels. The Gulf of Mexico produced about 292 million barrels of crude oil in 1995, an increase of 10 percent (27 million barrels) over 1994's production.

Operators Pursue More Deepwater Prospects: In 1995, just like in 1994, major U.S. operators allocated a great deal of their domestic resources evaluating and developing large prospects in the deepwater areas of the Gulf of Mexico. Deepwater activity in the Gulf of Mexico (beyond 600 feet of water depth) has intensified in recent years due to new and improved technology, particularly floating and subsea production systems. Enhanced geophysical technology, such as 3-D seismic surveying (see survey ship pictured on cover), lets operators efficiently target new prospects for drilling. The application of this technology in the Gulf of Mexico Federal Offshore is primarily responsible for 1995's record level of *new reservoir discoveries in old fields*.

Having completed its highly successful Auger project in 1994, Shell Oil Company is now increasing the peak daily production capacity of the platform to over 70,000 barrels of oil and 300 million cubic feet of gas per day{27}. Shell and its partners continued with development plans for the Ram/Powell and Mensa projects. Shell also began production operations at its Mars field in the summer of 1996.

Chasing Auger in oil production success, British Petroleum's Viosca Knoll 990 (Pompano) field produced 14,000 barrels of oil equivalents per day in 1995.{28} Phase two of its development, intended to raise Pompano's production to 60,000 barrels per day, included the installation of a ten-slot subsea drilling/production template in 1995.{29}

Oryx Energy Company and its partner Consolidated Natural Gas Corporation continued construction of the Neptune spar, a floating production system that will be the first of its kind in the Gulf of Mexico (Viosca Knoll 826 area, about 80 miles south of Mobile, Alabama). The Neptune spar, which will be operated by Oryx, will be completed in 1996. First production is anticipated early in 1997 with estimated peak production in the range of 24-30,000 barrels per day.{30}

Wasatch: Wasatch (sometimes referred to as Zodiac or Troika) is a Marathon Oil Company prospect in 2,672 feet of water on Green Canyon Blocks 200 and 244. An appraisal well in July 1995 extended this field 1.5 miles north from Green Canyon Block 244 into Block 200. The well was drilled to a total depth of 18,758 feet, and confirmed development potential of more than 100 million barrels of oil.{31}

Green Canyon Block 205: Chevron's first deep water project is the Green Canyon 205 field (rumored to be called the Genesis prospect) where the company plans

to install a floating drilling and production platform in 2,600 feet of water. The platform would be 100 miles offshore Louisiana.{32}

Ursa: In September 1995, Shell Exploration & Production Company formed a joint project team with co-venturers to begin final design of a tension-leg platform (TLP) to develop the Ursa prospect (Shell Oil interest 45.4 percent). The Ursa TLP will set a new world record for TLP water depth at approximately 3,950 feet in Mississippi Canyon Block 854. The TLP is expected to be installed in early 1999, with first production anticipated in mid-1999. Peak daily production is expected to be 150,000 barrels of oil and 400 million cubic feet of gas. Estimated gross ultimate recovery for Ursa is between 250 and 500 million barrels of crude oil equivalents.{33}

Mahogany: On April 17, 1995, Anadarko Petroleum Corporation and partners Phillips Petroleum Company and Amoco Production Company declared the Mahogany Field commercial. By December 1995, four wells were completed in the field, and a platform that began construction in May 1995 was installed in the summer of 1996. Peak daily production from the initial completions is expected to reach 22,000 barrels of oil and 30 million cubic feet of gas. Production is expected to increase as additional development wells are drilled and completed.

Milne Point Field, Alaska

Although Alaska's proved oil reserves declined 3 percent (187 million barrels), one field in Alaska increased its reserves dramatically—Milne Point field. British Petroleum (BP) acquired a 91 percent interest and began operating Milne Point Field in 1993. Production rates steadily increased to 29,000 barrels per day by the end of 1995. BP is currently completing a second stage of the expansion, the development of the North West Milne and Cascade discoveries, which will increase production to more than 50,000 barrels per day. These developments hold a total potential of around 100 million barrels of proved reserves.{34}

The Permian Basin

The Permian Basin in west Texas and eastern New Mexico was the most active area for crude oil development onshore in the lower 48 States. Enhancements in drilling technology, coupled with improved economics (from reductions in development

well costs and higher oil prices in the second half of 1995), caused increased operator activity.

Not taking into account reserves from other areas of Texas and New Mexico, Texas Railroad Commission Districts 8 and 8A and eastern New Mexico (the bulk of the Permian basin) contain 4.98 billion barrels of crude oil proved reserves. This is 77 percent of the crude oil reserves of both States. Operators in these three areas alone reported net reserve additions of 51 million barrels in 1995.

Operators in eastern New Mexico and Texas Railroad Commission Districts 8 and 8A in 1995 reported 40 percent more *total discoveries* of crude oil proved reserves than in 1994. Also, through infill drilling and the successful implementation (or expansion) of enhanced oil recovery methods, operators reported 44 percent more *revision increases* to crude oil proved reserves than in 1994. Similarly, due to improved economics, *revision decreases* in these same areas decreased 46 percent from 1994.

CO₂ Flooding Success Prompts Infrastructure Expansion: Amoco Production Company's Permian Basin business unit began a \$17.8 million drilling program to develop more carbon dioxide (CO₂) reserves on northeast New Mexico's Bravo Dome. Growing CO₂ demand for improved oil recovery projects in the Permian Basin prompted plans for the program. Amoco's 31-well drilling campaign aims to increase Bravo Dome's CO₂ flow by about 65 million cubic feet per day to a total of 400 million cubic feet per day.{35}

Wasson Field: Shell Western E&P Inc., in late June 1995, began injecting CO₂ in the first phase of an enhanced oil recovery program on the Bennett Ranch unit in Wasson field, Yoakum County, Texas. Shell installed eight injection patterns on a 140 acre tract within the unit. Each pattern included one injector and two to four production wells flanking each injector. Shell expects production from wells on this tract to jump to 1,400 barrels of oil per day from their current level of 400 barrels per day. The entire program calls for 32 injection patterns in a 540 acre area.{35}

South Cowden Field: Phillips Petroleum Company applied modern technology to save this mature oil field in west Texas. The South Cowden field, after 30 years, was nearing the end of economic production. Rather than abandon the field, Phillips will use horizontal injection wells to flood the reservoir with CO₂. This is

expected to triple production rates to a peak of 1,300 net barrels a day.[36]

Other Gain Areas

Wyoming: Wyoming's proved oil reserves increased by 40 million barrels. Although there were no new fields reported, several operators increased their reserves with *extensions and revisions and adjustments*.

Kansas: Kansas' proved oil reserves increased by 15 million barrels. There were no new fields of note—the boost was due to *extensions and revisions and adjustments*.

North Dakota: Operators in North Dakota found 9 million barrels of *new field discoveries* in 1995. This is the second highest amount of *new field discoveries* for an individual State in the lower 48 States, but is far behind the Gulf of Mexico Federal Offshore. North Dakota's proved oil reserves increased by 7 million barrels.

Areas of Note: Large Reserve Declines

The following areas had large declines in crude oil proved reserves due to *revision decreases* or unreplaced production. These deducted 503 million barrels of crude oil proved reserves from the U.S. total.

Alaska

Alaska's proved oil reserves declined by 187 million barrels in 1995—the greatest decline of any State in 1995. Alaska's 1995 production was 540 million barrels, which was 31 million less than what Alaska produced in 1994.

Prudhoe Bay field: Prudhoe Bay Field, the largest producing oil field in the United States, installed additional production equipment in late 1994. The new equipment allowed operators to produce an additional 100,000 barrels per day of liquids. Prudhoe Bay Field had a large net decline of crude oil proved reserves in 1995.

California

California's proved oil reserves decreased by 111 million barrels. The largest decline was in the San Joaquin Basin Onshore, home of California's "heavy oil" fields. This region's reserves declined by 70 million

barrels. California's production also declined by about 3 percent from 1994's level.

Drilling off the California coast was stymied when the moratorium that blocks offshore drilling in Federal waters was continued for parts of Alaska, Washington, Oregon, California, Florida, and the eastern Atlantic coast.[37] Near Santa Barbara, four platforms owned by Chevron, "Hilda", "Hazel", "Hope" and "Heidi", which had been shut-in for 2 years, were contracted in March for removal by yearend 1995.[38]

Texas

Texas' proved oil reserves declined by 104 million barrels in 1995. Texas' production also declined almost 8 percent from 1994 levels. The largest reserves decline (63 million barrels) was in RRC District 3 Onshore. In this district, revisions and extensions were exceeded by production. Other areas where oil reserves significantly decreased were RRC District 7B (19 million barrels), and RRC District 7C (17 million barrels).

These declines were counterbalanced somewhat by reserves increases in other RRC Districts. In Texas' Permian Basin (RRC Districts 8 and 8A) a net of 40 million barrels of proved reserves were added.

Other Decline Areas

In the following areas of the United States, development of existing or new oil fields was outpaced by crude oil production, which remained at roughly the same level as the previous year.

Pacific Federal Offshore: This region's proved oil reserves decreased by 13 percent (82 million barrels).

Colorado: This State's proved oil reserves decreased by 7 percent (19 million barrels).

Reserves in Nonproducing Reservoirs

Not all proved reserves of crude oil were contained in reservoirs that were producing. Operators reported 3,563 million barrels of proved reserves in nonproducing reservoirs. This is 31 percent more than reported in 1994 (2,727 million barrels).

The reasons for the nonproducing status of these proved reserves are not collected by the EIA. However, previous surveys showed that most of the wells or

reservoirs were not producing for operational reasons. These included waiting for well workovers, drilling additional development or replacement wells, installing production or pipeline facilities, and awaiting depletion of other zones or reservoirs before recompletion in reservoirs not currently open to production.

Indicated Additional Reserves

In addition to proved reserves of crude oil, Category I and Category II operators estimate the quantities of

crude oil, other than proved reserves, that may become economically recoverable from known reservoirs through the application of improved recovery techniques using current technology. The 1995 volume, 2,669 million barrels, is about 15 percent less than was reported in 1994 (3,151 million barrels).

Table 7 lists the indicated additional reserves by selected States and State subdivisions. The presence of large indicated additional reserves in Alaska, California, south Louisiana and west Texas implies that significant *revision increases* to proved crude oil reserves could occur in the future.

4. Natural Gas Statistics

Dry Natural Gas

Proved Reserves

The Nation's proved reserves of dry natural gas were 165,146 billion cubic feet, 0.8 percent (1,309 billion cubic feet) more than in 1994 (Table 8), continuing the growth of the previous year. As a result of the consecutive increases, gas reserves now stand about 3 trillion cubic feet above the 1993 total. Additions to reserves replaced 107 percent of gas production in 1995 (Figure 18). These additions are attributed to both higher *revisions and adjustments* to total reserve estimates of old fields, and to discoveries, including field *extensions, new field discoveries, and new reservoir discoveries in old fields.*

U.S. proved reserves of dry natural gas increased in 1995, for the second year in a row. However, there was a drop in one important component. *Total discoveries* were down from their high 1994 level, but still 14 percent higher than the prior 10-year average. Over two-thirds of the *total discoveries* were in Texas and the

Gulf of Mexico Federal Offshore, where improved exploration and deepwater production technologies enhanced the ability to discover and develop offshore fields.

Technological advances will continue to spur offshore development. For example, Shell Oil Company plans to install a tension leg platform (TLP) to develop its *Prospect Ursa* in the Gulf of Mexico. This TLP will set a new world record at a water depth of approximately 3,950 feet.

The volumetric differences between the estimates reported in Table 8 (dry) and Table 9 (wet) are due to the removal of natural gas liquids at natural gas processing plants. All natural gas proved reserves data in this report exclude natural gas held in underground storage.

Of the top five areas for reserves, which account for 65 percent of the reserves, all had increases except Oklahoma, which had a small decline. Proved reserves by State are shown on the map in Figure 19.

Figure 18. Reserve Additions Exceed U.S. Natural Gas Production 2 Years in a Row

Source: Energy Information Administration, Office of Oil and Gas.

Area	Percent of U.S. Gas Reserves
Texas	22
Gulf of Mexico Federal Offshore	17
New Mexico	11
Oklahoma	8
Wyoming	7
Total	65

Changes in 1995 to the reserves are shown by State on the map in Figure 20. Notable increases are those that occurred in Wyoming (1,287 billion cubic feet), Texas (568 billion cubic feet), the Gulf of Mexico Federal Offshore (699 billion cubic feet), and Colorado (503 billion cubic feet). Lower 48 States gas reserves have been generally declining since natural gas prices peaked in 1983, but lower 48 States gas reserves were up 1 percent (1,545 billion cubic feet) in 1995.

Revisions

Revisions and adjustments were up in 1995. The net volume of *revisions and adjustments* to reserves played a significant role in increasing U.S. natural gas proved reserves. It amounted to 8,314 billion cubic feet in 1995, a 12 percent increase over 1994. Successful infill drilling

^aIncludes Federal offshore Alabama.

^bIncludes Arizona, Illinois, Indiana, Maryland, Missouri, Nebraska, Nevada, Oregon, South Dakota, and Tennessee.

^cIndicates the estimate is associated with a sampling error (95 percent confidence interval) that exceeds 20 percent of the estimated value.

Note: The production estimates in this table are based on data reported on Form EIA-23. They may differ from the official Energy Information Administration production data for natural gas for 1995 contained in the *Natural Gas Annual 1995*, DOE/EIA-0131(95).

Source: Energy Information Administration, Office of Oil and Gas.

in existing fields played a major role. Wyoming had the largest increase in *revisions and adjustments*. These included proved undeveloped methane reserves in deep Paleozoic formations in the Big Piney area of 1,287 billion cubic feet. Additional carbon dioxide processing facilities will have to be brought on-line prior to the production.

Discoveries

Total discoveries were down from 1994. The last time that gas reserves increased for two years in a row was in 1967. *Total discoveries* are those reserves attributable to field extensions, new field discoveries, and new reservoir discoveries in old fields; they result from drilling exploratory wells. *Total discoveries* of dry natural gas reserves were 10,961 billion cubic feet, a decrease of 11 percent (1,354 billion cubic feet) from the very high level reported in 1994. These *total discoveries* are equivalent to 61 percent of the level of 1995 gas production. About one-half of the *total discoveries* were in the Gulf of Mexico Federal Offshore and south Texas (RRC District 4). Other areas with large volumes were the rest of Texas (18 percent), Louisiana (9 percent), Oklahoma (7 percent), and New Mexico (6 percent). *New field discoveries* (1,666 billion cubic feet) were 12 percent lower than in 1994. Those areas with the largest *new field discoveries* were the Gulf of Mexico Federal Offshore (with 70 percent of the total), Texas (16 percent), and Colorado (5 percent).

New reservoir discoveries in old fields were 2,452 billion cubic feet, 30 percent lower than 1994. Among the areas with the largest *new reservoir discoveries in old fields* were the Gulf of Mexico Federal Offshore (68 percent), Texas (11 percent), and Louisiana (10 percent). The Louisiana portion of the Gulf of Mexico Federal Offshore accounted for 57 percent of the *new reservoir discoveries in old fields*. *Extensions* were 6,843 billion cubic feet, 1 percent lower than in 1994. Areas with the largest *extensions* were Texas (37 percent), the Gulf of Mexico Federal Offshore (23 percent), Oklahoma (10 percent), New Mexico (9 percent), and Louisiana (9 percent).

Production

Dry natural gas production decreased 1 percent in 1995 (Table 8). This ended the trend of increasing gas production since 1981. Of the five leading producing areas in 1995, only New Mexico increased production. This increase was primarily the result of coalbed methane production in the San Juan basin. As in 1994,

the Gulf of Mexico Federal Offshore and Texas, each with over one-fourth of the U.S. total, were the leading producers of dry natural gas in 1995. The next three States combined, Oklahoma (9 percent), Louisiana (8 percent), and New Mexico (8 percent) contributed another one-fourth of the production.

Wet Natural Gas

U.S. proved reserves of wet natural gas, as of December 31, 1995, were 173,476 billion cubic feet, an increase of 1 percent (1,537 billion cubic feet), from that reported in 1994 (Table 9). Proved wet natural gas reserves for the lower 48 States were higher by 1 percent (1,775 billion cubic feet) than in 1994, while those of Alaska decreased by 238 billion cubic feet.

Nonassociated Natural Gas

Proved Reserves

U.S. proved reserves of nonassociated (NA) natural gas, wet after lease separation, of 142,679 billion cubic feet increased one percent (1,140 billion cubic feet) in 1995 (Table 10). This increase was for the second year in a row. Lower 48 States NA wet natural gas proved reserves increased by 1,156 billion cubic feet, or 0.8 percent. Those areas with the largest increases in NA wet natural gas reserves were Wyoming, Texas, and Colorado. There were large decreases in NA wet natural gas reserves in Kansas and Louisiana South Onshore.

Discoveries

NA wet natural gas *total discoveries* of 9,692 billion cubic feet represented a decrease of 14 percent (1,572 billion cubic feet) in 1995. The Gulf of Mexico Federal Offshore, Texas, Louisiana, and Oklahoma accounted for 8,009 billion cubic feet or 83 percent of U.S. NA wet natural gas *total discoveries* in 1995.

Production

U.S. production of NA wet natural gas decreased by 2 percent (315 billion cubic feet) in 1995 (Table 10). This ended the trend of increasing NA gas production since 1986. As in 1994, the Gulf of Mexico Federal Offshore and Texas, each with over one-fourth of the U.S. total, were the leading producers of dry natural gas in 1995.

^bIncludes Arizona, Illinois, Indiana, Maryland, Missouri, Nebraska, Nevada, Oregon, South Dakota, and Tennessee.

Note: The production estimates in this table are based on data reported on Form EIA-23, "Annual Survey of Domestic Oil and Gas Reserves." They may differ from the official Energy Information Administration production data for natural gas for 1995 contained in the *Natural Gas Annual 1995*, DOE/EIA-0131(95).

Source: Energy Information Administration, Office of Oil and Gas.

Associated-Dissolved Natural Gas

Proved Reserves

U.S. proved reserves of associated-dissolved (AD) natural gas, wet after lease separation, increased by 1.3 percent in 1995 to 30,797 billion cubic feet (Table 11). Lower 48 States proved reserves of AD wet natural gas increased by 619 billion cubic feet to 24,532 billion cubic feet. Those areas of the country with the largest AD wet natural gas reserves were Texas (25 percent), the Gulf of Mexico Federal Offshore (20 percent), Alaska (20 percent), New Mexico (5 percent), and California (5 percent). These areas logically correspond to the areas of the country with the largest volumes of crude oil reserves and production.

Production

U.S. production of AD wet natural gas decreased by 1 percent (21 billion cubic feet) in 1995 (Table 11). Production of AD wet natural gas in the lower 48 States decreased slightly, by 4 billion cubic feet to 2,650 billion cubic feet. Declines in Texas production were essentially replaced by increases in the Gulf of Mexico Federal Offshore.

Coalbed Methane

Proved Reserves

Reserves of coalbed methane resumed their growth, more than replacing the decline of 1994 and accounting for over 6 percent of 1995 natural gas reserves (Table 12). Federal tax incentives for new coalbed methane wells expired at the end of 1992. Reserves in coalbed methane fields increased to 10,499 billion cubic feet, 8 percent more than in 1994. The EIA estimates that the 1995 proved gas reserves of fields identified as having coalbed methane are now about double those reported only 5 years ago (Figure 21). Coalbed methane proved reserves are principally in New Mexico, Colorado, Alabama, and Virginia. Estimates of proved coalbed methane reserves increased in all except Alabama in 1995. The coalbed methane volumes are a subset of the volumes reported in Tables 8, 9, 10, 11, and 13.

Production

Coalbed methane production grew by more than 12 percent in 1995. Most of the increase occurred in the San

Figure 21. Coalbed Methane Proved Reserves 1989-1995

Source: Energy Information Administration, Office of Oil and Gas.

Juan basin of Colorado and New Mexico. Coalbed methane production in 1991 represented about 2 percent of the Nation's total dry gas production, by 1995, this proportion grew to over 5 percent. When the Federal tax incentive to spud coalbed methane wells expired at year-end 1992, companies that had positioned themselves to take advantage of the credit began to concentrate on building production from qualified wells. As a result, much of the Basin's upstream activity in 1994 and 1995 involved operators consolidating their coalbed methane portfolios, completing wells spudded in previous years, installing surface production equipment, and laying gathering systems.

Areas of Note

The following State and area discussions summarize notable activities during the year concerning expected new field reserves, development plans, and possible production rates. These are largely based on information from various trade publications and company reports. The citations do not necessarily reflect EIA's concurrence, but are considered important enough to be brought to the reader's attention.

Gulf of Mexico

Deep Water: Advances in 3-D seismic technology and previous deepwater successes have encouraged the oil and gas industry to search and drill for hydrocarbons farther offshore. Deepwater drilling in the Outer

Continental Shelf (OCS) of the Gulf of Mexico has greatly increased these last few years, and production from deepwater reservoirs is increasing. As of December 31, 1995 the Minerals Management Service (MMS) reported that 12 fields in water depths of over 976 feet were producing: Ewing Banks 914 (Seattle Slew), Garden Banks 387 (Cooper), Garden Banks 426 (Auger), Green Canyon 65 (Bullwinkle), Green Canyon 136 (Shasta), Green Canyon 184 (Joliet), Mississippi Canyon 109 (Amberjack), Mississippi Canyon 194 (Cognac), Mississippi Canyon 281 (Lena), Mississippi Canyon 354 (Zinc), Mississippi Canyon 397 (Alabaster), Mississippi Canyon 445, Viosca Knoll 783 (Tahoe), Viosca Knoll 862, Viosca Knoll 990 (Pompano). There were 46 deepwater discoveries in the Gulf of Mexico as of April 1996. At present, there are five types of deepwater development and production systems used in the Gulf of Mexico: fixed platforms, compliant towers, floating production systems, tension leg platforms (TLP), and subsea systems.[39]

In April 1996, there were as many as 17 deepwater rigs drilling in Gulf of Mexico water depths greater than 1,000 feet (305 meters) as opposed to 9 rigs in 1990. In Gulf waters over 1,000 feet, there are 11 permanent production systems in place. Of these, eight are platforms and three are subsea systems.

To date, there are 98 fields (69-active, 29-expired) in the Gulf in waters greater than 656 feet (200 meters) deep. Seventy-two (45 active, 27 expired) of these are in waters greater than 1,000 feet. MMS classifies these fields as qualified fields prospects that may not be economically viable to invest in beyond exploratory drilling. Of these, only 20 are classified as fields with proven reserves by the MMS.[40]

First production from Prospect Popeye occurred in early January 1996, from two subsea wells. The Popeye field produced at an average rate of 90 million cubic feet

of natural gas per day in January. Gross ultimate recovery from the first phase of Popeye is estimated at 200 billion cubic feet of natural gas and 7 million barrels of condensate. A second phase of development, if undertaken after review of results from phase one, could raise gross ultimate recovery to 320 billion cubic feet of natural gas and 10 million barrels of condensate.[41]

"Plans to develop Prospect Mensa in a world record water depth of 5,400 feet were announced in May 1995. Gross ultimate recovery from Mensa is estimated at 720 billion cubic feet of natural gas. Initial production from Mensa is targeted for late 1997, with peak production of 300 million cubic feet of natural gas per day occurring shortly thereafter. Mensa will be a subsea development, with up to 4 wells located on the sea floor with flowlines connecting to a conventional platform some 68 miles away in shallower water." [41]

"In September 1995, Shell Oil announced formation of a joint project team with co-venturers to begin final design for a TLP to develop Prospect Ursa. The Ursa TLP, which will set a new world record for TLP water depth at approximately 3,950 feet, is expected to be installed in early 1999, with first production anticipated in mid 1999. Anticipated peak daily production is expected to be 150,000 barrels of oil and 400 million cubic feet of gas. Gross ultimate recovery for Ursa is estimated to be between 250 and 500 million barrels of crude oil equivalents." [41]

In 1994, the High Island A-576 block discovery well encountered 168 feet of net pay in the Lower Pleistocene sands. The well is located 110 miles off the Texas coast in 290 feet of water. This development, the Sherman Project, began production in December 1995. Peak production was 7 thousand equivalent barrels per day.[42]

The four-block High Island 384 unit (Patton Project) is located approximately 112 miles off the Texas coast in water averaging 360 feet. In the early part of 1994, the discovery well encountered 80 feet of net pay. Production in January 1995 and in September achieved the expected peak rate of 20 thousand oil equivalent barrels per day. Late in 1995, the No. 3 High Island 385 well encountered 158 feet of net gas pay. Further delineation wells found the same pay interval in nearby fault blocks. First production from phase II development is expected by the fourth quarter of 1996 with gross peak gas production estimated to be 30-40 million cubic feet per day.{42}

Garden Banks Block 127/128 (Prospect Enchilada) is a subsalt natural gas discovery. The field should begin production in 1997, with peak gas rates estimated at 250 to 300 million cubic feet per day in 1998.{43}

Natural gas production began in mid-year 1995 from the Seastar field, in the Garden Banks area. A development plan utilizing subsea well completions is being used. Natural gas production averaged 60 million cubic feet per day in December 1995.{44}

At a water depth of 850 feet, Shasta Prospect in the Green Canyon area incorporates production equipment installed on the sea floor that links a number of production wells. This technology eliminates the need for multiple producing platforms. Shasta is producing 58 million cubic feet of gas a day.{45}

Texas

South Texas: Operators remain active in the Lobo Trend in the lower Rio Grande Valley of south Texas (Railroad Commission District 4). The Lobo Trend occurs primarily in Webb and Zapata counties and has four producing horizons, (Wilcox, Expanded Wilcox, Frio, and Lobo). Unlike some other parts of the country, no one or two fields dominate the area. However, the top five fields based on reported reserves (Bob West, McAllen Ranch, Tordilla, Laredo, and Cuba Libre), account for about one-fifth of the production and reserves in the District. This District has 21 percent of Texas dry natural gas reserves.

East Texas: The top five fields based on reserves (Carthage, Oak Hill, Willow Springs, Whelan, and Hawkins) account for about one-half of the production and for over one-half of the reserves of total gas in

reported in Railroad Commission District 6. This District has 16 percent of Texas dry natural gas reserves.

West Texas: The top five fields based on reserves (Gomez, Spraberry Trend Area, Keystone, Sugg Ranch, and Puckett) reported over one-fourth of the production and over one-third of the reserves in West Texas (Railroad Commission District 8). This District has 15 percent of Texas dry natural gas reserves.

Panhandle: Two fields (Panhandle West and Texas Hugoton) reported more than one-third of the production and about one-half the reserves in the Panhandle (Railroad Commission District 10) of Texas. This District has 12 percent of Texas dry natural gas reserves.

Mid Continent

Kansas: Two fields (Hugoton and Panoma Gas Area) reported about four-fifths of the production and about nine-tenths of the total reserves of gas in Kansas.

Oklahoma: The top five fields, based on reserves, (Red Oak-Norris, Guymon-Hugoton Gas Area, Mocane-Laverne Gas Area, Strong City District, and Watonga-Chickasha Trend) accounted for about one-fourth of the production and about one-third the reserves of the total gas in Oklahoma.

Rockies

Colorado: The top five fields, based on reserves, (Wattenburg, Ignacio-Blanco, Rulison, Grand Valley, and Dragon Trail) accounted for over one-third of the production and the reserves of the total gas in Colorado. Strong coalbed methane activity in the area helped increase production and reserves.

New Mexico: Two fields (Basin and Blanco) reported about one-fourth of the production and about one-half of the total reserves of gas in New Mexico.

Wyoming: The top five fields, based on reserves, (Big Piney-LaBarge, Whitney Canyon-Carter Creek, Lake Ridge, Fogarty Creek, and Madden) accounted for about one-fifth of the production and over one-third the total reserves of gas in Wyoming. The major gas story in Wyoming was the Big Piney-LaBarge field where large *revision increases* were responsible for making the field the largest in the State.

Reserves in Nonproducing Reservoirs

Proved natural gas reserves, wet after lease separation, of 33,676 billion cubic feet were reported in nonproducing reservoirs in 1995 (Table 13). This was 2,958 billion cubic feet or about 10 percent higher than in 1994. Two areas, Wyoming and the Gulf of Mexico Federal Offshore, accounted for 84 percent of the increase. About 42 percent of the reserves in nonproducing reservoirs are located in the Gulf of Mexico Federal Offshore area. Much of the new deepwater reserves are presently in the nonproducing

category. Proved reserves in nonproducing reservoirs were reported by Category I and II operators, who collectively account for about 93 percent of the estimated total wet natural gas production in the United States. The reasons for the nonproducing status of these proved reserves were not collected by EIA in 1995. However, past surveys showed that most of the wells or reservoirs were not producing for operational reasons. These included waiting for well workovers, drilling additional development or replacement wells, installing production or pipeline facilities, and awaiting depletion of other zones or reservoirs before recompletion in reservoirs not currently open to production.

5. Natural Gas Liquids Statistics

Natural Gas Liquids

Proved Reserves

U.S. natural gas liquids proved reserves increased 3 percent to 7,399 million barrels in 1995 (Table 14). This was the first increase in reserves since 1988. The 229 million barrel increase occurred predominantly in the lower 48 States, which increased to 7,093 million barrels in 1995. This was also the first increase in lower 48 States reserves since 1988. Overall, reserve additions replaced 129 percent of 1995 natural gas liquids production. Reserve additions from the Louisiana South Onshore and Texas more than compensated for those States with proved reserve losses. The reserves of six areas account for 81 percent of the Nation's natural gas liquids proved reserves. Of these, Texas had 34 percent, New Mexico had 13 percent, Oklahoma had 9 percent, and the Gulf of Mexico Federal Offshore, Louisiana, and Utah-Wyoming had about 8 percent each. The volumes of natural gas liquids proved reserves and production shown in Table 14 are the sum of the natural gas plant liquid volumes listed in Table 15 and the lease condensate volumes listed in Table 16. From 1985 through 1995, reserves of natural gas liquids have declined less than 1 percent per year whereas crude oil reserves have declined over 2 percent per year.

Discoveries

Total discoveries of natural gas liquids reserves increased by 10 percent in 1995 to 551 million barrels, the highest level since 1982. Areas with the largest *total discoveries* were Texas (33 percent), the Gulf of Mexico Federal Offshore (29 percent), Louisiana (16 percent), Oklahoma (7 percent), and New Mexico (6 percent). *New field discoveries*, at 52 million barrels, were 2 million barrels less than in 1994. Areas with the largest *new field discoveries* were the Gulf of Mexico Federal Offshore (48 percent), Texas (33 percent), and Louisiana (12 percent). *New reservoir discoveries in old fields*, at 67 million barrels, were half what they were in 1994. Areas with the largest *new reservoir discoveries in old fields* were the Gulf of Mexico Federal Offshore (45 percent), Louisiana (27 percent), and Texas (19 percent). *Extensions* were 432 million barrels, an increase of 38 percent over 1994. Areas with the largest *extensions* were Texas (35 percent), the Gulf of Mexico Federal Offshore (25 percent), Louisiana (15 percent), Oklahoma (8 percent), New Mexico (7 percent), and Colorado (4 percent).

Production

Natural gas liquids production remained at 791 million barrels in 1995. Alaska production increased 15 percent to 30 million barrels in 1995, while lower 48 States production declined 1 percent to 761 million barrels. Five areas accounted for about 80 percent of the Nation's natural gas liquids production. Of these, Texas had 39 percent, Louisiana had 12 percent, the Gulf of Mexico Federal Offshore had 11 percent, Oklahoma had 10 percent, and New Mexico had 8 percent.

Natural Gas Plant Liquids

Proved Reserves

Natural gas plant liquids proved reserves increased 3 percent in 1995 to 6,202 million barrels (Table 15). Five areas accounted for about 76 percent of the Nation's natural gas plant liquids proved reserves: Texas (37 percent), New Mexico (14 percent), Oklahoma (10 percent), Utah-Wyoming (8 percent), and Louisiana (7 percent). The level of natural gas plant liquids reserves depends on both the volume of natural gas reserves and the amount of plant liquids that can be extracted per cubic foot from them. In 1995, more liquids were extracted per cubic foot of gas production than in 1994. Therefore, the ratio of liquids reserves to natural gas reserves increased, leading to a larger percentage increase in proved reserves of natural gas plant liquids than in natural gas reserves.

Production

Natural gas plant liquids production increased 2 percent to 646 million barrels in 1995 (Table 15). Five areas accounted for about 78 percent of the Nation's natural gas plant liquids production: Texas (41 percent), Oklahoma (11 percent), Louisiana (11 percent), New Mexico (9 percent), and Utah-Wyoming (6 percent). Of the 16.9 trillion cubic feet of natural gas processed in 1995, about 16.5 trillion cubic feet was both produced and processed in the same State (Table E4, Appendix E). Natural gas processing plants are usually located in the same general area where the natural gas is produced.

According to the State of Alaska, production of natural gas from the Prudhoe Bay Field increased in 1995 to 2.6 trillion cubic feet, 13 percent over 1994.{46}

Lease Condensate

Proved Reserves

Proved reserves of lease condensate in the United States were 1,197 million barrels in 1995 (Table 16). This was 50 million barrels or 4 percent higher than in 1994. The reserves of four areas account for about 77 percent of the Nation's lease condensate proved reserves. Of these, the Gulf of Mexico Federal Offshore had 34 percent, Texas had 21 percent, Louisiana had 14 percent, and Utah-Wyoming had 8 percent.

Production

Production of lease condensate was 145 million barrels, a decrease of 12 million barrels, or 8 percent, in 1995. The production from four areas accounts for about 84 percent of the Nation's lease condensate production. Of

these, the Gulf of Mexico Federal Offshore had 34 percent, Texas had 26 percent, Louisiana had 18 percent, and Utah-Wyoming had 6 percent.

Reserves in Nonproducing Reservoirs

Like crude oil and natural gas, not all lease condensate proved reserves were contained in reservoirs that were producing during 1995. Proved reserves of 440 million barrels of lease condensate, an increase of 33 percent from 1994, were reported in nonproducing reservoirs in 1995. These reserves were reported by Category I and Category II operators who collectively accounted for more than 97 percent of total lease condensate production. About 56 percent of the nonproducing lease condensate reserves were located in the Gulf of Mexico Federal Offshore.

Appendix A

Operator Data by Size Class

Operator Data by Size Class

To remain competitive in the domestic industry, companies have to reduce costs and look for areas of profitable growth. Over the past few years, we have seen companies restructure to focus on their core areas of profit. This restructuring has taken many forms, for example, laying off employees, early retirements and buyouts, flattening management structure, selective sales of marginally profitable properties, and acquisitions. Documenting some of these changes is important. Appendix A contains tables of the proved reserves and production of the top 2,500 oil and gas well operators by production size class for the years 1990 through 1995. The tables show the volumetric change and percent change from the previous year and from 1990. In addition they show the 1995 average per operator in each class. All companies operating in the United States that reported to EIA were ranked by production size for each of the six years. We computed company production size classes as the sum of the barrel oil equivalent of the crude oil production, lease condensate production, and wet gas production for each operator. The companies were then placed in the following production size classes: 1-10, 11-20, 21-100, 101-500, 501-2,500, and all "other" oil and gas operators. The "other" category contains 18,792 small operators. We estimate production and reserves of small operators each year from a sample of approximately 8 percent of these operators.

Class 1-10 contains the 10 highest producing companies each year on a barrel oil equivalent basis. These companies are not necessarily the same 10 companies each year. For example in 1994 an operator moved from the 11-20 production size class to the 1-10 class, displacing an operator from the group that had been there since 1991. Most of the apparent changes in these two size classes resulted from the movement of operators from size class to size class.

We also include statistics for operator Category sizes at the bottom portion of tables in this appendix. These are the categories used by EIA in processing and assessing reserves surveys and are presented here as additional perspective. For further explanation of categories sizes see definitions and descriptions in Appendix E.

Natural Gas

Proved Reserves

The wet natural gas proved reserves reported for 1990 through 1995 have decreased from 177.6 trillion cubic feet to 173.5 trillion cubic feet (Table A1) a 3 percent decrease. Reserves have increased for the last two years in a row and are back to the 1993 level. These back to back increases are the first in the last 28 years. These proved reserves are highly concentrated in the larger companies. Although not as highly concentrated as oil reserves, in 1995, the top 20 (Class 1-10 and Class 11-20) producing companies had 58 percent of the proved reserves of natural gas. The next two size classes contain 80 and 400 companies and account for 25 and 12 percent of the U.S. natural gas proved reserves, respectively. On average, a company in the top 20 production size class has more than 30,000 times the wet natural gas reserves as the average operator in the "other" class of small operators. The top 20 operators had a decline of 7 percent in their natural gas proved reserves from 1990 to 1995. While the rest of the operators (Class 21-100, Class 101-500, Class 501-2,500, and Class Other) had an increase of 3 percent. In 1995, the top 20 operators' natural gas reserves increased by 1 percent. In addition in 1995, the rest of the operators had an increase of 3 percent.

Production

Wet natural gas production reported from 1990 through 1995 has steadily increased from 18.0 trillion cubic feet to 18.9 trillion cubic feet (Table A2) an increase of 5 percent. In 1995, the top 20 producing companies had 54 percent of the production of natural gas, while having 58 percent of the proved reserves. The next two size classes have 26 and 13 percent of the gas production, respectively. The average top 20 company has more than 20,000 times the wet gas production as the average operator in the "other" class of small operators. The top 20 operators had an increase of 6 percent in their natural gas production from 1990 to 1995. The rest of the operators had an increase of 3 percent from 1990 to 1995. The top 20 operators' wet

natural gas production remained the same as 1994, while the rest of the operators had a decrease of 4 percent, in 1995 from 1994.

Crude Oil

Proved Reserves

Proved reserves of crude oil are more highly concentrated in a few companies than those of natural gas. The 20 largest oil and gas producing companies in 1995 had 73 percent of U.S. proved reserves of crude oil (Table A3), in contrast to wet natural gas where these same companies operated only 58 percent of the total proved reserves. The average top 20 company had more than 21,000 times the oil reserves as the average operator in the "other" category. These companies have tended in the past few years to concentrate their domestic operations in fewer fields and focus more of their resources on their foreign operations.

U.S. proved reserves of crude oil declined 0.5 percent in 1995. The top 20 producing companies had a decline of 2 percent in their domestic proved reserves of crude oil during 1995. The top 20 class had a decline of 21 percent in their crude oil proved reserves from 1990 to 1995. The next two size classes account for 12 and 8 percent of the U.S. crude oil proved reserves, respectively. The rest of the operators had a 5 percent increase from 1990 to 1995. A portion of this increase came from property acquisitions. During the 1990-1995 period, many operators were actively buying, selling, and restructuring their oil property positions.

Production

Crude oil production reported for 1990 through 1995 has decreased from 2.5 billion barrels to 2.2 billion barrels (Table A4). The 20 largest oil and gas producing companies had 67 percent of U.S. production of crude oil, or 1.5 billion barrels, in 1995, while in 1990 they accounted for 71 percent of production. This is in contrast to wet natural gas where these same companies produced only 54 percent of the total. The average "top 20" operator had more than 12,000 times the oil production of the average operator in the "other" class.

U.S. production of crude oil declined by 12 percent from 1990 to 1995. The top 20 operators had a decline of 21 percent in their oil production during the same period. U.S. production of crude oil declined by 2 percent from 1994 to 1995, while the top 20 operators production increased by 2 percent. The next two size classes account for 13 and 9 percent of the U.S. crude oil production, respectively.

Fields

The number of fields in which Category I and Category II operators were active dropped significantly during the 1990-1995 period. From 1990 through 1995, fields in which these large operators were active dropped by 4,089 or 14 percent (Table A5). The trend continued in 1995 with a 2 percent decline. Most of the changes in operator field counts resulted from the top 20 operators class concentrating their effort in a diminishing number of fields. From 1990 through 1995, the number of fields in which the top 20 operators were active in dropped by 3,442 or 37 percent, while in 1995 the number dropped 3 percent.

Table A1. Natural Gas Proved Reserves, Wet After Lease Separation, by Operator Production Size Class, 1990-1995
(Billion Cubic Feet at 14.73 psia and 60° Fahrenheit)

Appendix B

Top 100 Oil and Gas Fields for 1993

Top 100 Oil and Gas Fields for 1993

The data in Appendix B was not updated for this year's report because resource restraints prevented the timely updating of the necessary field files. Updates will be provided in future reports.

Estimates of the proved reserves, cumulative production, and ultimate recovery of the top 100 oil and gas fields are contained in Tables B1 and B2 of this Appendix. The oil field production and reserves data include both crude oil and lease condensate. The gas field production and reserves data is wet gas, after lease separation.

The top 100 oil fields in the United States as of December 31, 1993, had 15,914.9 million barrels of proved reserves accounting for 66 percent of the total United States (Table B1). For the top 100 oil fields, this is a decrease of 2.8 percent from 1992. Although there is considerable grouping of field-level statistics within the tables, rough orders of magnitude can be estimated for the proved reserves, cumulative production, and ultimate recovery of most fields. Many fields in the top 100 groups are operated by only one or two operators, therefore, the totals for proved reserves are grouped as top 10, top 20, top 50, and top 100 to avoid revealing company proprietary data. In the top 20 oil fields for 1993 there is only one newcomer, Mississippi Canyon Block 807, the Mars prospect, in the Gulf of Mexico Federal Offshore. This field displaced the Rangely field in Colorado from the top 20 fields in terms of reserves. The top 100 oil fields in the United States as of December 31, 1993, had 1,340.5 million barrels of production or 54 percent of the total (Table B1). For the top 100 oil fields, this is a decrease of 5 percent from 1992. These are approximately the same percentages of reserves and production as in the 1993 annual report.

The top 100 gas fields in the United States as of December 31, 1993, had 80,769.9 billion cubic feet of proved reserves or 47 percent of the total (Table B2). For the top 100 gas fields, this is only a decrease of 0.9 percent from 1992. Unlike the oil fields, the top 100 gas fields show a lesser degree of concentration. Many, but not all, of the same fields are in both tables. As an example, the top three gas fields, Basin, Hugoton Gas Area, and Blanco, are not found in the oil table. Unlike the top 20 in the oil table there was shifting in the rank of the gas fields, most notable was the addition of the

Mobile Bay of Alabama to the top 10 which dropped the Elk Hills field in California into the next ranking group. The Mobile Bay field is a combination of the North Central Gulf and Northwest Gulf fields which were reported separately in the previous report. In the 11-20 group there were three new fields added, Oakwood in Virginia, Whitney Canyon-Carter Creek in Wyoming, and Cook Inlet North in Alaska. Dropping out of the top 20 was Big Sandy in Kentucky and McArthur River in Alaska. The top 100 gas fields in the United States as of December 31, 1993, had 5,944.7 billion cubic feet of production or 31 percent of the total (Table B2). For the top 100 gas fields, this is only a decrease of 1.3 percent from 1992.

The field name, location, years of discovery, and an estimate of 1993 annual production are also a part of the information found in the tables. Where two or more States are listed, the name of the field shown is that name recognized by the State listed first. The additional States listed may recognize an alternative field name for the area. A list of all U.S. oil and gas fields that cross State boundaries is included in the annual EIA report *Oil and Gas Field Code Master List*, published each year.

The top 100 field lists usually lag 1 year behind the report data on which this publication focuses. A 1 year lag reflects the analysis time needed to estimate field totals beyond that associated with preparation of the annual reserves report. There were two difficulties encountered in constructing the lists. The first was that Form EIA-23 survey data, from which the national and State estimates are derived, do not always provide field totals, nor do they show the degree of field coverage attained by the survey. The second is that there is a significantly greater chance of releasing proprietary data when presenting field-by-field statistics, as compared to State and State Subdivision statistics.

The coverage problem was solved by using an EIA data base system, the Oil and Gas Integrated Field File (OGIFF) System. It matches fields reported in Form EIA-23 with two oil and gas data bases gotten from Dwight's Energydata, Inc., of Richardson, Texas. The measure of Form EIA-23 coverage for a given field is determined by comparing the volumes of oil and gas annual production available from each source. One of several methods of imputing the reserves associated

with production missed by Form EIA-23 is carried out when necessary. The resultant total field reserves estimates are then subjected to small adjustments to force the field totals within a State to sum to those reported by EIA.

The OGIFF data base system contained information on more than 45,000 fields in 1993. It is also being used in

preparation of a series of special reports illustrating selected oil and gas distributions not found in the annual oil and gas reserve's report. Three reports have already been published: *U.S. Oil and Gas Reserves by Year of Field Discovery*{24}, *Geologic Distributions of U.S. Oil and Gas*{47}, and *Largest U.S. Oil and Gas Fields*.{48}

^aIncludes lease condensate.

- = Not Applicable.

Note: Fields are grouped in "proved reserves rank groups" and then listed within that group in descending order by National 1993 annual production rank. The U.S. total production estimate, 2,499.033 million barrels, used to calculate the percentages in this table, is from the official Energy Information Administration production data for crude oil and lease condensate for 1993 contained in the *Petroleum Supply Annual 1994*, DOE/EIA-0340(94), p. 6. They differ from the U.S. total data reported in this publication. Column totals may not add due to independent rounding.

Source: Energy Information Administration, Office of Oil and Gas.

^aWet after lease separation.

- = Not Applicable.

Note: Fields are grouped in "proved reserves rank groups" and then listed within that group in descending order by National 1993 annual production rank. The U.S. total production estimate, 19,422.097 billion cubic feet, used to calculate the percentages in this table, is from the official Energy Information Administration production data for natural gas for 1993 contained in the *Natural Gas Annual 1993*, DOE/EIA-0131 (93). They differ from the U.S. total data reported in this publication. Column totals may not add due to independent rounding.

Appendix C

Conversion to the Metric System

Conversion to the Metric System

Public Law 100-418, the Omnibus Trade and Competitiveness Act of 1988, states: "It is the declared policy of the United States—

(1) to designate the metric system of measurement as the preferred system of weights and measures for United States trade and commerce. . . .

(2) to require that each Federal agency, by the end of Fiscal Year 1992, use the metric system of measurement in its procurements, grants, and other business-related activities."{49}

Table C1 is in keeping with the spirit of this law. The petroleum industry in the United States is slowly moving in the direction prescribed by this law and the data collected by EIA are collected in the units that are still common to the U.S. petroleum industry, namely barrels and cubic feet. Standard metric conversion factors were used to convert the National level volumes in Table 1 to the metric equivalents in Table C1. Barrels were multiplied by 0.1589873 to convert to cubic meters and cubic feet were multiplied by 0.02831685 to convert to cubic meters.

Table C1. U.S. Proved Reserves of Crude Oil, Dry Natural Gas, and Natural Gas Liquids, in Metric Units, 1985 - 1995

^aRevisions and adjustments = Col. 1 + Col. 2 - Col. 3.

^bTotal discoveries = Col. 5 + Col. 6 + Col. 7.

^cProved reserves = Col. 10 from prior year + Col. 4 + Col. 8 - Col. 9.

^dAn unusually large revision decrease to North Slope dry natural gas reserves was made in 1988. It recognizes some 696.59 billion cubic meters of downward revisions reported during prior years by operators because of economic and market conditions. EIA in previous years carried these reserves in the proved category.

Notes: Old means discovered in a prior year. New means discovered during the report year. The production estimates in this table are based on data reported on Form EIA-23, "Annual Survey of Domestic Oil and Gas Reserves" and Form EIA-64A, "Annual Report of the Origin of Natural Gas Liquids Production." The following conversion factors were used to convert data in Columns 2, 3, 5, 6, 7, 9, and 10: barrels = 0.1589873 per cubic meter, cubic feet = 0.02831685 per cubic meter. Number of decimal digits varies in order to accurately reproduce corresponding equivalents shown on Table 1 in Chapter 2.

Appendix D

Historical Reserves Statistics

Appendix D

Historical Reserves Statistics

These are selected historical data presented at the State and National level. All historical statistics included have previously been published in the annual reports of 1977 through 1994 of the EIA publication *U.S. Crude Oil, Natural Gas, and Natural Gas Liquids Reserves*, DOE EIA-0216.(1-18)

Liquid volumes are in million barrels of 42 U.S. gallons. Gas volumes are in billion cubic feet (Bcf), at 14.73 psia and 60° Fahrenheit. NA appears in this appendix wherever data are not available or are withheld to avoid disclosure of data which may be proprietary. An asterisk (*) marks those estimates associated with sampling errors (95 percent confidence interval) greater than 20 percent of the value estimated.

^aIncludes operator reported corrections for the years 1978 through 1981. After 1981 operators included corrections with revisions.

^bRevisions and adjustments = Col. 1 + Col. 2 - Col. 3.

^cTotal discoveries = Col. 5 + Col. 6 + Col. 7.

^dProved reserves = Col. 10 from prior year + Col. 4 + Col. 8 - Col. 9.

^eBased on following year data only.

^fConsists only of operator reported corrections and no other adjustments.

— = Not applicable.

Notes: Old means discovered in a prior year. New means discovered during the report year. The production estimates in this table are based on data reported on Form EIA-23, "Annual Survey of Domestic Oil and Gas Reserves". They may differ from the official Energy Information Administration production data for crude oil contained in the *Petroleum Supply Annual*, DOE/EIA-0340.

Source: U.S. Crude Oil, Natural Gas, and Natural Gas Liquids Reserves, 1977 through 1994 annual reports, DOE/EIA-0216.{1-18}

Summary of Data Collection Operations

Summary of Data Collection Operations

Form EIA-23 Survey Design

The data collected on Form EIA-23, "Annual Survey of Domestic Oil and Gas Reserves," were used to produce this report. This section provides information concerning the survey design, response statistics, reporting requirements, and frame maintenance.

Form EIA-23 is mailed annually to all known large and intermediate size operators, and a scientifically selected sample of small operators. Operator size categories were based upon their annual production as indicated in various Federal, State, and commercial records. The term *State/subdivision* refers to an individual subdivision within a State or an individual State that is not subdivided. Operators were divided into the three size categories shown below.

- **Category I - Large Operators:** Operators who produced 1.5 million barrels or more of crude oil, or 15 billion cubic feet or more of natural gas, or both.
- **Category II - Intermediate Operators:** Operators who produced at least 400,000 barrels of crude oil or 2 billion cubic feet of natural gas, or both, but less than Category I operators.
- **Category III - Small Operators:** Operators who produced less than the Category II operators.

Category III operators were further subdivided into operators sampled with *Certainty* (*Certainty*) and operators that were randomly sampled (*Noncertainty*).

Data were filed for calendar year 1995 by crude oil or natural gas well operators who were active as of December 31, 1995. EIA defines an operator as an organization or person responsible for the management and day-to-day operation of crude oil or natural gas wells. The purpose of this definition is to eliminate responses from royalty owners, working interest owners (unless they are also operators), and others not directly responsible for operations. An operator need not be a separately incorporated entity. To minimize reporting burden, corporations are permitted to report on the basis of operating units of the company

convenient for them. A large corporation may be represented by a single form or by several forms.

Table E1 shows a comparison of the EIA-23 sample and sampling frame between 1988 and 1995, and depicts the number of active operators, 1989 showing the largest in the series. The 1995 sampling frame consisted of 161 Category I, 476 Category II, 1,596 Category III *Certainty*, and 20,533 Category III *Noncertainty* operators, for a total of 22,766 active operators. The survey sample consisted of 2,233 operators selected with *certainty* that included all of the Category I and II *Certainty* operators, the 1,596 smaller operators that were selected with *certainty* because of their size in relation to the area or areas in which they operated, and 1,632 *Noncertainty* operators selected as a systematic random sample of the remaining operators.

Form EIA-23 Response Statistics

Each company and its parent company or subsidiaries were required to file Form EIA-23 if they met the survey specifications. Response to the 1995 survey is summarized in Table E2. EIA makes a considerable effort to gain responses from all operators. About 7 percent of those selected turned out to be nonoperators (those that reported being nonoperators during the report year and operators that could not be located). Of the 282 nonoperators, 8 had successor operators that had taken over the production of the nonoperator. These successor operators were subsequently sampled. The overall response rate for the 1995 survey was 100 percent. This compares with a 99.8 percent overall response rate for all operators in 1994.

Form EIA-23 Reporting Requirements

The collection format for Form EIA-23 actually consists of two forms. The form the respondent is required to file is dependent upon the annual production levels of crude oil, natural gas, and lease condensate. Category I and Category II operators file a more detailed field level

Table E1. Comparison of the EIA-23 Sample and Sampling Frame, 1988-1995

Total	3,865	8	0	-282	3,591	3,591	100.0	0	0.0

^aSuccessor operators are those, not initially sampled, that have taken over the production of a sampled operator.

^bNet of recategorized operators in the sample (excluding nonoperators).

^cIncludes former operators reporting that they were not operators during the report year and operators that could not be located who are treated as nonoperators.

Source: Form EIA-23, "Annual Survey of Domestic Oil and Gas Reserves" 1995.

data form. Category III operators file a summary report which is aggregated at a State/subdivision level.

The cover page required of all respondents identifies each operator by name and address (Figure I1, Appendix I). The oil and gas producing industry includes a large number of small enterprises. To minimize reporting burden, only a sample of small operators were required to file a summary report of Form EIA-23 (Figures I2 and I3, Appendix I). Report year production data were required by State/subdivision areas for crude oil, natural gas, and

lease condensate. Proved reserves data for operators were required only for those properties where estimates existed in the respondent's records.

All Category I and Category II operators were required to file field level data on Schedule A, "Operated Proved Reserves, Production, and Related Data by Field," for each oil and/or gas field in which the respondent operated properties (Figure I4, Appendix I). All Category I and those Category II operators who had reserve estimates were required to file on a total operated basis for crude oil, nonassociated natural gas,

associated-dissolved natural gas, and lease condensate. The following data items were required to be filed: proved reserves at the beginning and the end of the report year, revision increases and revision decreases, extensions, new field discoveries, new reservoirs in old fields, production, indicated additional reserves of crude oil, nonproducing reserves, field discovery year, water depth, and field location information.

Category II operators who did not have reserves estimates were required to file the field location information and report year production for the four hydrocarbon types from properties where reserves were not estimated. These respondents used Schedule B, "Footnotes," to provide clarification of reported data items when required in the instructions, or electively to provide narrative or detail to explain any data item filed (Figure I5, Appendix I).

Crude oil and lease condensate volumes were reported rounded to thousands of barrels of 42 U.S. gallons at 60° Fahrenheit, and natural gas volumes were reported rounded to millions of cubic feet. All natural gas volumes were requested to be reported at 60° Fahrenheit and a pressure base of 14.73 pounds per square inch absolute. Other minor report preparation standards were specified to assure that the filed data could be readily processed.

Oil and Gas Field Coding

A major effort to create standardized codes for all identified oil or gas fields throughout the United States was implemented during the 1982 survey year. Information from previous lists was reviewed and reconciled with State lists and a consolidated list was created. The publication of the *Oil and Gas Field Code Master List 1995*, in December of 1995, was the 14th annual report and reflected data collected through October 1995. This publication was mailed to operators to assist in identifying the field code data necessary for the preparation of Form EIA-23. A copy of this publication may be purchased from the National Energy Information Center (see inside cover page).

Form EIA-23 Comparison with Other Data Series

Estimated crude oil, lease condensate, and natural gas production volumes from Form EIA-23 were compared with official EIA production data supplied by Federal and State oil and natural gas regulatory agencies and

published in EIA's monthly and annual reports. Reports published by the Federal and State oil and natural gas regulatory agencies were used to compare specific operator production responses to these agencies with Form EIA-23 responses. When significant differences were found, responses were researched to detect and reconcile possible reporting errors.

For 1995, Form EIA-23 National estimates of production were 2,358 million barrels for crude oil and lease condensate or 36 million barrels (1.5 percent) lower than that reported in the *Petroleum Supply Annual 1995* for crude oil and lease condensate. Form EIA-23 National estimates of production for dry natural gas were 18,599 billion cubic feet or 633 billion cubic feet (3.4 percent) lower than the *Natural Gas Annual 1995* for 1995 dry natural gas production.

Form EIA-23 Frame Maintenance

Operator frame maintenance is a major data quality control effort. Extensive effort is expended to keep the frame as current as possible. The Form EIA-23 frame contains a listing of all crude oil and natural gas well operators in the United States and must be maintained and updated regularly in order to ensure an accurate frame from which to draw the sample for the annual crude oil and natural gas reserves survey. The original frame, created in 1977, has been revised annually. In addition, outside sources, such as State publications and computer tapes, and commercial information data bases such as Dwight's Energydata and Petroleum Information, are used to obtain information on operator status and to update addresses for the frame each year.

A maintenance procedure is utilized, using a postcard form with prepaid return postage, to contact possible active crude oil and natural gas well operators presently listed on EIA's master frame, but for whom the listing had not been updated for 2 years. This procedure identifies active operators and nonoperators which improves the frame for future sample selections for the survey. Table E3 provides a summary of changes made to the Form EIA-23 frame of crude oil and natural gas well operators for the 1995 survey mailing. These changes resulted from all frame maintenance activities.

The Form EIA-23 operator frame contained a total of 64,049 entries as of December 12, 1995. Of these, 22,695 were confirmed operators. These are operators who have filed in the past or for whom the EIA has recent production data from an outside source. The remaining

operators (including both definite and probable nonoperators) exist as a pool of names and addresses that may be added to the active list if review indicates activity.

Form EIA-64A Survey Design

The data for this report are also collected on Form EIA-64A, "Annual Report of the Origin of Natural Gas Liquids Production." This section provides information concerning the survey design, response statistics, reporting requirements, and frame maintenance for Form EIA-64A.

Form EIA-23 for report years 1977 and 1978 required natural gas well operators to report their natural gas data on a fully dry basis. It was discovered in the course of those surveys that many operators had little or no knowledge of the extraction of liquids from their produced natural gas streams once custody transfer had taken place. Therefore, these operators reverted to reporting the only natural gas volume data they had in their possession. These volume data were for dryer natural gas than that which had passed through the wellhead, but wetter than fully dry natural gas. With reference to Figure E1, they reported their volumes either at the wellhead or after removal of lease condensate in their lease or field separation facilities.

Some of the larger operators, however, also owned or operated natural gas processing plants. They reported their volumes after removal of both lease condensate and plant liquids, as required by Form EIA-23. The aggregate volumes resulting from the 1977 and 1978 surveys, therefore, were neither fully dry (as was intended) nor fully wet. They do appear to have been more dry than wet simply because the operators who reported fully dry volumes also operated properties that contained the bulk of proved natural gas reserves.

The EIA recognized that its estimates of proved reserves of natural gas liquids (NGL) had to reflect not only those volumes extractable in the future under current economic and operating conditions at the lease or field (lease condensate), but also volumes (plant liquids) extractable downstream at existing natural gas processing plants. Form EIA-64, which already canvassed these processing plants, did not request that the plants' production volumes be attributed to source areas. Beginning with the 1979 survey, a new form to collect plant liquids production according to the area or areas where their input natural gas stream had been produced was mailed to all of the operating plants. The instructions for filing the Form EIA-23 were altered to collect data from natural gas well operators that reflected those volumes of natural gas dried only through the lease or field separation facilities. The reporting basis of these volumes are referred to as "wet after lease separation." The methodology used to estimate NGL reserves by State and State subdivision is provided in Appendix F.

Form EIA-64A Response Statistics

EIA mailed EIA-64A forms to all known natural gas processing plant operators as of January 3, 1996. In addition, plant operators whose plants were shut down or dismantled during 1995 were required to complete forms for the portion of 1995 when the plants were in operation.

Natural gas processing plant operators were requested to file a Form EIA-64A for each of their plants. A total of 271 operators of 788 plants were sent forms. This number included 4 new plants and 25 successor plants identified after the initial 1995 survey mailing. A total of 55 plants were reported as nonoperating according to the Form EIA-64A definition. The response rate was again 100 percent.

Figure E1. Natural Gas Liquids Extraction Flows

Source: Energy Information Administration, Office of Oil and Gas.

Form EIA-64A respondents were requested to report natural gas liquids production data by area of origin. Table E4 summarizes the responses by plant operators of the volume and origin of natural gas delivered to the processing plants and the volume of the natural gas liquids extracted by the plants by State. The majority of the plant operators reported only one area of origin for the natural gas that was processed by a plant. The State or area of origin reported is generally also the plant's location.

Natural gas liquids volumes were reported rounded to thousands of barrels of 42 U.S. gallons at 60° Fahrenheit, and natural gas volumes were reported rounded to millions of cubic feet. All natural gas volumes were requested to be reported at 60° Fahrenheit and a pressure base of 14.73 pounds per square inch absolute. Other minor report preparation standards were specified to assure that the filed data could be readily processed.

Form EIA-64A Reporting Requirements

Form EIA-64A consisted of the reporting schedule shown in Figure I6, Appendix I. The form identifies the plant, its geographic location, the plant operator's name and address, and the parent company name. The certification was signed by a responsible official of the operating entity. The form pertains to the volume of natural gas received and of natural gas liquids produced at the plant, allocated to each area of origin. Operators also filed the data pertaining to the amount of natural gas shrinkage that resulted from extraction of natural gas liquids at the plant, and the amount of fuel used in processing.

Form EIA-64A Comparison with Other Data Series

Form EIA-64A plant liquids production data were compared with data collected on Form EIA-816, "Monthly Natural Gas Liquids Report." Aggregated production from Form EIA-816 represents the net volume of natural gas processing plant liquid output less input for the report year. These data are published in EIA's *Petroleum Supply Annual* reports. The Form EIA-64A annual responses reflect all corrections and revisions to EIA's monthly estimates. Differences, when found, were reconciled in both sources. For 1995, the Form EIA-64A National estimates were 0.9 percent (6 million barrels) higher than the *Petroleum Supply Annual* 1995 volume for natural gas plant liquids production.

Table E4. Natural Gas Processed and Liquids Extracted at Natural Gas Processing Plants, 1995

Form EIA-64A Frame Maintenance

The Form EIA-64A plant frame contains data on all known active and inactive natural gas processing plants in the United States. The 1995 plant frame was compared to listings of natural gas processing plants from Form EIA-816, "Monthly Natural Gas Liquids Report"; the *LPG Almanac*; and the *Oil and Gas Journal*. A list of possible additions to the plant frame was compiled. Table E5 summarizes the Form EIA-64A plant frame changes made as a result of the comparisons as of December 12, 1995.

Table E5. Summary of the 1995 Plant Frame Activity, Form EIA-64A

Frame as of 1994 survey mailing	789
Additions	112
Deletions	-142
Frame as of 1995 survey mailing	759

Note: Includes operator frame activity through December 12, 1995.

Statistical Considerations

Statistical Considerations

Survey Methodology

The Form EIA-23 survey is designed to provide reliable estimates for reserves and production of crude oil, natural gas, and lease condensate for the United States. Operators of crude oil and natural gas wells were selected as the appropriate respondent population because they have access to the most current and detailed information, and therefore, presumably have better reserve estimates than do other possible classes of respondents, such as working interest or royalty owners.

While large operators are quite well known, they comprise only a small portion of all operators. The small operators are not well known and are difficult to identify because they go into and out of business, alter their corporate identities, and change addresses frequently. As a result, EIA conducts extensive frame maintenance activities each year to identify all current operators of crude oil and natural gas wells in the country.

Sampling Strategy

EIA publishes data on reserves and production for crude oil, natural gas, and lease condensate by State for most States, and by State subdivision for the States of California, Louisiana, New Mexico, and Texas. To meet the survey objectives, while minimizing respondent burden, a random sampling strategy has been used since 1977. Each operator reporting on the survey is asked to report production for crude oil, natural gas, and lease condensate for each State/subdivision in which he operates. The term *State/subdivision* refers to an individual subdivision within a State or an individual State that is not subdivided.

The total volume of production varies among the State/subdivisions. To meet the survey objectives while controlling total respondent burden, EIA selected the following target sampling error for the 1995 survey for each product class.

- 1.0 percent for National estimates.
- 1.0 percent for each of the 5 States having subdivisions: Alaska, California, Louisiana,

New Mexico, and Texas. For selected subdivisions within these States, targets of 1.0 percent or 1.5 percent as required to meet the State target.

- 2.5 percent for each State/subdivision having 1 percent or more of estimated U.S. reserves or production in 1994 (lower 48 States) for any product class.
- 4 percent for each State/subdivision having less than 1 percent of estimated U.S. reserves or production in 1994 (lower 48 States) for all 3 product classes.
- 8 percent for States not published separately. The combined production from these States was less than 0.2 percent of the U.S. total in 1994 for crude oil and for natural gas.

The volume of production defining the Certainty stratum, referred to as the *cutoff*, varies by product or State/subdivision. The cutoff criteria and sampling rates are shown in Table F1. The Certainty stratum, therefore, has three components.

- **Category I - Large Operators:** Operators who produced a total of 1.5 million barrels or more of crude, or 15 billion cubic feet or more of natural gas, or both in 1994.
- **Category II - Intermediate Operators:** Operators who produced a total of at least 400,000 barrels of crude oil or 2 billion cubic feet of natural gas, or both, but less than Category I operators in 1994.
- **Category III - Small Operators:** Operators who produced less than the Category II operators in 1994, but which were selected with certainty. Category III operators were subdivided into operators sampled with certainty (*Certainty*) and operators that were randomly sampled (*Noncertainty*).
- **Certainty - A small operators who satisfied any of the following criteria based upon their production shown in the operator frame:**
 - Operators with annual crude oil production of 200 thousand barrels or more, or reserves of 4 million barrels or more; or annual natural gas production of 1 billion cubic feet or more, or reserves of 20 billion cubic feet or more.

- All other operators with production or reserves in a State/subdivision that exceed selected cutoff levels for that State/subdivision.
- The largest operator in each State/subdivision regardless of level of production or reserves.
- Operators with production or reserves of oil or gas for six or more State/subdivisions.
- **Noncertainties** - Small operators not in the certainty stratum were classified in a noncertainty stratum and sampled at a rate of 8 percent.

In each State/subdivision the balance between the number of small certainty operators and the sample size was determined in an iterative procedure designed to minimize the number of total respondents. The iteration for each State/subdivision began with only the Category I and Category II operators in the certainty stratum. The size of the sample of small operators required to meet the target variance was calculated based on the variance of the volumes of those operators. For a number of State/subdivisions with high correlations between frame values across pairs of consecutive years, an adjusted target variance was calculated, that utilized the information about the correlations. This allowed the selection of a smaller sample that still met the target sampling error criteria. At each iteration a small operator, beginning with the largest of the Category III operators, was added to the certainty group and the required sample size was again calculated. The procedure of adding one operator at a time stopped when the proportion of operators to be sampled at random dropped below 8 percent. Independent samples of single location operators (operators who, according to the sampling frame, operate in only one State/subdivision) were selected from each State/subdivision using systematic random sampling.

An additional complexity is introduced because some small operators selected for the sample in another region or regions, sometimes report production volumes in a region in which EIA has no previous record of production.

State/subdivision volume estimates are calculated as the sum of the certainty strata and all of the estimates for the sampling strata in that region. The sampling variance of the estimated total is the sum of the sampling variances for the sampling strata. There is no sampling error associated with the certainty stratum.

The square root of the sampling variance is the standard error. It can be used to provide confidence intervals for the State/subdivision totals.

For the States in which subdivision volume estimates are published, the State total is the sum of the individual volume estimates for the subdivisions. The U.S. total is the sum of the State estimates. A sampling variance is calculated for each State subdivision, State, and for the U.S. total.

Total U.S. Reserve Estimates

Conceptually, the estimates of U.S. reserves and production can be thought of as the sum of the estimates for the individual States. Correspondingly, the estimates for the four States for which estimates are published separately by subdivision (California, Louisiana, New Mexico, and Texas) can be thought of as the sum of the estimates by subdivision. The remaining States are not subdivided and may be considered as a single subdivision.

The estimates of year-end proved reserves and annual production for any State/subdivision is the sum of the volumes in the State/subdivision reported by the certainty stratum operators and an estimate of the total volume in the State/subdivision by the noncertainty stratum operators. Mathematically, this may be stated as the following sum:

$$\hat{V}_S = V_{sc} + \hat{V}_{sr}$$

where

$\hat{V}_S$ = estimated total volume in the State/subdivision

V_{sc} = total volume in the State/subdivision reported by Certainty operators

$\hat{V}_{sr}$ = estimated total volume in the State/subdivision of Noncertainty operators.

The total volume of Certainty operators in the State/subdivision is simply the sum of individual operator's volumes:

$$V_{sc} = \sum_{m=1}^{n_{sc}} V_{scm}$$

where

n_{sc} = number of Certainty operators reporting production in the State/subdivision

V_{scm} = volume reported by the m -th certainty stratum operator in the State/subdivision.

The estimated total volume of Noncertainty operators in the State/subdivision is the weighted sum of the reports of the noncertainty sample operators:

$$\hat{V}_{sr} = \sum_{m=1}^{n_{sr}} W_{srm} V_{srm}$$

where

n_{sr} = number of Noncertainty operators reporting production in the State/subdivision

V_{srm} = volume reported by the m -th Noncertainty sample operator in the State/subdivision

W_{srm} = weight for the report by the m -th Noncertainty sample operator reporting production in the State/subdivision.

In many State/subdivisions, the accuracy of the oil and gas estimates was improved by using a difference estimator for many of the Noncertainty operators. This difference estimator took advantage of the stability of production reports from year-to-year in those State/subdivisions. The difference estimator was only applied to operators who had known production greater than 1 thousand barrels of oil and/or 1 million cubic feet of natural gas in the previous year. For those State/subdivisions and operators the above formula was modified with V_{srm} replaced by V'_{srm} :

$$V'_{srm} = V_{srm} + k (\bar{X}_{sr} - X_{srm})$$

where

k = 1 when estimating production volumes

k = regional R/P ratio (Table F6) when estimating reserve volumes

$\bar{X}_{sr}$ = average production volume reported in the State/subdivision for the preceding year by all qualifying Noncertainty operators

X_{srm} = production volume reported by the m -th Noncertainty sample operator in the State/subdivision for the preceding year.

In selecting the Noncertainty sample, the number of sample operators with production in a given State/subdivision is not controlled to the number

expected based on the sampling rate, but is subject to some variation. The weight used is the reciprocal of the actual sampling rate that resulted for the stratum from which the sample operator was selected, rather than the reciprocal of the expected sampling rate. The sample estimate with either set of weights is an unbiased estimator of the noncertainty stratum total. However, use of the actual sampling rates is expected to lead to smaller sampling errors for the estimates. In making estimates for a State/subdivision, separate weights are applied as appropriate for Noncertainty operators shown in the frame as having had production in only the State/subdivision, for those shown as having had production in that State/subdivision and up to four other States/subdivisions, and for operators with no previous record of production in the State/subdivision. National totals were then obtained by summation of the component totals.

Imputation for Operator Nonresponse

The response rate for Certainty and Noncertainty operators for the 1995 survey was 100 percent. Due to the 100 percent response rate, imputation for the nonresponding operators was not necessary.

Imputation and Estimation for Reserves Data

In order to estimate reserve balances for National and State/subdivision levels, a series of imputation and estimation steps at the operator level must be carried out. Year-end reserves for operators who provided production data only were imputed on the basis of their production volumes. Imputation was also applied to the small and intermediate operators as necessary to provide data on each of the reserve balance categories (i.e., revisions, extensions, or new discoveries). Finally, an imputation was required for the natural gas data of the small operators to estimate their volumes of associated-dissolved and nonassociated natural gas. The final manipulation of the data accounts for the differences caused by different sample frames from year to year. Each of these imputations generated only a small percentage of the total estimates. The methods used are discussed in the following sections.

The actual data reported on an operated basis by Form EIA-23 respondents for the report year 1995 are summarized in Tables F2, F3, F4, and F5. The differences between these sums and the total estimates shown in Tables 9, 10, 6 and 16 in the main text represent the aggregate result of statistical estimation

and imputation performed by EIA. The reported data in Table F2 shows that those responding operators accounted for 97.5 percent of the published production for natural gas shown in Table 9 and 93.9 percent of the reserves. Data shown in Table F3 indicate that those responding operators accounted for 94.5 percent of the nonassociated natural gas production and 92.5 percent of the reserves published in Table 10. The reported data shown in Table F4 indicate that those responding operators accounted for 95.1 percent of published crude oil production and 94.1 percent of the reserves shown in Table 6. Additionally, Table F5 indicates that those responding operators accounted for 99.4 percent of the published production and 99.3 percent of the published proved reserves for lease condensate shown in Table 16.

Imputation of Year-End Proved Reserves

Category I operators were required to submit year-end estimates of proved reserves. Category II and Category III operators were required to provide year-end estimates of proved reserves only if such estimates existed in their records. Some of these respondents provided estimates for all of their operated properties, others provided estimates for only a portion of their properties, and still others provided no estimates for any of their properties. All respondents did, however, provide annual production data. The production reported by Noncertainty sample operators and the corresponding reserves imputed were weighted to estimate the full noncertainty stratum when calculating reserves and production as previously described in the section "Total U.S. Reserves Estimates" in this appendix.

A year-end proved reserves estimate was imputed in each case where an estimate was not provided by the respondent. Reserves were imputed from reported production data for all Noncertainty operators. The reported annual production was multiplied by a reserves-to-production (R/P) ratio (Table F6) characteristic of operators of similar size in the region where the properties were located. The regional R/P ratios in this report are averages calculated by dividing the mean of reported reserves by the mean of reported production for selected respondents of similar size who did report estimated reserves. A cutoff level for each region was determined based upon the largest Certainty operator that reported production, but did not provide a reserve estimate. Data from respondents whose production in a region exceeded the regional cutoff level was excluded from the R/P ratio calculation for that region. In addition, operators that had R/P ratios that exceeded 25 to 1 and Category I operators were excluded from the respondents selected to calculate the characteristic regional R/P ratio. All other respondents who reported both production and reserves were used to calculate the regional R/P ratio characteristic.

The R/P ratio varied significantly from region to region. This variation was presumably in response to variation in geologic conditions and the degree of development of crude oil and natural gas resources in each area. The average R/P ratio was computed for regional areas similar to the National Petroleum Council regional units (Figure F1). These units generally follow the boundaries of geologic provinces wherein the stage of resource development tends to be somewhat similar. Table F6 lists the R/P ratio

Table F6. Statistical Parameters of Reserve Estimation Equation by Region for 1995

calculated for each region that required such imputations and the number of observations on which it was based.

The regional R/P ratio is determined primarily to provide a factor that can be applied to the production reported by operators without reserve estimates to provide an estimate of the reserves of these operators when aggregated to the regional level. The average R/P ratio, when multiplied by each individual production in the distribution of R/P pairs used to calculate it, will exactly reproduce the sum of the reported reserves in the distribution.

Imputation of Annual Changes to Proved Reserves by Component of Change

Category II and Category III operators that do not keep reserves data were not asked to provide estimates of beginning-of-year reserves or annual changes to proved reserves by component of change, i.e., revisions, extensions, and discoveries. When they did not provide estimates, these volumes were estimated by applying an algebraic allocation scheme which preserved the

relative relationships between these items within each State/subdivision, as reported by Category I and Category II operators, and also preserved an exact annual reserves balance of the following form:

Published Proved Reserves at End of Previous Report Year
+ Adjustments
+ Revision Increases
- Revision Decreases
+ Extensions
+ New Field Discoveries
+ New Reservoir Discoveries in Old Fields
- Report Year Production
= Published Proved Reserves at End of Report Year

A ratio was calculated as the sum of the annual production and year-end proved reserves of those respondents who did not provide the reserves balance components, divided by the sum of year-end proved reserves and annual production of those respondents of similar size who did provide these quantities. This ratio was then multiplied by each of the reserves balance components reported by Category I and some Category II operators, to obtain imputed volumes for the reserves

Figure F1. Form EIA-23 Regional Boundaries

Source: Energy Information Administration, Office of Oil and Gas.

balances of the other Category II operators and Certainty and Noncertainty operators. These were then added to the State/subdivision totals.

Imputation of Natural Gas Type Volumes

Operators in the State/subdivision certainty and noncertainty strata were not asked to segregate their natural gas volumes by type of natural gas, i.e., nonassociated natural gas (NA) and associated-dissolved natural gas (AD). The total estimated year-end proved reserves of natural gas and the total annual production of natural gas reported by, or imputed to, operators in the State/subdivision certainty and noncertainty strata were, therefore, subdivided into the NA and AD categories, by State/subdivision, in the same proportion as was reported by Category I and Category II operators in the same area.

Adjustments

The instructions for Schedule A of Form EIA-23 specify that, when reporting reserves balance data, the following arithmetic equation must hold:

Proved Reserves at End of Previous Year
+ Revision Increases
- Revision Decreases
+ Extensions
+ New Field Discoveries
+ New Reservoir Discoveries in Old Fields
- Report-Year Production
= Proved Reserves at End of Report Year

Any remaining difference in the State/subdivision annual reserves balance between the published previous year-end proved reserves and current year-end proved reserves not accounted for by the imputed reserves changes was included in the adjustments for the area. One of the primary reasons that adjustments are necessary is that very few of the same Noncertainty operators are sampled each year. Less than 8 percent of the Noncertainty stratum operators sampled in 1994 were sampled again in 1995, and there is no guarantee that in the smaller producing States/subdivision the same number of small operators will be selected each year, or that the operators selected will be of comparable sizes when paired with operators selected in a prior year. Thus, some instability of this stratum from year to year is unavoidable, resulting in minor adjustments.

Some of the adjustments are, however, more substantial, and could be required for any one or more of the following reasons:

- The frame coverage may or may not have improved between survey years, such that more or fewer Certainty operators were included in 1995 than in 1994.
- One or more operators may have reported data incorrectly on Schedule A in 1994 or 1995, but not both, and the error was not detected by edit processing.
- Operation of properties was transferred during 1995 from operators not in the frame or Noncertainty operators not selected for the sample to Certainty operators or Noncertainty operators selected for the sample.
- Operations of properties was transferred during 1995 to an operator with a different evaluation of the proved reserves associated with the properties than that of the 1994 operator.
- Respondent changed classification of natural gas from NA to AD or vice versa.
- The trend in reserve changes imputed for the small operators, that was based on the trend reported by the large operators, did not reflect the actual trend for the small operators.
- Noncertainty operators, who have grown substantially in size since they were added to the frame, occasionally cause a larger standard error than expected.
- The Noncertainty sample for either year in a state may have been an unusual one.

The causes of adjustments are known for some but not all areas. The only problems whose effects cannot be expected to balance over a period of several years are those associated with an inadequate frame or those associated with any actual trend in reserve changes for small operators not being the same as those for large operators. EIA continues to attempt to improve sources of operator data to resolve problems in frame completeness.

Sampling Reliability of the Estimates

The sample of Noncertainty operators selected is only one of the large number of possible samples that could have been selected and each would have resulted in different estimates. The standard error or sampling error of the estimates provides a measure of this variability. When probability sampling methods are

used, as in the EIA-23 survey, the sampling error of estimates can also be estimated from the survey data.

The estimated sampling error can be used to compute a confidence interval around the survey estimate, with a prescribed degree of confidence that the interval covers the value that would have been obtained if all operators in the frame had been surveyed. If the estimated volume is denoted by $\hat{V}_s$ and its sampling error by S.E. ($\hat{V}_s$), the confidence interval can be expressed as:

$$\hat{V}_s \pm k \text{ S.E. } (\hat{V}_s)$$

where k is a multiple selected to provide the desired level of confidence. For this survey, k was taken equal to 2. Then there is approximately 95 percent confidence that the interval:

$$\hat{V}_s \pm 2 \text{ S.E. } (\hat{V}_s)$$

includes the universe value, for both the estimates of reserves and production volumes. Correspondingly, for approximately 95 percent of the estimates in this report, the difference between the published estimate and the value that would be found from a complete survey of all operators is expected to be less than twice the sampling error of the estimate. Tables F7, F8, F9, and F10 provide estimates for $2 \text{ S.E. } (\hat{V}_s)$ by product. These estimates are directly applicable for constructing approximate 95 percent confidence intervals. For example, the 95 percent confidence interval for dry natural gas proved reserves is $165,146 \pm 575$ billion cubic feet. The sampling error of $\hat{V}_s$ is equal to the sampling error of the noncertainty estimate $\hat{V}_{sr}$, because the certainty total is not subject to sampling error. The estimated sampling error of a noncertainty estimate is the square root of its estimated sampling variance.

The noncertainty estimate for a given State/subdivision had two separately weighted components based on reports of:

- Type 1 Operators shown in the frame as having had crude oil or natural gas production in the State/subdivision.
- Type 2 Operators shown in the frame as having had no crude oil or natural gas production in the State/subdivision.

Correspondingly, the sampling variance had two components associated with the estimated production from each component:

$$\text{Var}(\hat{V}_{sr}) = \text{Var}(\hat{V}_{sr1}) + \text{Var}(\hat{V}_{sr2})$$

The $\text{Var}(\hat{V}_{sr})$ was estimated as the sum of the estimated variances of the two component estimates. The variance for any component, say component j , was estimated from the formula:

$$\text{Var}(\hat{V}_{srj}) = n_{srj} \left(\frac{W_{srj} - 1}{W_{srj}} \right) S_{srj}^2$$

In general, $\hat{V}_{srj}$ denotes the production estimate from component j for each of the two types of operator, and $\text{Var}(\hat{V}_{srj})$ denotes its variance where

n_{srj} = number of operators in sample in component j

w_{srj} = weight for operator reports in component j

S_{srj}^2 = variance between operator reports in component j .

If the subscripts sr are dropped, S_j^2 can be expressed as:

$$S_j^2 = \frac{\sum_i^{n_j} V_{ji}'^2 - \left(\sum_i^{n_j} V_{ji}' \right)^2 / n_j}{n_j - 1}$$

where

V_{ji}' = weighted production or reserves volume for the i -th sample operator in the component j .

The variance of the estimated total volume for a State having subdivisions is the sum of corresponding Type 1 and Type 2 components where the classification of operators by type is with regard to the State as a whole; e.g., Type 2 operators at the State level are those that were not shown in the sample frame as having production anywhere in the State.

Since there are no operators in the frame who would be classified as Type 2 at the U.S. level, there would be no Type 2 components at the U.S. level. Therefore, at the U.S. level, there was only one sample variance component calculated for Type 1 operators.

Nonsampling Errors

Several sources of possible error, apart from sampling error, are associated with the Form EIA-23 survey.

These include bias due to nonresponse of operators in the sample, proved reserve estimation errors, and reporting errors on the part of the respondents to the survey. On the part of EIA, possible errors include inadequate frame coverage, data processing error, and errors associated with statistical estimates. Each of these sources is discussed below. An estimate of the bias from nonresponse is presented in the section on adjustment for operator nonresponse.

Assessing the Accuracy of the Reserve Data

The EIA maintains an evaluation program to assess the accuracy and quality of proved reserve estimates gathered on Form EIA-23. Field teams consisting of petroleum engineers from EIA's Dallas Field Office conduct technical reviews of reserve estimates and independently estimate the proved reserves of a statistically selected sample of operator properties. The results of these reviews are used to evaluate the accuracy of reported reserve estimates. Operators are apprised of the team's findings to assist them in completing future filings. The magnitude of errors due to differences between reserve volumes submitted by operators on the Form EIA-23 and those estimated by EIA petroleum engineers on their field trips were generally within accepted professional engineering standards.

Respondent Estimation Errors

The principal data elements of the Form EIA-23 survey consist of respondent estimates of proved reserves of crude oil, natural gas, and lease condensate. Unavoidably, the respondents are bound to make some estimation errors, i.e., until a particular reservoir has been fully produced to its economic limit and abandoned, its reserves are not subject to direct measurement but must be inferred from limited, imperfect, or indirect evidence. A more complete discussion of the several techniques of estimating proved reserves, and the many problems inherent in the task, appears in Appendix G.

Reporting Errors and Data Processing Errors

Reporting errors on the part of respondents are of definite concern in a survey of the magnitude and complexity of the Form EIA-23 program. Several steps were taken by EIA to minimize and detect such problems. The survey instrument itself was carefully

developed, and included a detailed set of instructions for filing data, subject to a common set of definitions similar to those already used by the industry. Editing software is continually developed to detect different kinds of probable reporting errors and flag them for resolution by analysts, either through confirmation of the data by the respondent or through submission of amendments to the filed data. Data processing errors, consisting primarily of random keypunch errors, are detected by the same software.

Imputation Errors

Some error, generally expected to be small, is an inevitable result of the various estimations outlined. These imputation errors have not yet been completely addressed by EIA and it is possible that estimation methods may be altered in future surveys. Nationally, 5.9 percent of the crude oil proved reserve estimates, 6.1 percent of the natural gas proved reserve estimates, and 0.7 percent of the lease condensate proved reserve estimates resulted from the imputation and estimation of reserves for those Certainty and Noncertainty operators who did not provide estimates for all of their properties, in combination with the expansion of the sample of Noncertainty operators to the full population. Errors for the latter were quantitatively calculated, as discussed in the previous section. Standard errors, for the former, would tend to cancel each other from operator to operator, and are, therefore, expected to be negligible, especially at the National level of aggregation. In States where a large share of total reserves is accounted for by Category III and smaller Category II operators, the errors are expected to be somewhat larger than in States where a large share of total reserves is accounted for by Category I and larger Category II operators.

Frame Coverage Errors

Of all the sources of controllable error connected with the Form EIA-23 survey, errors in the operator frame were expected to be the most important. If the frame does not list all operators in a given State, the sample selected from the frame for the State will not represent the entire operator population, a condition called undercoverage. Undercoverage is a problem with certain States, but it does not appear to be a problem with respect to the National proved reserve estimates for either crude oil or natural gas. While it is relatively straightforward to use existing sources to identify large operators and find addresses for them, such is not the case for small operators. A frame such as that used in

the 1995 survey is particularly likely to be deficient in States where a large portion of total reserves and production is accounted for by small operators. These States are not likely to allocate sufficient resources to keep track of all operators on a current basis. Some undercoverage of this type seems to exist, particularly, with reference to natural gas operators. EIA is continuing to work to remedy the undercoverage problem in those States where it occurred.

Calculation of Reserves of Natural Gas Liquids and Dry Natural Gas

Natural Gas Liquids Reserve Balance

The published reserves, production, and reserves change statistics for crude oil, lease condensate, and natural gas, wet after lease separation, were derived from the data reported on Form EIA-23 and the application of the imputation methods discussed previously. The information collected on Form EIA-64A was then utilized in converting the estimates of the wet natural gas reserves into two components: plant liquids reserve data and dry natural gas reserve data. The total natural gas liquids reserve estimates presented in Table 14 were computed as the sum of plant liquids estimates (Table 15) and lease condensate (Table 16) estimates.

To generate estimates for each element in the reserves balance for plant liquids in a given producing area, the first step was to group all natural gas processing plants that reported this area as an area-of-origin on their Form EIA-64A, and then sum the liquids production attributed to this area over all respondents. Next, the ratio of the liquids production to the total wet natural gas production for the area was determined. This ratio represented the percentage of the wet natural gas that was recovered as natural gas liquids. Finally, it was assumed that this ratio was applicable to the reserves and each component of reserve changes (except adjustments), as well as production. Therefore, each element in the wet natural gas reserves balance was multiplied by this recovery factor to yield the corresponding estimate for plant liquids. Adjustments of natural gas liquids were set equal to the difference between the end of previous year reserve estimates, based upon the current report year Form EIA-23 and Form EIA-64A surveys, and the end of current year reserve estimates published in the preceding year's annual reserves report.

Natural Gas Reserve Balance

This procedure involved downward adjustments of the natural gas data, wet after lease separation, in estimating the volumes of natural gas on a fully dry basis. These reductions were based on estimates of the gaseous equivalents of the liquids removed (in the case of production), or expected to be removed (in the case of reserves), from the natural gas stream at natural gas processing plants. Form EIA-64A collected the volumetric reduction, or shrinkage, of the input natural gas stream that resulted from the removal of the NGL at each natural gas processing plant.

The shrinkage volume was then allocated to the plant's reported area or areas of origin. Because shrinkage is, by definition, roughly in proportion to the NGL recovered, i.e. the NGL produced, the allocation was in proportion to the reported NGL volumes for each area of origin. However, these derived shrinkage volumes were rejected if the ratio between the shrinkage and the NGL production (gas equivalents ratio) fell outside certain limits of physical accuracy. The ratio was expected to range between 1,558 cubic feet per barrel (where NGL consists primarily of ethane) and 900 cubic feet per barrel (where NGL consists primarily of natural gasolines). When the computed gas equivalents ratio fell outside these limits, an imputed ratio was utilized to estimate the plant's natural gas shrinkage allocation to each reported area of origin.

This imputed ratio was that calculated for the aggregate of all other plants reporting production and shrinkage, and having a gas equivalent ratio within the aforesaid limits, from the area in question. The imputed area ratio was applied only if there were at least five plants to base its computation on. If there were less than five plants, the imputed ratio was calculated based on all plants in the survey whose individual gas equivalents ratio was within the acceptable limits. Less than one percent of the liquids production was associated with shrinkage volumes imputed in this manner. Based on the 1995 Form EIA-64A survey, the national weighted average gas equivalents ratio was computed to be 1,398 cubic feet of natural gas shrinkage per barrel of NGL recovered, the same as that in the 1994 survey. The total shrinkage volume (reported plus imputed) for all plants reporting a given area of origin was then subtracted from the estimated value of natural gas production, wet after lease separation, yielding dry natural gas production for the area. The amount of the reduction in the wet natural gas production was then expressed as a percentage of the wet natural gas production. Dry natural gas reserves and reserve

changes were determined by reducing the wet natural gas reserves and reserve changes by the same percentage reduction factor.

A further refinement of the estimation process was used to generate an estimate of the natural gas liquids reserves in those States with coalbed methane fields. The States where this procedure was applied were Alabama, Colorado, Kansas, New Mexico, Oklahoma, Pennsylvania, Utah, Virginia, West Virginia, and Wyoming. The first step in the process was to identify all Form EIA-23 reported coalbed methane fields. The assumption was made that coalbed methane fields contained little or no extractable natural gas liquids. Therefore, when the normal shrinkage procedure was applied to the wet gas volume reserve components, the estimate of State coalbed methane volumes were excluded and were not reduced for liquid extraction. Following the computation for shrinkage, each coalbed field gas volume reserve components was added back

to each of the dry gas volume reserve components in a State. The effect of this is that the large increases in reserves in some States from coalbed methane fields did not cause corresponding increases in the State natural gas liquids proved reserves.

Adjustments of dry natural gas were set equal to the difference between the end of previous year reserves estimates, based upon the current report year Form EIA-23 and Form EIA-64A surveys, and the end of current year reserve estimates published in the preceding year's annual reserves report.

Each estimate of end of year reserves and report year production has associated with it an estimated sampling error. The standard errors for dry natural gas were computed by multiplying the wet natural gas standard errors by these same percentage reduction factors. Table F7 provides estimates for 2 times the $S.E.(V_s)$ for dry natural gas.

Appendix G

Estimation of Reserves and Resources

Estimation of Reserves and Resources

Oil and Gas Resource Base

Universally accepted definitions have not been developed for the many terms used by geologists, engineers, accountants and others to denote various components of overall oil and gas resources. In part, this is because most of these terms describe estimated and therefore uncertain, rather than measured, quantities. The lack of standardized terminology sometimes leads to inaccurate understanding of the meaning and/or import of estimates. Particularly common is an apparently widespread lack of understanding of the substantial difference between the terms "reserves" and "resources", as indicated by the frequent misuse of either term in place of the other.

The total resource base of oil and gas is the entire volume formed and trapped in-place within the Earth before any production. The largest portion of this total resource base is nonrecoverable by current or foreseeable technology. Most of the nonrecoverable volume occurs at very low concentrations throughout the earth's crust and cannot be extracted short of mining the rock or the application of some other approach that would consume more energy than it produced. An additional portion of the total resource base cannot be recovered because currently available production techniques cannot extract all of the in-place oil and gas even when present in commercial concentrations. The inability to recover all of the in-place oil and gas from a producible deposit occurs because of unfavorable economics, intractable physical forces, or a combination of both. Recoverable resources, the subset of the total resource base that is of societal and economic interest, are defined so as to exclude these nonrecoverable portions of the total resource base.

The structure presented in Figure G1 outlines the total resource base and its components. The total resource base first consists of the recoverable and nonrecoverable portions discussed above. The next level down divides recoverable resources into discovered and undiscovered segments. Discovered resources are further separated into cumulative (i.e., all past) production, and reserves. Reserves are

Figure G1. Components of the Oil and Gas Resource Base

¹Of the numerous other reserve classifications, only "Indicated Additional" reserves are included in this report.

Source: Energy Information Administration, Office of Oil and Gas.

additionally subdivided into proved reserves and "other reserves".

Recoverable Resources

Discovered recoverable resources are those economically recoverable quantities of oil and gas for which specific locations are known. While the specific locations of estimated undiscovered recoverable resources are not yet known, they are believed to exist in geologically favorable settings.

Current estimates of undiscovered recoverable resources merit discussion in order to provide a useful sense of scale relative to proved reserves. The sources of official estimates of domestic undiscovered recoverable

resources are two agencies of the Department of the Interior (DOI), the United States Geological Survey (USGS) for onshore areas and those offshore waters subject to State jurisdiction, and the Minerals Management Service (MMS) for those offshore waters under Federal jurisdiction.

The USGS defines undiscovered recoverable conventional resources as those expected to be resident in accumulations of sufficient size and quality that they could be produced using conventional recovery technologies, without regard to present economic viability. Therefore, only part of the USGS undiscovered recoverable conventional resource is economically recoverable now. The USGS also defines a class of resources that occur in "continuous-type" accumulations. Unlike conventional oil and gas accumulations, continuous-type accumulations do not occur in discrete reservoirs of limited areal extent. They include accumulations in low-permeability (tight) sandstones, shales, and chinks, and those in coal beds. Again, only part of the continuous-type technically recoverable resource is economically recoverable now. In fact, only a small portion of the in-place continuous-type resource accumulations are estimated to be technically recoverable now. Table G1 presents the latest available USGS and MMS estimates, along with the EIA 1995 proved reserves estimates.

Technically recoverable resources of wet natural gas (discovered, both proved and unproved, and undiscovered) are estimated at 1,419 trillion cubic feet (Table G1). Subtracting U.S. proved reserves of 173 trillion cubic feet yields an unproved technically recoverable resource target of 1,246 trillion cubic feet. This is about 66 times the 1995 gas production level.

Other organizations have also estimated unproved technically recoverable gas resources. For example, the Potential Gas Committee (PGC), an industry sponsored group, provides detailed geology-based gas resource estimates every 2 years. In 1994 the PGC mean estimate of potential gas resources was 1,028 trillion cubic feet, about 218 trillion cubic feet less than the DOI estimates in Table G1. Another recent estimate was made by the National Petroleum Council (NPC), an industry-based group that serves in an advisory capacity to the U.S. Secretary of Energy. The NPC's estimate, based on data available at year-end 1990, was 1,135 trillion cubic feet, 111 trillion cubic feet less than the DOI estimates summarized in Table G1. The differences among these estimates are usually due to the availability of newer data, the differences in coverage or resource category definitions, and to legitimate but differing data

interpretations. The USGS estimates of reserve growth in known fields are much larger than previous estimates due to the utilization of newer EIA reserves growth data.

While the estimation of undiscovered resources is certainly a more imprecise endeavor than is the estimation of proved reserves, it is clear that substantial volumes of technically recoverable oil and gas resources remain to be found and produced domestically. Current estimates indicate that as much domestic gas remains to be found and then produced as has been to date. Of course, much effort, investment and time will be required to bring this gas to market.

The oil resource base has been more intensively developed than the gas resource base. More oil has been produced in the United States than is estimated as remaining recoverable. Nevertheless, the ratio of 1995 unproved technically recoverable oil resources to oil production (Table G1) was about 64 to 1.

Discovered Resources

In addition to cumulative production, which is the sum of current year production and the production in all prior years, estimates of discovered recoverable resources include estimates of reserves. Broadly, reserves are those volumes that are believed to be recoverable in the future from known deposits through the eventual application of present or anticipated technology.

Reserves

Reserves include both proved reserves and other reserves. Several different reserve classification systems are in use by different organizations, as preferred for operational reasons. These systems utilize and incorporate various definitions of terms such as *measured reserves*, *indicated reserves*, *inferred reserves*, *probable reserves*, and *possible reserves*. As used by the different organizations, the definitions that attach to these terms sometimes overlap, or the terms may require a slightly different interpretation from one organization to the next. Nevertheless, all kinds of "other reserves" are generally less well known and therefore less precisely quantifiable than proved reserves, and their eventual recovery is less assured.

Measured reserves are defined by the USGS as that part of the identified (i.e., discovered) economically recoverable resource that is estimated from geologic evidence and supported directly by engineering

Table G1. Estimated Oil and Gas Reserves and Mean Estimates of Technically Recoverable Oil and Gas Resources

Categories	Crude Oil ^a (billion barrels)	Natural Gas (Wet) (trillion cubic feet)	Natural Gas Liquids (billion barrels)

^a Condensate is included with crude oil for MMS estimates in Federal Offshore regions.

^b Includes 10.499 trillion cubic feet of coalbed methane (EIA, end 1995).

^c Using USGS definition, 2.087 billion barrels of indicated additional oil reserves in the lower 48 States were included (EIA, end 1995).

^d Reserve growth in the Pacific Federal offshore is not included and was not estimated by the MMS.

^e Total undiscovered natural gas liquids for Federal offshore are 1.8 billion barrels; MMS source did not separate lower 48 and Alaska estimates of undiscovered natural gas liquids (end 1986).

^f Using USGS definition, 0.582 billion barrels of indicated additional oil reserves in Alaska were included (EIA, end 1995).

NE = not estimated.

NA = not applicable.

Notes: **Onshore plus** indicates USGS estimates for all onshore plus State Offshore (near-shore, shallow-water areas under State jurisdictions). **Fed. Offshore** indicates MMS estimates for Federal Offshore jurisdictions (Outer Continental Shelf and deeper water areas seaward of State Offshore). **ss** = sandstone and **sh** = shale. End years indicate the latest data used. Energy Information Administration (EIA), onshore and offshore estimated reserves. U.S. Geological Survey (USGS): 1995 National Assessment mean estimates as of the end of 1993 (onshore and State Offshore). Minerals Management Service (MMS): 1996 National Assessment mean estimates as of the end of 1994. The MMS also has end-1994 estimates for economically recoverable resources. Probable and Possible reserves are considered by USGS definition to be part of USGS Reserve Growth, but are separately considered by the MMS as its Unproved Reserves term. The USGS did not set a time limit for the duration of Reserve Growth; the MMS set the year 2020 as the time limit in its estimates of Reserve Growth in existing fields of the Gulf of Mexico. Excluded from the estimates are undiscovered oil resources in tar deposits and oil shales, and undiscovered gas resources in geopressured brines and gas hydrates.

Sources: Energy Information Administration, Office of Oil and Gas; USGS and MMS - *Estimates of Undiscovered Conventional Oil and Gas Resources in the United States—A Part of the Nation's Energy Endowment* (1989), U.S. Department of the Interior; *1995 National Assessment of United States Oil and Gas Resources*, USGS Circular 1118, U.S. Department of the Interior; and *An Assessment of the Undiscovered Hydrocarbon Potential of the Nation's Outer Continental Shelf* (1996), U.S. Department of the Interior.

data.[50] They are similarly defined by the MMS, although its system also subdivides them by degree of development and producing status.[51] Measured reserves are demonstrated with reasonable certainty to be recoverable in future years from known reservoirs under existing economic and operating conditions, and are essentially equivalent to proved reserves as defined by the EIA. Effectively, estimates of proved reserves may be thought of as reasonable estimates (as opposed to exact measures) of "on-the-shelf inventory".

Inferred reserves and indicated reserves, due to their more uncertain economic or technical recoverability, are included in the "other reserves" category. The USGS defines inferred reserves as that part of the identified economically recoverable resource, over and above both measured and indicated (see below) reserves, that will be added to proved reserves in the future through extensions, revisions, and the discovery of new pay zones in already discovered fields.[50] Inferred reserves are considered equivalent to "probable reserves" by many analysts, for example, those of the PGC.

Indicated additional reserves, a separate category, are defined by both the DOI and the EIA as quantities of crude oil that may become economically recoverable in the future from existing productive reservoirs through the application of currently available but as-yet uninstalled recovery technology. At such time as the technology is successfully applied, indicated additional reserves are reclassified to the proved reserves category. Of all the various "other reserves" categories, only indicated additional reserves are estimated by the EIA and reported herein.

Proved Reserves

The EIA defines proved reserves as those volumes of oil and gas that geological and engineering data demonstrate with reasonable certainty to be recoverable in future years from known reservoirs under existing economic and operating conditions. Proved reserves are either proved producing or proved nonproducing (i.e., resident in reservoirs that did not produce during the report year). The latter may represent a substantial fraction of total proved reserves.

Reserve Estimation Methodologies

The adoption of a standard definition of proved reserves for each type of hydrocarbon surveyed by the Form EIA-23 program provided a far more consistent

response from operators than if each operator had used their own definition. Such standards, however, do not guarantee that the resulting estimates themselves are determinate. Regardless of the definition selected, proved reserves cannot be measured directly. They are estimated quantities that are inferred on the basis of the best geological, engineering, and economic data available to the estimator, who generally uses considerable judgment in the analysis and interpretation of the data. Consequently, the accuracy of a given estimate varies with and depends on the quality and quantity of raw data available, the estimation method used, and the training and experience of the estimator. The element of judgment commonly accounts for the differences among independent estimates for the same reservoir or field.

Data Used in Making Reserve Estimates

The raw data used in estimating proved reserves include the engineering and geological data for reservoir rock and its fluid content. These data are obtained from direct and indirect measurements. The data available for a given reservoir vary in kind, quality, and quantity. When a reservoir is first discovered only data from a single well are available, and prior to flow testing or actual production, proved reserves can only be inferred. As development of the reservoir proceeds, and flow tests are made or actual production commences, more and more data become available, enabling proved reserves estimates to become more accurate.

Many different kinds of data are useful in making reserves estimates. They may include: data on porosity, permeability, and fluid saturations of the reservoir rocks (obtained directly from core analysis or from various types of electrical measurements taken in a well or several wells); data on the production of fluids from a well or several wells; geologic maps of the areal extent, thickness, and continuity of the reservoir rocks (inferred from well logs, geophysical, and geological data); and reservoir pressure and temperature data. Also involved are economic data including the current price of crude oil and natural gas, and various developmental and operating costs.

Reserve Estimation Techniques

Depending on the kinds and amounts of data available, and a judgment on the reliability of those data, the

estimator will select one of several methods of making a proved reserves estimate. Methods based on production performance data are generally more accurate than those based strictly on inference from geological and engineering data. Such methods include the *Production Decline* method (for crude oil or natural gas reservoirs), the *Material Balance* method (for crude oil reservoirs), the *Pressure Decline* method (which is actually a material balance, for natural gas reservoirs), and the *Reservoir Simulation* method (for crude oil or natural gas reservoirs). The reservoir type and production mechanisms and the types and amounts of reliable data available determine which of these methods is more appropriate for a given reservoir. These methods are of comparable accuracy.

Methods not based upon production data include the *Volumetric* method (for crude oil or natural gas reservoirs) and the *Nominal* method. Of these, the *Volumetric* method is the more accurate. Both methods, however, are less accurate than those based on production data. Table G2 summarizes the various methods.

Judgmental Factors in Reserve Estimation

The determination of rock and hydrocarbon fluid properties involves judgment and is subject to some uncertainty; however, the construction of the geologic maps and cross sections and the determination of the size of the reservoir are the major judgmental steps in the *Volumetric* method, and are subject to the greatest uncertainty. Estimates made using the *Material Balance* method, the *Reservoir Simulation* method, or the *Pressure Decline* method are based on the estimator's judgment that the type of reservoir drive mechanism has been identified and on the specification of abandonment conditions. Estimates based on the *Production Decline* method are subject to judgment in constructing the trend line, and are based on the estimator's assumption of reservoir performance through abandonment.

Contributing to the degree of uncertainty inherent in the above methods for estimating reserves are other factors associated with economic considerations and the perceived reservoir limits, which together influence the final reserves estimate. A brief discussion of these other factors follows.

Economic considerations: There has been continuing debate about the effects of prices on proved reserves. Although no all-inclusive statement can be made on the

Table G2. Reserve Estimation Techniques

Method	Comments
Volumetric	Applies to crude oil and natural gas reservoirs. Based on raw engineering and geologic data.
Material Balance	Applies to crude oil and natural gas reservoirs. Is used in estimating reserves. Usually of more value in predicting reserves, and reservoir performance.
Pressure Decline	Applies to nonassociated and associated gas reservoirs. The method is a special case of material balance equation in the absence of water influx.
Production Decline	Applies to crude oil and natural gas reservoirs during production decline (usually in the later stages of reservoir life).
Reservoir Simulation	Applies to crude oil and natural gas reservoirs. Is used in estimating reserves. Usually of more value in predicting reservoir performance. Accuracy increases when matched with past pressure and production data.
Nominal	Applied to crude oil and natural gas reservoirs. Based on rule of thumb or analogy with another reservoir or reservoirs believed to be similar; least accurate of methods used.

impact of price, the points at issue can be discussed and some general remarks can be made about some circumstances where price may be a factor.

- *Developed gas fields* - In a gas reservoir, price affects the economic limit (i.e., the production rate required to meet operating costs) and, therefore, the abandonment pressure. Thus, price change has some effect on the conversion of noneconomic hydrocarbon resources to the category of proved reserves. In both nearly depleted reservoirs and newly developed reservoirs, the actual increase in the quantity of proved reserves resulting from price rises is generally limited in terms of national volumes (even though the percentage increase for a given reservoir may be great).
- *Developed oil fields* - In developed crude oil reservoirs many of the same comments apply; however, there is an additional consideration. If the price is raised to a level sufficient to justify initiation of an improved recovery project, and if the improved recovery technique is effective, then the addition to ultimate recovery from the reservoir can be significant. Because of the speculative nature of predicting prices and costs many years into the future, proved reserves are

estimated on the basis of current prices, costs, and operating practices in effect as of the date the estimation was made.

- *Successful exploration efforts* - Price can have a major impact on whether a new discovery is produced or abandoned. For example, the decision to set casing in a new onshore discovery, or to install a platform as the result of an offshore discovery, are both price-sensitive. If the decision is made to set pipe or to install a platform, the discoveries in both cases will add to the proved reserves total. If such projects are abandoned, they will make no contribution to the proved reserves total.

Effect of operating conditions: Operating conditions are subject to change caused by changes in economic conditions, unforeseen production problems, new production practices or methods, and the operator's financial position. As with economic conditions, operating conditions to be expected at the time of abandonment are speculative. Thus, current operating conditions are used in estimating proved reserves. In considering the effect of operating conditions, a distinction must be made between processes and techniques that would normally be applied by a prudent operator in producing his oil and gas, and initiation of changes in operating conditions that would require substantial new investment.

- *Compression* - Compression facilities are normally installed when the productive capacity or deliverability of a natural gas reservoir or its individual wells declines. In other cases compression is used in producing shallow, low-pressure reservoirs or reservoirs in which the pressure has declined to a level too low for the gas to flow into a higher pressure pipeline. The application of compression increases the pressure and, when economical, is used to make production into the higher pressure pipeline possible. Compression facilities normally require a significant investment and result in a change in operating conditions. It increases the proved reserves of a reservoir, and reasonably accurate estimates of the increase can be made.
- *Well stimulation* - Procedures that increase productive capacity (workovers, such as acidizing or fracturing, and other types of production practices) are routine field operations. The procedures accelerate the rate of production from the reservoir, or extend its life, and they

have only small effect on proved reserves. Reasonable estimates of their effectiveness can be made.

- *Improved recovery techniques* - These techniques involve the injection of a fluid or fluids into a reservoir to augment natural reservoir energy. Because the response of a given reservoir to the application of an improved recovery technique cannot be accurately predicted, crude oil production that may ultimately result from the application of these techniques is classified as "indicated additional reserves of crude oil" rather than as proved reserves until response of the reservoir to the technique has been demonstrated. In addition, improved recovery methods are not applicable to all crude oil reservoirs. Initiation of improved recovery techniques may require significant investment.
- *Infill drilling* - Infill drilling (drilling of additional wells within a field/reservoir) may result in a higher recovery factor, and, therefore, be economically justified. Predictions of whether infill drilling will be justified under current economic conditions are generally based on the expected production behavior of the infill wells.

Reservoir limits: The initial proved reserves estimate made from the discovery well is subject to significant uncertainty because one well provides little information on the size of the reservoir. The area proved by a discovery well is frequently estimated on the basis of experience in a given producing region. Where there is continuity of the producing formation over wide geographic areas, a relatively large proved area may be assigned. In some cases where reliable geophysical and geological data are available, a reasonable estimate of the extent of the reservoir can be made by drilling a relatively small number of delineation wells. Conversely, a relatively small proved area may be assigned when the producing formation is of limited continuity, owing to either structural or lithological factors.

Additional wells provide more information and reduce the uncertainty of the reserves estimate. As additional wells are drilled, the geometry of the reservoir and, consequently, its bulk volume, become more clearly defined. This process accounts for the large extensions to proved reserves typical of the early stages of most reservoir development.

Glossary

Glossary

This glossary contains definitions of the technical terms used in this report and employed by respondents in completing Form EIA-23, "Annual Survey of Domestic Oil and Gas Reserves," or Form EIA-64A, "Annual Report of the Origin of Natural Gas Liquids Production," for the report year 1995.

Adjustments: The quantity which preserves an exact annual reserves balance within each State or State subdivision of the following form:

Published Proved Reserves at End of Previous Report Year
+ Adjustments
+ Revision Increases
- Revision Decreases
+ Extensions
+ New Field Discoveries
+ New Reservoir Discoveries in Old Fields
+ Report Year Production
= Published Proved Reserves at End of Report Year

These adjustments are the yearly changes in the published reserve estimates that cannot be attributed to the estimates for other reserve change categories because of the survey and statistical estimation methods employed. For example, variations as a result of changes in the operator frame, different random samples or imputations for missing or unreported reserve changes, could contribute to adjustments.

Affiliated (Associated) Company: An "affiliate" of, or a person "affiliated" with, a specific person is a person that directly, or indirectly through one or more intermediaries: controls; or is controlled by; or is under common control with, the person specified. (See Person and Control)

Control: The term "control" (including the terms "controlling," "controlled by," and "under common control with") means the possession, direct or indirect, of the power to direct or cause the direction of the management and policies of a person, whether through the ownership of voting shares, by contract, or otherwise. (See Person)

Corrections: (See Revisions)

Crude Oil: A mixture of hydrocarbons that exists in the liquid phase in natural underground reservoirs

and remains liquid at atmospheric pressure after passing through surface separating facilities. Crude oil may also include:

1. Small amounts of hydrocarbons that exist in the gaseous phase in natural underground reservoirs but are liquid at atmospheric pressure after being recovered from oil well (casinghead) gas in lease separators, and that subsequently are comingled with the crude stream without being separately measured
2. Small amounts of nonhydrocarbons produced with the oil.

When a State regulatory agency specifies a definition of crude oil which differs from that set forth above, the State definition is to be followed and its use footnoted on Schedule B of Form EIA-23.

Extensions: The reserves credited to a reservoir because of enlargement of its proved area. Normally the ultimate size of newly discovered fields, or newly discovered reservoirs in old fields, is determined by wells drilled in years subsequent to discovery. When such wells add to the proved area of a previously discovered reservoir, the increase in proved reserves is classified as an extension.

Field: An area consisting of a single reservoir or multiple reservoirs all grouped on, or related to, the same individual geological structural feature and/or stratigraphic condition. There may be two or more reservoirs in a field that are separated vertically by intervening impervious strata, or laterally by local geologic barriers, or by both.

Field Area: A geographic area encompassing two or more pools that have a common gathering and metering system, the reserves of which are reported as a single unit. This concept applies primarily to the Appalachian region. (See Pool)

Field Discovery Year: The calendar year in which a field was first recognized as containing economically recoverable accumulations of oil and/or gas.

Field Separation Facility: A surface installation designed to recover lease condensate from a

produced natural gas stream frequently originating from more than one lease, and managed by the operator of one or more of these leases. (See Lease Condensate)

Gross Working Interest Ownership Basis: Gross working interest ownership is the respondent's working interest in a given property plus the proportionate share of any royalty interest, including overriding royalty interest, associated with the working interest. (See Working Interest and Royalty (including Overriding Royalty) Interest)

Indicated Additional Reserves of Crude Oil: Quantities of crude oil (other than proved reserves) which may become economically recoverable from existing productive reservoirs through the application of improved recovery techniques using current technology. These recovery techniques may:

1. Already be installed in the reservoir, but their effects are not yet known to the degree necessary to classify the additional reserves as proved
2. Be installed in another similar reservoir, where the results of that installation can be used to estimate the indicated additional reserves.

Indicated additional reserves are not included in proved reserves due to their uncertain economic recoverability. When economic recoverability is demonstrated, the indicated additional reserves must be transferred to proved reserves as positive revisions.

Lease Condensate: A mixture consisting primarily of pentanes and heavier hydrocarbons which is recovered as a liquid from natural gas in lease or field separation facilities, exclusive of products recovered at natural gas processing plants or facilities.

Lease Separator: A lease separator is a facility installed at the surface for the purpose of (a) separating gases from produced crude oil and water at the temperature and pressure conditions of the separator, and/or (b) separating gases from that portion of the produced natural gas stream which liquefies at the temperature and pressure conditions of the separator.

Natural Gas: A mixture of hydrocarbon compounds and small quantities of various nonhydrocarbons existing in the gaseous phase or in solution with crude oil in natural underground reservoirs at

reservoir conditions. The principal hydrocarbons normally contained in the mixture are methane, ethane, propane, butane, and pentanes. Typical nonhydrocarbon gases which may be present in reservoir natural gas are water-vapor, carbon dioxide, helium, hydrogen sulfide, and nitrogen. Under reservoir conditions, natural gas and the liquefiable portions occur either in a single gaseous phase in the reservoir or in solution with crude oil, and are not distinguishable at the time as separate substances. (See Natural Gas, Associated-Dissolved and Natural Gas, Nonassociated)

Natural Gas, Associated-Dissolved: The combined volume of natural gas which occurs in crude oil reservoirs either as free gas (associated) or as gas in solution with crude oil (dissolved).

Natural Gas, "Dry": The actual or calculated volumes of natural gas which remain after:

1. The liquefiable hydrocarbon portion has been removed from the gas stream (i.e., gas after lease, field, and/or plant separation)
2. Any volumes of nonhydrocarbon gases have been removed where they occur in sufficient quantity to render the gas unmarketable.

Natural Gas, Nonassociated: Natural gas not in contact with significant quantities of crude oil in a reservoir.

Natural Gas Liquids: Those hydrocarbons in natural gas which are separated from the gas through the processes of absorption, condensation, adsorption, or other methods in gas processing or cycling plants. Generally such liquids consist of propane and heavier hydrocarbons and are commonly referred to as condensate, natural gasoline, or liquefied petroleum gases. Where hydrocarbon components lighter than propane are recovered as liquids, these components are included with natural gas liquids.

Natural Gas Processing Plant: A facility designed to recover natural gas liquids from a stream of natural gas which may or may not have passed through lease separators and/or field separation facilities. Another function of the facility is to control the quality of the processed natural gas stream. Cycling plants are considered natural gas processing plants.

Natural Gas, Wet After Lease Separation: The volume of natural gas remaining after removal of lease condensate in lease and/or field separation facilities, if any, and after exclusion of

nonhydrocarbon gases where they occur in sufficient quantity to render the gas unmarketable. Natural gas liquids may be recovered from volumes of natural gas, wet after lease separation, at natural gas processing plants. (See Lease Condensate, Lease Separator, and Field Separation Facility)

Net Revisions: (See Revisions)

New Field: A field discovered during the report year.

New Field Discoveries: The volumes of proved reserves of crude oil, natural gas and/or natural gas liquids discovered in new fields during the report year.

New Reservoir: A reservoir discovered during the report year.

New Reservoir Discoveries in Old Fields: The volumes of proved reserves of crude oil, natural gas, and/or natural gas liquids discovered during the report year in new reservoir(s) located in old fields.

Nonproducing Reservoirs: Reservoirs in which proved liquid or gaseous hydrocarbon reserves have been identified, but which did not produce during the last calendar year regardless of the availability and/or operation of production, gathering, or transportation facilities.

Old Field: A field discovered prior to the report year.

Old Reservoir: A reservoir discovered prior to the report year.

Operator, Gas Plant: The person responsible for the management and day-to-day operation of one or more natural gas processing plants as of December 31 of the report year. The operator is generally a working interest owner or a company under contract to the working interest owner(s). Plants shut down during the report year are also to be considered "operated" as of December 31. (See Person)

Operator, Oil and/or Gas Well: The person responsible for the management and day-to-day operation of one or more crude oil and/or natural gas wells as of December 31 of the report year. The operator is generally a working interest owner or a company under contract to the working interest owner(s). Wells included are those which have proved reserves of crude oil, natural gas, and/or

lease condensate in the reservoirs associated with them, whether or not they are producing. Wells abandoned during the report year are also to be considered "operated" as of December 31. (See Person, Proved Reserves of Crude Oil, Proved Reserves of Natural Gas, Proved Reserves of Lease Condensate, Report Year, and Reservoir)

Ownership: (See Gross Working Interest Ownership Basis)

Parent Company: The parent company of a business entity is an affiliated company which exercises ultimate control over that entity, either directly or indirectly through one or more intermediaries. (See Affiliated (Associated) Company and Control)

Person: An individual, a corporation, a partnership, an association, a joint-stock company, a business trust, or an unincorporated organization.

Pool: In general, a reservoir. In certain situations a pool may consist of more than one reservoir. (See Field Area)

Plant Liquids: Those volumes of natural gas liquids recovered in natural gas processing plants.

Production, Crude Oil: The volumes of crude oil which are extracted from oil reservoirs during the report year. These volumes are determined through measurement of the volumes delivered from lease storage tanks, (i.e., at the point of custody transfer) with adjustment for (1) net differences between opening and closing lease inventories, and for (2) basic sediment and water. Oil used on the lease is considered production.

Production, Lease Condensate: The volume of lease condensate produced during the report year. Lease condensate volumes include only those volumes recovered from lease or field separation facilities. (See Lease Condensate)

Production, Natural Gas, Dry: The volume of natural gas withdrawn from reservoirs during the report year less (1) the volume returned to such reservoirs in cycling, repressuring of oil reservoirs and conservation operations; less (2) shrinkage resulting from the removal of lease condensate and plant liquids; and less (3) nonhydrocarbon gases where they occur in sufficient quantity to render the gas unmarketable. Volumes of gas withdrawn from gas storage reservoirs and native gas, which has been

transferred to the storage category, are not considered production. This is not the same as marketed production, since the latter also excludes vented and flared gas, but contains plant liquids.

Production, Natural Gas, Wet after Lease Separation: The volume of natural gas withdrawn from reservoirs during the report year less (1) the volume returned to such reservoirs in cycling, repressuring of oil reservoirs and conservation operations; less (2) shrinkage resulting from the removal of lease condensate; and less (3) nonhydrocarbon gases where they occur in sufficient quantity to render the gas unmarketable. Volumes of gas withdrawn from gas storage reservoirs and native gas, which has been transferred to the storage category, are not considered production. This is not the same as marketed production, since the latter excludes vented and flared gas.

Production, Natural Gas Liquids: The volume of natural gas liquids removed from natural gas in lease separators, field facilities, gas processing plants or cycling plants during the report year.

Production, Plant Liquids: The volume of liquids removed from natural gas in natural gas processing plants or cycling plants during the report year.

Proved Reserves of Crude Oil: Proved reserves of crude oil as of December 31 of the report year are the estimated quantities of all liquids defined as crude oil, which geological and engineering data demonstrate with reasonable certainty to be recoverable in future years from known reservoirs under existing economic and operating conditions.

Reservoirs are considered proved if economic producibility is supported by actual production or conclusive formation test (drill stem or wire line), or if economic producibility is supported by core analyses and/or electric or other log interpretations. The area of an oil reservoir considered proved includes (1) that portion delineated by drilling and defined by gas-oil and/or oil-water contacts, if any; and (2) the immediately adjoining portions not yet drilled, but which can be reasonably judged as economically productive on the basis of available geological and engineering data. In the absence of information on fluid contacts, the lowest known structural occurrence of hydrocarbons is considered to be the lower proved limit of the reservoir.

Volumes of crude oil placed in underground storage are not to be considered proved reserves.

Reserves of crude oil which can be produced economically through application of improved recovery techniques (such as fluid injection) are included in the "proved" classification when successful testing by a pilot project, or the operation of an installed program in the reservoir, provides support for the engineering analysis on which the project or program was based.

Estimates of proved crude oil reserves do not include the following: (1) oil that may become available from known reservoirs but is reported separately as "indicated additional reserves"; (2) natural gas liquids (including lease condensate); (3) oil, the recovery of which is subject to reasonable doubt because of uncertainty as to geology, reservoir characteristics, or economic factors; (4) oil that may occur in undrilled prospects; and (5) oil that may be recovered from oil shales, coal, gilsonite, and other such sources. It is not necessary that production, gathering or transportation facilities be installed or operative for a reservoir to be considered proved.

Proved Reserves of Lease Condensate: Proved reserves of lease condensate as of December 31 of the report year are the volumes of lease condensate expected to be recovered in future years in conjunction with the production of proved reserves of natural gas as of December 31 of the report year, based on the recovery efficiency of lease and/or field separation facilities installed as of December 31 of the report year. (See Lease Condensate and Proved Reserves of Natural Gas)

Proved Reserves of Natural Gas: Proved reserves of natural gas as of December 31 of the report year are the estimated quantities which analysis of geological and engineering data demonstrate with reasonable certainty to be recoverable in future years from known reservoirs under existing economic and operating conditions.

Reservoirs are considered proved if economic producibility is supported by actual production or conclusive formation test (drill stem or wire line), or if economic producibility is supported by core analyses and/or electric or other log interpretations.

The area of a gas reservoir considered proved includes: (1) that portion delineated by drilling and defined by gas-oil and/or gas-water contacts, if any; and (2) the immediately adjoining portions not yet drilled, but which can be reasonably judged as economically productive on the basis of available geological and engineering data. In the absence of

information on fluid contacts, the lowest known structural occurrence of hydrocarbons is considered to be the lower proved limit of the reservoir.

Volumes of natural gas placed in underground storage are not to be considered proved reserves.

For natural gas, wet after lease separation, an appropriate reduction in the reservoir gas volume has been made to cover the removal of the liquefiable portions of the gas in lease and/or field separation facilities and the exclusion of nonhydrocarbon gases where they occur in sufficient quantity to render the gas unmarketable.

For dry natural gas, an appropriate reduction in the gas volume has been made to cover the removal of the liquefiable portions of the gas in lease and/or field separation facilities, and in natural gas processing plants, and the exclusion of nonhydrocarbon gases where they occur in sufficient quantity to render the gas unmarketable.

It is not necessary that production, gathering, or transportation facilities be installed or operative for a reservoir to be considered proved. It is to be assumed that compression will be initiated if and when economically justified.

Proved Reserves of Natural Gas Liquids: Proved reserves of natural gas liquids as of December 31 of the report year are those volumes of natural gas liquids (including lease condensate) demonstrated with reasonable certainty to be separable in the future from proved natural gas reserves, under existing economic and operating conditions.

Report Year: The calendar year to which data reported in this publication pertain.

Reserves: (See Proved Reserves)

Reserve Additions: Consist of adjustments, net revisions, extensions to old reservoirs, new reservoir discoveries in old fields, and new field discoveries.

Reserves Changes: Positive and negative revisions, extensions, new reservoir discoveries in old fields, and new field discoveries, which occurred during the report year.

Reservoir: A porous and permeable underground formation containing an individual and separate natural accumulation of producible hydrocarbons (oil and/or gas) which is confined by impermeable rock

or water barriers and is characterized by a single natural pressure system.

Revisions: Changes to prior year-end proved reserves estimates, either positive or negative, resulting from new information other than an increase in proved acreage (extension). Revisions include increases of proved reserves associated with the installation of improved recovery techniques or equipment. They also include correction of prior report year arithmetical or clerical errors and adjustments to prior year-end production volumes to the extent that these alter reported prior year reserves estimates.

Royalty (Including Overriding Royalty) Interests: These interests entitle their owner(s) to a share of the mineral production from a property or to a share of the proceeds therefrom. They do not contain the rights and obligations of operating the property, and normally do not bear any of the costs of exploration, development, and operation of the property.

Subdivision: A prescribed portion of a given State or other geographical region defined in this publication for statistical reporting purposes.

Subsidiary Company: A company which is controlled through the ownership of voting stock, or a corporate joint venture in which a corporation is owned by a small group of businesses as a separate and specific business or project for the mutual benefit of the members of the group. (See Control)

Total Discoveries: The sum of extensions, new reservoir discoveries in old fields, and new field discoveries, which occurred during the report year.

Total Liquid Hydrocarbon Reserves: The sum of crude oil and natural gas liquids reserves volumes.

Total Operated Basis: The total reserves or production associated with the wells operated by an individual operator. This is also commonly known as the "gross operated" or "8/8ths" basis.

Working Interest: A working interest permits the owner(s) to explore, develop and operate a property. The working interest owner(s) bear(s) the costs of exploration, development and operation of the property, and in return is (are) entitled to a share of the mineral production from the property or to a share of the proceeds therefrom.

Introducing the Energy InfoDisc...

How much oil does the U.S. import from the Persian Gulf?

How many U.S. households use personal computers?

What's the long range outlook for nuclear power, and how will it affect other fuels?

How are clean air regulations affecting emissions in the electric power industry?

Find answers to all your energy questions with **Energy InfoDisc**, the new CD-ROM providing the most comprehensive collection of energy information and analysis tools available today. **Energy InfoDisc** is a valuable resource for industry and government analysts, forecasters, journalists, and academic researchers - almost anyone needing access to current or historical energy information.

The **Energy InfoDisc** comes with advanced search capability to find the information you need in seconds - from over 180 of the most current periodicals and analytical publications of the Energy Information Administration (EIA), the independent statistical and analytical agency within the U.S. Department of Energy. With **Energy InfoDisc**, you also have instant access to EIA's wide range of national energy databases and special analysis applications. Don't be without this important resource; subscribe today.

NOTE: Documents can be accessed using either Microsoft Windows or Macintosh System 7 operating systems. Databases and applications can only be accessed using Microsoft Windows.
