Abstract

We present the recent results on top quark physics and $B$ physics with the Collider Detector at Fermilab (CDF). These results come from analyses using a full data sample at an integrated luminosity of 109 pb$^{-1}$. We describe the measurements of the top quark mass and the $t\bar{t}$ production cross section in 1.8-TeV $p\bar{p}$ collisions. We measure the top quark mass to be $175.8\pm 6.5$ GeV/c$^2$ and the $t\bar{t}$ production cross section to be $7.6^{+1.8}_{-1.5}$ pb. We also present the measurements of the lifetimes of $B$-hadrons and the time-dependent $B^0 - \bar{B}^0$ mixing which results in the mass difference between heavy and light $B_d^0$ mesons ($\Delta m_d$) of $0.464\pm 0.030$ (stat)$\pm 0.026$ (syst) ps$^{-1}$.

1 Introduction

In Tevatron Run1 (1992-1995), we collected the data corresponding to an integrated luminosity of $109\pm 7$ pb$^{-1}$, and we had over $5 \times 10^{12}$ $p\bar{p}$ collisions.

Top quarks are predominantly produced in pairs by the process $p\bar{p} \rightarrow t\bar{t}X$. About 500 $t\bar{t}$ pairs were produced in Run1. It is a good place to look for extensions beyond the standard model such as new objects and new phenomena.

Since a discovery of a bottom quark in 1977 [1], a top quark which is a weak-isospin partner of the bottom quark has been searched for at various collider experiments. In April 1994, the CDF collaboration reported the first evidence for top quark production [2] where 15 $t\bar{t}$ candidates events were found against 6.0 background events expected. It corresponded to 2.8$\sigma$ excess. CDF measured the top quark mass $M_{top}$ to be $174\pm 17$ GeV/c$^2$ and the $t\bar{t}$ production cross section $\sigma_{t\bar{t}}$ to be $13.9^{+6.1}_{-4.8}$ pb. In February 1995, the CDF and D0 confirmed the existence of top quark production [3, 4]. The CDF reported that $t\bar{t}$ signals had 4.8$\sigma$ excess, $M_{top}=176\pm 8$ (stat)$\pm 10$ (syst) GeV/c$^2$ and $\sigma_{t\bar{t}} = 6.8^{+3.6}_{-2.4}$ pb. The D0 reported that $t\bar{t}$ signals had 4.6 $\sigma$ excess, $M_{top} = 199^{+19}_{-21}$ (stat)$^{+14}_{-31}$ (syst) GeV/c$^2$ and $\sigma_{t\bar{t}} = 6.4\pm 2.2$ pb. We will present the measurements of the top quark mass and the $t\bar{t}$ production cross section and the search for top quark rare decays with a full data sample in Run1.
In Run1, we collected 243 k $J/\psi$ events, fully reconstructed decays of about 1,000 $B \rightarrow J/\Psi K$ and 58±12 $B_\ast \rightarrow J/\Psi \phi$ events, and partially reconstructed decays of about 6,000 $B \rightarrow D(D^\ast)\ell\nu X$ events. Using these candidates events of $b$ quark production, we have studied $B$ physics such as the masses and lifetimes of $B$-hadrons. We here present the measurements of the lifetimes of $B$-hadrons and the time-dependent $B^0 - \bar{B}^0$ mixing which results in the mass difference between heavy and light $B^0_\mu$ mesons ($\Delta m_d$).

2 The CDF detector

The CDF detector consists of a magnetic spectrometer surrounded by calorimeters and muon chambers [5]. A silicon vertex detector (SVX), located immediately outside the beampipe, provides precise track reconstruction in the plane transverse to the beam and is used to identify secondary vertices from $b$ and $c$ quark decays [6]. The momenta of charged particles are measured in the central tracking chamber (CTC) which is in a 1.4 T superconducting solenoidal magnet. Outside the CTC, electromagnetic and hadronic calorimeters cover the pseudorapidity [7] region $|\eta| < 4.2$ and are used to identify jets and electron candidates. Outside the calorimeters, drift chambers in the region $|\eta| < 1.0$ provide muon identification.

3 Top Quark Physics

Within the standard model, the top quark decays predominantly to $Wb$. We categorize the decays of $t\bar{t}$ pairs into the following three channels by the decay of the two $W$ bosons:

- Dilepton channel: Both $W$ bosons decay leptonically. The final state is $l^+\nu l^-\bar{\nu}b\bar{b}$ ($l = e$ or $\mu$; BR = 5%).
- Lepton+jets channel: One $W$ decays hadronically and another decays leptonically. The final state is $l^+\nu q\bar{q}'b\bar{b}$ ($l = e$ or $\mu$; BR = 30%).
- All hadronic channel: Both $W$ bosons decay hadronically. The final state is $q\bar{q}' q\bar{q}'' b\bar{b}$ (BR = 44%)

In this paper, we mainly describe the analyses in the lepton+jets channel. In the lepton+jets channel, we require one isolated high $P_T$ lepton ($e$ or $\mu$) with $P_T > 20$ GeV/c, high missing transverse energy ($E_T > 20$ GeV) and 3 or more jets with $E_T > 15$ GeV in $|\eta| < 2.0$.

Dominant background is $p\bar{p} \rightarrow W(\rightarrow l\nu)+$jets. In order to separate $t\bar{t}$ events in the lepton+jets channel from the large $W+$jets background, we require that one of the jets be identified as a $b$-quark jet. We tag $b$-jets by reconstructing displaced vertices from $b$-quark decay using the SVX (SVX tagging), or identifying an additional lepton from a semileptonic $b$ decay (SLT tagging). The SVX and SLT tagging algorithms are described in Reference [3].
3.1 $t\bar{t}$ Production Cross Section

We measure the $t\bar{t}$ production cross section [8] which tests both the production and decay mechanics of the standard model. Recent calculations based on Quantum Chromodynamics (QCD) [9] have led to predictions for the cross section from 4.8 to 5.5 pb at a top quark mass of 175 GeV/c² with a theoretical uncertainty of less than 15%.

The efficiency for the SVX tagging at least one $b$ tagging in a $t\bar{t}$ event with $\geq 3$ jets is found to be (39±3)%. Of the 39%, a factor of 67% comes from the fiducial acceptance of the SVX. The SLT algorithm identifies both muons and electrons with $P_T > 2.0 GeV/c$ in $|\eta| < 1.0$. The probability of finding an additional $e$ or $\mu$ from a $b$ quark decay in a $t\bar{t}$ event with $\geq 3$ jets is found to be (18±2)%.

In the $t\bar{t}$ signal region of $W^+ \geq 3$jets, there are 34 SVX-tagged events containing a total of 42 SVX tags, and 40 SLT-tagged events containing a total of 44 SLT tags. Of these, 11 events are tagged by both the SVX and SLT algorithms.

The most important source of backgrounds in the $b$-tagged lepton+jets channel is inclusive $W$ production in association with jets containing $b$ or $c$ quarks, e.g. $p\bar{p} \rightarrow Wg (g \rightarrow b\bar{b})$. In addition, there are contributions to the background from mistags which are tags in non-$b$ jets, and small contributions from the following processes: non-$W$ (e.g. direct $b\bar{b}$ production), single top production, $WW$, $WZ$, and Drell-Yan.

To calculate the background from $W^+$heavy flavor events, we use HERWIG [10] and VECBOS [11] Monte Carlo programs to predict the fraction of $W^+$jets events which are $Wb\bar{b}, Wc\bar{c}$ and $Wc$ as a function of jet multiplicity. These fraction are applied to the number of $W^+$jet events seen in the data to give an expected background from these sources for each jet multiplicity. The details of this method can be found in Reference [2].

Thus we have 34 SVX-tagged (40 SLT-tagged) events with an expected background of 9.2 (22.6) events as listed in Table 1.

Table 1: Summary of event yields from the lepton+jets analyses. The expected $t\bar{t}$ yields are calculated using the measured cross section from this paper.

Our best measurement of the $t\bar{t}$ cross section comes from combining the results of the lepton+jets analyses with the dilepton and all hadronic analyses [12, 13]. The results of the individual analyses are summarized in Table 2. The dilepton analysis finds 9 candidate
events, with an expected background of 2.4±0.5 events. The all hadronic analysis has two parallel paths, one with a single SVX tagged jet plus kinematic cuts and another with only two SVX tagged jets. We have 187 candidates events with an expected background of 142±12 events in single SVX tag sample, and 157 candidates events with an expected background of 120±18 events in double SVX tag sample. There are 34 candidates events in common between the two samples. The dilepton, lepton+jets and all hadronic data samples are exclusive sets.

Table 2: Summary of total efficiency and measured cross section for each analysis channel. The acceptances are calculated for a top quark mass of 175 GeV/c².

We calculate the $tt$ production cross section to be $7.6^{+1.8}_{-1.3}$ pb by combining the results in the dilepton, lepton+jet and all hadronic channels, where the quoted uncertainty includes both statistical ($±1.2$ pb) and systematic uncertainties. This result is consistent with both the theoretical prediction and the D0 results of $5.6±1.8$ pb.

### 3.2 Top Quark Mass

A top quark mass is a fundamental parameter of the standard model. We report the measurement of the top quark mass in the lepton+jets channel [14]. We require an additional jet with $E_T > 8$ GeV and $|\eta| < 2.4$ in the $W + > 3$ jet event sample to make a $W + > 4$ jet sample for the top quark mass analysis.

At first we perform an event fitting: In the sample of $W + > 4$ jet events, we can make a one-to-one mapping of jets to quarks (using the 4 highest $E_T$ jets) assuming the decay chain:

$$pp \rightarrow t_1 + t_2 + X$$
$$t_1 \rightarrow b_1 + W_1$$
$$t_2 \rightarrow b_2 + W_2$$
$$W_1 \rightarrow \ell + \nu$$
$$W_2 \rightarrow j_1 + j_2$$

There are 24 combinations with which to try. We impose $M_{t_1} = M_{t_2}$ and $m(j_1,j_2) = m(\ell\nu) = M_W$, the measured $W$ mass. Energy and momentum conservation plus these constraints give 20 equations with 18 unknowns which results in a 2-C constrained fit. As a $b$-tagged jet is only used as a $b$, there are 12 possible combinations with 1 $b$ tag and 4
combinations with 2 $b$ tags. The $\chi^2$ for the specific combination is used to choose the best mass for the event. With a $b$ tag, the lowest $\chi^2$ combination is only the correct one $\sim 35\%$ of the time. Wrong combinations give a broader mass distribution but are centered at the correct mass.

Next we use a likelihood method to fit data to a sum of the reconstructed top mass distributions for the $t\bar{t}$ signal at a certain top quark mass $M_{top}$ and the background which we call templates. The $t\bar{t}$ signal template is a smooth function represented by $M_{top}$ and several parameters. The background template is also a smooth function represented by several parameters. We make a likelihood as a function of $M_{top}$, a background fraction and the template parameters by the sum of the signal and background templates. By maximizing this likelihood, we measure $M_{top}$ and $\sigma_{M_{top}}$.

The precision of the top quark mass measurement is expected to increase with the number of observed events, the signal-over-background ratio, and the naturalness of the reconstructed-mass distribution. These characteristics vary significantly between samples with different $b$ tagging requirements. Therefore, to make optimal use of all the available information, we partition the top mass sample into non-overlapping subsamples. Monte Carlo studies showed that a good partition is made up of four subsamples: events with a single SVX tag, events with two SVX tags, events with an SLT tag but no SVX tag, and events with no tag, but with the tighter kinematic requirement of four jets with $E_T > 15$ GeV and $|\eta| \leq 2$.

We measure the top quark mass to be $175.8 \pm 4.8 \text{(stat)} \pm 4.9 \text{(syst)}$ GeV/c$^2$ as shown in Fig. 1. Systematic uncertainties on the top quark mass are listed in Table 3. The largest one comes from the jet energy measurement. The jet energy corrections carry an energy-dependent uncertainty. For an observed jet $E_T$ of 40 GeV, the total uncertainty on the corrected $E_T$ varies between 3.4 and 5.6% depending on the proximity of the jet to cracks between detector components.

Table 3: Systematic uncertainties on top quark mass.

Summarizing the top quark mass analysis, we obtain new precise results with the optimal use of the information. The CDF top quark mass is $M_{top} = 175.8 \pm 6.5$ GeV/c$^2$ in the lepton+jets channel and a combined top quark mass with D0 is $M_{top} = 175.6 \pm 5.5$ GeV/c$^2$. A top quark mass together with a $W$ mass yields a constraint to a Higgs mass as shown in Fig. 2. The present allowed Higgs mass is $115^{+116}_{-56}$ GeV/c$^2$ and less than 430 GeV/c$^2$ at 95% confidence level [15] from this plot combined with a LEP $W$ mass.
Figure 1: The reconstructed-mass distribution of the four top mass samples combined. The data (points) are compared with the result of the combined fit (dark shading), and with the background component of the fit (light shading). The inset shows the variation of the combined negative log-likelihood with top quark mass.

Figure 2: W mass versus top quark mass. Prediction curves are shown for various Higgs masses.
3.3 Hadronic W decays in W+ ≥4 jet events

In the above lepton+jet analyses, we assume that one W decays hadronically into qq'. In order to confirm that this assumption is right, we need present that hadronic W decays exist in W+ ≥4 jet events which is consistent with the expectation from t\bar{t} signals.

We search the second W decaying hadronically as a dijet invariant mass peak in the lepton+jets channel applying either of the following two selection criteria [16]:

- \( H_T > 310 \text{GeV} \) cut, where \( H_T \) is a scalar sum of parton \( P_T \)'s (\( H_T \) cut sample).
- requiring two b-tagged jets (two b-tagged sample).

We observe a W mass peak with a significance of 2.8\( \sigma \) in the \( H_T \) cut sample and of 2.9\( \sigma \) in the two b-tagged sample as shown in Fig. 3. Combining these two results, we obtain that W mass peak significance is 3.3\( \sigma \) (\( \text{Prob} = 5.4 \times 10^{-4} \)). The measured W mass is 77.2±3.5(stat)±2.9(syst) GeV/c\(^2\). This is consistent with the current world-average W mass of 80.375±0.120 GeV/c\(^2\) [17].

Top mass analysis is the first measurement of a new particle mass using jet four momenta. Top mass measurement together with hadronic W decay observation presents that we can use jet four momenta as quark/gluon four momenta for new particle searches.

3.4 Measurement of \( V_{tb} \)
Unitarity within a three-generation standard model implies $V_{tb}$ is almost 1.0. We have analyzed the lepton+jets and dilepton samples to measure the ratio of events with 0, 1, and 2 $b$-tags and extract $b = \frac{BR(t \rightarrow Wb)}{BR(t \rightarrow WX)}$ [18]. By comparing ratios of these event yields, this result is independent of the values of $\sigma_H$ and $\frac{BR(W \rightarrow l\nu)}{BR(W \rightarrow q\bar{q})}$.

We obtain the results with a maximum likelihood to combine all information. The $b$ is measured to be $0.99 \pm 0.29$ and $b > 0.58$ at 95% confidence level. In a three-generation standard model,

$$b = \frac{|V_{ts}|^2}{|V_{td}|^2 + |V_{ts}|^2 + |V_{tb}|^2}.$$ 

Assuming three-generation unitarity this yields that $|V_{ts}| = 0.99 \pm 0.15$ and $|V_{tb}| > 0.76$ at 95% confidence level.

3.5 Search for Rare Decays

Within the standard model, Flavor Changing Neutral Current (FCNC) decays of a top quark are suppressed at the level of $10^{-10}$ to $10^{-12}$. Any appearances of FCNC decays would signal the appearance of physics beyond the standard model.

We search $t\bar{t}$ events with one top decaying in the standard fashion ($t \rightarrow Wb$) and the other top quark decaying to a rare mode [19]:

- $t \rightarrow \gamma c, \quad t \rightarrow \gamma u$ (BR $\approx 10^{-10}$)
- $t \rightarrow Zc$

A preliminary search for $t \rightarrow \gamma q$ by CDF yields: (Search $\gamma$+4 jets and $\gamma$+lepton+jet+MET)

$$BR(t \rightarrow c\gamma) + BR(t \rightarrow u\gamma) < 2.9\% \quad (95\%C.L.).$$

A preliminary search for $t \rightarrow Zq$ by CDF yields: (assumes $Z$ decays leptonically and $t$ decays hadronically)

$$BR(t \rightarrow Zu) + BR(t \rightarrow Zc) < 33\% \quad (95\%C.L.).$$

4 B Physics

4.1 Hadron Lifetime Measurements

There is a question about the decay mechanism of heavy flavor mesons whether the heavy quark in a meson decays alone, or the other quark is an essential part of the process. About charm mesons, $\tau(D^+)/\tau(D^0)$ is about 2.5 because a non-spectator diagram has significant contribution. In the case of bottom mesons higher $b$ mass makes a spectator diagram dominates and theoretical prediction yields that $\tau(B^+)/\tau(B^0)$ is about 1.05. We utilize the following decay modes for $B$-hadron lifetime measurement: fully reconstructed decays $B \rightarrow J/\Psi K$ and partially reconstructed decays $B \rightarrow Dl\nu X$. 

8
In fully reconstructed decays $B \to J/\Psi K$, we have a clean signal peak in the distribution of $J/\Psi K$ invariant mass as shown in Fig. 4. We perform the lifetime measurement with $B \to J/\Psi K$ signal sample [20]. Though this sample includes the background, the proper decay length distribution for this background is determined from the sideband sample outside of the $B$ peak region in this mass distribution. The two sideband regions have each 60 MeV/$c^2$ width and start at ±60 MeV/$c^2$ away from the world average $B$-mass of 5.279 MeV/$c^2$ [17]. The background shape is a sum of a central Gaussian, a left side exponential and a right side exponential. The two exponentials account for any non-Gaussian tails. Then the proper decay length distribution for the signal sample is fitted to a sum of the $B \to J/\Psi K$ signal shape (an exponential convoluted with a Gaussian resolution function) and the background shape as shown in Fig. 5. We measure the lifetime of $B$ mesons to be $1.68\pm0.07$ (stat)±0.02 (syst) ps for $B^\pm$ mesons and $1.58\pm0.09$ (stat)±0.02 (syst) ps for $B^0$ mesons, and the lifetime ratio $\tau(B^+)/\tau(B^0)$ to be $1.06\pm0.07$ (stat)±0.02 (syst).

In partially reconstructed decays $B \to D\ell\nu X$, we use the following four modes:

(a) $D^0 \to K^-\pi^+$ (non-$D^*$)
(b) $D^{*+} \to D^0\pi^+, D^0 \to K^-\pi^+
(c) D^{*+} \to D^0\pi^+, D^0 \to K^-\pi^+\pi^+
(d) D^{*+} \to D^0\pi^+, D^0 \to K^-\pi^+\pi^0$

The distributions of the $D$ meson mass or the mass difference between $D$ and $D^*$ mesons have a clean peak for the signal as shown in Fig. 6. The pseudo-proper decay length
Figure 5: The lifetime distribution for $J/\Psi K$ for charged $B$ mesons.

distributions are fitted to a sum of the $B$ signal shape and the background shape as shown in Fig. 7. We measure the lifetime of $B$ mesons to be $1.64 \pm 0.06 \text{(stat)} \pm 0.05 \text{(syst)}$ ps for $B^\pm$ mesons and $1.48 \pm 0.04 \text{(stat)} \pm 0.05 \text{(syst)}$ ps for $B^0$ mesons, and the lifetime ratio $\tau(B^+)/\tau(B^0)$ to be $1.11 \pm 0.06 \text{(stat)} \pm 0.03 \text{(syst)}$.

4.2 $B^0 - \bar{B}^0$ Mixing

$B^0$ and $\bar{B}^0$ are distinct to strong interaction and mix via the weak interaction. The free propagation and decay eigenstates are

$$|B_L\rangle = \frac{1}{\sqrt{2}}[|B^0\rangle - |\bar{B}^0\rangle]$$

$$|B_H\rangle = \frac{1}{\sqrt{2}}[|B^0\rangle + |\bar{B}^0\rangle]$$

with masses $m_L$ and $m_H$. Our goal is to measure $\Delta m = m_H - m_L$ which yields $|V_{td}|$ and $|V_{ts}|$.

A produced $B^0$ is initially $\Psi(0) = \frac{1}{\sqrt{2}}[|B_L\rangle + |B_H\rangle]$. With time, $B_L$ and $B_H$ components develop the relative phase and make a non-zero $\bar{B}^0$ component:

$P(t)_{B^0 \rightarrow B^0} = \frac{1}{2\tau} e^{-\frac{t}{\tau}} (1 + \cos \Delta mt)$: unmixed probability,

$P(t)_{B^0 \rightarrow \bar{B}^0} = \frac{1}{2\tau} e^{-\frac{t}{\tau}} (1 - \cos \Delta mt)$: mixed probability,

where $\tau$ is a lifetime and $t$ is a proper time.

Asymmetry is defined by

$$A(t) \equiv \frac{N_{B^0 \rightarrow B^0}(t) - N_{B^0 \rightarrow \bar{B}^0}(t)}{N_{B^0 \rightarrow B^0}(t) + N_{B^0 \rightarrow \bar{B}^0}(t)} = D_0 \cos \Delta mt$$
Figure 6: The distributions of the $D$ meson mass for (a) and the mass difference between $D$ and $D^*$ mesons for (b) through (d). Shaded histograms correspond to wrong sign combination.

Figure 7: The lifetime distribution for $B \rightarrow D\ell\nu X$. 
Mistags, i.e. incorrect flavor determinations, result in a decrease of the oscillation amplitude by the $B^0$ dilution factor $D_0$. We measure the asymmetry as a function of the proper decay length $ct$ and fit them with their expected time dependence, obtaining $\Delta m_d$ and $D_0$. The decay time is measured using $\ell^- +$ inclusive "charm" vertex or $\ell^- +$ exclusive $D$ reconstruction. The former has high statistics but low $B^0$ contents, while the latter has low statistics but high $\bar{B}^0$ contents.

We use the tagging techniques such as the sign of lepton in decay ( $b \rightarrow \mu^-$; $\bar{b} \rightarrow \mu^+$ ) and the momentum weighted charge of the particles in the decay, i.e. jet charge ( $b$ is $-$; $\bar{b}$ is $+$ ) in the opposite side. In the same side, we use the electric charge of particles produced near a $B$ meson which provides a basis for Same Side Tagging (SST) [21]. For example, if a $\bar{b}$ quark combines with a $u$ quark to form a $B^+$ meson, the remaining $\bar{d}$ quark may combine with a $d$ quark to form a $\pi^+$. We have four kinds of analyses as listed in Table 4 and obtained oscillation results as shown in Fig. 8. Combining these four results, we measure $\Delta m_d$ to be $0.464 \pm 0.030\,(\text{stat}) \pm 0.026\,(\text{syst}) \, \text{ps}^{-1}$. A world average of $\Delta m_d$ measurements yields including this CDF result $0.473 \pm 0.011\,(\text{stat}) \pm 0.014\,(\text{syst}) \, \text{ps}^{-1}$ which results in $|V_{ud}| = (8.6 \pm 0.2\,(\text{stat}) \pm 0.2(\Delta m_{top}) \pm 1.7(\text{theory})) \times 10^{-3}$.

5 Future Prospects at the Tevatron

We are upgrading the CDF detector [22] so as to work on the upgraded Tevatron collider in the next Run2 which will start in the beginning of 2000. By the accelerator upgrade, the center-of-mass energy will be increased from 1.8 TeV to 2.0 TeV ($\sigma_d$ becomes higher by a factor of 1.4) and the integrated luminosity will be increased from 0.1 fb$^{-1}$ to 2 fb$^{-1}$ by a factor of 20. By the detector upgrade, the acceptance for $t\bar{t} \rightarrow W(\rightarrow \ell\nu) + \geq 3$ jet events will increase from 9.5% to 12% (by a factor of 1.3) and the b-tagging efficiency for b-jets will increase from 42% to 80% (by a factor of 2). From the above, we have 70 times higher rate of $t\bar{t} \rightarrow W(\rightarrow \ell\nu) + \geq 3$ jet events with one b-tagged jet in Run2. In Run2, we expect $t\bar{t}$ events such as 1,200 $W(\rightarrow \ell\nu) + \geq 4$ jet events with one b-tagged jet, and 600 $W(\rightarrow \ell\nu) + \geq 4$ jet events with two b-tagged jets.

5.1 Top Quark Physics in Run2
Figure 8: Time-dependent $B^0 - \bar{B}^0$ mixing for Analysis I (Top Left) with a signal of $\ell^+$ inclusive vertex and a b-tag of soft $\ell$ or Jet charge, for Analysis II (Top Right) with a signal of $e(\mu)^+$ inclusive vertex and a b-tag of soft $\mu(e)$, for Analysis III (Bottom Left) with a signal of $\ell^- + D^{(*)+}$, and a b-tag of same side pion for Analysis IV (Bottom Right) with a signal of $\ell^- + D^{(*)+}$, and a b-tag of soft $\ell$. 
We will measure the top quark mass with an uncertainty $\Delta M_{\text{top}} < 4 \text{GeV/c}^2$ which will yield a tighter constraint to a Higgs mass together with a new $W$ mass as shown in Fig. 9. We will also measure the $t\bar{t}$ production cross section with $\Delta \sigma/\sigma \sim 7\%$ and the top quark decay width $\Gamma_{\text{top}}$ from $q\bar{q} \rightarrow W^* \rightarrow t\bar{t}$. We will search for new particles such as $X \rightarrow t\bar{t}$ where $X$ is a color octet vector meson, $Z'$ or something else.

### 5.2 B physics in Run2

To find the CP violation in B meson system, we need observe the unequal number of $B^0 \rightarrow J/ \Psi K_s$ and $\bar{B}^0 \rightarrow J/ \Psi K_s$. In Run2, we will have $10,000 \sim 15,000 \, J/ \Psi K_s$ events with $\varepsilon_{\text{eff}} = 4 \sim 8\%$ which enables us to measure $\sin 2\beta$ with $\delta \sin 2\beta = 0.08 \sim 0.14$ while the theoretical prediction of $\sin 2\beta$ is between 0.2 and 0.8. Another CP violation causes the unequal number of $B^0 \rightarrow \pi^+\pi^-$ and $\bar{B}^0 \rightarrow \pi^+\pi^-$. To observe this is much harder because it is hard to trigger on with SVT and has more difficult backgrounds than the first one as shown in Fig. 10. $dE/dX$ measurement will be helpful for the separation of $B^0 \rightarrow \pi^+\pi^-$ from the backgrounds. In Run2, we expect about 10,000 $B^0 \rightarrow \pi^+\pi^-$ events and $\delta \sin 2\alpha$ around 0.10.

On the $B_s^0 - \bar{B}_s^0$ mixing we need the $b$-tagging capability and the good proper-time resolution. The oscillation length for $B_s^0 - \bar{B}_s^0$ mixing is much shorter than for $B_d^0 - \bar{B}_d^0$ mixing. Assuming $\varepsilon_s = 20 \, \Delta m_s/\Gamma(B_s)$, we will have a plot of a mixed fraction against a proper decay length as shown in Fig. 11 for $B_s^0 \rightarrow J/ \Psi \phi$ decays of about 2,000 tagged events (about 9,000 before tag-requirement) in Run2. Thus we will be
able to observe this oscillation for $x_s = 20$. We have the sensitivity over full range of oscillation length using both the partially reconstructed decays $B_s \rightarrow D_s \ell \nu X$ and the fully reconstructed decays $B_s \rightarrow J/\Psi \phi$. The difference between $\tau(B_s^H)$ and $\tau(B_s^L)$ yields $\Delta \Gamma(B_s)$. It yields $\Delta m_s$ together with a theoretical calculation of $\Delta \Gamma(B_s)/\Delta m_s$.

6 Summary

Top quark production has been observed and the $t\bar{t}$ production cross section was measured in the dilepton, lepton+jets and all hadronic channels. The combined $t\bar{t}$ production cross section between the three channels is $7.6^{+1.8}_{-1.5}$ pb. The new results of top quark mass is obtained with the optimal use of information. The top quark mass is $175.8 \pm 6.5$ GeV/c$^2$. Nothing observed in top production and decay is inconsistent with the standard model. In the next run of the Fermilab Collider, we will measure the top quark mass more accurately which yields a more stringent Higgs mass limit together with a new W mass.

Basic techniques for detailed $B$ studies have been successfully carried out with the CDF detector. CDF is producing many high quality $B$ physics measurements. There is much to be learned about CP violation in $B - \bar{B}$ system in the next run of the Fermilab Collider.
