

1A-SUB-- 96-8

Report of tests carried out on Viton O-ring Seals to assess suitability for operation over the temperature range -40°C to +220°C when used in Package Design 2863B

1. Introduction

To satisfy the requirements of US Regulatory bodies the O-ring seals in the containment vessels of Package Design 2863B have to be shown to operate satisfactorily (ie remain leaktight) at the extremes of temperature that they are expected to experience during both normal and hypothetical accident conditions of transport. For Package Design 2863B this effectively means that the seals must remain leaktight over the temperature range -40° C to $+ 220^{\circ}$ C, but to ensure that an adequate safety margin exists the seals should preferably remain leaktight over the range -50° C to $+250^{\circ}$ C.

This test report describes the procedures and results of tests carried out on Viton seals over the temperature range -50° C to $+250^{\circ}$ C.

2. <u>Administrative Details</u>

- 2.1 The tests were carried out by M Lam and M B Johnson with the assistance, where appropriate, of the Inspection and Testing Services Division of AEA Technology, Harwell.
- 2.2 The work was carried out under Croft project reference Z93/11/10 during the period August 1994 October 1994.

3. <u>Test Procedures and Objective</u>

The general procedure followed during the tests was to measure the leaktightness of the seals whilst assembled into a mechanical assembly ('Test Head Assembly') which exactly represented the vessel closure section of the 2870 vessel. The test head assembly however had a shortened body, which enabled the assembly to be placed into the controllable temperature region of a temperature adjustable environmental chamber, thereby allowing leakage tests to be carried out over the whole temperature range from -50°C to +250°C. Assessment of seal temperature was made by the temperature measurement system contained in the environmental chamber, and cross-checked by thermocouples located close to the seals in the test head assembly.

The objective of the tests was to show that the seals remained leaktight as defined in ANSI N14.5 (Ref 1) throughout the temperature -50 to +250. Leakage tests were performed using helium mass spectrometry leakage testing. However, prior to carrying out these tests it was decided to first carry out a series of 'scoping' tests using pressure drop testing. The detailed procedures followed for these tests are

contained in Croft procedures CP 157 Issue A and CP 158 Issue A.

4. <u>Selection of Seal Material</u>

Commercially available seals made from compounds based on Viton Fluorocarbon material are widely used in the UK in radioactive packagings.

Drop tests have been previously carried out on a prototype of the 2863B package, the seals in which were procured to a Dowty Seals Limited Viton Specification (Dowty Material Type 9775).

Subsequently it was recognised that not all aspects of performance of the Dowty Specification were needed to obtain satisfactory seal performance when used in the 2870 containment vessel.

After consideration of what parameters were essential to be included in the procurement specification for such seals, specification CM 055 Issue B was produced to include these. The seals used in the tests described in this report were therefore procured from Ceetak Limited (Ref 2) to Material Specification CM 055 Issue B, and dimensional requirements as defined for containment vessel Design Number 2870, in drawing number 1C-2415 Issue E.

5. <u>Results</u>

5.1 <u>Test Head Assembly</u>

The test head assembly was manufactured by Oxford Engineering Limited (Ref 3) to Drawing List DL-OC-4027 Issue A under Croft project reference Y93/9/18.

Prior to use, however, 2 additional features were added to facilitate the testing; firstly an additional connection was made through the lid to enable the test head cavity to be evacuated through one hole and back filled with helium through the other; secondly 2 additional holes were added to allow use of 4 (rather than 2) thermocouples for monitoring the seal temperature.

Detailed metrology carried out on the test head assembly showed that with the exception of the above two modifications the test head complied in all respects with the design requirements detailed under drawing list DL-OC-4027 Issue A. In particular the O-ring groove profiles and positions were all within specification, with the groove depths being measured at an actual dimension of 2.23 mm which is within specification requirements of 2.17/2.32 mm.

5.2 Environmental Chamber and Thermocouples

The environmental chamber equipment used during the tests was supplied by Climatic Systems Limited (Ref 4).

The equipment was purpose-built for this test work but the design was based on a standard Climatic Systems product (Model BT 125 L), with a modification to enable it to operate at a higher temperature ($250^{\circ}C$ compared to $180^{\circ}C$ for the standard equipment). The chamber temperature is measured by a calibrated measurement system contained within the equipment. The system uses platinum resistance thermometry and the temperature is displayed on an integral display panel. Temperature stability of the chamber is stated to be within $\pm 0.5^{\circ}C$, with thermal gradient within the chamber to within $\pm 1^{\circ}C$.

The voltages developed by the thermocouples installed in the test head were converted to temperatures by an interface which fed directly into a data logging system. The accuracy of the logged temperatures was checked by comparison with independent thermocouple measurements made with a calibrated instrument (Digitron Model 3202K, Serial No 051/9). Measurements agreed to within 2-3°C. Comparison of the temperatures measured by the environmental chamber measurement system with the data logged temperatures measured on the thermocouples showed agreement generally to within $\pm 1^{\circ}$ C.

Because the thermocouple measurements were not directly calibrated measurements they were only used to verify temperature stability of the test head during leakage testing. Measured temperatures quoted later in this report therefore refer to the figures taken from the environmental chamber display.

5.3 Seals

7 sets of seals were used during the tests; 4 sets for the initial pressure drop testing trials, and 3 further sets for the helium leakage tests.

No tests were performed on the seals to verify that the seal material was indeed a Viton formulation, but certificates of conformity supplied with the O-rings certified that they met specification, and as the supplier, Ceetak Ltd (Ref 1), is a recognised O-ring supplier approved by Lloyds Register as an approved stockist to ISO 9002, it was decided that Certificates of Conformity provided adequate guarantee of material conformance to specification.

The cross section diameter and hardness were checked prior to use and found to be within specification on all O-rings. Before each test the O-rings were visually inspected to confirm that they were free from mechanical defects

(cuts, scratches, etc).

The low temperature pressure drop tests were performed with the O-rings lightly lubricated by wiping with silicone grease. The high temperature pressure drop tests however were performed with un-lubricated rings.

It was initially intended to perform comparative measurements at both high and low temperatures with both lubricated and un-lubricated rings. However, due to time pressure it was not possible to complete these measurements before proceeding to the helium leakage tests, which were carried out with lubricated O-rings only.

5.4 <u>Seal Compression/Torque Setting</u>

The operating procedure for the 2863B package design specifies that the 2870 containment can should be closed using a torque of between 160 and 180 Nm applied to the screw retaining ring. Pre-test trials showed that although the package will, at room temperature, be leaktight to the required level when closed at this torque setting the lid and vessel body will not quite be in metal to metal contact. Further trials showed a torque of 195 Nm was needed to provide a metal to metal condition, and therefore all tests were carried out after closing the test head assembly using a torque of 200 Nm. The relative positions of the screw retaining ring and test head were marked in the metal to metal condition to provide a further check that the same condition was achieved on subsequent assembly of the components.

As stated in 5.1 the depths of the O-ring grooves were measured to be 2.23 mm, therefore in the metal to metal condition the seal compression was nominally 25.7%, based on the nominal O-ring cross section diameter of 3mm.

5.5 Pressure Drop Leakage Tests

The general set up and test procedure used for the pressure drop tests was as detailed in procedure CP 158 Issue A. A CALT 5 Leakage Tester was used to perform the leakage rate measurements. The pass criterion was set arbitrarily as a leakage rate of 5×10^4 bar cc/s SLR.

The full set of results from all the pressure drop tests are listed in Appendix 1. These results are summarised in Table 1. The tests can be broadly classified into 4 categories; initial set-up trials, low temperature tests, high temperature tests, and finally confirmatory low temperature tests prior to helium leakage testing.

The initial set up trials concentrated on low temperature performance since it is at low temperatures that Viton's ability to remain leaktight is most in question.

More than one set of seals were used during the set up trials. The seals were then replaced at the start of each of the subsequent phases of testing and the seals were not changed during these test phases. The test head assembly was cleaned each time it was dismantled for replacement of the seals.

The results of the leakage tests during the set-up trials indicated that although there was no gross leakage, the leakage rate exceeded the pass criterion in 3 of the 7 tests (all at $<-40^{\circ}$ C).

The results of the low temperature and high temperature tests showed that the seals achieved the pass criterion of leakage rate $<5 \times 10^{-4}$ bar cc/s SLR throughout, including after returning the seals to ambient temperature.

The results of the leakage tests during the confirmatory low temperature tests indicated that the seals leaked (at a leakage rate greater than 5 x 10^4 bar cc/s SLR) when the temperature was at, or below, -30° C.

No obvious reason was found for why the confirmatory tests in particular did not follow the pattern of the earlier low temperature testing, and as the prime objective of the test program was to assess the ability of these Viton seals to remain leaktight to helium at an even lower leakage rate pass criterion it was decided to discontinue further pressure drop testing and proceed with the helium tests.

Visual examination of each set of seals after testing showed no obvious signs of physical degradation of the seals either at high or low temperatures.

5.6 <u>Helium Leakage Tests</u>

The general set up and test procedure used for the helium leakage tests was as detailed in procedure CP 157 Issue A.

The tests were carried out by the Inspection and Testing Services section of AEA Technology, Harwell under the supervision of Croft Associates staff.

Before carrying out the leakage tests the rate at which helium permeated through the Viton seals was assessed in accordance with the procedure described in Appendix A of CP 157. It was found that it took approximately 60 minutes for the apparent leakage rate due to permeation to increase from a background rate of 1×10^{-9} bar cc/s to 1×10^{-7} bar cc/s. On the basis of this result it was therefore decided that during leakage tests the monitoring

time should be limited to a maximum of 10 minutes.

The full set of results of the helium leakage tests is summarised in Table 2.

3 sets of seals were used during these tests; set 1 for tests VH1 and VH2; set 2 for tests VH3 and VH4; and set 3 for all subsequent tests. Set 1 was not the same set that was used for the confirmatory pressure drop tests.

From the results (VH1 and VH2) it can be seen that the seals (Set 1) which were leaktight at ambient were leaking when retested after the test assembly had been cooled down to -40° C. A similar result was then subsequently obtained on testing seal set 2 which was found to be leaking on testing at -30° C.

The intention in testing the third set of seals was to determine the lowest temperature at which the seals remained leaktight, but, as can be seen from the results, the seals remained leaktight down to -45°C during these tests, and were confirmed to still be leaktight on warming back up to room temperature.

A single test was performed at high temperature but a high helium background level was found at the start of this test. It was concluded that this was due to outgassing of helium which had been absorbed into the seals during the low temperature tests. Further testing was suspended pending a review of the results obtained to date.

6. <u>Conclusions</u>

The variability of the results at low temperature, by both pressure drop and helium leakage testing, would indicate that the particular formulation of Viton tested cannot be used to provide a reliable leaktight seal at -40° C.

Although the results of the pressure drop tests at high temperature were satisfactory, insufficient testing has been carried out using helium leakage testing to draw a firm conclusion about the high temperature performance of the material tested.
