COMMON VOLE OR MEADOW MOUSE (Microtus pennsylvanieus).

# LETTER OF TRANSMITTAL.

U. S. DEPARTMENT OF AGRICULTURE, Washington, D. C., March 10, 1900.

Sir: I have the honor to transmit for publication, as No. 17 of North American Fauna, 'A Revision of the American Voles of the Genus *Microtus*,' by Vernon Bailey, Chief Field Naturalist of the Biological Survey.

Respectfully,

C. HART MERRIAM, Chief, Biological Survey.

Hon. James Wilson,

Scoretary of Agriculture.

### REVISION OF AMERICAN VOLES OF THE GENUS MICROTUS.

By VERNON BAILEY.

#### INTRODUCTION.

The following synopsis of American voles is based on a study of between 5,000 and 6,000 specimens from more than 800 localities, including types or topotypes of every recognized species with a known type locality, and also types or topotypes of most of the species placed in synonymy. Voles, or meadow mice, occur throughout the greater part of the northern hemisphere north of the Tropics. In North America both species and individuals reach their maximum abundance in the Canadian and Transition zones, and from this broad belt the number of species decreases on both sides. On the north a few species occur in the Hudsonian and Arctic zones, and individuals are abundant even in the barren grounds, or 'tundras,' north to the arctic coast. South of the Transition zone the decrease in species and individuals is rapid. In the Upper Austral zone they are scarce; in the Lower Austral rare and exceedingly local; while in the Tropical only a single species, of very limited distribution, is known. To the south, as individuals decrease in abundance and species become restricted to distinct areas, the degree of specific and superspecific differentiation becomes more and more marked. Of the nine American subgenera, one (Neofiber) is confined to Florida, and two (Orthriomys and Herpetomys) are restricted to two isolated mountains in southern Mexico. Another (*Pitymys*) is mainly Austral, and is confined to the southeastern United States and a small area in southeastern Mexico. Three others (Pedomys, Lagurus, and Chilotus) are found mainly in the Transition zone, and reach but little north of the United States. The subgenus Arvicola belongs to mountains in the Hudsonian and Canadian zones; and the polymorphous subgenus Microtus is the only one that enters the arctic regions.

Voles adapt themselves to the most diverse conditions of environment. Many of the species inhabit moist or wet ground and several are mainly aquatic; others inhabit areas of excessive humidity, while

a few live in dry and even arid regions. Some live in the perpetual shade of dense forests, others are exposed to the full effects of light on the open plains. Some of the most striking peculiarities of the different species result from these different conditions of environment. The development of oil and musk glands is most pronounced in the aquatic species of the subgenera Neofiber and Arvicola and least in the subgenera Lagurus and Pedomys of the dry regions. The color is palest in species most exposed to light and dryness, as in curtatus and pallidus, and darkest and richest in species from shaded and humid areas, as in quasiater and umbrosus.

The ranges of most of the species and subspecies conform to the limits of well-defined life zones, except in the subaquatic species, which follow water courses and often have the appearance of being out of their proper zones.

#### HABITS.

Certain peculiarities of habits are common to nearly all of the species. None are known to hibernate, but in the North they have snug winter homes under the snow, where they move about freely in numberless tunnels. They burrow in the ground, and are famous for their little roads or smooth trails which run through the grass from burrow to burrow or away to their feeding grounds. Bulky nests of grass and soft plant fibers are placed in underground cavities, or on the surface of the ground under cover of snow, logs, or dense vegetation. The nest is depressed globular in form, with an open chamber in the center, which contains a soft bed, and has one or two round entrances at the sides. These nests are the sleeping places of the old and the nurseries of the young. They are kept surprisingly clean and fresh, and new ones are frequently made to take the place of those that are old or imperfect.

Breeding.—Voles seem to have no definite breeding season. Four to eight young are usually produced at a birth, and as far north as Minnesota I have found them in the nests at all seasons of the year. Their increase is accordingly very rapid, and is only partially counterbalanced by the host of enemies that prey upon them. They form the principal food of nearly all owls and some hawks, while weasels, minks, foxes, coyotes, cats, badgers, skunks, and many other animals, as well as certain snakes, feed extensively on them. But in spite of their enemies they seem to hold their own, and tend to increase faster as the country becomes more thickly settled and the larger mammals and birds are destroyed.

Food.—Meadow mice choose a somewhat varied diet, but their food consists mainly of green vegetation, roots, and bark. Grass, especially the tender base of grass stems, forms the bulk of their food, but almost every plant with which they come in contact is eaten to some extent. Bark, both from roots and trunks of trees and shrubs, is a favorite winter food. Seeds and grain are eaten when found, but are not especially sought; flesh in any form is never refused. As the animals are

active all winter and food is always abundant, they do not ordinarily lay up stores, although Mr. E. W. Nelson found M. operarius, of Alaska, storing roots.

#### ECONOMIC STATUS.

Injury to trees and crops.—Though small enough to be commonly called mice (meadow mice, upland mice, field mice, pine mice, ground mice, bear mice, etc.), they make up in numbers what they lack in size, and over the whole breadth of the continent lay a heavy tribute on many products of the farm. Too small and too numerous to be successfully destroyed by traps, guns, or poison, they prove one of the most difficult enemies with which the farmer has to contend. If they would confine themselves to meadows, their mischief would be limited to the destruction of a comparatively small amount of grass; but they prefer growing grain to grass, and by running long tunnels under ground, or making little paths under cover of the vegetation, gain easy and safe access to the fields. With a stroke of their chisel-like teeth they fell the stalks of wheat and oats and eat the tender parts, together with some of the grain. It is so easy to cut down the stalks that they destroy many times as much as they need for food. The work of a few animals is insignificant, but the work of millions makes heavy inroads on growing crops. Later in the season, when the grain is cut and left standing in shocks or stacks, the field mice take possession, building their nests and establishing their homes under its cover. In shocks of corn and wheat left for a long time the grain is often completely devoured, and that remaining all winter in stacks suffers in proportion to the number of the little animals that make their homes in it. Even stacks of hay are often found in spring with the lower parts cut to chaff and filled with the nests of meadow mice.

When the snow comes these little rodents can safely leave their cover of weeds, grass, or bushes and plow their way under the snow on long exploring expeditions. The tunnels thus formed remain as open passages until the snow melts in spring, giving the animals free and safe conduct from the meadows to the uplands, into fields, orchards, gardens, and nurseries. There is no sign from above of what is happening below the surface; but later on, in spring, when the snow disappears, trees and shrubs are found stripped of their bark for a wide space near the ground. The marks of tiny teeth remain in the hard wood, and little piles of dry outer bark, mixed with characteristic pellets of excreta, show what animal has been at work. uncovered roads may be seen leading from tree to tree, to winter nests on the surface of the ground, and back to the cover of brush or meadows. Shrubs and small trees are often stripped of their bark and killed, and sometimes even well-grown apple trees, 10 inches or a foot in diameter, are completely girdled. Usually, however, large trees are

Proc. Biol. Soc. Wash., VIII, 140, 1893.

gnawed on only one side. In this case, although they are not killed at once, the wood thus exposed usually decays in a few years, the trees become hollow at the base, their productiveness is impaired, and they die prematurely.

Protection of trees from voles.—Various means have been resorted to for protecting fruit trees and shrubs from these ravages, but with only partial success. Wire netting and tin cylinders placed around the bases of the trees in autumn are generally considered the surest protection, but in most cases this is too expensive to be practicable. Wrapping the trunks with burlap or twisted ropes of straw, or coating them with whitewash, tar, or other unpalatable substances, are common methods of protection used with varying degrees of success. But as some species of voles eat the bark from the roots below the surface of the ground, none of these resources insure perfect protection.

Destruction of voles.—The importance of placing every possible check on the increase of these animals and of reducing their numbers when they become too numerous is obvious. No direct method of accomplishing these ends has as yet been devised, but the desired result can be attained indirectly by avoiding or preventing the useless destruction of their natural enemies. Owls and some species of hawks live almost exclusively upon them, watching for them night and day in the grass, and are always ready to pounce on any that appear above the snow. Weasels run through their burrows and trails, and not only kill enough for food, but destroy great numbers for the mere pleasure of killing. In spite of these well-known and often reiterated facts, bounties are still paid for the destruction of hawks and owls in counties where the annual loss in fruit trees and grain from the ravages of field mice if computed would amount to a startling sum. In the spring of 1895 I examined a small apple orchard in Washtenaw County, Mich., in which several choice trees had been killed and many others injured during the preceding winter by the common vole (Microtus pennsylvanicus). The owner of the orchard considered \$50 a low estimate of the damage done. At the same time the county of Washtenaw was taxing the farmers to pay a bounty of 25 cents each on all hawks and owls. while the several gun clubs of the county gave these birds a high count in their competitive hunting matches. Many similar instances could be cited. Who was ever known to miss an opportunity to destroy a hawk or weasel? The diminution of foxes, minks, coyotes, and such predatory mammals may be necessary, but if so, the protection and encouragement of other less harmful species becomes doubly important, and in fact imperative, if we are to escape such devastating hordes of voles as have occasionally swept over certain parts of Europe, particularly in Scotland,1 Germany,2 Italy,2 Russia,2 and Thessaly.1

Parliamentary Report of Plague of Field Voles in Scotland, London, 1893.

#### DETERMINATION OF SPECIES.

It is not many years since certain prominent writers treated as mere varieties, or subspecies, animals that belong to widely different subgenera, while others described and named with full specific rank every different condition of pelage in a single species. In some cases the original type was not preserved, or no type was designated by the describer, or still worse, the type locality was not given, so that subsequent writers renamed these same species or confounded them with others. The resulting confusion can now be cleared up by means of series of specimens collected within the past ten years at most of the known type localities, and in the general region of those not definitely known. The series of specimens available, and the number of localities represented, make it possible to define almost every North American species from typical specimens, and in most cases to give the various changes of pelage due to season and age. When possible, the original types have been compared with the new series of specimens from the type localities, and in this way the names californicus, trowbridgi, edax, occidentalis, townsendi, longirostris, and modestus have been sifted out with the following result: californicus stands for a widely distributed western species with trowbridgi as a synonym; edax as a well-marked species, but one in which the name has been persistently misapplied; occidentalis as a synonym of townsendi; longirostris as a synonym of montanus; and modestus as a western form of pennsylvanicus. The type of montanus is lost, but a series of 57 specimens from the type locality agrees with Peale's description of the species. The types of modestus and edax are immature specimens made up with the skulls inside the skins. It was only by the removal of the skulls that even the group to which the species belonged could be determined.1

#### MATERIAL EXAMINED.

The following synopsis of the genus *Microtus* is based mainly on a study of specimens in the collection of the Biological Survey and that of Dr. C. Hart Merriam, both of which are in the United States National Museum. For the use of much additional material, including types and topotypes, my thanks are heartily extended to Dr. F. W. True, executive curator, and Mr. Gerrit S. Miller, jr., assistant curator of mammals, United States National Museum; to Dr. J. A. Allen, curator of mammals and birds, and Mr. Frank M. Chapman, assistant curator, American Museum of Natural History; to Mr. D. G. Elliot, curator of the Department of Zoology, Field Columbian Museum; and to Mr. Outram Bangs. Most of all, I am indebted to Dr. C. Hart Merriam,

<sup>&</sup>lt;sup>1</sup>Through the kindness of Dr. True and Mr. Miller, skulls have also been removed from a large number of specimens from Alaska and Arctic America, so that it has been possible for the first time to identify the species and make use of the localities in determining their ranges.

who, after doing much work on the genus, has placed his manuscript, drawings, and large private collection of specimens at my disposal, besides giving me constant criticism and advice. Among others who have contributed material or notes my thanks are especially due to Mr. E. W. Nelson, who has collected all the known Mexican species of *Microtus* and has contributed the notes on their zonal distribution.

Seventy species and subspecies are here recognized. Of these 54 actual types and series of topotypes of 13 additional forms have been examined, while of the three remaining forms, for which no type exists or is accessible and no definite type locality is known, specimens have been examined from the type region, or as near to it as can be determined. Three forms, *Microtus californicus constrictus*, *M. ludovicianus* and *M. scirpensis* are described as new. Except for a relatively small number of alcoholics and a few skeletons, the specimens are mostly well-prepared skins with cleaned skulls and are accompanied by collectors' measurements.

All measurements are in millimeters, and external measurements, unless otherwise stated, are taken in the flesh by collectors. Skull measurements are my own, made from perfect skulls unless otherwise stated. The skull drawings are by Dr. James C. McConnell. Most of the drawings of teeth have been used in previous publications of the Biological Survey.

#### Subfamily MICROTINÆ Cope.

The subfamily *Microtina* includes the Voles of the genera *Microtus*, *Evotomys*, and *Phenacomys*; the Lemmings of the genera *Lemmus*, *Discrostonyx*, and *Synaptomys*; and the Muskrats of the genus *Fiber*. As the genera and subgenera of the family have been recently treated in detail by Mr. Gerrit S. Miller, jr.,<sup>2</sup> it is only necessary to give briefly the characters distinguishing the genus *Microtus*.

#### Genus MICROTUS Schrank.

Generic characters.—Lower incisors with roots extending far behind and on outer side of molar series; upper incisors not grooved; molars rootless, with outer and inner reentrant angles approximately equal. Palate with median ridge, distinct lateral pits, complete lateral bridges (not terminating in posterior shelf in any American species). Tail as long as or longer than hind foot, terete; claw of thumb pointed, not strap-shaped.

#### SUBGENERA.

Nine subgenera are here recognized among the living species of North America.<sup>4</sup> Five of these (*Chilotus*, *Pedomys*, *Herpetomys*, *Orthriomys*, and *Neofiber*) are found only in North America. The remaining

<sup>&</sup>lt;sup>1</sup>Microtida: Cope, Syllabus Lectures Geol. and Paleout., p. 90, 1891. Microtina: Rhoads, Am. Nat., XXIX, 940, Oct., 1895.

<sup>&</sup>lt;sup>2</sup> North American Fauna No. 12, Genera and Subgenera of Voles and Lemmings, 1896.

<sup>3</sup> Usually incomplete in Neofiber.

The extinct species of Microtus are not included in the present paper.

four (Microtus, Pitymys, Arvicola, and Lagurus) include also Old World species. All of the nine subgenera, save Microtus, are sharply defined and easily distinguished by either cranial or external characters. The subgenus Microtus contains many more species than all of the other subgenera together, and species differing so widely that only the most general characterization can be applied to it. It is a composite group containing all forms that do not fit into the other more restricted subgenera and yet are not sufficiently differentiated to merit subgeneric rank.

#### LIST OF SPECIES AND SUBSPECIES, WITH TYPE LOCALITIES.

Microtus abbreviatus Miller. Hall Island, Bering Sea, Alaska.

acadicus Bangs. Digby, Nova Scotia.

alleni (True). Georgiana, Brevard County, Florida.

alticolus (Merriam). Little Spring, San Francisco Mountain, Arizona, 8,200 feet.

angusticeps Bailey. Crescent City, California.

arizonensis Bailey. Springerville, Arizona.

arricoloides (Rhoads). Lake Keechelus, Washington, 8,000 feet.

auricularis Bailey. Washington, Mississippi.

austerus (Le Conte). Racine, Wisconsin.

aztecus (Allen). Aztec, Rio Arriba County, New Mexico, 5,900 feet.

bairdi Merriam. Crater Lake (Glacier Peak), Oregon, 7,800 feet. breweri (Baird). Muskeget Island, Massachusetts.

californicus (Peale). San Francisco Bay, California.

canescens Bailey. Conconully, Washington.

canicaudus Miller. McCoy, Oregon.

chrotorrhinus (Miller). Mount Washington, head of Tuckerman Ravine. New Hampshire, 5,300 feet.

Except Microtus breweri, in which 2 are usually confluent, and chrotorrhinus, which has 5 closed triangles.

<sup>&</sup>lt;sup>2</sup> Except in the Microtus mexicanus group, in which the number is 4.

```
Microtus constrictus Bailey. Cape Mendocino, California.
```

curtatus (Cope). Pigeon Spring, Mount Magruder, Nevada.

drummondi (Aud. & Bach.). Rocky Mountains, vicinity of Jasper House, Alberta, Canada.

dutcheri Bailey. Big Cottonwood Meadows, near Mount Whitney, California, 10,000 feet.

edax (Le Conte). California (south of San Francisco).

enixus Bangs. Hamilton Inlet, Labrador.

fisheri Merriam. St. Matthew Island, Bering Sea, Alaska.

fontigenus Bangs. Lake Edward, Quebec.

fulviventer Merriam. Cerro San Felipe, Oaxaca, Mexico.

guatemalensis Merriam. Todos Santos, Huehuechenango, Guatemala, 10,000 feet.

haydeni (Baird). Fort Pierre, South Dakota.

innuitus Merriam. St. Lawrence Island, Bering Sea, Alaska.

kadiacensis Merriam. Kadiak Island, Alaska.

labradorius Bailey. Fort Chimo, Ungava, Labrador.

leucophaus (Allen). Graham Mountains, Arizona.

longicaudus (Merriam). Custer, South Dakota.

ludovicianus Bailey. Iowa, Calcasieu Parish, Louisiana.

macfarlani Merriam. Fort Anderson (north of Great Bear Lake), Arctic America.

macropus (Merriam). Pahsimeroi Mountains, Idaho, 9,700 feet.

macrurus Merriam. Lake Cushman, Olympic Mountains, Washington.

mexicanus (De Saussure). Mount Orizaba, Mexico.

minor (Merriam). Bottineau, North Dakota.

modestus (Baird). Sawatch Pass (Cochetopa Pass). Colorado.

mogollonensis (Mearus). Baker Butte, Mogollon Mountains, Arizona.

montanus (Peale). Headwaters of Sacramento River, near Mount Shasta, California.

mordax (Merriam). Sawtooth (or Alturas) Lake, Idaho, 7,200 feet.

nanus (Merriam). Pahsimeroi Mountains, Idaho.

nemoralis Bailey. Stillwell (Boston Mountains), Indian Territory.

nesophilus Bailey. Great Gull Island, New York.

nevadensis Bailey. Ash Meadows, Nye County, Nevada.

nigrans Rhoads. Currituck, North Carolina.

operarius (Nelson). St. Michael, Alaska.

oregoni (Bachman). Astoria, Oregon.

pallidus (Merriam). Fort Buford, North Dakota.

pauperrimus (Cooper). Plains of Columbia, near Snake River, Washington. pennsylvanicus (Ord). Pennsylvania (near Philadelphia).

phœus Merriam. North slope Sierra Nevada de Colima, Jalisco, Mexico, 10,000 feet.

pinetorum (Le Conte). Pine forests of Georgia (probably near the old Le Conte plantation at Riceboro, Georgia.)

popofensis Merriam. Popof Island, Shumagin Islands, Alaska.

quasiater (Cones). Jalapa, Vera Cruz, Mexico.

rivularis Bailey. St. George, Utah.

richardsoni (De Kay). Near foot of Rocky Mountains, vicinity of Jasper House, Alberta, Canada.

scalopsoides (Aud. & Bach.). Long Island, New York.

scirpensis Bailey. Amargosa River, California, near California-Nevada line. serpens Merriam. Agassiz, British Columbia.

sitkensis Merriam. Sitka, Alaska.

Microtus terrænovæ (Bangs). Codroy, Newfoundland.

tetramerus (Rhoads). Beacon IIII Park, Victoria, British Columbia.
townsendi (Bachman). On or near Wappatoo (Sauvie) Island, Willamette
River, Oregon.

umbrosus Merriam. Mount Zempoultepec, Oanaca, Mexico, 8,200 feet.
unalascensis Merriam. Unalaska Island, Alaska.
vallicola Bailey. Loue Pine, Inyo County, California.
yakutatensis Merriam. Yakutat Bay, Alaska.
xanthognathus (Leach). Hudson Bay.

#### Subgenus MICROTUS Schrank.

Type.—Microtus terrestris Schrank (=Mus arvalis Pallas). Microtus Schrank, Fauna Boica, I, 1ste Abth., 72, 1798. Microtus Miller, N. Am. Fauna No. 12, 63, July 23, 1896 (subgenus).

Geographic distribution (in North America).—From the Arctic Ocean southward to southern Mexico, and across the continent, mainly in Boreal, Transition, and Upper Austral zones.

Subgeneric characters.—Plantar tubercles 6; lateral glands on hips in adult males; mammae normally 8, 4 inguinal and 4 pectoral; ears usually overtopping fur; m1 normally with 5 closed triangles; m3 with 3 transverse loops and no triangles; m2 with 4 closed sections, and in most eastern species an additional posterior inner loop; m3 with 3 closed triangles (except in chrotorrhinus and abbreviatus groups).

#### GROUPS IN THE SUBGENUS MICROTUS,

The subgenus *Microtus* is readily divided into 10 fairly well-marked groups of slightly superspecific rank that may be conveniently designated by the name of their best-known or most characteristic species. These groups are not of great importance or of equal rank, but for showing the relationship of species and for convenience in arrangement they serve a useful purpose.

- 1. Pennsylvanicus Group, characterized by a posterior fifth loop to middle upper molar, includes pennsylvanicus, nigrans, acadicus, modestus, fontigenus, labradorius, enixus, aztecus, drummondi, terranova, nesophilus, and breweri.
- 2. Montanus Group, characterized by moderately short tail and constricted incisive foramina, includes montanus, arizonensis, nanus, canescens, canicandus, nevadensis, rivularis, and dutcheri.
- Townsendi Group, characterized by large size, long tail, and dark-brown color, includes townsendi and tetramerus.
- Californicus Group, characterized by large size and wide-open incisive foramina, includes californicus, constrictus, vallicola, edax, and scirpensis.
- Longicaudus Group, characterized by long tail and gray color, includes longicaudus, mordax, macrurus, angusticens, alticolus, and lencopheus.
- Mexicanus Group, characterized by short tail, brown color, and only 4 mamme, includes mexicanus, phacus, fulvirenter, and mogollonensis.

<sup>&</sup>lt;sup>1</sup> In front of hips in xanthognathus and probably in chrotorrhinus.

Four in the mexicanus group, a pair of inguinal and a pair of pectoral.

<sup>&</sup>lt;sup>3</sup> With only four closed triangles in most of the Alaska species.

- 7. Operarius Group, characterized by short tail and only 4 closed triangles in anterior lower molar, includes operarius, macfarlani, kadiacensis, unalascensis, sitkensis, yakutatensis, popofensis, and innuitus.
- 8. Abbreviatus Group, characterized by robust form, very short tail, 5 closed triangles in anterior lower molar, and two closed and one open in posterior upper, includes abbreviatus and fisheri.
- Chrotorrhinus Group, characterized by yellow nose and five closed triangles in posterior upper molar, includes chrotorrhinus and ravus.
- 10. Xanthognathus Group, characterized by yellow nose, large size, glands on flanks, and 3 closed triangles in posterior upper molar, includes one species, xanthognathus.

In using the following key it will be necessary to have both skins and skulls in hand, and even then it will be impossible to identify some of the forms without actual comparison with their nearest allies. Whenever possible, several specimens should be examined, to avoid the danger of being led astray by abnormal molar patterns, for even the widest ranges of subgeneric differences are sometimes covered by individual variation or abnormal tooth pattern.

#### KEY TO SPECIES AND SUBSPECIES OF THE SUBGENUS MICROTUS.

m2 with 4 closed angular sections and a rounded posterior loop.
m3 with two of the 3 triangles usually confluent.
Interparietal about as wide as long, colors palebreweri
Interparietal much wider than long, colors darknesophilus
m3 with 3 closed triangles.
m1 with usually a sharp point or spur at base of posterior triangle; belly white
with a median dusky lineterranora
mt with normal truncate posterior triangle; belly without median dusky line.
Interparietal more than half as long as wide, belly white.
Skull long and narrow, braincase long, feet and tail stoutazteous
Interparietal about half as long as wide, belly usually dull colored.
Skull wide, braincase short, molars smallenixus
Skull not wide, braincase medium, molars medium.
Colors dusky or blackish.
Size large, hind foot 23
Size small, hind foot 21
Colors brownish or dark grayish. Size medium.
Belly white or whitishacadicus
Belly dull.
Colors bright or dark brownishpennsylvanicus
Colors paler, size less
Size small, feet and tail very slender.
Skull low, incisors projecting, bulle not largelabradorius
Skull high, incisors decurved, bulke largedrummondi
m2 with 4 closed sections and no posterior loop (except irregularly in Californicus
group.
Mammae 4, inguinal, 1-1; pectoral, 1-1. Skull short and wide. Incisive foramina
not constricted.
Colors bright rich brown above and below
Colors dull brownish above and below.
Belly but little lighter than back. Size medium mexicanus
Size slightly larger
Belly much lighter than back; size small moyollonensis
Don't many regulation and wash's sense sense.

Mammae 8, inguinal, 2-2; pectoral, 2-2.
ml with normally 4 closed triangles (sometimes 5 in sitkensis) and rounded anterior
loop.
Bulla very small and narrow, molars very light.
Skull narrow and slender operarius
Skull wider and heavierkadiacensis
Bulla: medium, molars moderately heavy.
Incisors strongly projecting.
Size large, hind foot 23innuitus
Size small, hind foot 19 macfarlani
Incisors not strongly projecting, size medium.
Frontals heavily ridged in adult males.
Prezygomatic notch deep, color dusky gray or ochraceous.
Color dark ochraceous, belly duskysitkensis
Color dusky gray, belly buffy grayyakutatensis
Prezygomatic notch shallow, color ochraceousunalascensis
Frontals not ridged in adults, color ochraceouspopofensis
m1 with 5 or 6 closed triangles.
A pair of glands on flanks of males, nose yellowish.
Size large, side glands conspicuous in adult males, m3 with 3 closed tri-
angles
Size smaller, glands obscure or wanting, m3 with 5 closed triangles.
Color bister
Color grayishravus
A pair of glands on hips of males, nose not yellow.
Incisive foramina not constricted posteriorly, m2 with or without posterior loop.
Size large, colors dark, young blackish.
Nasals emarginate posteriorlyedax
Nasals truncate posteriorlyscirpensis
Size smaller, colors grayish, young dusky
Colors clearer gray, bullæ smaller.
Skull wide
Skull narrow constrictus
Incisive foramina constricted posteriorly, m2 normally without posterior loop.
Tail very short, size medium.
Belly dusky, lips and tip of nose white
Belly, lips, and nose buffy.
Rostrum and nasals slenderabbreviatus
Rostrum and nasals heavy
Tail medium, size large or small.
m1 with 6 closed triangles and deep-lobed trefoil.
Size large, hind foot 24nevadensis
m1 with 5 closed triangles and anterior trefoil.
Size large, hind foot 23rivularis
Size medium or small; hind foot 18-22, belly gray or whitish, ears
large.
Hind foot 20 or more.
Color dark gray above
Color rusty gray abovearizonensis Hind foot 20 or less.
Lateral pits of palate deep, tail bicolor.
Color grizzled gray
Lateral pits of palate shallow, tail mostly graycanicaudus
Denotes here of battere enasted, fast moons graft cautchance

#### KEY TO SPECIES AND SUBSPECIES OF THE SUBGENUS MICROTUS-Cont'd.

Tail long, about \( \frac{1}{2} \) of total length.
Hip glands conspicuous in males, colors dark brown.
Hind foot averaging 25.4townsendi
Hind foot averaging 22tetramerus
Hip glands not conspicuous, colors grayish, belly whitish.
Size large, bind foot 24
Size medium, hind foot 22.
Anterior arm of frontal acuminate.
Skull narrow, bulla smallangusticeps
Skull normal, bullæ large.
Sides much grayer than backmordax
Sides scarcely grayer than backlongicandus
Anterior arm of frontal obliquely truncate.
Size small, foot 20alticolus
Size larger, foot 22leucophaus
a

#### MICROTUS PENNSYLVANICUS (Ord). Meadow Vole.

Mus pennsylvanica Ord, Guthrie's Geography, 2d American edition, II, 292, 1815. (Rhoads' reprint.) Based on Wilson's description of the meadow mouse from meadows below Philadelphia and along the seashore.

Mynomes pratensis Rafinesque, Am. Monthly Mag., II, 45, 1817. Based on Wilson's description of meadow mouse.

Lemmus noveboracensis Rafinesque, Annals of Nature, 3, 1820. (New York and New Jersey.)

Arvicola riparius Ord, Journ. Acad. Nat. Sci. Philadelphia, IV, Pt. II, 305-306, 1825. (Type locality not given.)

Arricola palustris Harlan, Fauna Americana, 136-138, 1825. (Swamp along the shores of the Delaware.)

Arvicola hirsutus Emmons, Rept. Quad. Mass., 60, 1840.

Arvicola alborufescens Emmons, Rept. Quad. Mass., 60-61, 1840. (Williamstown, Mass.)

Arvicola fulva Aud. and Bach., Proc. Acad. Nat. Sci. Phila., I, 96, 1841. ("One of the Western States; we believe Illinois.")

Arvicola nasuta Aud. and Bach., Proc. Acad. Nat. Sci. Phila., I, 96-97, 1841. (Near Boston, Mass.)

Arricolá rufescens DeKay, Zool. N. Y., Mammals, I, 85, 1842. (Oneida Lake, N. Y.)
 Arricola oneida DeKay, Zool. N. Y., Mammals, I, 88-89, 1842. (Oneida Lake, N. Y.)
 Arricola dekayi Aud. and Bach., Quad. N. Am., III, 287-288, 1854. (New York or Illinois.)

Arvicola riparia var. longipilis Baird, Mammals N. Am., 524, 1857. (West Northfield, Ill., and Racine, Wis.)

Arvicola rufidorsum Baird, Mammals N. Am., 526, 1857.1 (Holmes Hole, Marthas Vineyard, Mass.)

Type locality.—Pennsylvania (meadows below Philadelphia).

Geographic distribution.—Eastern United States and westward as far as Dakota and Nebraska, shading into modestus of the western plains and Rocky Mountains. In a general way it occupies the Transition zone from the Atlantic coast to the edge of the Great Plains.

Habitat.-Meadows, fields, and especially grassy places near water.

<sup>&</sup>lt;sup>1</sup> Not having seen the type of rufidorsum or any specimen from Marthas Vineyard, I hesitate to place this name in synonomy.

General characters.—Size medium; tail at least twice as long as hind foot; fur long, overlaid with coarse hairs; ears moderate, conspicuous above fur in summer, almost concealed in winter pelage; colors dusky gray or brownish; skull long, well arched, and rather smooth; middle upper molar with four triangles and a posterior loop.

Color.—Summer pelage: Upperparts dull chestnut brown, varying to bright yellowish chestnut, darkened along the back with coarse black hairs; belly dusky gray or tinged with cinnamon; feet brownish; tail dusky above, slightly paler below. Winter pelage: Duller and grayer throughout; tail indistinctly bicolor. Young: Blackish.

Cranial characters.—Skull long, usually not angular or much ridged; incisors projecting well in front of nasals; incisive foramina long, occupying two-thirds of the space between molars and incisors; bullæ mod-

erately large and well rounded; molar series long; m2 with 4 closed triangles and a posterior loop; m3 with an anterior crescent, 3 closed triangles, and a posterior loop with two inner lobes; m1 with 5 closed triangles, anterior trefoil, 4 outer and 5 inner salient angles; m3 with 3 long inner and 3 short outer salient angles.

Fig. 1.—Molar enamel pattern of Microtus pennsylvanicus (× 5).

Measurements.—Average of 5 adults from  $(\times 5)$ . Washington, D. C.: Total length, 171; tail vertebræ, 46; hind foot, 21.2. Skull (No. 30321,  $\S$  ad., from Washington, D. C.): Basal length, 27.4; nasals, 8.3; zygomatic breadth, 17.2; mastoid breadth, 12.7; alveolar length of upper molar series, 7.2.

Remarks.—The above description is based on a good series of specimens from the District of Columbia, showing the seasonal changes of pelage and agreeing perfectly with the Pennsylvania animal. From Pennsylvania south along the Atlantic coast, specimens show a noticeable increase in size and intensity of coloration, which reaches its maximum in the subspecies nigrans of North Carolina; while to the north they show a corresponding decrease in size and intensity of coloration, which reaches its extreme in the subspecies acadicus of Nova To the westward pennsylvanicus is fairly typical as far as southern Michigan and Iowa, but on the plains of Nebraska and South Dakota it grows paler as it grades into modestus. Northward in Minnesota it becomes smaller until scarcely distinguishable from and perhaps grading into drummondi of northwest Canada. Three skulls in the U.S. National Museum, that seem to be typical pennsylvanicus, are labeled as coming from Prairie Mer Rouge, La., but I am inclined to question the authenticity of the labeling.

Specimens examined.—Total number, 716, from the following localities:

Pennsylvania: Philadelphia, 1; Chester County, 1; Carlisle, 6; Columbia, 2; Drurys Run (near Renovo), 6; Foxbury, 2; Pine Glen, 1; Leasuresville, 2; Bear Lake (Warren County), 2.

18392—No. 17——2

New York: Owego, 2; Nichols, 24; Lake George, 20; Alder Creek, 2; Locust Grove, 55; Peterboro, 9; Troy, 5; Geneva, 5; Brandon, 4; Catskill Monntains, 3; Highland Falls, 12; Mott Haven, 1; Oyster Bay, 2; Lake Grove, 2; Montauk Point, 45; Shelter Island, 6; Plum Island, 14; Roslyn, 4.

Connecticut: East Hartford, 2.

Massachusetts: Wilmington, 13; Middleboro, 19; Newtonville, 4; Holmes Hole, 1; Woods Holl, 1.

Vermont: Burlington, 4. New Hampshire: Ossipee, 15. Maine: Addison, 1; Calais, 1.

New Jersey: Tuckerton, 4; Mays Landing, 1; Sea Island City, 1.

Maryland: Laurel, 23; Hyattsville, 7; Bladensburg, 1; Mountain Lake Park, 2; Finzel, 1; Grantsville, 1.

District of Columbia: Washington, 64.

Virginia: Falls Church, 2; Dunn Loring, 2; Arlington, 2; Fort Myer, 1; Bristoe, 1.

West Virginia: Travellers Repose, 2; White Sulphur Springs, 3.
North Carolina: Roan Mountain, 45; Old Richmond, 3; Raleigh, 20.

Ohio: Garrettsville, 10; Salem, 1.

Michigan: Detroit River, 1; Manchester, 3; Ann Arbor, 2.

Michigan: Detroit kiver, 1; manchester, 3; Ann Arbor, 2. Illinois: West Northfield. 6.

Wisconsin: Racine, 14; Busseyville, 1; Milwaukee, 4; Saxeville, 1; Fisher Lake (Iron County), 14.

Iowa: Knoxville, 2. Missouri: St. Louis, 5.

Louisiana: Prairie Mer Rouge, 3. Nebraska: Blair, 3; Valentine, 2.

Minnesota: Elk River, 112; Fort Snelling, 3; Heron Lake, 1; Ortonville, 1;

Tower, 6.

South Dakota: Vermilion, 2; Pierre, 2; Travere, 1; Flandreau, 4; Fort Sisseton, 18; Fort Wadsworth, 2.

Ontario: Toronto, 1; Lorne Park, 6.

MICROTUS PENNSYLVANICUS NIGRANS Rhoads. Albemarle Meadow Vole.

Microlus pennsylvanicus nigrans Rhoads, Proc. Acad. Nat. Sci. Phila., 1897, 307-308.

Type locality.—Currituck, N. C.

Geographic distribution.—(Typical form.) Coast region of northern North Carolina and southern Virginia, in the Austroriparian zone.

Habitat.—Marshes and localities close to water.

General characters.—Slightly larger than pennsylvanious, with noticeably larger hind feet and darker coloration.

Color.—Summer pelage: Upperparts dull bister, much obscured by black hairs; belly smoky gray to dull cinnamon; tail black above, sooty below; feet blackish. Winter pelage (partly retained in April specimens): Darker, with dorsal area almost black. Young (to nearly half grown): Sooty black all over.

Oranial characters.—Skull averaging slightly larger than in typical pennsylvanicus; rostrum slightly heavier, incisive foramina wider; dentition the same.

Measurements.—Average of three not fully adult males from type locality: Total length, 165; tail vertebræ, 48; hind foot, 23. Skull (No. 72374, & ad., from Eastville, Va.): Basal length, 29; nasals, 8.5; zygomatic breadth, 17.5; mastoid breadth. 13.4: alveolar length of upper molar series, 7.3.

Remarks.—Specimens of Microtus from a chain of localities along the Atlantic coast, from North Carolina to Nova Scotia, show a decrease in size and intensity of coloration from the south northward. Unfortunately the type of pennsylvanicus was taken from an intermediate locality, and it becomes necessary to recognize the extremes—acadicus and nigrans—as slightly differentiated forms.

Specimens examined.—Total number of typical specimens, 16, from the following localities:

North Carolina: Currituck, 6.

Virginia: Wallaceton, 7; Eastville, 1; Smiths Island, 2.

MICROTUS PENNSYLVANICUS ACADICUS Bangs. Acadian Vole.

Microtus pennsylvanicus acadicus Bangs, Am. Nat., XXXI, 239-240, March, 1897.

Type locality.—Digby, Nova Scotia.

Geographic distribution.—Nova Scotia and Prince Edward Island.

Habitat.—Fields and fresh-water marshes.

General characters.—Slightly smaller than M. pennsylvanicus; color slightly paler, both in summer and winter.

Color.—Summer pelage (July to October): Upper parts yellowish bister, slightly lined with black hairs; belly washed with white or smoky gray; tail indistinctly bicolor, brownish black above, slightly paler below; feet dusky plumbeous. Winter pelage: Back buffy gray; sides paler; ears nearly concealed under bright ochraceous patch; belly washed with pure white; tail sharply bicolor, blackish above, white below; feet plumbeous. Young: Not so dark as those of pennsylvanicus.

Cranial characters.—Skull usually distinguishable from that of pennsylvanicus by projecting posterior point of palate; posterior tip of nasals slightly emarginate or truncate, never rounded. Dentition as in pennsylvanicus.

Measurements.—Type: Total length, 172; tail vertebræ, 49; hind foot, 20. Average of 5 topotypes: 170; 47; 21. Skull (No. 2145, &—not fully adult): Basal length, 25.5; nasals, 7.7; zygomatic breadth, 14.8; mastoid breadth, 12; alveolar length of upper molar series, 6.5.

Remarks.—None of the 19 topotypes before me are old, and the majority are not fully adult, but in a series of 40 specimens from Prince Edward Island, including fully adult specimens in both summer and winter pelages, the principal characters of *M. acadicus* are accentuated. The winter pelage is rather more distinctive than the summer.

Specimens examined.—Total number, 67, from the following localities:

Nova Scotia: Digby, 19; Halifax, 1.

Prince Edward Island: 47.

MICROTUS PENNSYLVANICUS MODESTUS (Baird). Sawatch Vole.

Arvicola modesta Baird, Mamm. N. Am., 535-536, 1857. Arvicola insperatus Allen, Bul. Am. Mus. Nat. Hist., 347, 1894 (Custer, S. Dak.).

Type locality.—"Sawatch Pass, Rocky Mountains" [same as Cochetopa Pass], Colorado.

Geographic distribution.—Rocky Mountains and western Plains from New Mexico to British Columbia, and from the Black Hills of South Dakota to central Idaho, and beyond, with slight variation, to the plains of the Columbia, mainly in Transition zone.

Habitat.—Marshes and damp grassy places.

General characters.—Size of M. pennsylvanicus, tail slightly shorter, color paler, more yellowish, never chestnut in summer pelage; skull heavier, becoming more ridged and angular with age.

Color.—Summer pelage: Upperparts dull ochraceous, darkened with black-tipped hairs; belly washed with soiled whitish, smoky gray or pale cinnamou; feet plumbeous; tail indistinctly bicolor, blackish above, dull grayish below. Winter pelage: Much darkened above by long black hairs, especially early in the season, later becoming paler than in summer as the under-fur grows longer; belly heavily washed with creamy white; feet paler; tail more sharply bicolor. Young: Slightly less blackish than in pennsylvanicus.

Cranial character's.—Skull not positively distinguishable from that of pennsylvanicus, but in adults averaging heavier and more ridged.

Measurements.—Average of 10 adults from Cochetopa Pass, Colorado: Total length, 176; tail vertebræ, 44; hind foot, 20.6. Skull (No. 48053, ♀ ad.): Basal length, 27; nasals, 7.6; zygomatic breadth, 16; mastoid breadth, 12.4; alveolar length of upper molar series, 6.7.

Remarks.—Baird's type of modestus was collected at Sawatch or Cochetopa Pass in the Cochetopa Mountains. The type specimen in the United States National Museum is a half-grown young in the black pelage, and agrees perfectly in both external and cranial characters with specimens of the same age since collected at the type locality. The other specimen from Sawatch Pass (No. 593), which Professor Baird examined and believed to be distinct from modestus, but refrained from describing from a single immature specimen, is also in the United States National Museum, and proves to be Microtus nanus, a good series of which has since been collected at a point 3 miles east of Cochetopa Pass. Microtus mordax is the only other species known to occur in this part of Colorado. These three widely different species are readily distinguishable at any age.

Microtus modestus decreases in size to the northward until, in northwestern Montana, it seems to merge into the little drummondi of the region farther north. Westward it becomes darker, specimens from Salt Lake Valley, Utah, being practically indistinguishable from typical pennsylvanicus, while those from Cour d'Alene, Idaho, and the plains of the Columbia in eastern Washington are too small and dark to be typical modestus.

Specimens examined.—Total number, 259, from the following localities:

Colorado: Cochetopa Pass, 89; Fort Garland, 15; Loveland, 7; Twin Lakes, 1.

Wyoming: Newcastle, 1: Bear Lodge Mountains, 2: Syndance, 1: Lower

Wyoming: Newcastle, 1; Bear Lodge Mountains, 2; Sundance, 1; Lower Geyser Basin, Yellowstone Park, 1.

South Dakota: Custer, 2; Hill City, 1.

North Dakota: Fort Buford, 1.

Montana: Little Bighorn River, 2; Fort Custer, 3; Bozeman, 2; Fort Ellis, 1; Big Snowy Mountains, 13; Philbrook, 1; Stanford, 1; Choteau, 1; Robare, 1; Blackfoot, 1; Fort Assinniboine, 1; Tobacco Plains, 3; Stillwater Lake, 8; Flathead Lake, 9; Little Bitterroot Creek, 2; Hot Springs Creek, 1; Horse Plains (8 miles east), 1.

Idaho: Lemhi, 1; Salmon River, 3; Challis, 3; Birch Creek, 24; Cœur d'Alene, 3; Fort Sherman, 1.

Washington: Marshall, 15; Coulee City, 4; Conconully, 4; Colville, 20; Marcus, 1.

Utah: Ogden, 7; Salt Lake, 1.

MICROTUS PENNSYLVANICUS FONTIGENUS (Bangs). Forest Vole.

Microtus fontigenus Bangs, Proc. Biol. Soc. Wash., X, 48-49, March 9, 1896.
Microtus pennsylvanicus fontigenus Miller, Proc. Boston Soc. Nat. Hist., XXVIII, 14, April, 1897.

Type locality.—Lake Edward, Quebec.

Geographic distribution. Eastern Canada, in the Hudsonian zone.

Habitat.-Marshes, fields, dry banks, and deep woods.

General characters.—Smaller than pennsylvanicus, with short wide skull, large round bulke, and short incisive foramina.

Color.—Autumn pelage (September specimens in long fur): Upperparts dark bister mixed with black, slightly paler on sides and cheeks; belly washed with whitish or smoky gray; tail bicolor, blackish above, grayish below; feet plumbeous.

Cranial characters.—Skull light and smooth, not ridged or angular; rostrum and incisive foramina short; braincase wide; audital bullar large and smoothly rounded; interprerygoid space narrow, ending squarely at palate; dentition as in pennsylvanicus.

Measurements.—Type,  $\mathfrak P$  ad.: Total length, 151; tail vertebræ, 41; hind foot, 21. Topotype,  $\mathfrak F$  ad.: 150; 45; 21. Skull (No. 3839,  $\mathfrak F$ ): Basal length, 23, nasals, 6.2; zygomatic breadth, 14.3; mastoid breadth, 11.5; alveolar length of upper molar series, 6.

Remarks.—The short rostrum, short, wide braincase, and short incisive foramina distinguish fontigenus from both pennsylvanicus and drummondi, with both of which species it seems to intergrade.

In size it is intermediate, and in external characters not very different from either. It is recorded by Mr. Miller from Nepigon and Peninsula Harbor, Ontario, but he considers the specimens obtained at those places not quite typical. A series of 10 specimens from Godbout, Quebec, are rather nearer fontigenus than acadicus.

Specimens examined.—Total number, 6, topotypes (from the Bangs Coll.).

Proc. Boston Soc. Nat. Hist., XXVIII, 14, April, 1897.

MICROTUS PENNSYLVANICUS LABRADORIUS Bailey. Little Labrador Vole.

Microtus pennsylvanicus labradorius Bailey, Proc. Biol. Soc. Wash., XII, 88, April 30, 1898.

Type locality.—Fort Chimo, Ungava, Labrador.

Geographic distribution.—Known only from the type locality.

General characters.—Size of Microtus drummondi and of approximately the same proportions. Skull flatter, with smaller audital bullæ and more protruding upper incisors.

Color.—(Much changed by alcohol.) Upperparts dark brownish; belly whitish; tail bicolor; feet pale.

Cranial characters.—Skull low, not much ridged or angled; postorbital ridge prominent; nasals short, cureate and scarcely reaching base of incisors; audital bullæ small; incisive foramina short; first upper molar usually with an inner posterior point, molar pattern otherwise as in pennsylvanicus. The skull is readily distinguishable from that of either drummondi or fontigenus by the protruding incisors and small audital bullæ.

Measurements.—Type, ♀ ad. (in alcohol), measured by Dr. C. Hart Merriam: Total length, 139; tail vertebræ, 39; hind foot, 20. Average of 7 alcoholic specimens from type locality: 137; 37; 19. Skull (of type): Basal length, 24.3; nasals, 6.7; zygomatic breadth, 14.4; mastoid breadth, 11; alveolar length of upper molar series, 6.2.

Remarks.—M. labradorius shows closer affinity with drummondi than with fontigenus, though no doubt meeting and grading into the latter. It is widely different from enixus, and the two occur together at Fort Chimo.

Specimens examined.—Total number, 9, from the type locality.

MICROTUS DRUMMONDI (And. & Bach.). Drummond Vole.

Arvicola drummondi Aud. and Bach., Quad. N. Am., III, 166-167, 1854.

Arvicola (Mynomes) microcephalus Rhoads, Proc. Acad. Nat. Sci. Phila., 1894, 286-287 (Lac La Hache, B. C.).

Microtus stonei Allen, Bul. Am. Mus. Nat. Hist., XII, 4, March, 1899 (Liard River, N. W. T.).

Type locality.—Rocky Mountains, vicinity of Jasper House, Alberta. Geographic distribution.—From Hudson Bay to the west slope of the Rocky Mountains and Alaska, and from the northern edge of the United States north to Fort Anderson, N. W. T., in Canadian and Hudsonian zones.

Habitat.—Both marshes and dry upland.

General characters.—Similar to Microtus pennsylvanicus, but much smaller, with slenderer feet and tail, and paler color.

Color.—Summer pelage: Upperparts yellowish bister with numerous dark-brown or black-tipped hairs, sides of nose and hairs in front of ears more decidedly yellowish; belly white or rarely tinged with buffy, sometimes dusky during the molt; feet silvery gray; tail bicolor, blackish above, whitish below. Winter Pelage: Paler than in summer; yellow on ears and nose more conspicuous; Young: Paler and not so sooty as young pennsylvanicus.

Cranial characters.—Skull not much arched and rather flat topped, slender but sharply ridged in adults; audital bulke large and smoothly rounded; palate flattened in immature specimens, becoming higher with deep lateral pits in adults. Dentition as in pennsylvanicus. Except for the larger bulke and a few characters of minor weight, the skull of drummondi is a miniature of the skull of pennsylvanicus.

Measurements.—Average of 6 adult males and females from Muskeg Creek, Alberta: Total length, 145; tail vertebræ, 39; hind foot, 17.8. Largest specimen from Muskeg Creek: 160; 41; 18. Skull (No. 81487, ♀ ad., same locality): Basal length, 23; nasals, 6; zygomatic breadth, 14; mastoid breadth, 11; alveolar length of upper molar series, 6.

Remarks.—The characters separating drummondi from pennsylvanicus and modestus are relative. There is no sharp distinction and the forms either merge into each other, or after approaching each other in size overlap in range and occur together at the same localities. Specimens from Blackfoot, Montana, are nearer modestus, while those from Summit and St. Marys Lake are almost typical drummondi. At Elk River, Minnesota, about half of the specimens are almost typical drummondi, while the others are a small form of pennsylvanicus; but, as others fall between and cannot positively be placed with either form, it is impossible to decide whether the difference is due to individual variation in an intermediate form or whether two species meet and interbreed.

To the eastward drummondi merges into fontigenus, from which it differs in such slight degree that the two are not easily distinguishable. On the west slope in British Columbia drummondi becomes slightly darker, and in that respect less unlike fontigenus in appearance, but rétains its cranial characters, Alaska and northwestern specimens (from Fort Wrangel, Nulato, and Fort Simpson) are larger and in general appearance less different from pennsylvanicus, but detailed cranial characters show them to be but a robust form of drummondi. Specimens from Liard River, including the type of M. stonei, are indistinguishable from typical drummondi.

Specimens examined.—Total number, 355, from the following localities:

Alberta: Muskeg Creek (15 miles south of Smoky River), 13; Smoky Valley (50 miles north of Jasper House), 5; Fishing Lake (90 miles north of Jasper house), 2; Henry House (15 miles south), 4; South Edmonton, 110; St. Alberts, 26; Canmore, 2; Banff, 1; Red Deer, 1.

Athabasca: Lesser Slave Lake, 1.

Assiniboia: Indian Head, 30; Medicine Hat, 1.

British Columbia: Shuswap, 13; Sicamous, 1; Cariboo Lake, 2; Okanagan, 11; Ducks, 2; Stuart Lake, 1.

Saskatchewan: Cumberland House, 2; St. Louis, 1.

Manitoba: Carberry, 2.

Ontario: Rat Portage, 2; Coney Island (Lake of the Woods), 2.

Northwest Territory: Fort Churchill, 2; Fort Simpson, 2; Fort Rae, 3; Fort Reliance, 1; Big Island (Great Slave Lake), 1; Fort Good Hope, 1; Fort MacPherson, 1; Fort Anderson, 2; head of Liard River, 1; Chandindu River, 1; Dawson, 1; Sixty-Mile Creek, 1; Fort Selkirk, 3; 50 miles below Fort Selkirk, 1; Rink Rapids, 6; Thirty-Mile River, 3; Lake Lebarge, 4; Fifty-Mile River, 6; Lake Marsh, 22; Caribou Crossing, 16.

Alaska: Fort Wrangell, 1; Nulato, 1; Charlie Creek (Yukon River), 2; Canadian Boundary and Yukon River, 4.

North Dakota: Portland, 4; Lisbon, 1; Bottineau, 1.

Montana: St. Marys Lake, 6; Summit, 8.

Idaho: Priest Lake, 5.

Washington: Loon Lake, 9.

#### MICROTUS AZTECUS (Allen). Aztec Vole.

Arricola (Mynomes) aztecus Allen, Bul. Am. Mus. Nat. Hist., V, 73-74, April 28, 1893.

Type locality. -- Aztec, New Mexico (altitude, 5,900 feet).

Geographic distribution .-- Valley of the San Juan River in northwestern New Mexico, in Transition zone.

Habitat.—Grassy places along the river banks and near irrigation ditches.

General characters. - In size similar to M. pennsylvanicus, but with shorter tail and larger hind foot; skull long; braincase narrow; interparietal long.

Color .- Winter pelage: Upperparts dull buffy, heavily mixed with black hairs; belly washed with creamy or pale buff; feet plumbeous; tail sharply bicolor, black above, soiled whitish below. Young (halfgrown specimens in Dec.): Scarcely different in color from adults. (Summer pelage not examined.)

Cranial characters.-Skull long; braincase high and narrow; interparietal more than half as long as wide, extending back to plane of foramen magnum; audital bulke large; mandible short and heavy; angular process of mandible wide; dentition as in pennsylvanicus.

Measurements .-- Average of 7 adults from type locality: Total length, 171; tail vertebræ, 43; hind foot, 22. Skull (No. 57432, & ad.): Basal length, 28.8; nasals, 8.4; zygomatic breadth, 17; mastoid breadth, 12.5; alveolar length of upper molar series, 7.2.

Remarks .- Microtus aztecus belongs to the pennsylvanicus group. Externally it is not very different from modestus, but none of the specimens show any signs of intergradation; and the skull characters are so well marked that there seems no doubt of its full specific rank.

Specimens examined .-- Total number, 45, from the following localities:

New Mexico: Aztec, 42; La Plata, 3.

MICROTUS ENIXUS Bangs. Large Labrador Vole.

Microtus enixus Bangs, Am. Nat., XXX, 1051-1052, Dec. 5, 1896.

Type locality.—Hamilton Inlet (north shore), Labrador.

Geographic distribution.—Eastern coast of Labrador from Hamilton Inlet to Ungava Bay, in Hudsonian zone.

General characters.—Size slightly larger than M. pennsylvanicus, with relatively longer tail and larger ears; coloration duller and darker; skull smaller, shorter, and wider, with lighter molars. Hip glands present in adult males.

Color.—Summer pelage (July and Aug. specimens): Upperparts dark yellowish bister mixed with blackish; belly smoky gray or soiled whitish, sometimes tinged with buffy; feet dusky or blackish; tail black above, grayish brown below.

Cranial characters.—Outline of skull shorter, wider, and less arched than in pennsylvanicus; prezygomatic notch deep; coronoid notch of mandible wide and rounded; molar series small and slender; m2 with posterior loop completely closed and circular in form; m3 with terminal loop shortened; dentition otherwise as in pennsylvanicus.

Measurements.\(^1\)—Type, \(^2\) ad.: Total length, 210; tail vertebræ, 67; hind foot, 22.5. Average of 10 adult topotypes: 189.4; 60.4; 22.4. Skull (No. 4018, \(^2\) ad.): Basal length, 27.3; nasals, 8.6; zygomatic breadth, 16.7; mastoid breadth, 12.3; alveolar length of upper molar series, 6.5.

Remarks.—Microtus enixus appears to be a distinct and well marked species of the pennsylvanicus group, the long tail and small molars being the most convenient characters for recognition. From its geographically nearest neighbors, Microtus p. fontigenus, of Lake Edward, Quebec, and Microtus p. labradorius, of Ungava, it shows a wider difference than from typical pennsylvanicus.

Specimens examined.—Total number, 16, from the following localities:

Labrador: Hamilton Inlet, 13; Fort Chimo, Ungava, 3.

MICROTUS TERRÆNOVÆ (Bangs). Newfoundland Vole.

Arricola terrænoræ Bangs, Proc. Biol. Soc. Wash., IX, 129-132, July 27, 1894.

Type locality.—Codroy, Newfoundland.

Geographic distribution.—Newfoundland and Penguin Island.

General characters.—Slightly larger than pennsylvanicus, with decidedly larger hind foot, and more yellowish colors; belly with dusky median line; nose patch buffy; skull wide and angular.

Color.—Summer pelage (in July and August specimens): Upperparts dark russet, darkened by brown-tipped hairs, becoming paler on sides and across face; nose patch dark buffy or dull russet; belly whitish or smoke gray with a median streak of dusky cinnamon; tail distinctly bicolor, blackish above, soiled whitish below; feet grayish brown. Winter pelage (retained in April specimens): Slightly paler russet above, whiter below, with sharper markings throughout. Young (nearly half-grown): Similar to adults.

Cranial characters.—Skull short with wide-spreading zygomata; prezygomatic notch deep; nasals terminating even with arms of premaxillæ; lateral pits of palate deep and wide; interpterygoid space narrow with median constriction; m1 with an anterior spur or loop; m3 with posterior loop short, irregularly rounded, triangular or trifoliate; m2 and m3 normally with anterior point or spur.

From original description.

Measurements.—Average of 10 adults from type locality: Total length, 182; tail vertebræ, 52; hind foot, 23.4. Skull (No. 74029, 5 ad.): Basal length, 28.5; nasals, 8.4; zygomatic breadth, 17; mastoid breadth, 13; alveolar length of upper molar series, 7.

Remarks.—Microtus terrænovæ shows very distinctive characters, and no close affinity with any neighboring species. Specimens showing very young and full winter pelage are still needed for a comprehensive description

Specimens examined.—Total number, 43; from the following localities: Newfoundland: Codroy, 35; Penguin Island, 8.

MICROTUS BREWERI (Baird). Beach Vole.

Arvicola breweri Baird, Mamm. N. Am., 525-526, 1857.

Type locality.—Muskeget Island, Massachusetts.

Geographic distribution .- Muskeget Island.

Habitat.—Beach plum thickets on the sandy island.

General characters.—Size a little larger than pennsylvanicus; colors pale grayish; pelage long and coarse; skull heavy with wide nasals and quadrate interparietal.

Color.—Summer pelage (July 18): Upperparts buffy gray with scattered brown- and black-tipped hairs, paler on sides; belly tinged with sulphur yellow; feet silvery gray; tail bicolor, rusty brown or blackish above, soiled whitish below. Young: Rather paler and duller than adults.

Cranial characters.—Skull massive; nasals wide anteriorly; interparietal more than half as long as wide; inner edges of zygomata sharply notched close to lachrymals; rostrum heavy; upper incisors bent abruptly downward; molar pattern not very different from that of pennsylvanicus.

Measurements.—Average of 10 adults from Muskeget Island: Total length, 182; tail vertebræ, 54; hind foot, 22.3. Skull (No. 73141, & ad.): Basal length, 28.7; nasals, 8.3; zygomatic breadth, 17.3; mastoid breadth, 13; alveolar length of upper molar series, 7.2.

Remarks.—Nine of the 26 specimens have a small white spot on the forehead. This may be accidental or an only partially acquired character.

Specimens examined.—Total number, 26; all from the type locality.

MICROTUS NESOPHILUS Bailey. Gull Island Vole.

Microtus insularis Bailey, Proc. Biol. Soc. Wash., XII, 86, April 30, 1898. Name preoccupied by Lemmus insularis, Nillson (= Microtus agrestis L.). Microtus nesophilus Bailey, Science, N. S., VIII, 782, Dec. 2, 1898.

Type locality.—Great Gull Island, New York.

Geographic distribution.—Great Gull Island (at entrance to Long Island Sound).

General characters.—Size of pennsylvanicus; colors darker; skull shorter and wider with more spreading zygomata and deeper prezygomatic notches.

Color.—Summer pelage: Upperparts, dark yellowish bister heavily mixed with black hairs, darkest on nose and face; belly dusky, washed with cinnamon; feet blackish; tail blackish above, dark brown below.

Cranial characters.—The skull differs from that of pennsylvanicus in shorter, wider braincase, wider and more abruptly spreading zygomatic arches, more expanded jugal, and smaller audital bulke; palate short, with a median point or spur and deep lateral pits; m3 normally with anterior inner and outer triangles approximately opposite and confluent; dentition otherwise similar to that of pennsylvanicus.

Measurements.—Type (measured in dry skin): Tail, 29; hind foot, 20. No. 1943, Am. Mus., 3 ad., 185: 41:21. Skull (No. 53969): Basal length, 26; zygomatic breadth, 16.2; mastoid breadth, 12.3; alveolar length of upper molar series, 6.8. (No. 1943) 26.6; 8.5; 16.2; 13; 6.6.

Remarks.—Microtus nesophilus needs no comparison with breweri or terranova, the other two insular forms from the Atlantic coast. In general appearance it more nearly resembles pennsylvanicus, but in cranial characters it is as distinctly different as either of the other island species.

During the month of August, 1898, Mr. A. H. Howell visited Great Gull Island for the purpose of getting specimens of *Microtus*, but he found their old haunts covered by the earth moved in grading the island for fortifications, while no trace of the animals remained. He thinks they are completely exterminated.

Specimens examined.—Total number, 15; all from the type locality.

MICROTUS MONTANUS (Peale). Peale Vole.

Arvicola montanus Peale, U. S. Exploring Exp'd., Mammalogy, 44, 1848.

Arvicola longirostris Baird, Mamm. N. Am., 530-531, 1857. (From upper Pitt River, California.)

Type locality.—Headwaters of Sacramento River, near Mount Shasta, California.

Geographic distribution.—Northeastern California, eastern Oregon, northern Utah and Nevada, in the Upper Sonoran and Transition zones.

Habitat.—Marshes, meadows, and tule swamps.

General characters.—Size medium (about as in pennsylvanicus); tail about twice as long as hind foot; colors dark; hip glands conspicuous in adult males; incisors projecting well in front of nasals; incisive foramina narrow and constricted posteriorly.

Color.—Summer pelage: Upperparts bister or ashy mixed with blackish; belly washed with soiled whitish, giving a smoky gray or dusky color; feet plumbeous; tail indistinctly bicolor, blackish above, plumbeous below; lips usually showing a trace of whitish.

Cranial characters.—Skull generally slender and smooth, becoming angular and ridged in only a few very old individuals; nasals narrow and short; interparietal wide and normally strap-shaped; incisive foramina narrow and constricted posteriorly; bulka medium and well

CAROLOGO CO

Fig. 2.—Molar enamel pattern of Microtus montanus (×5).

بعريبة المداعدة العاليبية

rounded; dentition rather light; m2 with 4 closed sections; m3 with 3 closed triangles; m1 normally with 5 closed triangles.

Measurements.—Average of 10 specimens from Sisson, Cal.: Total length, 175; tail vertebrie, 52; hind foot, 21.5. Extremely large specimens from Sisson run as high as 192; 54; 23. Skull (No. 98689, & ad., from Sisson): Basal length, 28; na-

sals, 8; zygomatic breadth, 17; mastoid breadth, 13.5; alveolar length of upper molar series, 7.3.

General remarks.—The original description of M. montanus, though meager, agrees in all particulars with the animal from Sisson, at the west base of Mount Shasta. The measurements (total length,  $6\frac{1}{5}$  inches; tail,  $1\frac{1}{2}$  inches=156 mm. and 38 mm.) give it too short a tail, which only serves to restrict it more closely to this form in distinction from either of the longer-tailed species (mordax or californicus) that occur at or near the type locality. Three mounted specimens in the United States National Museum, which Baird referred to montanus, and which came from Upper Klamath Lake and the Upper Des Chutes, are identical with those of the present series from Sisson, Fort Klamath, and Fort Crook. Specimens from the south end of Goose Lake, which is the source of Pitt River, are the same as those from Sisson and from Fort Crook, lower down the river, and also the same as Baird's type of M. longirostris from 'Upper Pitt River.'

M. montanus has a somewhat scattered and interrupted distribution and shows considerable geographic variation in widely separated localities. The extreme development of large size, large feet, and heavy angular skull is found in the big marshes of the Carson Sink, Nevada, while specimens from higher levels in the Transition zone are smaller, with slenderer feet and grayer coloration. The variation is mainly, but not entirely, zonal. To separate either extreme would tend to confusion rather than convenience, as the extremes point to nevadensis on the one hand and to nanus on the other.

Specimens examined.—Total number, 263, from the following localities:

California: Sisson, 57; Fort Crook, 23; Hayden Hill, 2; Fall Lake, 2; Cassel, 1; Tule Lake, 2; Goose Lake, 8; Greenville (8 miles NW.), 3; Bucks Rauch (Plumas Co.), 1; Quincy, 3; Summit, 1.

Nevada: Washoe, 1; Deep Hole (south end of Granite Range), 1; Pine Forest Range, 1; Mountain City, 4; Wells, 13; Austin, 7; Carson, 16; Stillwater, 10; Newark Valley, 5; Monitor Valley, 5; Ruby Lake, 5; Ruby Mountains, 3.

Oregon: Klamath Basin (Lost River), 8; Klamath Falls, 1; Fort Klamath, 5; Swan Lake Valley, 5; Plush (west side Warner Lake), 9; Shirk, 2; Steen Mountains (east slope), 1; Summit NE. of Steen Mountains), 2; Burns, 2; Wapinitia, 4.

Utah: Ogden, 16; Salt Lake City, 3; Provo, 1; Fairfield, 10; Manti, 20.

MICROTUS MONTANUS ARIZONENSIS Bailey. Arizona Vole.

Microtus montanus arizonensis Bailey, Proc. Biol. Soc. Wash., XII, 88, April 30, 1898.

Type locality.—Springerville, Ariz.

Geographic distribution.—Plateau country of eastern Arizona, at head of Little Colorado, in the Transition Zone.

Habitat.—Creek banks and damp meadows.

General characters.—Similar to M. montanus, but brighter and more ferruginous in color; lateral pits of palate shallower.

Color.—Early winter pelage (October and November specimens): Upperparts yellowish or rusty brown; belly washed with white; feet dark grayish; tail bicolor, blackish above, grayish below; lips whitish. Slightly immature specimens are a little duller colored than adults.

Cranial characters.—Skull very similar to that of montanus, but easily distinguished by the flatter palate with shallower lateral pits and by thicker pterygoids; condyloid process of mandible slightly shorter. Dentition not different.

Measurements.—Type: Total length, 184; tail vertebræ, 55; hind foot, 20. Average of 7 specimens from type locality: 158; 41; 20.6. Skull (of type): Basal length, 27.3; nasals, 8; zygomatic breadth, 16; mastoid breadth, 12.2; alveolar length of upper molar series, 6.5.

General remarks.—Although widely separated geographically from *M. montanus* by desert country through which continuity of range is improbable, this form is so closely related to that species that its position is best indicated by subspecific rank.

Specimens examined.—Total number, 12, from the following localities:

Arizona: Springerville, 11. New Mexico: Nutria, 1.

MICROTUS MONTANUS RIVULARIS Bailey. Utah Vole.

Microtus nevadensis rivularis Bailey, Proc. Biol. Soc. Wash., XII, 87, April 30, 1898.

Type locality.—St. George, Utah.

Geographic distribution.—Known only from type locality, probably restricted to Lower Sonoran zone.

Habitat.—Tule marshes along the banks of the Virgin River. The runways were always found in wet places among sedges and rushes.

General characters.—Larger and lighter colored than typical montanus; skull more arched; nasals narrower.

Color.—Winter pelage: Upperparts dull bister, darkened with blackish-tipped hairs; sides scarcely paler; belly washed with white; feet dull grayish; tail bicolor, blackish above, grayish below. Young: Darker than adult, but not black backed as in nevadensis.

Cranial characters.—Skull well arched, not much ridged; nasals conspicuously narrower than in montanus; frontals narrower posteriorly; basioccipital more constricted anteriorly; dentition essentially the same.

Measurements.—Type: Total length, 179; tail vertebræ, 48; hind foot, 23. A nearly adult female topotype: 163; 43; 21. Skull (of type): Basal length, 28.2; nasals, 8.3; zygomatic breadth, 17; mastoid breadth, 13.3; alveolar length of upper molar series, 7.3.

General remarks.—Since rivularis was described in 1898 as a subspecies of nevadensis, a series of 50 specimens has been collected at the type locality of montanus, showing for the first time the real characters and the range of variation in that species, and, moreover, as Dr. Merriam had previously suggested to me, that rivularis comes nearer to typical montanus than to nevadensis. So far as at present known it has an isolated range in a Lower Sonoran valley, but it may readily extend northward to meet and merge into montanus in central Utah.

Specimens examined. - Total number, 4, from the type locality.

#### MICROTUS NANUS (Merriam). Dwarf Vole.

Arvicola nanus Merriam, North American Fauna No. 5, 62-63, pl. 11, figs. 5 and 6, July 30, 1891.

Type locality.—Pahsimeroi Mountains, Idaho (altitude 9,350 feet).

Geographic distribution.—Rocky Mountains and outlying ranges, from central Idaho southward to central Nevada and southern Colorado, in Canadian zone.

Habitat.-Dry, grassy parks on mountain slopes.

General characters.—Size small; tail short; ears short and rounded; color dark grayish; skull slender.

Color.—Summer pelage: Upperparts uniformly grizzled gray mixed with sepia and blackish hairs; belly washed with white; feet grayish or plumbeous; tail bicolor, dusky gray above, whitish below. (Winter pelage unknown.) Young: Similar to adult, but slightly duller throughout.

Cranial characters.—Skull small, slender and well arched, with slender zygomata and large well-rounded bulke; superciliary ridges prominent, sometimes confluent in old age; incisors projecting well beyond nasals; molars light, with short, wide triangles; enamel pattern scarcely distinguishable from that of mordax and montanus.

Measurements.—Type, & ad.: Total length, 151; tail vertebræ, 41; hind foot, 18. Average of five adults from type locality: 143; 37; 18.4. Skull (of type): Basal length, 23.7; nasals, 6.7; zygomatic breadth, 14; mastoid breadth, 10.8; alveolar length of upper molar series, 5.8.

Remarks.—Microtus nanus belongs to the montanus group but occupies a higher zone and has more of the habits of Pedomys or Lagurus. It is rarely found in wet places or near water. Specimens from certain isolated localities are not entirely typical, but do not differ enough to warrant separation.

Specimens examined.—Total number, 114, from the following localities:

Idaho: Pahsimeroi Mountains, 13; Lost River Mountains, 1; Challis, 7; Sawtooth Lake, 5; Three Creek, 3; Montpelier Creek, 3; Seven Devils Mountains, 4.

Utah: Uinta Mountains, head of Smith Fork, 1.

Wyoming: Fort Bridger, 9; Kinney Ranch, 6; Beaver, 1 (no skull); La Barge Creek (near head), 1; Cheyenne, 3; Sherman, 2; Laramie, 2; South Pass City, 20; Bighorn Mountains, head of Powder River, 9.

Montana: Beartooth Mountains, 3; Big Snowy Mountains, 1.

Colorado: Estes Park, 1; Cochetopa Pass, 17; Twin River, 1; Twin Lakes, 1.

MICROTUS NANUS CANESCENS Bailey. Gray Vole.

Microtus nanus canescens Bailey, Proc. Biol. Soc. Wash., XII, 87, April 30, 1898.

Type locality.—Conconully, Washington.

Geographic distribution.—Northern Washington and southern British Columbia, east of the Cascades. Apparently confined to the Transition zone.

Habitat.—Dry grassy ground.

General characters.—Like nanus but lighter, clearer gray; skull with larger bulke and greater mastoid breadth; zygomatic arches less widely spreading; upper incisors bent more abruptly downward. Hip glands conspicuous in adult males.

Color.—Summer pelage: Upperparts clear, dark grayish, formed by pale buffy and black tipped hairs; sides shading to lighter gray and belly to white; feet dark gray; tail bicolor, blackish above, grayish below. (Young and winter pelage not shown in present material.)

Cranial characters.—Skull slightly narrower and more elongate than in nanus; interparietal averaging longer; bulke decidedly larger and fuller; mastoid breadth relatively greater; incisors scarcely reaching beyond nasals; molar pattern as in nanus.

Measurements.—Type: Total length, 149; tail vertebræ, 42; hind foot, 20. Skull (of type): Occipital condyle to anterior base of molars, 17.4; posterior tip of nasals to foramen magnum, 19.2; zygomatic breadth, 15; mastoid breadth, 12.3; alveolar length of upper molar series, 6.3.

General remarks.—In its extreme development this northern form is readily distinguishable from typical nanus. From intermediate localities, Flathead Lake and the Plains of the Columbia, specimens are not typical of either but show slight peculiarities of local development interesting in themselves but not sufficiently marked for even subspecific distinction. To a certain extent they are intermediate between nanus and canescens.

Specimens examined.—Total number, 47, from the following localities:

British Columbia: Okanagan, 11; Ducks, 2; Vernon, 7.

Washington: Conconully, 1; Wenatchee, 1; Fort Walla Walla, 1; Oakesdale, 2; Wawawai, 4; Cheney, 1.

Oregon: Elgin, 2; Wallowa Mountains (near Joseph), 6.

Montana: West arm of Flathead Lake, 5; Hot Spring Creek (a branch of the Little Bitterroot), 4.

MICROTUS CANICAUDUS Miller. Gray-tailed Vole.

Microtus canicaudus Miller, Proc. Biol. Soc. Wash., XI, 67-68, April 21, 1897.

Type locality.—McCoy, Oregon.

Geographic distribution.—Willamette Valley, Oregon, and the east base of the Cascades in southern Washington, in Transition zone.

General characters.—Size and proportions about as in nanus; cars larger, skull heavier, more arched, with fuller, rounder bulke, and shallower lateral pits of palate, coloration more yellowish, tail grayer.

Color.—Winter pelage: Upperparts bright yellowish bister, darkened with blackish-tipped hairs, slightly paler on sides; belly and whole lower parts whitish-gray; feet grayish or pale plumbeous; tail in winter adults uniformly grayish, with a half-concealed dusky dorsal line. In the only summer specimen (from North Yakima, Wash., and perhaps not typical) the tail is sharply bicolor with a blackish dorsal line. Young (half-grown November specimens): Sooty gray above and scarcely lighter below; feet dusky; tail gray, with a blackish dorsal stripe.

Cranial characters.—Skull high, smooth, and well arched, with scarcely a trace of superciliary ridges; interparietal lozenge-shaped; bullæ larger and more rounded than in nanus; interpterygoid fossa narrower and more acuminate; lateral pits of palate shallower; incisors less protruding; enamel pattern of molars the same as in nanus.

Measurements.—Type: Total length, 135; tail vertebra, 33; hind foot, 20. Average of 8 adults from type locality: 141; 35.7; 20. Skull (of type): Basal length, 24.2; nasals, 7.3; zygomatic breadth, 15.3; mastoid breadth, 12.8; alveolar length of upper molar series, 6.

Remarks.—A single specimen with a badly broken skull from North Yakima, Wash., seems to be true canicaudus in summer pelage, and indicates that the range of the species is much more extensive than is at present known.

Specimens examined.—Total number, 14, from the following localities:

Oregon: McCoy, 9; Beaverton, 2; Sheridan, 2 (im). Washington: North Yakima, 1.

MICROTUS DUTCHERI Bailey, Dutcher Vole.

Microtus dutcheri Bailey, Proc. Biol. Soc. Wash., XII, 85, April 30, 1898.

Type locality.—Big Cottonwood Meadows, near Mount Whitney, California (altitude, 10,000 feet).

Geographic distribution.—Hudsonian zone of the southern Sierra Nevada.

Habitat.—Wet alpine meadows.

General characters.—Size rather small; tail short; ears small, nearly concealed by fur; colors dark above and below; lips and usually nose white; hip glands present in adult males.

Color.—Summer pelage: Upperparts dark bister with brown tips to the long hairs; below, dull cinnamon or buffy-brown; feet whitish or

plumbeous-gray; tail bicolor, brown or blackish above, whitish below; lips and usually tip of nose white. (Winter pelage unknown.) Young: Dull brown above and scarcely lighter below; feet and tail blackish; lips and nose usually white.

Cranial characters.—Skull similar to that of montanus but differing in many details; rostrum slightly longer; bulke smaller and less globular; lateral pits of palate shallower; dentition the same.

Measurements.—Type, & ad.: Total length, 167; tail vertebræ, 35; hind foot, 20. Average of 10 adults, 5 males and 5 females, from type locality: 163; 37; 20.6. Skull (of type): Basal length, 27.4; nasals, 8; zygomatic breadth, 16.7; mastoid breadth, 12.2; alveolar length of upper molar series, 6.5.

General remarks.—The nearest relative of M. dutcheri is montanus, but the two species occupy widely separated zones, and show no evidence of intergradation.

Specimens examined.—Total number, 65, from the following localities in the Sierra Nevada:

California: Big Cottonwood Meadows, 28; Whitney Meadows, 11; Menache Meadows, 2; Olancha Peak, 3; Head of Kern River, 1; Mammoth, 12; Pine City, 3; Head of San Joaquin River, 5.

MICROTUS NEVADENSIS Bailey. Nevada Vole.

Microtus nevadensis Bailey, Proc. Biol. Soc. Wash., XII, 86, April 30, 1898.

Type locality.—Ash Meadows,1 Nye County, Nevada.

Geographic distribution.—Known only from the type locality and Pahranagat Valley, about 100 miles to the northeast. Both localities are in the Lower Sonoran zone.

Habitat.—Salt grass and tule marshes in alkaline valleys. Runways always found in wet, muddy places, and often extending through shallow water.

General characters.—Size large; ears small; tail rather short; fur coarse and lax; colors dark; hip glands conspicuous in adult males. Skull massive and angular; incisive foramina narrow and closing to a point posteriorly.

Color.—Winter pelage (March specimens): Upperparts dark sepia or bister, much obscured by blackish hairs; sides lighter; belly smoky gray; feet dark gray; tail indistinctly bicolor, blackish above, gray or brownish below; lips usually white; tip of nose usually whitish. Young: With a blackish dorsal stripe and dusky feet and tail.

Cranial characters.—Skull heavy, angular, and much ridged; frontals high; rostrum bent downward; nasals truncate or rounded posteriorly, terminating even with arms of premaxillar; incisive foramina short, rather narrow and constricted to a point posteriorly; dentition heavy; upper incisors curved abruptly downward; molar pattern vari-

<sup>&</sup>lt;sup>1</sup>Ash Meadows is on the Nevada side of the Nevada-California line near where the Amargosa River crosses the boundary. The exact locality is a big salt marsh below Watkins ranch.

<sup>18392—</sup>No. 17——3

able; m2 with 4 closed sections in 8 out of 16 specimens, in the other 8, with a slight inner lobe or loop at base of posterior triangle; m3 with anterior crescent, three closed triangles, and a posterior loop with two inner lobes; m1 usually with 6 closed triangles.

Measurements.—Type: Total length, 210; tail vertebre, 55; hind foot, 25.5. Average of 8 specimens from type locality: 176; 47; 23. Skull (of type): Basal length, 32; nasals, 10.2; zygomatic breadth, 19.3; mastoid breadth, 14.3; alveolar length of upper molar series, 8.

Remarks.—Three specimens taken May 26 in Pahranagat Valley differ slightly from the type series, but the cranial differences are slight and the darker color may be only seasonal. The species inhabits marshes and wet places, which are so rare and isolated in the desert region that it can have no extensive continuous range. It is one of the few forms of *Microtus* inhabiting a part of the Lower Sonoran zone.

Specimens examined.—Total number, 19, from the following localities:

Nevada: Ash Meadows, 16; Pahranagat Valley, 3.

#### MICROTUS CALIFORNICUS (Peale,) California Vole,

Arricola californica Peale, U. S. Expl. Expl., Mammalogy, 46, 1848. Arricola trowbridgi Baird, Mamu. N. Am., 529, 1857. (Montercy, California.)

Type locality.—San Francisco Bay, California.

Habitat.—Dry meadows and grassy uplands, Upper Sonoran zone. Geographic distribution.—California, west of the Colorado Desert and the Sierra Nevada, and from Santa Ysabel, San Diego County, Calif., north to the Rogue River and Umpqua valleys, Oregon.

General characters.—Size rather large, ears conspicuous above fur; pelage coarse and harsh, color similar to that of the house mouse; skull of adult heavy and angular, incisive foramina wide and open, usually widest posteriorly; a trace of hip glands in adult males.

Color.—Summer pelage: Upperparts dull buffy or elay-colored, slightly lined with blackish-tipped hairs; sides paler; belly light buffy or soiled whitish; tail bicolor, brownish above, buffy below; feet clear gray. Winter pelage: Much darker than the summer, with an excess of black-tipped hairs over the back; tail more sharply bicolor, blackish above. Young: Fur woolly and soft, duller and darker throughout than in the adult; belly dusky or plumbeous; feet and tail dusky.

Cranial characters.—Skull of adult heavy, angular, and ridged; nasals long, bent well down, widening abruptly in front, narrow and notched at posterior end, not reaching tip of ascending arm of premaxillæ; prezygomatic notch deep; postorbital processes prominent; frontals concave posteriorly; incisive foramina open, rounded at both ends and usually widest posterior to middle. Incisors heavy, the upper bent abruptly downward, not extending beyond tip of nasals; molars large and irregular, posterior triangle of m1 normally with an inner point or angle; posterior triangle of m2 with an inner point or angle or loop, 1

<sup>&</sup>lt;sup>1</sup> In 100 specimens, 77 have 4 closed triangles in m2, 20 have an open posterior loop, and 3 have a closed posterior loop as in prinsylvanicus.

suggesting the posterior loop in pennsylvanicus; m3 with three closed triangles, 3 outer and 4 inner salient angles; m1 with 5 closed triangles and 9 or 11 salient angles.

Measurements.-Average of 4 adults, 2 males and 2 females from

Walnut Creek, Calif.: Total length, 171; tail vertebræ, 49; hind foot, 21.1. Of 10 adults from Monterey: 172; 52; 22.3. Skull (& ad., No. 44678, from Walnut Creek, Calif.): Basal length, 27.5; nasals, 8.5; zygomatic breadth, 16.6; mastoid breadth, 13.6; alveolar length of upper molar series, 6.8.

the larger, darker, longer-tailed species, M. edax.

Fig. 3.-Molar enamel pattern of

Microtus californicus (×5).

Remarks.—But slight variation is shown throughout the range of the species. Specimens from Santa Ysabel and the base of San Bernardino Mountains are indistinguishable from those of the shores of San Francisco Bay or from the Rogue River Valley, Oregon. A slight brightening in color is noticeable in specimens from Auburn.1 The species is conspicuously absent from the bottom, or Lower Sonoran area, of the San Joaquin and Sacramento valleys, its place being taken in the tule marshes of these valleys by

The skin of the type of M. californicus in the United States National Museum agrees perfectly with series of specimens from Berkeley, Walnut Creek, and other localities around San Francisco Bay, but the slightly immature skull is either abnormal or else never came from the same animal as did the skin. By some error it was given the same catalogue number as the type skull of M. occidentalis, a synonym of M. townsendi, but it is not the skull of that species.

Specimens examined.—Total number, 338, from the following localities:

California: Walnut Creek, 6; Oakland, 1; Berkeley, 44; San Lorenzo, 3; San Mateo, 14; Novato, 7; Glen Ellen, 9; Nicasio, 16; Point Reyes, 34; Cape Mendocino, 2; Mill Valley, Marin County, 3; Olema, 5; Cloverdale, 14; Ukiah, 2; Laytonville, 2; Round Valley, 1; Upper Lake, 1; Leesville, 10; Bartlett Mountain, 1; Rio Dell, 1; Hornbrook, 3; Little Shasta, 4; Mayten, 2; Cassel, 6; Red Bluff, 1; near Edgewood, 2; Grindstone Creek, Tehama County, 2; Auburn, 5; Jackson, 7; Chinese Camp, 2; Boulder Creek, 2; Monterey, 22; Jamesburg, 12; Jolon, 4; San Simcon, 1; Paso Robles, 1; Morro, 4; Pozo, 1; Gaviota Pass, Santa Barbara County, 4; Santa Barbara, 2; Ventura River, 3; San Emigdio Canyon, Kern County, 7; Mount McGill, Ventura County, 2; Calabasas, 3; San Fernando, 4; San Bernardino, 2; San Bernardino Mountains, 9; San Diego, 1; Riverside, 5; Techelote Canyon, Riverside County, 1; Little Bear Valley (San Bernardino Mountains), 1; Las Virginias Creek, 1; Radec, Riverside County, 1; Santa Ysabel, 10; near Tejon Pass, 1; Fort Tejon, 1; South Fork Kern River, 6.

Oregon: Rogue River Valley (near Grants Pass), 7; Siskiyou, 4; Drain, 6.

and the second contract of the second second

The effect of red soil is noticeable in these as in some other mammals from the vicinity of Auburn.

MICROTUS CALIFORNICUS VALLICOLA Bailey. Valley Vole.

Microtus californicus vallicola Bailey, Proc. Biol. Soc. Wash., XII, 89, 1898.

Type locality.—Lone Pine, Inyo County, California.

Geographic distribution.—Valleys east of the Sierra Nevada, California. Confined mainly to Upper Sonoran zone.

Habitat.—Dry, grassy banks, upland meadows, and old weedy fields. General characters.—Similar to californicus, but averaging slightly larger and darker. Proportions the same.

Color.—Summer pelage: Upperparts dull sepia, darkened by black-tipped hairs, darker and with less buffy suffusion than in californicus; belly dull grayish or smoky plumbeous; feet dusky; tail bicolor, blackish above, grayish below. Winter pelage: Darker throughout, with the black hairs of the back longer and more conspicuous. Young: Sooty gray above, plumbeous below, not black backed; feet and tail dusky.

Cranial characters.—Skull like that of californicus, but usually with smaller audital bullæ, more abruptly truncated occiput, and nasals reaching nearer to tips of premaxillæ; lobe at base of 4th triangle of middle upper molar sometimes developed into a loop.

Measurements.—Type,  $\mathfrak P$  ad.: Total length, 200; tail vertebra, 57; hind foot, 23. Average of 7 specimens from type locality: 188; 56; 23. Skull (of type): Basal length, 29.4; nasals, 9.5; zygomatic breadth, 17.6; mastoid breadth, 13.4; alveolar length of upper molar series, 7.4.

Remarks.—The range of this form is not widely separated from that of californicus on the west slope of the mountains, and the two forms may meet by way of Walker Pass and the South Fork of Kern River. The difference is not sufficiently marked to warrant full specific separation, in view of the fact that their ranges are so nearly continuous that they occupy the same zone and have essentially the same habits.

Specimens examined.—Total number, 52, from the following localities:

California: Lone Pine, 26; Olancha, 3; Cartago (west side of Owens Lake), 3; Independence Creek, 1; Alvord, 8; Bishop Creek, 2; Panamint Mountains (head of Willow Creek at east end of Nelson Range), 9.

MICROTUS CALIFORNICUS CONSTRICTUS subsp. nov. Coast Vole.

Type from Cape Mendocino, California. No. 98347, U. S. Nat. Mus., Biological Survey Collection. Collected Sept. 6, 1899, by Vernon Bailey. Original number, 7174.

Geographic distribution .- Coast region near Cape Mendocino.

Habitat.—Open grassy hillsides and old fields and pastures.

General characters.—Smaller and grayer than californicus, with narrower skull, smaller audital bullæ, and narrower interprerygoid fossa.

Color.—Summer pelage (in September specimens): Buffy gray above, whitish below; tail almost concolor, dull grayish; feet gray.

Cranial characters.—Skull smaller and especially narrower than that of californicus, with slender nasals and rostrum; bulke small and narrow; pterygoids close together; zygomatic arches not abruptly spreading and not notched at anterior junction with premaxillæ; dentition as in californicus; tooth rows noticeably closer together.

Measurements.—Average of 4 adults from type locality: Total length, 163; tail vertebræ, 55; hind foot, 21.5. Skull (of type): Basal length, 26; nasals, 8.9; zygomatic breadth, 15.6; mastoid breadth, 12; alveolar length of upper molar series, 6.7.

General remarks.—There is a striking similarity in the characters separating this narrow-skulled form from its widely distributed species californicus, and those separating angusticeps of the coast region a little farther north from the still more widely distributed mordax, that shows an interesting parallelism in geographic modifications. Both forms are from the wind-beaten coast strip where arboreal vegetation is scanty and dwarfed, and, like some of the trees, they apparently represent depauperate forms of widely distributed and more protected inland species. At Capetown, just back of Cape Mendocino, California, I found constrictus in great abundance on the open grassy hills. In some places the ground was perforated with their burrows, while on the surface their runways crossed in all directions.

Specimens examined.—Four from the type locality, besides a large number in the flesh.

MICROTUS EDAX (Le Conte). Tule Vole.

Arricola edax Le Conte, Proc. Acad. Nat. Sci. Phila., VI, 405, 1853.

Type locality.—California [south of San Francisco].1

Geographic distribution.—Bottom of the San Joaquin and Sacramento valleys, in Lower Austral zone.

Habitat.—Tule swamps and wet places, under heavy grass, where the runways usually extend through mud and water and in places are flooded by the tide.

General characters.—Size large; feet large and stout; hair long and coarse; skull long, angular, and much ridged in adults; hip glands inconspicuous or rudimentary in adult males.

Color.—Winter pelage: Much blacker than in californicus; gray of upperparts more or less obscured by black; that in full, ripe pelage is glossed with iridescent purple; sides more grayish; belly washed with whitish; feet dusky; tail bicolor, black above and gray below or dusky gray above and whitish below. Summer pelage: Upperparts less glossed with black. Young: With black back, dusky sides, and paler dusky belly; feet and tail dark.

Cranial characters.—Skull similar to that of californicus, but larger, more elongated, more heavily ridged in adults, with more expanded jugal and heavier dentition; molar pattern similar; m2 with usually an open posterior fifth loop.

Measurements.—No.58128, & ad., from near Tracy, Calif.: Total length, 217; tail vertebre, 72; hind foot, 25. An immature ♀ from the same place: 167; 49; 23. An adult &, No. 70602, from near Marysville Buttes: 208; 67; 25. Skull (No. 70602, & ad.): Basal length, 30; nasals, 9.2;

<sup>&</sup>lt;sup>1</sup>Baird, Mamm. N. Am. 532, 1857.

<sup>&</sup>lt;sup>2</sup>M. californicus and many other species show a purple gloss in high pelage, but less marked than in some specimens of edax.

zygomatic breadth, 17.7; mastoid breadth, 13.9; alveolar length of upper molar series, 7.8.

Remarks.—The type of M. edax in the United States National Museum, at Dr. Merriam's request, has been relaxed, the skull removed, and the skin made over and greatly improved for purposes of comparison. The base of the skull has been cut away, but enough remains to show that the specimen is immature and is the large swamp species, instead of californicus. The hind foot gives the only reliable measurement. In the dry skin it measures, flattened out, 23.5, and is proportionately stout. This is fully up to the flesh measurement of No. 57900 from Tracy, though the skull shows the latter to be slightly older.

M. californicus and M. cdax differ widely in habits, their ranges conform to different zones, the distinctive characters are certainly strong enough for full specific recognition, and the present series shows no intergradation.

Specimens examined.—Total number, 50, from the following localities:

California: Tracy, 2; Marysville, 1; near Marysville Buttes, 1; Union Island (San Joaquin River), 1; Suisun, 24; Tulare Lake, 2; Mendota, 19.

MICROTUS SCIRPENSIS sp. nov. Desert Vole.

Type from Amargosa River (near Nevada line), Inyo County, Calif. No. \$\frac{25475}{3475}, \times ad.,
U. S. Nat. Mus., Biological Survey Collection. Collected February 26, 1891, by
Vernon Bailey. Original number, 2520.

Geographic distribution.—Known only from the type locality.

Habitat.—Wet ground under tall tules (Scirpus olneyi), where the runways extend through mud and water in a little marsh around a warm spring.

General characters.—Size and proportions about as in edax, colors not so dark, tail long, skull heavy and angular, middle upper molar with rounded open or closed posterior loop.

Colors.—Winter pelage: Upperparts dark buffy gray, slightly darker than in californicus, but not so black as in edax; belly smoky gray, tail indistinctly bicolor, brown above, grayish below; feet brownish gray, not dusky. Young: Upperparts black, belly grayish, a black dorsal stripe retained until the animals are half grown.

Cranial characters.—Skull of adult angular and heavily ridged; in general characters resembling that of edax, but with more truncate posterior tip of nasals, heavier dentition, and well-developed inner posterior loop of middle upper molar. The same characters and larger size distinguish it from those of vallicola and californicus, and the wide incisive foramina with many other characters distinguish it from that of its nearest neighbor—nevadensis.

Measurements.—Type: Total length, 210; tail vertebræ, 67; hind foot, 25. Average of 6 adults: 203; 65; 25.1. Skull (of type): Basal length, 31; nasals, 10; zygomatic breadth, 19; mastoid breadth, 13.6; alveolar length of upper molar series, 8.7.

General remarks,—Microtus scirpensis stands nearest to M. edax, and, except for the more completely developed posterior loop of middle upper molar, fits into the californicus group. Among 14 specimens the loop is closed in 7 and open in 7, while among 43 specimens of edax it is closed in 2, open in 32, and absent in 9, and among 100 specimens of californicus it is closed in 3, open in 20, and absent in 77. Although resembling pennsylvanicus in the fifth loop, in other characters it does not approach that group or any of its forms. In range it comes nearer to vallicola than to edax or californicus, but from rallicola it differs in the same way as from californicus.

Specimens examined.—Total number, 14, from the type locality.

MICROTUS OPERARIUS (Nelson). Tundra Vole.

Arricola operarius Nelson, Proc. Biol. Soc. Wash., VIII, 139, Dec. 28, 1893.

Type locality.—St. Michael, Alaska.

Geographic distribution.—Barren grounds from Bristol Bay, St. Michael, and Kowak River, Alaska, east to Anderson River.

Habitat.-Mossy tundras.

General characters.—Size small; tail short, densely haired; ears small and wholly concealed in long winter fur; colors yellowish; skull slender and narrow; dentition light.

Color.—Winter pelage: Upperparts dark rich buff, slightly tinged along back with black-tipped hairs; sides paler; belly pale buffy or creamy white; tail soiled whitish below and on sides, a partly concealed blackish dorsal line; feet gray; heels tinged with dusky. Summer pelage: Darker yellowish above, more buffy below.

Cranial characters.—Skull rather slender and narrow, angular and well ridged in adults; nasals slender, ending even with arm of premaxille; bulke small and narrow; palate low; incisive foramina short,

constricted posteriorly; incisors projecting well in front of nasals; molars very light; m2 with 4 closed sections; m3 with 3 closed triangles, 3 outer and 3 inner salient angles and terminal loop; m1 with 4 closed triangles, 3 outer and 5 inner salient angles, and fifth triangle open and confluent with short terminal loop, as in *M. ratticeps* of Europe.

Fig. 4.—Molar enamel pattern of *Microtus opera*rius (× 5).

Measurements.—Type (immature, measured in dry skin): Total length, 110; tail vertebra, 28; hind foot, 18. Average of 10 adult topotypes, 168; 40; 19.7. Skull (of type): Basal length, 22.4; nasals, 5.8; zygomatic breadth, 12.4; mastoid breadth, 10.7; alveolar length of upper molar series, 5.5. Skull (of adult &, No. 9899): 27; 8; 16; 12.3; 6.3.

General remarks.—Mr. E. W. Nelson found these voles abundant along the coast tundras of Bering Sea from Cape Vancouver north to Bering Strait, and on Nelson, St. Michael, and Stewart islands. Mr. W. H. Osgood found them extending southward into the timbered region as far as the point where the Yukon crosses the Alaska boundary.

Specimens examined.—Total number, 81, from the following localities:

Alaska: St. Michael, 65; Kowak River, 1; Kagiktowik, 1; Bristol Bay, 1; Fort Yukon, 8; Circle, 1; 40 miles above Circle, 2; International boundary on Yukon, 1; Yukon River (200 miles southwest of Fort Yukon), 1.

MICROTUS MACEARLANI Merriam. Macfarlane Volc.

Microtus macfarlani Merriam, Proc. Wash. Acad. Sci., II, 24, March 14, 1900.

Type locality.—Fort Anderson, Anderson River, Northwest Territory.

Geographic distribution.—Tundra region of Arctic America, east of the Mackenzie River.

General characters.—Similar to operarius in external characters, but with shorter tail, shorter, wider skull and more projecting incisors. Fur very long and soft in winter specimens.

Color.—Winter pelage: Upperparts light buffy gray; belly whitish; feet silvery gray; tail sharply bicolor, black above, white below. Summer pelage: Darker and brighter buff or ochraceous. Young: More grayish.

Cranial characters.—Compared with operarius: Skull short and wide; nasals shorter; incisors more projecting; bullar wider; incisive foramina shorter; molars slightly heavier; enamel pattern the same. With yakutatensis: Size smaller; coloration brighter; skull flatter; nasals shorter; incisors more projecting; interparietal smaller.

Measurements.—Type (in dry skin): Tail vertebræ, 29; hind foot, 18.5; topotype (No. 9144): tail, 27; hind foot, 19. Skull (of type): Basal length, 26; nasals, 7; zygomatic breadth, 15.5; mastoid breadth, 12.5; alveolar length of upper molar series, 6.

General remarks.—Material is so scanty from the Arctic regions that little is known of the range of this form, whether it meets and grades into operarius or yakutatensis, or whether it has a restricted and isolated range.

Specimens examined.—Total number, 18, from the following localities:

Northwest Territory: Fort Anderson, 4; Mackenzie River, 11; 'Arctic Coast,' 3.

MICROTUS YAKUTATENSIS Merriam. Yakutat Vole,

Microtus yakutatensis Merriam, Proc. Wash. Acad. Sci., II, 22. March 14, 1900.

Type locality.-Yakutat Bay (north shore), Alaska.

Geographic distribution.—Mainland of Alaska from Glacier Bay to Prince William Sound.

General characters.—Size medium, about equal to operarius, less than that of any of the island forms of the group. Color dusky, as in sitkensis, but belly whitish. Skull of adult male heavily ridged; bulle medium, rounded; interparietal large, shield-shaped.

Color.—Summer pelage: Upperparts dusky gray, with a trace of brownish, darker dorsally; belly washed with soiled white or pale buffy; tail sharply bicolor, sooty or black above, whitish below; feet silvery gray, soles black. Young: Quarter-grown specimen (June 19), darker gray than adult, with black nape, whitish belly, sharply bicolor, black and white tail.

Oranial characters.—Skull heavy, ridged and angular in adult male; interparietal large, shield-shaped; nasals long, with median constriction; dentition heavy. From the skull of operarius it differs in greater width, larger bulle, heavier dentition; from that of unalascensis in smaller size, larger interparietal, slenderer nasals, smaller bulle, shorter pterygoids. Molar pattern as in operarius. Skulls of adult females conspicuously smoother and less ridged than in males.

Measurements.—Average of 10 adults (5 males and 5 females) from type locality: Total length, 161; tail vertebræ, 37; hind foot, 20.6. Skull (of type, 3 ad., No. 98005): Basal length, 28; nasals, 8; zygomatic breadth, 16; mastoid breadth, 13; alveolar length of upper molar series, 7.

General remarks.—This mainland form is readily distinguished from any of the island species of the group by either cranial or external characters, although it shows closer relationship with some of them than with the neighboring mainland species, operarius. If it has an uninterrupted range to the north it may grade into operarius, but at present there is no intermediate material to show whether it does or not.

Specimens examined.—Total number, 47, from the following localities:

Alaska: Yukutat, 29; Glacier Bay, 17; Prince William Sound, 1.

MICROTUS KADIACENSIS Merriam. Kadiak Vole.

Microtus kadiacensis Merriam, Proc. Biol. Soc. Wash., XI, 222, July 15, 1897.

Type locality.—Kadiak Island, Alaska.

Geographic distribution.—Known only from the type locality.

General characters.—Size about that of sitkensis; belly white; ears very small; bullæ small and narrow; basioccipital short and wide.

Color.—Summer pelage: Yellowish brown above, with scattered black hairs; sides paler; belly washed with pure white; feet silvery gray, heels dusky, soles blackish; tail not sharply bicolor, black above, whitish below. Young (in June): Dull buffy gray above, maltese below.

Cranial characters.—Skull flat, long, and narrow; audital bullæ small and laterally compressed; basioccipital short and wide; palate low, with sloping median ridge, lateral pits deeper, and incisive foramina wider than in sitkensis; nasals short, not reaching posterior tips of pre-

maxille; incisors projecting; molars small; m3 with 3 closed triangles and elliptical terminal loop, making 3 inner and 3 outer salient angles, as in operarius.

Measurements.—Average of five adult males: Total length, 188; tail vertebræ, 50; hind foot, 21. Skull (of topotype, 3 ad. No. 97969,): Basal length, 28; nasals, 8; zygomatic breadth, 16.5; mastoid breadth, 13.2; alveolar length of upper molar series, 6.4.

Remarks.—This insular species belongs to the operarius group, but differs from operarius in larger size, smaller bulke, and transversely longer and narrower interparietal.

Specimens examined.—Total number, 12, from the type locality.

MICROTUS UNALASCENSIS Merriam. Unalaska Vole.

Microtus unalascensis Merriam, Proc. Biol. Soc. Wash., XI, 222, July 15, 1897.

Type locality.—Unalaska, Alaska.

Geographic distribution-Island of Unalaska.

General characters.—Larger and more robust than operarius; belly white; feet light gray; skull well arched and heavily ridged; bulke large and well rounded.

Color.—Upperparts dull yellowish brown, darkest on head and rump; end of nose whitish; belly white or slightly soiled whitish; feet light gray with dusky soles; tail bicolor, a narrow line of blackish above, soiled white below. Young: Similar to adult.

Cranial characters.—Skull considerably arched, deep, heavy, and angular; frontals heavily ridged in old age; bulle medium, much larger than in operarius or kadiacensis; basioccipital narrowly constricted between bulke; dentition actually and relatively heavier than in operarius; molar pattern the same; m3 with 3 closed triangles and an inner salient angle confluent with rounded posterior loop; m1 with 4 closed triangles, the fifth triangle confluent with shortened anterior loop.

Measurements.—Type,  $\circ$  im.: Total length, 122; tail vertebræ, 28; hind foot, 19. Adult  $\circ$  topotype, No. 97963: 181; 38; 22. Skull (of topotype): Basal length, 30; nasals, 8; zygomatic breadth, 17.7; mastoid breadth, 14; alveolar length of upper molars, 7.

Specimens examined.—Total number, 9, from the type locality.

MICROTUS UNALASCENSIS POPOFENSIS Morriam. Popof Island Vole.

Microtus unalascensis popofensis Merriam, Proc. Wash. Acad. Sci., II, 22, March 14, 1900.

Type locality.—Popof Island, Shumagin group, Alaska.

Geographic distribution.—Known only from Popof Island.

General characters.—Similar to kadiacensis, but slightly larger, with larger feet, relatively shorter and sharply bicolor tail. Skull less ridged, with larger bullæ and heavier molars. In size and proportions more nearly agreeing with unalascensis, from which it differs in wholly dusky nose, less ridged skull, smaller audital bullæ and deeper prezygomatic notch.

Color.—General coloration not readily distinguishable from that of kadiacensis; upperparts dark yellowish brown; nose dusky to tip; belly soiled white or pale buffy; tail sharply bicolor, whitish below, dusky or black above; feet silvery gray, with black soles and dusky heels.

Cranial characters.—Skull rather long and narrow; frontals not ridged in adults; prezygomatic notch deep; audital bulle medium, not narrowly constricted as in kadiacensis, nor large and rounded as in unalascensis; palate with posterior point projecting into pterygoid fossa; incisive foramina short and wide; molar pattern as in operarius except in m3, which has normally 4 inner and 3 or 4 outer salient angles; m1 has 4 closed and 1 open triangle as in operarius.

Measurements.—Average of 3 topotypes: Total length, 165; tail vertebrae, 38; hind foot, 22.4. An adult 2, No. 97959: 188; 43; 22. Skull (of type, No. 97956, 3 ad.): Basal length, 29.4; nasals, 8.5; zygomatic breadth, 17.5; mastoid breadth, 13.5; alveolar length of upper molar series, 7.2.

General remarks.—This species needs comparison only with unalascensis and kadiacensis, from both of which it differs in slight external and well-marked cranial characters. The three are evidently from the same original stock that from long insular separation has been modified by somewhat varied conditions.

Specimens examined.—Total number, 7, from the type locality.

### MICROTUS SITKENSIS Merriam. Sitka Vole.

Microtus sitkensis Merriam, Proc. Biol. Soc. Wash., XI, 221, July 15, 1897.

Type locality.—Sitka, Alaska.

Geographic distribution.—Known only from Baranof Island, Alaska. General characters.—Size medium, about that of unalascensis; color yellowish brown above and below; skull rather flat, wide interorbitally; interparietal triangular; molars small; m1 with 4 or 5 closed triangles.

Color.—August pelage: Upperparts rusty brown, brightest on rump and nose, besprinkled with blackish hairs; sides paler; belly washed with dark buff; nose blackish; feet silvery plumbeous; heels and soles black; tail sharply bicolor, black above, pale buff below.

Cranial characters.—Skull long and flat, with no trace of superciliary ridges, wide interorbitally; tip of nasals reaching back of premaxilla; interparietal narrow, subtriangular; bullae medium and globose; palate long and flattened, lateral bridges low, lateral pits shallow; incisive foramina short and narrow; incisors projecting well beyond nasals; dentition slightly more intricate than in operarius; m1 has 4 or 5 closed triangles and a rounded terminal loop with a sharp inner salient angle; m3 has 3 closed triangles and 4 inner and 4 outer salient angles.

Measurements.—Type, & ad.: Total length, 155; tail vertebræ, 42; hind foot, 23. Adult & topotype: 190; 45; 22. Skull: Basal length, 25.5; nasals, 7; zygomatic breadth, 14.2; mastoid breadth, 11.3; alveolar length of upper molar series, 6. Skull (of topotype, & ad.): 30; 8; 17.7; 14; 7.

Remarks.—Microtus sithensis belongs to a well-marked group of the subgenus Microtus with the molar pattern of M. ratticeps of Europe, although in sithensis m1 is usually closed up, making 5 triangles instead of 4.

Specimens cramined.—Total number, 2, from the type locality.

MICROTUS INNUITUS Merriam. Innuit Vole.

Microtus innuitus Merriam, Proc. Wash. Acad. Sci., II, 21, March 14, 1900.

Type locality.—St. Lawrence Island, Bering Sea, Alaska.

Geographic distribution.—Known only from St. Lawrence Island.

General characters.—Size large; tail of medium length, sharply bicolor; skull wide and low, with projecting incisors; dentition mainly as in the operarius group.

Cranial characters.—Skull ridged and angular, not much arched; braincase short and wide; nasals short and cuneate, falling considerably back of base of incisors; interparietal small, semicircular; bulke large, somewhat flattened and angular; pterygoids short; interpterygoid fossa very narrow; dentition heavy, incisors conspicuously projecting; molars with sharply constricted enamel folds; in with only 4 closed triangles, in 3 with three closed triangles, a short posterior loop, and long posterior inner salient angle.

Measurements.—Tail vertebra, 44; hind foot, 23. Skull (of type): Basal length, 32.5; nasals, 9; zygomatic breadth, 19.5; mastoid breadth, 15.3; alveolar length of upper molar series, 7.2.

General remarks.—The specimens from St. Lawrence Island were taken from regurgitated pellets of owls and jaegers, and consist of skulls, feet, tails, and imperfect skeletons. The animals are abundant. Many were seen running in the grass by members of the Harriman party who landed for a short time on the island. The species of Microtus coming geographically nearest to St. Lawrence Island is tshuktshorum Miller, from Plover Bay, on the Siberian coast, a tiny species bearing little resemblance to the present one.

Specimens examined.—Ten more or less imperfect skulls, besides feet, tails, and parts of skeletons, from the type locality.

## MICROTUS ABBREVIATUS Miller. Hall Island Vole.

Microtus abbreviatus Miller, Proc. Biol. Soc. Wash., XIII, 13, Jan. 31, 1899.

Type locality.—Hall Island, Bering Sea, Alaska.

Geographic distribution.—Known only from Hall Island.

General characters.—Size rather large; tail very short, and densely haired; ears concealed in long fur; feet large and stout, measuring about 23.

Color.—July pelage: Upperparts dark buff or yellowish brown, brightest over ears, face, and rump; belly creamy white or pale buff; tail sharply bicolor, a narrow line of dark brownish above, creamy below; feet soiled white. Young (half-grown specimens): Duller and darker.

Cranial characters.—Skull similar to that of unalascensis in size and general appearance, but more heavily ridged, with deeper prezygomatic notches, larger, more quadrangular interparietal, shallower lateral pits of palate; slightly smaller and especially narrower audital bulke; rather lighter dentition, with different molar pattern. m1 and m2 with base of posterior triangles broadly open; m3 shortened, with but 2

closed triangles, 3 outer, and 4 inner salient angles, the third triangle opening into short posterior loop; mI with 5 completely closed triangles, and a well developed anterior trefoil, 4 outer, and 5 inner sharp, salient angles back of terminal loop. From the St. Matthew Island subspecies fisheri, it differs in molar pattern as from unalascensis, and also in slenderer skull and rostrum, slenderer zygomata, and wider interpterygoid fossa.

CHANARON

Fig. 5.—Molar enamel pattern of Microtus abbreviutus (.15).

Measurements.—Average of 4 adult topotypes: Total length, 160; tail vertebrae, 25.7; hind foot, 23.3. Skull (of No. 97981, & ad.): Basal length, 30.3; nasals, 8.8; zygomatic breadth, 18; mastoid breadth, 14; alveolar length of upper molar series, 7.

General remarks.—Microtus abbreviatus was described from an alcoholic specimen retaining none of the original colors. On the Harriman expedition 7 specimens were collected July 14 on Hall Island, and for the first time the natural appearance of the animal was made known. In external characters it strongly resembles a lemming on account of the short tail, long fur, and stout form, but the skull is that of a robust Microtus. It belongs to the subgenus Microtus, and in general character comes nearest to the operarius group, from which it is excluded, however, by its unique molar pattern—m3 having but 2 closed triangles, while m1 has 5.

Specimens examined.—Total number, 8, from the type locality.

MICROTUS ABBREVIATUS FISHERI Merriam. St. Matthew Island Vole.

Microtus abbreviatus fisheri Merriam, Proc. Wash. Acad. Sci., II, 23, March 14, 1900.

Type locality.—St. Matthew Island, Bering Sea, Alaska.

Geographic distribution.—Known only from St. Matthew Island.

General characters.—Similar to abbreviatus, but slightly larger and darker; rostrum longer and heavier; nasals anteriorly expanded and posteriorly notched.

Color.—Summer pelage (July specimens): Upperparts dark rich buff, brightest over ears, face, and rump, sprinkled with black hairs over back; belly strong clear buff; tail buff, with concealed dusky line above; feet pale buffy. Young (half-grown specimens): Duller and darker.

Cranial characters.—Skull larger than in abbreviatus, with relatively narrower braincase; rostrum longer and heavier on account of the longer, anteriorly spreading nasals; posterior tip of nasals distinctly notched; dentition slightly heavier than in abbreviatus, but with essentially the same molar enamel pattern.

Measurements.—Average of 7 adults, 1 male and 6 females, from St. Matthew Island: Total length, 166; tail vertebræ, 27; hind foot, 22.7. One adult &: 178; 32; 24. Skull (No. 97976, & ad.): Basal length, 31.3; nasals, 9.8; zygomatic breadth, 19; mastoid breadth, 14; alveolar length of upper molar series, 7.3.

General remarks.—Microtus a. fisheri needs comparison only with abbreviatus, from which it differs in well-marked subspecific characters. The external differences are less marked than the cranial, as a natural result of the very similar conditions on the neighboring islands occupied by the two forms. Hall Island, the home of abbreviatus, is separated from St. Matthew Island, the home of fisheri, by about 4 miles of deep sea.

Specimens examined.—Total number, 8, from the type locality.

MICROTUS TOWNSENDI (Bachman). Townsend Vole.

Arvicola townsendi Bachman, Journ. Acad. Nat. Sci. Phila., VIII, 60, Pl. I, 1839.
Arvicola occidentalis Peale, U. S. Expl. Expd., Mammalogy, 45, 1848. (Puget Sound.)

Type locality.—Lower Columbia River, near mouth of Willamette, on or near Wappatoo (or Sauvie) Island.

Geographic distribution.—Low country west of the Cascades, from Port Moody, British Columbia, south to the Willamette Valley and to Yaquina Bay, Oregon, in Transition zone.

Habitat.—Open grass land, pastures, fields, and dry meadows.

General characters.—Size large; fur thin and harsh; ears conspicuous above fur; color dark brownish; a pair of conspicuous glands on hips in adult males.

Color.—Summer pelage: Back vandyke brown, much darkened with long black hairs; sides dark buffy gray; belly grayish or dusky; tail blackish, scarcely lighter below; feet plumbeous gray. Winter pelage (imperfect in late October and April specimens): Slightly grayer above and lighter below. Young: Darker than adult, with dusky belly and blackish feet and tail.

Cranial characters.—Skull long and not much arched; angular and heavily ridged in old age; superciliary ridges conspicuous; incisive foramina long and narrow, constricted posteriorly; lateral pits of palate deep; bulke medium in size and well rounded; dentition heavy; m2 with four closed sections; m3 with 3 closed triangles, 4 inner and 3 outer salient angles; m1 with 5 closed triangles, 5 inner and 4 outer salient angles. The long, narrow incisive foramina distinguish the skull most readily from that of californicus.

Measurements.—Adult male from Oregon City, Oreg.: Total length, 226; tail vertebræ, 66; hind foot, 26. Average of 10 adults, 5 & and 5  $\,^\circ$ , from Avon, Wash.: 193; 64; 25.4. Skull (No. 56907, from Oregon City, Oreg.): Basal length, 29.2; nasals, 8.4; zygo-

matic breadth, 17.1; mastoid breadth, 13.5; alveolar length of upper molar series, 7.5.

General remarks.—Microtus townsendi has no close affinities with any species except tetramerus of Vancouver Island. Except for the conspicuous hip glands, it comes nearest to the longicaudus and mordax group in com-

COCARAGARO

Fig. 6 -Molar enamel pattern of Microtus townsendi (× 5).

bination of general characters. Almost no variation is shown throughout its rather limited range, and there are no characters by which to recognize occidentalis even as a subspecies.

Specimens examined.—Total number, 74, from the following localities:

Oregon: Oregon City, 1; Aumsville, 2; Yaquina Bay, 5; Newport, 6; Shelburn, 1 (im); Salem, 1.

Washington: Tenino, 2; Steilacoom, 3; Roy, 2; Kent, 1; Lake Washington, Seattle (south end), 3; Avon, 25; Mount Vernon, 4; Sauk, 1.

British Columbia: Port Moody, 16; Chilliwack, 1.

MICROTUS TETRAMERUS (Rhoads). Vancouver Vole.

Arricola (Tetramerodon) tetramerus Rhoads, Proc. Acad. Nat. Sci. Phila., Oct., 1894, 283.

Type locality.—Beacon Hill Park, Victoria, British Columbia. Geographic distribution.—Southern end of Vancouver Island.

General characters.—Like townsendi, but slightly smaller, with slenderer feet and tail and narrower, slenderer skull.

Color.—Indistinguishable from that of townsendi, in either winter or summer pelage.

Cranial characters.—Skull smaller, slenderer, and less arched than in townsendi, with superciliary ridges never quite meeting; nasals relatively shorter and more spreading anteriorly; incisors slenderer; molars smaller but with the same enamel pattern.

Measurements.—Average of 6 adult males from Goldstream (near Victoria), Vancouver Island: Total length, 177; tail vertebræ, 54.3; hind foot, 22. The largest of a series of 14: 190; 60; 23. Skull (No. 91901, 3 ad.): Basal length, 27.3; nasals, 7.8; zygomatic breadth, 16; mastoid breadth, 12.4; alveolar length of upper molar series, 6.7.

General remarks.—The marked difference in size, together with slight cranial characters, separates this insular form as an easily recognizable species. Specimens of townsendi from the nearest localities on the mainland, Port Moody, British Columbia, and Avon, Wash., show no tendency toward tetramerus. The small series of specimens includes both summer and winter pelage.

Specimens examined.—Total number, 17, from near the type locality: Vancouver Island, B. C.: Goldstream, 16; near Victoria, 1.

MICROTUS LONGICAUDUS (Merriam). Long-tailed Vole.

Arricola (Mynomes) longicaudus Merriam, Am. Nat., XXII, 934-935, Oct., 1888.

Type locality.—Custer, S. Dak. (in the Black Hills at an altitude of about 5,500 feet).

Geographic distribution.—Boreal cap of the Black fills and down some of the cold streams well into the Transition zone.

Habitat.—Banks of cold streams and in mountain meadows.

General characters.—Size of body about equal to that of Microtus pennsylvanicus; tail much longer; ears larger; colors grayer; skull flatter; braincase wider.

Color.—Summer pelage: Upperparts dull bister, darkened with numerous black-tipped hairs, becoming grayish on the sides and shading into dull, buffy gray on belly; feet plumbeous; tail dimly bicolor, blackish above, soiled whitish below. Winter pelage (old and faded in a June specimen from Sundance, Wyo.): Upperparts grayish bister, mixed with blackish-tipped hairs, shading gradually into slightly paler sides and dull whitish belly; tail distinctly bicolor; feet soiled whitish.

Cranial characters.—Skull long and not much arched; rostrum long; nasals reaching to anterior plane of incisors; bulke large and rounded; molar pattern similar to that of pennsylvanicus, except for absence of posterior loop in middle upper molar; m3 with 3 closed triangles, 3 outer and 4 inner salient angles; m1 with anterior loop, 5 closed triangles, 4 outer and 5 inner salient angles. From mordax it differs in slightly shorter, heavier rostrum and wider nasals; narrower interpterygoid fossa; wider expansion of jugal; shorter and wider condyloid ramus of mandible.

Measurements.—Type,  $\circ$  ad.: Total length, 185; tail vertebræ, 65; hind foot, 21. Topotype,  $\circ$  ad.: 184; 61; 22. Skull (of type): Basal length, 25; nasals, 7.8; zygomatic breadth, 15.2; mastoid breadth, 11.6; alveolar length of upper molar series, 6.3.

General remarks.—Microtus longicaudus stands as one of the few outlying and isolated forms, though the first-described species of its widely distributed group. Its nearest neighbor is M. mordax of the Bighorn Mountains, Wyoming, between which range and the Black Hills neither species is known to occur.

Specimens examined.—Total number, 6, from the following localities:

South Dakota: Custer, 2.

Wyoming: Sundance (in the western edge of the Black Hills), 4.

MICROTUS MORDAX (Merriam). Cantankerous Vole.

Arricola (Mynomes) mordax Merriam, North American Fauna No. 5, 61, July 30, 1891.

Microtus vellerosus Alleu, Bul. Am. Mus. Nat. Hist., XII, 7, March, 1899. (Liard River, Northwest Territory.)

Microtus cantus Allen, Bul. Am. Mus. Nat. Hist., XII, 7, March, 1899. (Hell Gate, Liard River, Northwest Territory.)

¹The types of Microtus rellerosus and M. cautus, kindly loaned me for comparison by Dr. Allen, agree in every character with specimens in corresponding pelage of M. mordax from its type locality. The type of rellerosus, collected May 4, shows the dark brownish-gray back of imperfect summer pelage, while the type of cautus, collected November 29, shows the light gray pelage of early winter.

Type locality.—Sawtooth (or Alturas) Lake, east foot of the Sawtooth Mountains, Idaho.

Geographic distribution.—Rocky Mountains and outlying ranges from latitude 60° to northern New Mexico, and south in the Cascades and Sierra Nevada as far as Kaweah and Kern rivers, California. In the Cascades mainly confined to the east slope, but extending west to the Siskiyous, in southern Oregon, and Salmon and Trinity mountains, in northern California. Found in most of the isolated ranges of eastern Oregon and northern and central Nevada. Common in Canadian and Hudsonian zones.

Habitat.—Marshes and wet woods, but more especially the banks of cold mountain streams, down which it often extends into the Transition zone.

General characters.—Size medium; tail long; ears large; feet small; no conspicuous side or hip glands in males. Very similar to longicaudus.

Color.—Summer pelage: Back grayish bister; sides olive gray; belly washed with whitish; nose dusky; feet plumbeous; tail dimly bicolor, dusky above, soiled whitish below. Winter pelage: Lighter colored than in summer; dorsal stripe of yellowish bister more sharply contrasted with the deeper gray of sides and face; belly heavily washed with pure white; tail sharply bicolor; feet whitish. Young: Darker, less sharply marked than the adults; feet and tail dusky.

Cranial characters.—Skull light and slender, similar to that of longicaudus, but with slightly longer, slenderer rostrum and nasals; slen-

derer zygomata, and longer condylar ramus of mandible; dentition essentially the same; m2 with 4 closed sections, the posterior open; m3 with anterior crescent, 3 closed triangles, and posterior loop with 2 inner salient angles; m1 with 5 closed triangles, 5 inner and 4 outer salient angles back of anterior loop; second and third lower molars each with 3 outer and 3 inner salient angles.

Fig. 7.—Molar enamel pattern of *Microtus mordax* (×5).

Measurements.—Type: Total length, 200; tail vertebre, 77; hind foot, 22. Average of five adults from type locality, 182; 66; 22. Skull (of type): Basal length, 26.5; nasals, 8.6; zygomatic breadth, 16.2; mastoid breadth, 12.8; alveolar length of upper molar series, 6.6.

General remarks.—The species has a wide and frequently interrupted range, but shows remarkably slight variation of characters. Even from the southern extremities of the Rocky Mountains and Sierra Nevada the variation is too slight for subspecific recognition. Specimens from isolated ranges in Nevada are practically typical.

Specimens examined.—Total number, 708, from the following localities:

Idaho: Sawtooth Lake, 35; Lemhi, 4; Lost River Mountains, 2; Salmon River Mountains, 1; Three Creek, 1; Preuss Mountains, 1; Montpelier Creek, 3; Kingston, 1; Osborn, 1; Mullan, 10; Cœur d'Alene, 7; Craig Mountains, 1; Seven Devils Mountains, 3; Priest Lake (east side), 2.

Utah: Laketown, 6; Park City, 1; Barclay, 3; near Barclay, 4.

18392-No. 17----1

- Colorado: Estes Park, 2; Ward, 4; Gold Hill, 2; Longs Peak, 10; Canyon City, 1; Lake City, 2; Silverton, 5; Fort Garland, 12.
- New Mexico: Chama, 1; Martinez, 1; Agua de Lobo, 1 (no skull).
- Wyoming: Bridger Pass, 14; Bighorn Mountains, 1; Lake Fork, near Bull Lake, 4; Clark Fork, mouth of Crandle Creek, 3; Tower Falls, Yellowstone Park, 2.
- Montana: Red Lodge, 2; Pryor Mountains, 8; Fort Custer, 2; Big Snowy Mountains, 2; Jefferson River, 1; Blackfoot, 1; St. Marys Lake, 3; Java, 4; Summit, 5; Flathead Lake, 8; Tobacco Plains, 2; Horse Plains, 3; Upper Stillwater Lake, 6; Prospect Creek, 11; Thompson Falls, 2; Silver, 4.
- Nevada: Reese River, 18; Arc Dome, 15; Indian Creek, 1; Shoshone Mountains, north of Cloverdale, 5; Pine Forest Range, 3; Granite Creek, 8; Mountain City, 15; Bull Run Mountains, 1; White Mountains, 6; Ruby Mountains, 14; Monitor Mountains, 2.
- California: Near Mount Whitney, 31; Olancha Peak, 1; Mulkey Meadows (near Olancha Peak), 1; Soda Springs (on North Fork of Kern River), 1; Mineral King (on East Fork Kaweah River), 19; Upper San Joaquin River, 2; Lone Pine, 2; Bishop Creek, 2; Queen Station, 1; Sequoia National Park, 24; Yosemite Valley, 3; Pine City, 1; Mammoth, 7; White Mountains, 4; Donner, 3; Sierra Valley, 3; Hope Valley, 2; Carberry Ranch, 10; Emerald Bay, 5; Goose Lake, 2; Warner Creek, 1; Lassen Creek, 2; Lassen Peak, 19; Etna, 1; Trinity Mountains, 4; Canyon Creek, 16; Plumas County (20 miles southwest of Quincy), 2; Mount Shasta, 59; Sisson, 15; Goose Nest Mountain, 1; Bear Creek (Shasta County), 1.
- Oregon: Siskiyou, 6; Fort Klamath, 18; Crater Lake, 5; Diamond Lake, 5; Sink Creek (east of Mount Thielson), 1; Upper Des Chutes River, Little Meadows (near head of Des Chutes River), 2; Farewell Bend (Des Chutes River, 30 miles southwest Prineville), 2; Swan Lake Valley, 2; head of Drews Creek, 1; Warner Mountains, 3; Steen Mountains, 6; Summit (east of Malheur Lake), 1; 10 miles north of Harney, 9; Maury Mountains, 5; Wallowa Mountains, 3; Lone Rock, 1.
- Washington: Cleveland, 2; Wenatchee, 5; head of Lake Chelan, 12; Easton, 2; Conconully, 3.
- British Columbia: Mount Richter, 2; Nelson, 1; Sicamous, 5; Hope, 2; Shuswap, 1; Glacier, 3; Okanagan, 2; Bonnett City, 6.
- Alberta: Henry House, 19; 15 miles south of Henry House, 4; south of Smoky River, 3; Banff, 1.
- Northwest Territory: Liard River, 2; Rink Rapids (upper Yukon), 1; Lake Lebarge, 2; Lake Marsh, 1.
- Alaska: Charlie Creek (Upper Yukon), 4; Circle, 1; White Pass, 5; Skagway, 1.

MICROTUS MACRURUS Merriam. Olympic Vole.

Microtus macrurus Merriam, Proc. Acad. Nat. Sei. Phila., Aug., 1898, 353.

Type locality.—Lake Cushman, Olympic Mountains, Washington.

Geographic distribution.—(The typical form) Olympic Mountains. (With slight variation) along the coast strip of British Columbia and Alaska north to Yakutat.

Habitat.—Marshes and borders of cold streams.

General characters.—Like mordax, but considerably larger, with conspicuously larger hind foot and darker coloration.

Color.—Summer pelage: Upperparts dark bister, shaded with numerous black hairs, becoming sooty gray in some specimens; sides slightly paler; belly washed with dull buffy or whitish; feet plumbeous; tail distinctly bicolor, blackish or brownish above, soiled whitish below,

usually white-tipped. (Winter pelage unknown.) Young: Darker than adult, with blackish feet and tail.

Cranial characters.—Skull averaging much larger than mordax, with wider interorbital region, heavier rostrum, smaller audital bulle, and heavier dentition; molars especially wider; lower jaw conspicuously more massive, with wide, heavy molars.

Measurements.—Type: Total length, 220; tail vertebræ, 88; hind foot, 24. Average of five specimens from three localities in the Olympic Mountains: 204; 80; 24.3. Skull (of type, No. 66151, & ad.): Basal length, 27.7; nasals, 8.2; zygomatic breadth, 16; mastoid breadth, 12.5; alveolar length of upper molar series, 7.

General remarks.—Microtus macrurus is the most conspicuously marked and easily recognizable form of the longicaudus group, though with less deeply seated characters than some forms that are externally scarcely distinguishable from each other. In the Olympic Mountains its range is completely isolated, being separated from that of mordax by the intervening low country, the habitat of the larger townsendi, and by the high Cascades, in which neither form occurs. To the northward it again occurs, in nearly typical form, on the coast at Lund, British Columbia (lat. 50°), and extends northward along the coast to Yakutat, Alaska, becoming slightly smaller and less markedly different from true mordax.

Specimens examined.—Total number, 84, from the following localities:

Washington: Lake Cushman, 7; head of Skokomish River, 1; head of Soleduc River, 1; Quineault Lake, 4; Granville, 1.

British Columbia: Lund, on Malaspina Inlet, 3; River Inlet (head), 14; Fort Simpson, 6.

Alaska: Loring, 3; Wrangell, 4; Juneau, 12; Yakutat, 7; Yakutat Bay (north shore), 10; Glacier Bay, 11.

MICROTUS ANGUSTICEPS Bailey. Coast Vole.

Microtus angusticeps Bailey, Proc. Biol. Soc. Wash., XII, 86, April 30, 1899.

Type locality.—Crescent City, California.

Geographic distribution.—Coast region of northwestern California and southwestern Oregon.

Habitat.—Damp pastures in the Sitka spruce belt.

General characters.—Smaller and darker colored than typical mordax, with very narrow, slender skull and small audital bulke.

Color.—Summer pelage: Upperparts dark bister, lined with black hairs, darkest on face and nose; sides paler; belly washed with creamy white; feet plumbeous gray; tail distinctly bicolor, blackish above, soiled white below.

Cranial characters.—Skull small and very narrow, distinctly ridged in adults; nasals projecting in front of incisors; incisive foramina short; audital bullæ very small and constricted; coronoid notch of mandible narrow; incisors slender; molars small, with narrow, sharp angles; enamel pattern as in mordax.

Measurements.—Type, 3 ad.: Total length, 170; tail vertebre, 56; hind foot, 22. An adult 2 topotype: 170; 55; 22. Skull (of type): Basal length, 23.4; nasals, 7.6; zygomatic breadth, 13.5; mastoid breadth, 10.8; alveolar length of upper molar series, 6.

General remarks.—Externally this species is not very different from true mordax, but the skull shows such marked characters as to warrant full specific rank.

Specimens examined.—Total number, 45, from the following localities:

California: Crescent City, 31; Arcata (Humboldt Bay), 13.

Oregon: Gold Beach, 1.

MICROTUS ALTICOLUS (Merriam). Mountain Vole.

Arvicola (Mynomes) alticolus Merriam, North American Fauna No. 3, 67-69, Pl. V; figs. 1 and 2; Pl. VI, figs. 1, 2, 3, and 4; Sept. 11, 1890.

Type locality.—San Francisco Mountain, Arizona (Little Spring, on northwest side of mountain, altitude 8,200 feet).

Geographic range.—Boreal zone of San Francisco Mountain, from 8,200 feet altitude up to timberline at 11,000 feet.

Habitat.—Vicinity of springs and cold streams on the slopes of the mountain.

General characters.—Similar to longicaudus, but tail shorter, hind foot and ear smaller, and skull with truncate, instead of pointed, anterior end of frontal and deeper lateral pit of palate.

Color.—Summer pelage: Upperparts uniform sepia or dull bister, darkened with blackish-tipped hairs; sides scarcely lighter; belly pale buffy or whitish; feet dull grayish or dirty whitish; tail not sharply bicolor, blackish above, grayish below. Young: Similar to adults, but with woolly fur and long, scattered, black-tipped hairs. (Winter pelage unknown.)

Cranial characters.—Skull similar to that of mordax, but readily distinguished from it and those of all other forms of the group by truncate end of anterior arm of frontal. Other characters are, deeper lateral pits of the palate; wider interprerygoid fossa; slightly longer, more open, incisive foramina. Dentition similar to that of longicaudus and mordax.

Measurements.—Type, 9 ad.: Total length, 170; tail vertebræ, 56; hind foot, 20. Average of 5 adults from type locality: 178; 56; 20. Skull: Basal length, 25; nasals, 7.5; zygomatic breadth, 14.8; mastoid breadth, 12.3; alveolar length of upper molar series, 6.5.

General remarks.—Microtus alticolus, with its subspecies leucophæus, is the most isolated form in the longicaudus group. Its geographically nearest neighbor and probably nearest relative is mordax, in the mountains of Colorado and northern New Mexico.

Specimens examined.—Total number, 13, from the type locality. One immature specimen from Springerville, in the White Mountains, may be either alticulus or leucopheus.

MICROTUS ALTICOLUS LEUCOPHÆUS (Allen). Graham Mountain Vole.

Arvicola leucophous Allen, Bul. Am. Mus. Nat. Hist., VI, 320-321, Nov. 7, 1894.

Type locality.—Graham Mountains, Arizona.

Geographic distribution.—Known only from the type locality.

General characters.—Similar to alticolus, and of the same proportions, but slightly larger, color the same, skull wider interorbitally and with other slight differences.

Color.—Summer pelage: Upperparts sepia or dull bister, but little paler on sides and faintly lined with blackish hairs; belly washed with soiled whitish; feet dull grayish; tail distinctly bicolor, brown above, grayish below. (Young and winter pelages not represented.)

Cranial characters.—Skull wider interorbitally than in mordax or alticolus; anterior arm of frontal with triangular instead of truncate point; incisive foramina wider than in alticolus, slightly constricted posteriorly; latera pits of palate wide and shallow; coronoid notch narrow and sharp. Dentition as in alticolus and mordax.

Measurements.—Type,  $\circ$  ad.: Total length, 173; tail vertebrae, 50; hind foot, 22.5. Topotype,  $\circ$  ad.: 183; 50; 23. Skull (of type): Basal length, 26.5; nasals, 8.3; zygomatic breadth, 15.2; mastoid breadth, 12.3; interorbital width, 4.2; alveolar length of upper molar series, 6.3.

General remarks.—Microtus leucophaus belongs to the longicaudus group. It is closely related to alticolus, from which size and slight cranial characters separate it as a fairly well-marked subspecies.

Through the kindness of Dr. J. A. Allen, of the American Museum of Natural History, I have the type and a topotype of M. leucophaus for comparison with the Biological Survey series of alticolus, mordax, and longicaudus.

Specimens examined.—Total number, 2, from the type locality.

MICROTUS MEXICANUS (De Saussure). Mexican Vole.

Arvicola (Hemiotomys) mexicanus De Saussure, Revue et Mag. de Zool., 2e sér., XIII, 3, Jan., 1861.

Type locality.—Mount Orizaba, Puebla, Mexico.

Geographic distribution.—Eastern Puebla and to the north and west, grading into its subspecies phaus.

Habitat.—Grassy places in open forests, in upper Austral and Transition zones.

General characters.—Size rather small; tail short; ears conspicuous; pelage coarse and lax; colors brownish; skull wide, with short, wide incisive foramina; m1 normally with 6 inner salient angles.

Color.—Winter pelage: Upperparts grizzled brown, from a mixture of dull cinnamon and black; sides paler; belly washed with cinnamon or buffy, or rarely with whitish; sides of nose and ear coverts usually a brighter shade of cinnamon; feet clear gray; tail dusky above, gray below. Summer pelage (imperfectly represented): Evidently darker and less ferruginous. Young: Duller and darker than adult.

Cranial characters.—Skull rather angular, with wide-spreading zygomatic arches, narrow interorbital constriction, and large, well-rounded audital bulke; incisive foramina short and wide, truncate posteriorly; zygomata broadly flattened; palate with a median groove between the lateral pits where a spur or ridge appears in most species of Microtus; upper incisors abruptly decurved; molar pattern differing from that of nanus and montanus—mainly in extra angle of anterior trefoil of m1; most of the salient angles acute; m2 has 4 closed sections; m3 has 3 closed triangles, 3 outer and 4 inner salient angles; m1 has 5 closed triangles, 5 outer and 6 inner salient angles.

Measurements.—Average of 10 adults from the type locality (5  $\circ$  5  $\circ$ ): Total length, 138; tail vertebræ, 29; hind foot, 19.35; maximum: 148; 30; 20. Skull (of topotype, No. 54496,  $\circ$  ad.): Basal length, 24.5; nasals, 7.4; zygomatic breadth, 15.3; mastoid breadth, 11.6; alveolar length of upper molar series, 6.6.

General remarks.—Microtus mexicanus, phæus, fulviventer, and mogollonensis form a well-marked and closely united group of small, short-tailed, brownish voles, distinguished by the arrangement of mammae in two pairs, a pair of inguinal, and a pair of pectoral; by wide-spreading zygomatic arches and narrow interorbital constriction; by wide incisive foramina and grooved posterior ridge of palate; and by similar habits and habitat. They need comparison only among themselves. While mogollonensis and fulviventer are well-marked forms, occupying widely separated and probably disconnected areas, mexicanus and phæus merely show the extremes of differentiation found in one wideranging and somewhat variable form. As only those from the type localities are really typical, any line separating mexicanus and phæus is purely arbitrary.

Specimens examined.—Total number, 194, from the following localities in Mexico:

Puebla: Mount Orizaba, 27; Chalchicomula, 22. Vera Cruz: Cofre de Perote, 29; Las Vegas, 11. Tlaxcala: Mount Malinche, 1; Huamantia, 2.

Hidalgo: Sierra de Pachuca, 7; Tulaucingo, 7; Real del Monte, 10.

Morelos: Huitzilae, 4.

Mexico: Ajusco, 6; Toluca Valley, 20; North slope Volcan de Toluca, 9;

Mount Popocatepetl, 19; Amecameca, 1; Salazar, 19.

MICROTUS MEXICANUS PHÆUS (Merriam). Colima Vole.

Microtus phœus Merriam, Proc. Biol. Soc. Wash., VII, 171-172, Sept. 29, 1892.

Type locality.—North slope of Sierra Nevada de Colima, Jalisco, Mexico (altitude 10,000 feet).

Geographic distribution.—Southern Jalisco and northward to northwestern Chihuahua (to the eastward, grading into mexicanus), occupying Boreal and Transition zones.

<sup>&</sup>lt;sup>1</sup>This extra number of angles is a weak character depending on the slightly unusual development of the anterior trefoil of m1, so that a pair of short points or angles may in most cases be counted on its inner and outer sides.

Habitat.—Grassy parks in open timber.

General characters.—Similar to mexicanus, but slightly larger and a shade darker, and with slight cranial differences.

Color.—Winter pelage: Upperparts uniform dark cinnamon brown mixed with blackish; belly a lighter shade of cinnamon or buffy, or sometimes whitish; feet brownish gray; tail brownish gray, paler below. Summer pelage: Not shown in specimens from near the type locality, but June specimens from El Salto, Durango, are brighter and darker ferruginous than topotypes in winter pelage. Young: Dull brownish.

Cranial characters.—Skull similar to that of mexicanus, but with less constricted interorbital region, slightly shorter incisive foramina, and shallower prezygomatic notches. Dentition essentially the same.

Measurements.—Average of 10 adult topotypes (5  $\delta$  and 5  $\circ$ ): Total length, 151; tail vertebræ, 35; hind foot, 20.5. Skull (topotype,  $\delta$  ad., No. 45645): Basal length, 25.2; nasals, 7.3; zygomatic breadth, 15.5; mastoid breadth, 12; alveolar length of upper molar series, 6.08.

Fig. 8.—Molar enamel pattern of Microtus phæus (× 5).

General remarks,—Microtus m. phœus is not a strongly or sharply marked form of mexicanus, although apparently the more widespread form. Ajusco and Salazar specimens might as well be referred to it as to mexicanus. A large series from near Guadalupe, in southwestern Chihuahua, are indistinguishable from typical phœus, and those from Miquihuana, western Tamaulipas, are nearer to phœus than to mexicanus.

Specimens examined.—Total number, 136, from the following localities in Mexico:

Jalisco: Sierra Nevada de Colima, 17.

Michoacan: Nahuatzin, 23. Queretaro: Pinal de Amoles, 9. Tamaulipas: Miquihuana, 20.

Durango: El Salto, 25.

Chihuahua: Sierra Madre near Guadalupe y Calvo, 19; Colonia Garcia, 23.

MICROTUS FULVIVENTER Merriam. Oaxaca Vole.

Microtus fulviventer Merriam, Proc. Biol. Soc. Wash., XII, 106, April 30, 1898.

Type locality.—Cerro San Felipe, Oaxaca, Mexico.

Geographic distribution.—Central part of the State of Oaxaca.

Habitat.—Open grassy places and along edges of fields in the Boreal zone.

General characters.—Slightly larger than mexicanus and of nearly the same proportions; darker and richer in coloration; ears conspicuous above fur; tail a little more than one and a half times the length of hind foot.

Color.—Summer pelage: Upperparts umber brown, darkened by black hairs; under parts fulvous or dull chestnut brown; feet grayish brown;

tail dusky brown above, fulvous below, darker toward the end. Winter pelage (in October and March specimens): Less deeply colored. Young: Dull sooty, with scarcely a trace of fulvous.

Cranial characters.—Skull similar to that of mexicanus, but with smaller bulke, longer incisive foramina; sharper posterior point of frontals; molars slightly heavier, enamel pattern almost the same; mi has a more rounded anterior loop.

Measurements.—Average of 10 adult topotypes (5 & and 5 \, 2): Total length, 152; tail vertebræ, 35; hind foot, 20.5. Type ( & ad.): 154; 38; 20. Skull (of type): Basal length, 25.4; nasals, 7.4; zygomatic breadth, 15.5; mastoid breadth, 12.4; alveolar length of upper molar series, 6.5.

General remarks.—M. fulviventer belongs to the mexicanus group, but is sharply separated in its distinguishing characters as well as in geographic range. But little variation is shown throughout its range and although specimens from the mountains near Ozolotepec show differences, these are slight and unimportant.

Specimens examined.—Total number, 126, from the following localities in Mexico:

Oaxaca: Cerro San Felipe, 32; Reyes, 23; 15 miles west of Oaxaca, 20; Mount Zempoaltepec, 28; near Cajones, 5; Guajamaloya, 1 (im.); mountains near Ozolotepec, 9; Totontepec, 8.

MICROTUS MOGOLLONENSIS (Mearns). Mogollon Mountain Vole.

Arvicola mogollonensis Mearns, Bul. Am. Mus. Nat. Hist., II, No. 4, 283-284, Feb., 1830.

Type locality.—Baker Buttes, Mogollon Mountains, Arizona.

Geographic distribution .- Plateau country of central Arizona.

Habitat.—Dry grassy parks among the yellow pines of the Transition zone.

General characters.—Size small; tail and feet short; color dull rusty brown; fur long and soft; ears not concealed; skull short, wide, and angular; lateral pits of palate very deep; an inner projecting point at base of posterior triangle of middle upper molar.

Color.—Upperparts dull rusty brown, brightest on tips of ears; sides slightly paler; belly cinnamon or buffy gray; feet grayish brown; tail brownish gray above, grayish below.

Cranial characters.—Skull short and well arched, with wide-spreading zygomata and sharply constricted interorbital region; zygomatic shield broad and flat; interparietal small and narrow; nasals notched posteriorly, falling considerably short of terminus of premaxillæ; bullæ full and rounded; incisive foramina short, wide, and open; incisors wider than in nanus and bent more abruptly downward; molar pattern as in mexicanus, except in m2, which has an inner point at base of posterior triangle, and in m1, which has 5 closed triangles and only 5 inner and 4 outer salient angles and an abbreviated terminal loop.

Measurements.—Average of 10 adults from San Francisco Mountain, Arizona: Total length, 131; tail vertebræ, 28.5; hind foot, 18. Skull (adult &, No. 24563): Basal length, 23.6; nasals, 7; zyg matic breadth, 15.2; mastoid breadth, 12; alveolar length of upper molar series, 6.3.

Remarks.—M. mogollonensis is widely separated, both geographically and specifically, from the other members of its group. Its nearest ally is phaus from Mexico.

Specimens examined.—Total number, 51; from the following localities:
Arizona: San Francisco Mountain (Little Spring on north side of mountain),
15; Springerville, 35.

New Mexico: Fort Wingate, 1.

MICROTUS XANTHOGNATHUS (Leach). Yellow-cheeked Vole.

Arvicola xanthognatha Leach, Zool. Miscel., I, 60, 1814.

Type locality.—Hudson Bay.

Geographic distribution.—Northwestern Canada and Alaska, from central Alberta north to the Arctic coast and west to central Alaska.

General characters.—Size large, almost equaling that of richardsoni, but tail shorter and ears larger; colors dull; nose and ear patch yellow; skull heavy, ridged, and angular. Side glands as in richardsoni, or a little farther back on flanks.

Color (March and May specimens).—Upperparts dark sepia to bister, heavily lined with coarse black hairs over the back; sides of nose and ear patch bright rusty yellowish, a tinge of the same around eyes and on cheeks; belly dusky gray; breast sooty; tail indistinctly bicolor, blackish above, dusky gray below; feet sooty.

Cranial characters.—Skull smaller than that of richardsoni and relatively longer and narrower, with less projecting incisors; nasals long and narrow; bulke large; incisive foramina long and narrow; den-

tition heavy; molar pattern scarcely different from that of townsendi; anterior loop of m.1 small and triangular; middle section of m.3 frequently divided into two nearly closed triangles.

Measurements.—Two dry skins from Fort Resolution, Great Slave Lake, Canada, adult females, in U. S. Nat. Mus. No. 4504: Total length, 210; tail vertebræ, 50; hind fort 27 No. 4502; 218; 45: 25 Skyll

Fig. 9.—Molar enamel pattern of Microtus xanthognathus (× 5).

foot, 27. No. 4502: 218; 45; 25. Skull (No. 4504): Basal length (approximately), 34.5; nasals, 10.3; zygomatic breadth, 20; mastoid breadth, 15.7; alveolar length of upper molar series, 8.5.

Remarks.—Microtus xanthognathus shows no close relationship to any other American species. In the position of side glands it resembles richardsoni, but in no other characters. It shows a strong superficial resemblance to chrotorrhinus in color, but the great difference in size prevents the possibility of one ever being mistaken for the other.

Specimens examined.—Total number, 44, from the following localities:

Canada: Nelson River, N. W. T., 1; Cache Apocotte (40 miles east of Henry House, Alberta), 1; Fort Resolution, 22; Great Slave Lake, 1; Fort Rae, 1; Liard River, 1; La Pierre House, 1; Anderson River, 1; Arctic coast (east of Fort Anderson), 2.

Alaska: Mouth of Porcupine River, 1; Yukon (200 miles southwest of mouth of Porcupine), 3; Charlie Creek (Upper Yukon), 9.

MICROTUS CHROTORRHINUS (Miller). Rock Vole.

Arricola chrotorrhinus Miller, Proc. Boston Soc. Nat. Hist., XXVI, 189-193, pl. 3, 1894.

Type locality.—Mount Washington, New Hampshire, head of Tuckerman Ravine (altitude, 5,300 feet).

Geographic distribution.—Mount Washington, the Catskills, central Quebec, and northern New Brunswick, in the Hudsonian zone.

Habitat.—Rocky places near water on the mountains, and in deep spruce forests farther north.

General characters.—Size and proportions of pennsylvanicus except slightly smaller hind foot; ears larger; fur lax; conspicuously yellowish about nose, ears and rump; skull comparatively thin-walled and smooth; dentition unique.

Color.—Summer pelage (July 14): Upperparts hright glossy bister, lined with black hairs; nose to eyes dull orange rufus; hairs around ears and on rump yellowish; belly plumbeous; feet dark gray; tail grayish brown, slightly paler below. Worn, left-over winter pelage: Darker and more rusty above.

Cranial characters.—Skull light and smooth, somewhat flattened on top, superficially resembling that of Evotomys; bulle large and rounded; incisive foramina short and wide; dentition rather light; incisors bent down at right angles to axis of skull, extending scarcely beyond tip of nasals; m2 with 4 closed sections; m3 normally with 5 closed triangles, 5 inner and 5 outer salient angles and a double-lobed posterior loop; m3 with outer salient angles prominent and reentrant angles deep.

Measurements.—Type: Total length, 165; tail vertebræ, 45; hind foot, 19.4. Average of 4 adult topotypes: 170; 48; 19.6. Skull (of ad. 3, No. 2523, Bangs Coll.): Basal length, 25.4; nasals, 7.2; zygomatic breadth, 15; mastoid breadth, 12; alveolar length of upper molar series, 6.4.

Remarks.—Microtus chrotorrhinus shows a marked superficial resemblance to M. xanthognathus, but in cranial characters it differs widely from this and all other American species and is quite unique in the subgenus Microtus. In the specimens examined there is no trace of hip glands, but in two adult males (3845 and 3849) there appear to be rudiments of side glands on the flanks.

Specimens examined. 1—Total number, 8, from the following localities:2

New Hampshire: Mount Washington, 3.

New York: Catskill Mountains, 1.

Quebec: Lake Edward, 4.

<sup>&</sup>lt;sup>1</sup>Type in collection of G. S. Miller, jr.; other specimens in the collection of E. A. and O. Bangs.

<sup>&</sup>lt;sup>2</sup>Mr. Miller records a specimen in the Am. Mus. Nat. Hist. from Trousers Lake, New Brunswick—Proc. Bost. Soc. Nat. Hist., XXVI, 193, 1894.

MICROTUS CHROTORRHINUS RAVUS Bangs. Gray Rock Vole.

Microtus chrotorrhinus ravus Bangs, Proc. Biol. Soc. Wash., XII, 187, Nov. 16, 1898.

Type locality.—Black Bay (north shore of Strait of Belle Isle), Labrador.

Geographic distribution.—Known only from the type locality.

General characters. - Similar to chrotorrhinus, but slightly grayer, and with noticeably more yellowish on nose and face. Skull slenderer, with lighter dentition.

Color.—Summer pelage (July specimens): Upperparts grayish bister, becoming yellowish on rump; whole face from behind ears suffused with yellowish, brighter on nose; belly thinly washed with white over the plumbeous; feet buffy gray; tail brownish above, slightly paler below.

Cranial characters .- Skull, compared with that of chrotorrhinus, slightly thinner, lighter, and slenderer throughout; interorbital constriction narrower; rostrum longer and narrower; incisive foramina longer; molar series shorter and narrower; tooth pattern as in chrotorrhinus.

Measurements.—Type, dad.: Total length, 170; tail vertebræ, 50; hind foot, 22. Average of 4 adult topotypes: 159; 46; 21.25. (No. 7952, 9 ad.): Basal length, 25; nasals, 7; zygomatic breadth, 14.3; mastoid breadth, 11.3; alveolar length of upper molar series, 6.2.

General remarks.-July specimens from the type locality are in full, long pelage, with a freshness of appearance and brightness of color quite different from the type of chrotorrhinus of nearly the same date. There is a question as to whether the real summer pelage is shown.

Specimens examined.—Total number, 5, from the type locality.

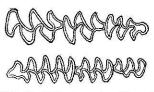

#### Subgenus ARVICOLA2 Lacépède.

Arvicola Lacépède, Nouv. Tableau Méthod. Mamm., in Mém. de l'Instit., Paris, III, 495, 1801. Type, Mus terrestris Linnaus (genus). Arvicola Lataste, Le Naturaliste, II, 349, 1883 (subgenus).

Geographic distribution.—(In America) Boreal zone of the Cascades and Rocky Mountains of Canada and the northern United States.

Subgeneric characters.—(In American species) plantar tubercles, 5;

side glands on flanks of males conspicuous; a musk-bearing anal gland; mammæ, 8; pectoral, 2-2; inguinal, 2-2; feet large; tail long; fur full and long; bullæ very small; incisors projecting far beyond premaxillæ; molars with constricted and tightly closed sections; m2 with 4 closed sections; m3 Fig. 10.-Molar enamel pattern of with 3 closed triangles; m1 with 5 closed

Microtus (Arvicola) macropus ( $\times 5$ ).

<sup>&</sup>lt;sup>1</sup>The measurements of type and 4 topotypes are from original description. In 3 adult topotypes the hind foot measures uniformly 20 mm. in dry skins with toes

<sup>&</sup>lt;sup>2</sup> For full synonymy of the subgenus Arricola, see Miller, N. Am. Fauna No. 12, 66, 1896.

triangles, 5 inner and 4 outer salient angles;  $\overline{m3}$  with 3 transverse loops. (In the European section of the subgenus  $\underline{m3}$  has but 2 closed triangles, and  $\overline{m1}$  but 3.)

MICROTUS RICHARDSONI (De Kay). Richardson Vole.

Arricola richardsoni De Kay, Zoology of New York, Mammalia, 91, 1842.

Type locality.—" Near the foot of the Rocky Mountains." (Type collected by Drummond in the vicinity of Jasper House, Alberta.)

Geographic distribution.—The typical form is known only from the vicinity of Jasper House and Henry House, Alberta, Canada. To the south it apparently grades into macropus in the Rocky Mountains, and arvicoloides in the Cascades.

General characters.—Size very large (probably not exceeded in America except by alleni); tail long; feet large; fur long and heavy: ears mostly concealed; colors dull; skull large and angular, with protruding incisors.

Color.—Early winter pelage (October 14 to 18): Upperparts uniformly grayish sepia, darkened by black-tipped hairs, becoming paler on the sides; belly washed with white over the plumbeous under fur; feet silvery gray; tail bicolor, dusky above, soiled whitish below.

Cranial characters.—Skull large, with wide-spreading zygomatic arches, long rostrum, very long and protruding incisors; nasals rather short and wide, rounded at both ends, not reaching to base of incisors; audital bullæ small for a *Microtus*, but slightly larger and more rounded than in either of the subspecies; incisive foramina longer and less constricted posteriorly; superoccipital smooth without median ridge; terminal loop of third upper molar normally not recurved.

Measurements.—Young adult, No. 81381, from 25 miles west of Henry House: Total length, 208; tail vertebræ, 61; hind foot, 28. Skull (of same): Basal length, 32.5 (over incisors); nasals, 8.3; zygomatic breadth, 19.9; mastoid breadth, 14.6; alveolar length of upper molar series, 7.5.

General remarks.—Richardson's specimens, which he referred to Arvicola riparius, and which were later re-described by De Kay, were collected by Thomas Drummond in the foothills of the Rocky Mountains, probably west of Jasper House. In October, 1896, J. Alden Loring collected a series of 8 specimens at points 15 and 25 miles west of Henry House (40 or 50 miles southwest of Jasper House), Alberta, on the very trail by which Drummond crossed from Jasper House to the Columbia in 1826. Unfortunately, none of this series are fully adult, and but one condition of pelage is shown. By comparing specimens of the same age it becomes evident that the species equals the larger of its two southern forms, arvicoloides, though in color it agrees more nearly with the Rocky Mountain form, macropus. A single specimen from Glacier, British Columbia, is fairly intermediate between richardsoni and its two southern subspecies.

Specimens examined.—Total number, 8, from west of Henry House, Alberta, Canada.

MICROTUS RICHARDSONI MACROPUS (Merriam). Big-tooted Vole.

Arvicola macropus Merriam, North American Fauna No. 5, 59-60, 1891.

Type locality.—Pahsimeroi Mountains, Idaho (altitude about 9,700 feet).

Geographic distribution.—Boreal zone of the Rocky Mountains from the Wasatch north to Canada, of the Wind River Mountains of Wyoming, the Blue Mountains of Oregon, and most of the intermediate ranges.

General characters.—Similar to richardsoni, but evidently somewhat smaller; colors the same in October specimens distinguished by less projecting incisors and other cranial characters.

Color.—Summer pelage: Upperparts dark sepia, lined with long, black hairs; slightly paler on sides; belly washed with silvery white; feet dusky gray; tail distinctly bicolor throughout its length, sooty above, whitish below. Winter pelage (imperfect in October and May specimens): Lighter, clearer gray above, black hairs less conspicuous, more heavily washed with white below. Young: Like adult or slightly darker, with long, woolly fur and dusky feet and tail; during one stage of pelage with entirely dusky belly.

Cranial characters.—Skull similar to that of richardsoni, from which it differs in less projecting upper incisors, longer masals with narrower posterior tips; supraoccipital with a median ridge; bullae smaller, more compressed and angular; incisive foramina sharply constricted posteriorly; third upper molar with terminal loop recurved in about half of the specimens.

Measurements.—Type, 2 ad.: Total length, 220; tail vertebræ, 71; hind foot, 26. Male from type locality (not fully adult): 202; 68; 28. Skull (of type): Basal length, 31.5; nasals, 9; zygomatic breadth, 19.7; mastoid breadth, 14.5; alveolar length of upper molar series, 7.5.

General remarks.—In a large series of specimens from numerous ranges of the Rocky Mountains the subspecies remains rather uniform. There is a slight increase in size toward the north, specimens from northern Montana averaging larger than from the type locality. Those from Strawberry Butte and the Wallowa Mountains of eastern Oregon are indistinguishable from the type series. Two half-grown specimens from the top of the Wasatch Mountains, near Park City, Utah, are too young to indicate reliable specific variation.

Specimens examined.—Total number, 113, from the following localities:

Idaho: Pahsimeroi Mountains, 8; Salmon River Mountains, 11; Sawtooth (or Alturas) Lake, 18; head of Wood River, 2; Summit, Alturas County, 1; Seven Devils Mountains, 2; head of Crow Creek, Preuss Mountains, 4; Thompson Pass, 3; Priest Lake, 1.

Utah: Park City, 2.

Wyoming: La Barge Creek, 5; South Pass City, 1; Lake Fork, Wind River Mountains, 10.

Montana: Beartooth Mountains, 17; Summit, Teton County, 2; St. Marys Lake, Teton County, 4.

Oregon: Strawberry Butte, 2; Wallowa Mountains, 20.

MICROTUS RICHARDSONI ARVICOLOIDES (Rhoads). Cascade Water-Vole.

Aulacomys arvicoloides Rhoads, Am. Nat., XXVIII, 182-185, Feb. 11, 1894.

Microtus principalis Rhoads, Am. Nat., XXIX, 940, Oct., 1895. (Mount Baker Range, British Columbia.)

Type locality.—Lake Keechelus, near Snoqualmie Pass, Kittitas County, Washington (altitude 8,000 feet).

Geographic distribution.—Boreal zone of the Cascade Mountains, in Washington and Oregon.

General characters.—Apparently equal to richardsoni in size, larger than macropus, and slightly darker than either. In cranial characters nearer macropus than richardsoni.

Color.—Summer pelage: Upperparts dark sepia, considerably dark ened with coarse black hairs; belly thinly washed with pearl gray or silvery whitish; feet dusky gray; tail bicolor, blackish above, soiled whitish below. Winter pelage: Darker than summer, with an excess of black hairs above; belly strongly washed with white; feet and tail as in summer. Young not different from young macropus.

Cranial characters.—Skull like that of macropus, but larger; rostrum and incisors slightly heavier; usuals more broadly spreading anteriorly, with a slight constriction near the middle, narrow, and pointed posteriorly; audital bulke, incisive foramina, and are of upper incisors as in macropus.

Measurements.—Average of 6 adults, 3 males and 3 females, from Easton, Wash. (near the type locality): Total length, 234; tail vertebre, 81; hind foot, 29.3. Largest specimen of the series: 253; 89; 29. Skull (No. 41578, 3 ad., from Easton): Basal length, 36; nasals, 10.8; zygomatic breadth, 23; mastoid breadth, 16.3; alveolar length of upper molar series, 8.3.

General remarks.—I have before me a series of 13 specimens, collected at Easton, on the outlet of Lake Keechelus, about 12 miles from the type locality, and a large number of specimens from the upper slopes of Mount Rainier, as well as farther north and south in the Cascades. It is safe to assume that these Easton specimens are typical, especially as there is little variation shown throughout the Cascades of Washington. As at present known, the ranges of arvicoloides and macropus are widely separated, but no doubt they meet and coalesce in richardsoni of the Canadian Rockies.

Specimens examined.—Total number, 101, from the following localities:

Washington: Easton, 13; head of Cascade River, 2; Mount Rainier and vicinity, 34; Mount St. Helens, 4; Wenatchee, 1.

Oregon: Mount Hood, 11; Marmot, 1; Mount Jefferson, 2; Detroit, 1; Crater Lake, 22; Anna Creek, base of Mount Mazama, 10.

### Subgenus PITYMYS 1 McMurtrie.

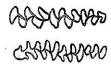

Psammomys Le Conte, Ann. Lyceum Nat. Hist. N. Y., III, 132, 1830. Type Psammomys pinetorum Le Conte. (Not Psammomys Cretzschmar, 1828).

Pitymys McMurtrie, Cuvier's Animal Kingdom, Am. edition, I, 434, 1831. Type Psammomys pinetorum Le Conte. (New name for Psammomys Le Conte.)

<sup>&</sup>lt;sup>1</sup> For full synonymy of the subgenus *Pitymys*, see Miller, N. Am. Fauna No. 12, 58, 1896.

Geographic distribution (in America).—Southeastern United States, mainly in Upper Austral zone, and a small area in the Tropical zone of southeastern Mexico.

Subgeneric characters.—Plantar tubercles, 5; mammæ, 4, two pairs of inguinal; lateral glands on hips in adult males; ears very small; tail short; fur short, dense, and glossy. Skull flat and wide, with quadrate braincase; bullæ small; molars narrow; m3 with 2 closed triangles; m1 with 3 closed and 2 Fig. 11 -Molar enamel open triangles; m2 with anterior pair of triangles confluent; m3 with 3 transverse loops.

pattern of Microtus (Pitymys) pinetorum

MICROTUS PINETORUM (Le Conte). Pine Vole.

Psammonys pinetorum Le Conte, Ann. Lyc. Nat. Hist. N. Y., III, 133, Pl. II, 1830 (read Dec. 21, 1829).

Type locality.—Pine forests of Georgia. Probably the old Le Conte plantation at Riceboro.

Geographic distribution.—Georgia and the Carolinas.

Habitat.—Fields, open woods, and grassy uplands.

General characters.—Size small; ears very small; tail short; fur short and fine; colors bright.

Color.—Upperparts bright russet brown with a distinct gloss, becoming lighter on sides; belly dusky, lightly washed with color of back: tail brownish, darker above; feet grayish brown; ears concealed in the fur.

Cranial characters.—Skull short and wide with a quadrangular braincase and abruptly truncate occiput; interparietal wide and normally somewhat lozenge-shaped; mastoids and bulke relatively small; interpterygoid fossa normally V-shaped. Molar series rather short and crowded; two middle triangles of m3 often confluent; first pair of reentrant angles in m1 usually not meeting between anterior loop and first pair of salient angles.

Measurements.—Average of 2 adult females from Georgetown, S. C.: Total length, 113; tail vertebræ, 18.5; hind foot, 15.5. Skull (No. 1523, Merriam Coll., & ad., from Frogmore, S. C.): Basal length, 22.3; nasals, 7.3; zygomatic breadth, 15; mastoid breadth, 12.5; alveolar length of upper molar series, 6.

General remarks.—No definite type locality was given in the original description of pinetorum, but the species was said to inhabit the sandy soil of the pine barrens of Georgia. Very probably the type came from the vicinity of the old Le Conte plantation, near Riceboro, Ga. Thirteen specimens in the Merriam collection, from Beaufort County, S. C., about 60 miles from Riceboro, are probably fairly typical, and are taken for the basis of the above description. They represent the extreme development of the bright cinnamon brown and small-eared form of the Atlantic coast region. Northward through the Atlantic States the

specimens become darker and duller colored without other important modifications, except a slight average increase in size. The species described as scalopsoides from Long Island, and later as apella from Pennsylvania, includes this Northern form and seems worthy of recognition as a subspecies.

Specimens examined.—Total number, 32, from the following localities:

Georgia: Columbus, 2.

South Carolina: Beaufort County (Beaufort, Frogmore, and St. Helena Island), 13; Georgetown, 2; Society Hill, 1.

North Carolina: Old Richmond, 1; Raleigh, 11; Tarboro, 2.

MICROTUS PINETORUM SCALOPSOIDES (Aud. & Bach.). Mole like Vole.

Arvicola scalopsoides Aud. & Bach., Proc. Acad. Nat. Sci. Phila., I, 97, 1841.

Arvicola apella Le Conte, Proc. Acad. Nat. Sci. Phila., VI, 405, 1853. Type from Pennsylvania.

Arvicola kennicotti Baird, Mamm. N. Am., 547, 1857. Type from Illinois.

Type locality.-Long Island, New York.

Geographic distribution.—Southern New York and westward to Illinois, southward along the coast, blending into true pinetorum.

Habitat.—Open grassy country, meadows, pastures, and waste places. General characters.—Larger, darker, and duller than true pinetorum.

Color.—Upperparts dull brownish chestnut, slightly darkened by dusky-tipped hairs; sides paler; belly lightly washed with dull buff over plumbeous under-fur; feet brownish gray; tail indistinctly bicolor, sooty above, grayish below.

Cranial characters.—Skull similar to that of pinetorum, but larger, with heavier molars.

Measurements.—Average of three adults from Lake Grove, Long Island: Total length, 125; tail vertebræ, 20; hind foot, 16.3. Skult (No. 88732, same locality): Basal length, 23.5; nasals, 7.4; zygomatic breadth, 16; mastoid breadth, 12.6; alveolar length of upper molar series, 6.6.

Specimens examined.—Total number, 83, from the following localities:

New York: Lake Grove, Long Island, 4; Millers Place, Long Island, 2; Oyster Bay, Long Island, 1; Sing Sing, 4; Lake George, 1; Locust Grove, 1.

Pennsylvania: Philadelphia, 1.

New Jersey: Tuckerton, 3.

Maryland: Laurel, 2; Kensington, 1; Bladensburg, 2.

District of Columbia: Washington, 27.

Virginia: Falls Church, 4; Dunn Loring, 1; Fort Myer, 1; Clark County, 2; Cape Charles, 4; Bellehaven, 1; Wallaceton (Dismal Swamp), 4.

North Carolina: Currituck, 2; Magnetic City, 1.

West Virginia: White Sulphur Springs, 6.

Ohio: A specimen in the U.S. Nat. Mus., collected by Kennicott, is labeled 'Ohio.'

Indiana: Brookville, 2 (approaching auricularis); Terre Haute, 1.

Illinois: West Northfield, 2; Warsaw, 2.

MICROTUS PINETORUM AURICULARIS Bailey. Bluegrass Vole.

Microtus 1 insterum auricularis Bailey, Proc. Biol. Soc. Wash., XII, 90, April 30, 1898.

Type locality .- Washington, Mississippi.

Geographic distribution.—Northern Mississippi, Tennessee, Kentucky, and southern Indiana, or in a general way the region between the Allegheny Mountains and the Mississippi River, mainly in the Lower Austral zone.

General characters.—Size small, about equaling that of pinetorum; ears very large for a Pitymys and conspicuous above fur; colors dark and rich, not always darker than scalopsoides but richer and more intense; fur short and dense like that of pinetorum.

Color.—Upperparts dark rich chestnut darkened by dusky tipped hairs; belly washed with paler chestnut over dark under-fur; projecting tip of ear with scattered dusky hairs; tail not bicolor, scarcely darker above, like the back or slightly darker; feet dull brownish.

Cranial characters.—Skull like that of pinetorum in form and general characters; interpterygoid fossa normally U-shaped instead of V shaped.

Measurements.—Type: Total length, 120; tail vertebræ, 22; hind foot, 16. Average of six adult specimens from the type locality, measured in the flesh by collector: 119; 22; 17. Skull (of type): Basal length, 22.3; nasals, 7; zygomatic breadth, 15.2; mastoid breadth, 12.3; alveolar length of upper molar series, 6.

General remarks.—A series of 31 specimens in the Merriam collection from Eubank, Ky., average darker and richer in coloration than the type series and have equally large ears. Specimens from Brookville, Ind., are dark and dull colored and might pass for either this species or scalopsoides. A single specimen from Hickman, Ky., is immature but apparently typical. A flat skin with crushed skull from Barron Springs, near Fredericksburg, Tex., has the large ear and small foot of auricularis but the dull color of nemoralis.

Specimens examined.—Total number, 45, from the following localities:

Mississippi: Washington, 10.

Kentucky: Hickman, 1; Eubank, 31.

Indiana: Brookville, 1.
Tennessee: Rogersville, 1.
Alabama: Greensboro, 1.

MICROTUS NEMORALIS Bailey. Woodland Vole.

Microtus nemoralis Bailey, Proc. Biol. Soc. Wash., XII, 89, April 30, 1898.

Type locality.—Stilwell (Boston Mountains), Indian Territory.

Habitat.-Open woods and brushland.

Geographic distribution.—West of the Mississippi River from central Arkansas north to Council Bluffs, Iowa.

General characters.—Size, larger than any other species of Pitymys in the United States; ears, relatively large; fur, comparatively long 18392—No. 17—5

and coarse; colors, duller than in pinetorum, not so dark as in sealop-soides or auricularis.

Color.—Upperparts dull chestnut, slightly lined with blackish-tipped hairs over the back and rump, becoming paler on the sides; belly washed with bright cinnamon; tail indistinctly bicolor; feet thinly clothed with pale buffy or sometimes dusky hairs. Young: Plumbeous or dark maltese, with a slight tinge of chestnut suffusing the back as maturity is approached.

Cranial characters.—Skull large and relatively elongated; supraoccipital sloping; interparietal short and wide; mastoids and audital bulke large and projecting farther back than in pinetorum; palate often with a posterior point projecting into the U-shaped interpterygoid fossa.

Measurements.—Type: Total length, 130; tail vertebræ, 24; hind foot, 18. Average of five females and five males from the type locality: 135; 25; 18.1. Skull (of type): Basal length, 25.3; nasals, 7.7; zygomatic breadth, 16.5; mastoid breadth, 13.4; alveolar length of upper molar series, 7.

General remarks.—Specimens from London, Nebraska, and Council Bluffs, Iowa, are typical or slightly larger than those from the type locality. Those from central Arkansas and eastern Missouri are nearly or quite typical. So far as shown by the present series of specimens, the species stands distinct and apparently unconnected with the other forms of *Pitymys* east of the Mississippi River.

Specimens examined.—Total number, 46, from the following localities:

Indian Territory: Stilwell, Boston Mountains, 16.

Arkansas: Beebe, 5; Hardy, 1.

Missouri: Hunter, 3; Williamsville, 5; Kimswick, 5.

Iowa: Council Bluffs, 4. Kansas: Neosho Falls, 1. Nebraska: London, 6.

#### MICROTUS QUASIATER (Coues). Jalapa Vole.

Arvicola (Pitymys) pinetorum quasiater Coues. Proc. Acad. Nat. Sci. Phila., 1874, 191-192.

Type locality.—Jalap 1, Vera Cruz, Mexico.

Geographic distribution.—Central Vera Cruz and eastern Puebla, on the east slope of the mountains (altitude 4,000 to 5,000 feet), in Humid Tropical and lower edge of Lower Austral zones.

Habitat.—Brushy woodland.

General characters.—Size of pinetorum; tail about as long as hind foot; ears large for a Pitymys; colors dark; fur glossy.

Color.—Summer pelage: Uniformly dark umber or seal brown, slightly paler on belly, feet, and tail; tail slightly paler below than above. Winter pelage (in January, specimens from Orizaba and Huauchinango): Darker, richer, and more glossy. Young: Darker and duller, inclining to sooty or plumbeous,

Cranial characters.—Skull similar to that of pinetorum, but with longer, more quadrate braincase, more prominent postorbital ridges, narrower interorbital space, and larger audital bulke; dentition slightly heavier; molar pattern the same.

Measurements.—Average of 6 adult males and females from the type locality: Total length, 130; tail vertebræ, 23; hind foot, 17.7. Skull (No. 55048, ♀ adult): Basal length, 24; nasals, 7; zygomatic breadth, 12; alveolar length of upper molar series, 6.3.

General remarks.—Microtus quasiater is by far the most divergent form of Pitymys in America. Its range, so far as known, is restricted to a comparatively small area, 1,000 miles from that of its nearest relative, and reaches into a zone not known to be inhabited by any other species of Microtus.

Specimens examined.—Total number, 44, from the following localities:

Vera Cruz: Jalapa, 6; Jico, 8; Orizaba, 10.

Puebla: Huauchinango, 20.

#### Subgenus LAGURUS Gloger.

Lagurus Gloger, Gemeinnitz. Hand- u. Hilfsbuch d. Naturgesch., I, 98, 1841. Type Lagurus migratorius Gloger.

Lagurus Merriam, Am. Naturalist, XXIX, 758, Aug., 1895 (subgenus).

Geographic distribution (in America).—Transition zone of the semiarid parts of the northwestern United States, east of the Cascades and Sierra Nevada.

Subgeneric characters.—(In American species) plantar tubercles, 5; mammæ, 8, inguinal 2-2, pectoral, 2-2; lateral glands on flanks; tail little little longer than hind foot; colors pale; fur lax. Skull low and wide; bullæ very large; mastoids

Fig. 12.—Molarenamel pattern of Microtus (Lagurus) pallidus(×5).

reaching plane of exoccipital condyles; molars slender, with wide reentrant angles; m3 with 2 closed triangles and narrow posterior loop; m1 with 5 closed triangles, 4 inner and 4 outer salient angles; m3 with two terminal transverse loops and a pair of median triangles.

MICROTUS CURTATUS (Cope), Short-tailed Vole.

Arricola curtata Cope, Proc. Acad. Nat. Sci. Phila., 1868, 2.

Arricola decurtata Cones, Mon. N. Am. Rodentia, 215 (in text), 1877, nomen nudum.

Type locality.--Pigeon Spring, Mount Magruder, Nevada.

Geographic distribution.—Transition zone of the low mountain ranges in western Nevada and eastern California, east of the Sierra Nevada and north of Death Valley.

Habitat.-Dry, barren country, usually in sagebrush.

General characters.—Tail very short; feet hairy; fur long and lax; color pale buffy gray; skull wide and flat, with very large audital bullæ.

Color.—Winter pelage: Upperparts uniform pale buffy gray, or ashy gray becoming paler on the sides, and silvery white or soiled whitish

below; tail like belly, except an indistinct dusky dorsal line; ears slightly buffy, more noticeably so in young than in adults; feet soiled silvery whitish. Summer pelage: Slightly darker. Young: Darkened above by long, dusky-tipped hairs; ears distinctly buff tipped.

Cranial characters.—Skull wide and flat, with short rostrum, spreading zygomatic arches, and great mastoid breadth; audital bullæ and mastoids much inflated, and with thick, spongy walls; mastoids projecting back to plane of exoccipital condyles. Molar series rather light, with narrow, tightly closed triangles and wide reentrant angles.

Measurements.—Average of five adults from the type locality: Total length, 141; tail vertebræ, 27; hind foot, 17.6. Skull (No. 41019,  $\circ$  ad.): Basal length, 24; nasals, 6.6; zygomatic breadth, 15; mastoid breadth, 13; alveolar length of upper molar series, 6.

General remarks.—This is the largest of the three species of Lagurus at present known in North America, size alone being sufficient to distinguish it from either pauperrimus or pallidus. It shows but slight variation throughout its somewhat restricted and probably interrupted range. Specimens from the head waters of Reese River, which is separated from the type locality by Sonoran valleys, show slightly larger audital bullæ and mastoids, but no characters of specific or subspecific value.

Specimens examined.—Total number, 54, from the following localities:

Nevada: Mount Magruder (near Pigeon Spring), 14; Reese River Valley, 7; Indian Creek (near head of Reese River), 2; head of Reese River, 10. California: Inyo Mountains, 17; White Mountains, 4.

Note.—Microtus (Lagurus) pumilus Elliot (Field Columbian Museum, Zool. Series, Vol. I, No. II, p. 226, Feb. 1, 1899) from the Olympic Mountains, Washington, proves to be a young *Phenacomys*, as I have ascertained by examination of the type specimen, kindly loaned me by Mr. D. G. Elliot, curator of mammals in the Field Columbian Museum.

MICROTUS PALLIDUS (Merriam.) Pallid Vole.

Arvicola pallidus Merriam, Am. Nat., XXII, 702-705, Aug., 1888.

Type locality.—Fort Buford, N. Dak. The type was taken on a northeast slope, near the top of a high, barren hill, 2 miles east of the fort.

Geographic distribution.—Transition prairies of western North Dakota, Montana, and as far north as Calgary, Alberta.

Habitat.—High, semi-arid prairies, usually on shady slopes.

General characters.—Slightly paler than curtatus; smaller; with relatively much smaller audital bullæ. The palest species of Microtus found in America, and probably the shortest tailed.

Color.—Upperparts uniform pale buffy gray with an extra tinge of buff about ears and nose; belly white or soiled whitish; tail silvery whitish below, dusky above; feet silvery whitish or pale gray. The type series was taken in September and shows what is probably the darkest phase of summer pelage.

Cranial characters.—Skull like that of curtatus in general, but averaging slightly smaller and with decidedly smaller audital bulke and narrower mastoid breadth. Teeth relatively heavy; incisors fully equaling those of larger skulls of curtatus; molar series heavy and actually longer in the smallest adults than in much larger specimens of curtatus; enamel pattern essentially the same.

Measurements.—Type,  $^{\circ}$  ad.: Total length, 121; tail vertebræ, 20; hind foot, 18 (measured dry). Skull (of type): Basal length, 22.3; nasals, 6.5; zygomatic breadth, 14.6; mastoid breadth, 11.6; alveolar length of upper molar series, 6.3.

General remarks.—In size pallidus falls between curtatus and pauperrimus, but in relative size of teeth curtatus comes in the middle, while in geographic position pauperrimus separates the other two. There is nothing in the material before me to indicate any intergradation between the forms or any subspecific relationship.

Specimens examined.—Total number, 8, from the following localities:

North Dakota: Fort Buford, 4. Montana: Philbrook, 1. Canada: Calgary, Alberta, 3.

MICROTUS PAUPERRIMUS (Cooper). Pigmy Vole.

Arvicola pauperrima Cooper, Am. Nat., II, 535-536, Dec., 1868.

Type locality.—Plains of the Columbia, near Snake River, Washington.

Geographic distribution.—Eastern Washington and Oregon, central Idaho, and the north slope of the Uinta Mountains, Utah, in Transition zone.

Habitat.—Open grassy ridges or high prairie, except in the Uinta Mountains, where they were found in grassy parks near the lower edge of pine timber.

General characters.—The smallest species of the subgenus Lagurus, with colors a shade darker than in curtatus or pallidus; skull small and very flat-topped, often concave postorbitally.

Color.—Summer pelage: Upperparts uniform buffy gray, slightly darkened with dusky-tipped hairs; ears and nose strongly tinged with buff; belly pale buffy; tail darkened above by a dusky line, buffy below; feet like belly. Young: Less buffy and slightly more dusky than adult.

Cranial and dental characters.—Skull small, relatively smooth, not ridged or angled, flat or concave on top; audital bulke relatively as well as actually smaller than in curtatus; hamular process of mandible short and slender, inclosing a wide two angled or rounded notch; incisors slender; molars differing from those of curtatus only in smaller size; enamel pattern essentially the same.

Measurements.—Average of 3 adults from the vicinity of Antelope, Oreg.: Total length, 115; tail vertebre, 20; hind foot, 16. Skull (of

adult  $\circ$ , No. 78534, from Antelope, Oreg.): Basal length, 20; nasals, 5.5; zygomatic breadth, 13.4: mastoid breadth, 11.3; alveolar length of upper molar series, 5.2.

General remarks.—The above description is based mainly on a series of 6 specimens collected near Antelope, Oreg., on top of the high prairie ridge between the John Day and Des Chutes rivers, and not more than 150 miles from where Dr. J. G. Cooper collected his type of pauperrimus on the plains of the Columbia, near Snake River, October 9, 1860. Antelope is in reality on the south edge of the plains of the Columbia, and specimens from that point agree in every way with the somewhat mutilated type of pauperrimus still in the United States National Museum. Specimens from the Salmon River Mountains, Idaho, do not differ perceptibly from the type or from the Antelope series. A single specimen from the top of Steen Mountain is not typical, but the characters are not sufficient to warrant separating it on a single specimen, and they may prove only individual. Four specimens from the north slope of the Uinta Mountains, Utah, show but little deviation from the typical series.

Specimens examined.—Total number, 19, from the following localities:

Washington: Plains of the Columbia, 1 (the type).

Oregon: Antelope, 6; Bake Oven, 1 (im.); Steen Mountain, 1.

Idaho: Salmon River Mountains, 6.

Utah: Uinta Mountains, 4.

# Subgenus CHILOTUS Baird.

Chilotus Baird, Maum. N. Am., 516, 1857. Type, Arvicola oregoni Bachman.

Geographic distribution.—Pacific slope from northern California to southern British Columbia.

Subgeneric characters.—Plantar tubercles, 5; mammæ, 8, inguinal, 2-2; pectoral, 2-2; side glands obscure or wanting; 1 ears rather small; fur deuse, without stiff hairs. Skull short, low, and with elliptical braincase; molars small; m3 with 2 or 3 closed triangles; m1 with 5 closed triangles; m2 with anterior pair of triangles usually confluent; m3 with 3 transverse loops.

# MICROTUS OREGONI (Bachman). Oregon Vole.

Arvicola oregoni Bachman, Journ. Acad. Nat. Sci. Phila., VIII, Pl. 1, 60-61, 1839.
 Microtus morosus Elliot, Field Columbian Mus., Zool. Series, Vol. I, No. II, 227, Feb. 1, 1899. (Olympic Mountains, Washington.)

Type locality.—Astoria, Oregon.

Geographic distribution.—Pacific coast region from northern California to Puget Sound.

<sup>&</sup>lt;sup>1</sup> In a large number of skins of adult males, about a dozen show what appear to be ill-defined glands on the sides, midway between hips and shoulders; but before stating postively the presence and position of these glands it will be necessary to examine specimens in the flesh.

Habitat.—Dry open ground, under cover of grass and low vegetation, and under logs in the open redwood forest of California.

General characters.—Size rather small; tail long; colors dark; fur short, without long hairs.

Color.—Upperparts mixed bister and blackish, with a pepper-and-

salt appearance; belly dusky, lightly washed with dull buffy; feet dusky gray; tail blackish, slightly lighter below; ears blackish, scantily haired, protruding from the fur.

Cranial characters.—Skull, compared with those of other species of the subgenus, long and slender, with narrower braincase, longer rostrum, more arched and less abruptly spreading zygomata, more

Fig. 13.—Molar enamel pattern of Microtus (Chilotus) oregoni (× 5).

quadrangular interparietal; superciliary ridges in adults well marked, approaching or meeting interorbitally; audital bullæ small and globose; dentition not peculiar.

Measurements.—Adult  $\mathfrak{F}$ , No.  $\frac{17330}{24255}$ , from Astoria: Total length, 140; tail vertebræ, 42; hind foot, 17. Skull (of same): Basal length, 22.2; nasals, 17; zygomatic breadth, 14.8; mastoid breadth, 11.8; alveolar length of molar series, 5.5.

General remarks.—The species shows some slight variation throughout its range, but all of the specimens examined from the low country south of Puget Sound are clearly referable to oregoni, and those from timberline in the Olympics do not vary sufficiently for even subspecific recognition.

Specimens examined.—Total number, 103, from the following localities:

Oregon: Astoria, 6; Oregon City, 6; Yaquina Bay, 1; Aumsville, 1; Elk Head, 1.

California: Crescent City, 12; Humboldt Bay, 1; Hoopa Valley, 2; Dyerville, 3. Washington: Tenino, 9; Roy, 1; Skamania County (45 miles southeast of Toledo), 1; Kent, 2; Steilacoom, 1; Aberdeen, 3; Granville, 6; Quineault Lake, Chehalis County, 3; La Push, 3; Suez, 1; Neah Bay, 10; Olympic Mountains (near head of Soleduc River), 9; Lake Cushman, 21.

MICROTUS SERPENS Merriam. Creeping Vole.

Microtus serpens Merriam, Proc. Biol. Soc. Wash., XI, 75, 1897.

Type locality.—Agassiz, British Columbia.

Geographic distribution.—Low country of southern British Columbia and northern Washington between the Cascade Mountains and Puget Sound.

General characters.—Size, largest of the subgenus; tail short; colors dark.

Color.—Winter pelage: Upperparts uniformly sooty gray, becoming slightly lighter on sides; belly dusky, washed with dull buff; tail sooty above, silvery gray below; feet dusky gray; ears nearly naked, concealed in long fur. Summer pelage: Paler and more brownish above, belly lightly washed with buffy; ears projecting slightly from thinner, coarser fur.

Cranial characters.—Skull rather wide and short; superciliary ridges not well defined; interorbital width greater than in oregoni; zygomata abruptly spreading anteriorly, interparietal lozenge-shaped; audital bullæ full and globose; incisors larger and stronger and molars slightly larger than in oregoni.

Measurements.—Type: Total length, 130; tail vertebræ, 31; hind foot, 18. Average of 7 adults from type locality: 129; 32; 17.5. Skull (of type): Basal length, 22.4; nasals, 6.6; zygomatic breadth, 14; mastoid breadth, 11.2; alveolar length of upper molar series, 5.9.

General remarks.—The range of this northern, more robust form of Chilotus, as at present known, is rather limited, but future collections may show it to be continuous with that of oregoni.

Specimens examined.—Total number, 56, from the following localities:

British Columbia: Agassiz, 7; Port Moody, 10; Langley, 3; Sumas, 10; Mount Baker Range, 4.

Washington: Mount Vernon, 19; Hamilton, 2; Sauk, 1.

MICROTUS BAIRDI Merriam. Baird Vole.

Microtus bairdi Merriam, Proc. Biol. Soc. Wash., XI, 74, 1897.

Type locality.—Glacier Peak, Crater Lake, Oregon (altitude, 7,800 feet).

Geographic distribution.—Known only from the type locality, but probably restricted to the Hudsonian zone of the higher Cascades.

Habitat.—Beds of Phyllodoce and Lutkea at timberline.

General characters.—Slightly smaller than M. oregoni; color yellowish brown; fur short and glossy; tail short; ears almost concealed in the fur.

Color.—Upperparts glossy yellowish bister; sides paler; belly washed with whitish; tail indistinctly bicolor, dusky above, dark gray below; feet dusky gray; nose dusky.

Cranial characters.—Skull relatively short, wide, and flat, with short rostrum; braincase subquadrate; interparietal narrow; audital bullæ large; ascending arm of premaxillæ not extending beyond nasals; incisive foramina short and wide; dentition not peculiar.

Measurements.—Type, No. 79906, ♀ ad.: Total length, 131; tail vertebræ, 33; hind foot, 17.5. A young adult ♂ from type locality: 130; 32; 17. Skull (of type): Basal length, 22; nasals, 6.6; zygomatic breadth, 14; mastoid breadth, 11.5; alveolar length of upper molar series, 5.5.

General remarks.—This species of Chilotus is as yet known only from 2 specimens from the type locality. No doubt it will eventually be found to extend along the crest of the Cascade Range in Oregon.

Specimens examined.—Total number, 2, from the type locality.

# Subgenus PEDOMYS Baird.

Pedomys Baird, Mamm. N. Am., 517, 1857. Type, Arvicola austerus Le Conte.

Geographic distribution.—Middle United States from southern Louisiana to Plains of the Saskatchewan.

Subgeneric characters.—Plantar tubercles, 5; side glands obscure or wanting, rarely discernible; mammæ, 6, inguinal, 2-2, pectoral, 1-1; ears medium; fur long and coarse. Skull high and narrow; molars with wide reentrant angles; m3 with 2 closed triangles; m1 with 3 closed and 2 open triangles; m2 with anterior pair of triangles confluent; m3 with 3 transverse loops, the middle loop sometimes constricted, or even divided into 2 triangles.

-Molar enamel pattern of Microtus (Pedomys) austerus  $(\times 5)$ .

# MICROTUS AUSTERUS (Le Conte). Prairie Vole.

Arvicola austerus Le Conte, Proc. Acad. Nat. Sci. Phila., VI, 405-406, 1853. Arricola (Pedomys) cinnamonea Baird, Manun. N. Am., 541, 1857. (Type from Pembina, N. Dak.)

Type locality.—Racine, Wisconsin.

Geographic distribution.—Central part of Mississippi Valley from southern Wisconsin to southern Missouri and Fort Reno, Oklahoma, and west into eastern Nebraska and Kansas.

Habitat.—Dry upland prairie under low grass, and in rose and hazel thickets.

General characters.—Size of Microtus pennsylvanicus, but with slightly shorter tail and apparently coarser pelage. Color, dark peppery gray above, dull fulvous below.

Color .- Winter pelage: Upperparts dark gray, with a peppery appearance from the mixture of black and pale fulvous tips of long hairs, black tips predominating; sides paler; belly washed with pale cinnamon or fulvous; tail sharply bicolor, feet dusky; a tuft of fulvous hairs in front of ear. Summer pelage: Darker throughout, with fewer light-tipped hairs and thinner fulvous wash below. Young: Slightly paler than adult.

Cranial characters.—Skull high, narrow, and well arched; interparietal small, lozenge shaped; premaxillæ extending well back of nasals; audital bullæ small and narrow; incisive foramina wide posteriorly; molar pattern, that of the subgenus.

Measurements.—No. 2928, & ad., from Racine, Wis., (measured from alcohol by Baird)2: Total length, 127; tail vertebræ, 32; No. 2897: hind foot, 19. Skull (No. 1999, ad., from Racine): Basal length, 27; nasals, 7.9; zygomatic breadth, 15.5; mastoid breadth, 12.6; alveolar length of upper molar series, 6.8. Skull (No. 948-not fully adultfrom Racine): 25; 7.9; 15.4; 11.8; 6,

A large number of skins of males show no trace of side glands, but a few show what appear to be very small glandular areas on the middle of the sides. It will be necessary to examine fresh specimens of old males before the presence or position of the glands is fully determined.

<sup>&</sup>lt;sup>2</sup> Mamm. N. Am., 541, 1857.

Considerable variation is shown throughout the range of the species. To the southwest, at Orlando and Fort Reno, Okla., the individuals show slightly deeper coloration and slight modifications of eranial characters. Except for a slightly abnormal tooth pattern Baird's type of cinnamonea is a large specimen of typical austerus. I cannot believe that it ever came from Pembina.

Specimens examined.—Total, 211, from the following localities:

Wisconsin: Racine, 4.

Illinois: West Northfield, 14; Warsaw, 1.

Indiana: Wheatland, 4.

Iowa: Fairfield, 1; Knoxville, 93.

Nebraska: Blair, 1 (im.) Columbus, 7; London, 13; Norfolk, 1.

Kansas: Cairo, 4; Ouaga, 13; Burlington, 1; Doniphan County, 1; Fort

Leavenworth, 21.

Missouri: Golden City, 2; Piedmont, 10; Bismark, 6; Kimswick, 6.

Oklahoma: Orlando, 1; Fort Reno, 7.

### MICROTUS LUDOVICIANUS sp. nov. Louisiana Vole.

Type from Iowa, Calcasieu Parish, Louisiana. No. 96624, 3 ad., U.S. Nat. Mus., Biological Survey Collection. Collected April 7, 1899, by Vernon Bailey. Collector's number, 6767.

Geographic distribution.—Coast prairie of southwestern Louisiana, in Lower Austral zone.

Habitat.—Dry grassy mounds on the flat, half-marshy coast prairie. General characters.—Size and proportions about as in M. austerus, color similar; rostrum and nasals slenderer and audital bullæ larger.

Color.—Winter pelage (in April specimens): Upperparts dark gray, with a coarse, peppery appearance, produced by the mixture of black-, brown-, and whitish-tipped hairs, and varying in color as these different colored hairs predominate; below dull fulvous or dark buffy; tail indistinctly bicolor, dusky above, buffy below; feet dusky. Young (quarter to half grown): Darker, more dusky, and less brownish than adult.

Cranial characters.—Skull like that of austerus with larger, more rounded audital bullæ, larger molars, and slenderer nasals. Middle section of  $\overline{m3}$  often constricted or separated into two closed triangles. (This may occur in any species of Pedomys.)

Measurements.—Average of 10 adults (5 males and 5 females) from type locality: Total length, 164; tail vertebræ, 33; hind foot, 18.5. Average of hind foot of males, 19; of females, 18. Type: 146; 36; 19. Skull (of type): Basal length, 25.8; nasals, 8; zygomatic breadth, 15; mastoid breadth, 11.5; alveolar length of upper molar series, 6.3.

Remarks.—A single imperfect skull in the United States National Museum collection from Calcasieu Parish, La., showed such pronounced characters as to suggest the collection of the present series of specimens. Some of the characters in the old skull prove to be abnormal, and the actual differences between this southern form and true austerus are not strongly marked. There is no known and probably no actual intergradation or continuity of range between the two forms, and per-

haps subspecific rank would show better the close relationship of ludovicianus to austerus.

Specimens examined.—Total number, 26, from Calcasieu Parish, La.

MICROTUS HAYDENI (Baird). Hayden Vole.

Arvicola haydeni Baird, Mamm. N. Am., 543-544, 1857.

Type locality.—Fort Pierre, South Dakota.

Geographic distribution.—Plains region of western South Dakota, Nebraska, and Kansas, eastern Colorado and Wyoming, and southern Moutana, in Transition zone.

Habitat.—Dry prairies. At the type locality, in sagebrush on badland hills.

General characters.—Considerably larger and lighter colored than M. austerus, with little or none of the fulvous or cinnamon wash below; fur very long and lax in winter and spring pelages; skull heavy and angular.

Color.—(May specimens from Fort Pierre): Upperparts uniform light gray, the color formed by a combination of whitish- and blackish-tipped hairs, with the white-tipped predominating; belly washed with silvery white, or sometimes soiled white, over plumbeous under-fur; feet dusky gray; tail bicolor. Summer pelage: Somewhat darker, with sometimes a slight wash of buff below. Young (one-fourth to one-half grown): Very woolly and slightly darker than adult.

Cranial characters.—Skull larger, more angular, and more heavily ridged than in austerus; anterior part of zygomatic arches more abruptly spreading; prezygomatic notch deeper; interparietal larger; palate higher, with more prominent median ridge.

Measurements.—Adult 2 from type locality (No. 4239, Merriam Coll.): Total length, 180; tail vertebræ, 47; hind foot, 22. Skull (No. 4971 from Fort Pierre): Basal length, 28; nasals, 8; zygomatic breadth, 17.6; mastoid breadth, 12.6; alveolar length of upper molar series, 7.4.

General remarks.—Probably haydeni intergrades with true austerus, and is merely a more robust and paler northwestern form. The ranges of the two almost meet, if they are not continuous.

Specimens examined.—Total number, 110, from the following localities:

South Dakota: Fort Pierre, 4; Pierre, 3; Buffalo Gap, 4; Rapid City, 4.

Nebraska: Valentine, 10; Kennedy, 11; Sidney, 2; Callaway, 4; Alliance, 2.

Kansas: Pendennis, 10; Banner, 11. Colorado: Loveland, 1; Canyon City, 1.

Wyoming: Beaver, 1; Newcastle, 1; Sundance, 1; Dayton, 1; Pass, 4.

Montana: Little Bighorn Valley, 8; Fort Custer, 24; Custer Station, 1; Lake Basin, 2.

MICROTUS MINOR (Merriam). Least Upland Vole.

Arvicola austerus minor Merriam, Am. Nat., XXII, 598-601, July, 1888.

Type locality.—Bottineau, at base of Turtle Mountains, North Dakota. Geographic distribution.—Northern border of the Great Plains from northeastern North Dakota to Edmonton, Alberta, and southeastward to Minneapolis, Minn.

Habitat .- Dry upland prairie.

General characters.—Size very small, scarcely as large as Evotomys gapperi and of about the same proportions; color peppery gray; pelage long, lax, and coarse; sixth tubercle on hind foot usually present, though small; skull small and slender.

Color.—Winter pelage: Upperparts uniform, clear peppery gray, from a combination of black- and whitish-tipped hairs; belly washed with soiled white or pale buffy; tail sharply bicolor, dusky above, buffy below; feet gray. Summer pelage: With a mixture of fulvous above; belly with thinner wash of light-tipped hairs over dark under-fur. Young: Slightly darker than adult with less peppery appearance of fur.

Cranial characters.—Skull very small, not much arched, slender and narrow, with relatively heavy rostrum, narrow strap-shaped interparietal and slender zygomata; audital bulke small and laterally compressed; molars with enamel pattern of the subgenus.

Measurements.—Type: Total length, 133; tail vertebræ, 36; hind foot, 16.5. Average of four adults from Sherbrook, N. Dak.: 128; 30; 16.7. Skull (No. 49230, ♀ ad., from Sherbrook): Basal length, 22.3; nasals, 6.4; zygomatic breadth, 12.2; mastoid breadth, 10; alveolar length of upper molar series, 5.

General remarks.—A mere glance at the skulls shows minor to be widely separated from any other species of the subgenus, differing from austerus in much smaller size, narrower braincase, and relatively smaller and narrower audital bulla. The species shows little variation throughout its range over the prairie region, but those occupying the half-timbered region of south-central Minnesota show a marked intensity of color.

Specimens examined.—Total number, 94, from the following localities:

North Dakota: Bottineau, 3; Sherbrook, 4; Devils Lake, 1.

South Dakota: Traverse, 7.

Minnesota: Ortonville, 6; Elk River, 40; Fort Snelling, 7; Hamlington, 1. Canada: Carberry, Manitoba, 1; Indian Head, Assinaboia, 11; Wingard, Saskatehewan, 10; Red Deer, Alberta, 1; Edmonton, Alberta, 2.

### Subgenus ORTHRIOMYS Merriam.

Orthriomys Merriam, Proc. Biol. Soc. Wash., XII, 107, April 30, 1898. Type, Microtus umbrosus Merriam.

Geographic distribution.—That of its only known species.

Subgeneric characters.—Plantar tubercles, 5 (a rudiment of 6th); side

Fig. 15.—Molar enamel pattern of Microtus (Orthriomys) umbrosus (x 5).

glands wanting or very rudimentary; mamma, 4, pectoral, 2-2; ears large and almost naked; feet large; tail long and scantily haired. Shull long and narrow; bulle very small; posterior median ridge of palate sloping and grooved; m3 with 2 closed rounded triangles, and a third open one; m1 with 3 closed triangles, 4 inner and 3 outer salient angles; m2 with the anterior pair of triangles

confluent; m3 with 4 closed sections including 2 median triangles.

MICROTUS UMBROSUS Merriam. Zempoaltepec Vole.

Microtus umbrosus Merriam, Proc. Biol. Soc. Wash., XII, 108, Apr. 30, 1898.

Type locality.—Mount Zempoaltepec, Oaxaca, Mexico (altitude 8,200 feet).

Geographic distribution.—Known only from the east slope of Mount Zempoaltepec, in the humid Upper Austral zone.

Habitat.—Dense oak forests, living in burrows and long underground tunnels.

General characters.—Size rather large; tail long; ears large; fur long and lax; colors dark; skull long and flat, with small bulke and peculiar dentition.

Color.—Upperparts uniform dusky, with brown-tipped hairs; below dark plumbeous thinly washed with fulvous; feet and tail thinly haired, concolor, dark brown.

Cranial characters.—Skull long, narrow, and but little arched, with smooth outlines, and slender zygomatic arches; bullæ very small; palate low, with slender or incomplete lateral bridges, shallow lateral pits and grooved posterior ridge; interpterygoid fossa wide and quadrate; incisive foramina short and widest in the middle. Dentition heavy; incisors abruptly decurved; inner salient 'angles' of upper and posterior lower molars rounded instead of acute; m3 with a small outer and a large inner closed triangle and a posterior trefoil with large inner and small outer lobe; m3 with 2 median closed triangles, an outer and inner, and broad terminal loops.

Measurements.—Average of 7 specimens from type locality: Total length, 184; tail vertebrae, 65; hind foot, 23. Type: 177; 61; 23.5. Skull (of type): Basal length, 26.5; nasals, 7.3; zygomatic breadth, 16; mastoid breadth, 12; alveolar length of upper molar series, 7.

Specimens examined: Total number, 15; from the following localities in Mexico.

Oaxaca: Mount Zempoaltepec (above Totontepec), 8; Totontepec, 7.

### Subgenus HERPETOMYS Merriam.

Herpetomys Merriam, Proc. Biol. Soc. Wash., XII, 107, April 30, 1898. Type, Microtus guatemalensis Merriam, from Todos Santos, Guatemala.

Geographic distribution.—That of the type species.

Subgeneric characters.—Plantar tubercles, 5; side glands on flanks of males small and obscure or sometimes wanting; mammæ, 6, pectoral, 2-2, inguinal, 1-1 (the latter apparently rudimentary and functionless); ears large; pelage long and soft; colors dark brownish. Skull with smooth outlines and large globose audital bullæ; m3 with 3 closed triangles; m1 with 3 closed triangles and an interior confluent

In some specimens no side glands can be discovered, and in others they are marked by a pencil of white hairs. There is some doubt as to whether the white hairs are a product of the glands or occur there accidentally or from injury, as they sometimes do over other parts of the body.

pair of triangles opening into terminal loop, and with 5 Inner and 4 outer salient angles; m3 with 4 closed sections including a pair of subequal median triangles.

# MICROTUS GUATEMALENSIS Merriam. Gnatemalan Vole.

Microtus guatemalensis Merriam, Proc. Biol. Soc. Wash., XII, 107, April 30, 1898.

Type locality.—Todos Santos, Huehnetenango, Guatemala (altitude 10,000 feet).

Geographic distribution.—Known only from type locality.

Habitat.—Open ground on damp north slopes under rank growth of brush and weeds in the Boreal zone (altitude 9,800-11,000 feet).

General characters.—Size medium; tail less than twice the length of hind foot; ears large but nearly concealed in the long fur; colors dark.

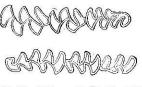

Fig. 16.—Molar enamel pattern of Microtus (Herpetomys) guatematensis (× 5).

Color.—Winter pelage: Upperparts dark umber brown; nose blackish; lips white; belly clear plumbeous or lightly washed with dull ochraceous; feet and tail dusky brown, concolor, and thinly haired. (Summer pelage not seen.) Young (half-grown individuals in December): Slightly duller than adult.

Cranial characters.—Skull rather long and but little arched, without conspicuous ridges and angles; interorbital space wide; braincase long; bullae large and globose (larger than those of any other Mexican species); palate with steep and lightly grooved posterior median ridge; incisive foramina wide and short. Dentition heavy; most of the salient angles of molars acute; prisms deltoid; m3 with anterior crescent, 3 closed triangles, and a posterior crescent with two inner horns; m3 with posterior and anterior transverse crescents and a pair of subequal median triangles.

Measurements.—Average of 20 specimens from the type locality: Total length, 150; tail vertebræ, 37; hind foot, 21. Type (å ad.): 155; 40; 21. Skull (of type): Basal length, 25.6; nasals, 7.6; zygomatic breadth, 15; mastoid breadth, 12.3; alveolar length of upper molar series, 7.

General remarks.—So far as at present known, this is the southernmost species of Microtus in America. Its nearest relatives are umbrosus and mexicanus, with both of which it has some characters in common, but from which it differs so widely as to require subgeneric separation.

Specimens examined: Total number, 34, from the type locality.

# Subgenus NEOFIBER True.

Neofiber True, Science, IV, 34, July 11, 1884 (genus). Type, Neofiber alleni True. Neofiber Merriam, North American Fauna No. 5, 59, July, 1891 (subgenus). Geographic distribution.—That of the type species.

Subgeneric characters.—Plantar tubercles, 5; side glands conspicuous in both sexes and in young, situated half-way between hips and

shoulders, the glandular area marked by brownish base of fur and half-encircled above by a semilunar area of fur with white base; mamma, 6, inguinal, 2-2, pectoral, 1-1; feet and fur modified for aquatic life; soles naked; a dorsal keel of long hair on rump. Skull massive; palate long with incomplete lateral bridges; pterygoids wing-

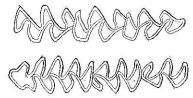

Fig. 17.—Molar enamel pattern of Microtus (Neofiber) alleni (× 5).

like; m3 with 2 closed triangles; m1 with 5 closed triangles; m3 with 2 median triangles and 2 transverse terminal loops.

MICROTUS ALLENI (True). Florida Water-Rat.

Neofiber alleni True, Science, IV, 31, July 11, 1881.

Microtus (Neofiber) alleni Miller, North American Fauna No. 12, 70, July 23, 1896.

Type locality.—Georgiana, Brevard County, Florida.

Geographic distribution.—Eastern and central Florida.

Habitat.—Marshes, shallow lakes, and banks of streams.

General characters.—In appearance very similar to a small muskrat, but with a round tail, a tuft of long hair above the tail, hind feet less modified for aquatic life; fur dense, with color and texture of muskrat fur; skull resembling that of the muskrat, but with the rootless molars of *Microtus*.

Color.—Upperparts dark brown, darkened on head and along back by coarse blackish hairs; nose black; chin dusky; belly pale buff or soiled silvery whitish; tail dark brown or blackish, darker toward the tip; feet dark brown. Young: Dark maltese, with sooty backs.

Cranial characters.—Skull high and short, with heavy ridges and sharp angles; prezygomatic notches deep; postorbital shelf projecting; palate bone longer than in any other *Microtus*, shorter than in *Fiber*; lateral bridges of palate interrupted; pterygoids wing-like (as in *Fiber*); dentition heavy; upper incisors bent abruptly downward.

Measurements.—Average of 3 adult specimens from Canaveral, Fla.: Total length, 320; tail vertebre, 121; hind foot, 44. Largest adult,  $\delta$ : 330; 130; 44. Skull (No. 23450,  $\Omega$  ad.): Basal length, 44.6; nasals, 12.5; zygomatic breadth, 26; mastoid breadth, 20.5; alveolar length of upper molar series, 12.

General remarks.—The striking resemblance between M. alleni of Florida and M. amphibius of England proves on comparison of cranial characters to be only superficial; the differences are subgeneric.

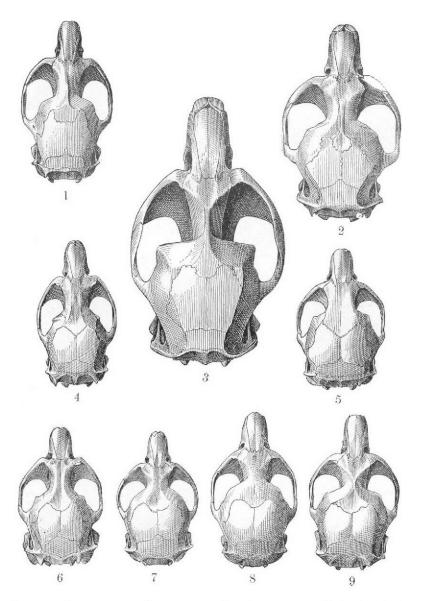

Specimens examined: Total number, 17, from the following localities: Florida: Georgiana, 3; Titusville, 1; Edon, 3; Canaveral, 5; Geneva, 3; Lake Harney, 1; Oaklodge (on peninsula opposite Micco), 1.
