HOW TO OBTAIN EIA PRODUCTS AND SERVICES

For further information on any of the following services, or for answers to energy information questions, please contact EIA's National Energy Information Center:

National Energy Information Center (NEIC)	(202) 586-8800
Energy Information Administration	(202) 586-0727 (fax)
Forrestal Building, Room 1F-048	TTY: (202) 586-1181
Washington, DC 20585	E-mail: infoctr@eia.doe.gov

Electronic Products and Services

EIA's Internet Site Services offer nearly all EIA publications. Users can view and download selected pages or entire reports, search for information, download EIA data and analysis applications, and find out about new EIA information products and services.

World Wide Web: <http://www.eia.doe.gov>
Gopher: <gopher://gopher.eia.doe.gov>
FTP: <ftp://ftp.eia.doe.gov>

EIA also offers a listserve service for EIA press releases and other short documents. Sign up on the EIA World Wide Web site.

EIA's CD-ROM, *Energy InfoDisc*, contains most EIA publications, several databases, and an energy forecasting model. The *Energy InfoDisc*, produced quarterly, is available for a fee from STAT-USA, Department of Commerce, 1-800-STAT-USA.

The Comprehensive Oil and Gas Information Source (COGIS), a bulletin board service, contains data files from most of EIA's oil- and gas-related reports. It is available for a fee from STAT-USA, on 1-800-STAT-USA.

EIA's Electronic Publishing System (EPUB) bulletin board contains data files, directories, and forecasts from most EIA reports. It can be accessed free of charge by dialing (202) 586-2557.

Many of EIA's data files and modeling programs are available for sale on diskette, tape, or cartridge, through either the National Technical Information Service or the Office of Scientific and Technical Information, Department of Energy. Contact NEIC for information on specific products, sources, and media, and ordering instructions.

Printed Publications

EIA directories are available free of charge from NEIC. Recent EIA periodicals and other publications are available from the Government Printing Office. Older reports are available from the National Technical Information Service:

Superintendent of Documents	National Technical Information Service
U.S. Government Printing Office	U.S. Department of Commerce
P.O. Box 371954	3285 Port Royal Road
Pittsburgh, PA 15250-7954	Springfield, VA 22161
(202) 512-1800; (202)-512-2250 (fax)	(703) 487-4650; (703) 321-8547 (fax)

Electronic Publishing System (EPUB) User Instructions

EPUB is an electronic publishing system maintained by the Energy Information Administration (EIA) of the U.S. Department of Energy. EPUB allows the general public to electronically access selected energy data from many of EIA's statistical reports. The system is a menu-driven, bulletin board type system with extensive online help capabilities that can be accessed free-of-charge 24 hours a day by using a terminal or PC with an asynchronous modem. (EPUB will be taken down briefly at midnight for backup).

PC users must provide the following information to their communications software in order to successfully access the EPUB system.

Communications Parameters:

Baud Rate: Up to 28,800 bps
Data Bits: 8; Stop Bits: 1
Parity: None; Duplex: Full
Terminal Type: ANSI, ANSI-BBS, VT100, etc.

Once your communications software and/or hardware has been configured, EPUB can be accessed by dialing (202) 586-2557. When a connection to the system has been made, some users may find that the menu-driven instructions and the online help capabilities will provide enough information to effectively use EPUB. If needed, more extensive information may be found in the *EPUB User's Guide*, which is available online from the EPUB system or from:

TTY: For people who are deaf or hard of hearing:
(202) 586-1191
Hours: 9 a.m. to 5 p.m., M-F, eastern time

For communication or technical assistance, call (202) 586-8959, 8 a.m. to 5 p.m. eastern time, Monday through Friday.

For questions about the content of EPUB reports and/or data, call (202) 586-8800, 9 a.m. to 5 p.m. eastern time, Monday through Friday.

Following is a list of some of the data and reports that are provided on EPUB:

- Heating fuel data (April through September)
Updated the 2nd week of the month.
- Oxygenate data
Updated approximately the 25th of the month.
- *Weekly Petroleum Status Report*
Updated on Wednesdays (Thursdays in the event of a holiday) at 9 a.m.
- *Petroleum Supply Monthly*
Updated between the 23rd and 26th of the month.
- *Petroleum Marketing Monthly*
Updated on the 20th of the month.
- *Natural Gas Monthly*
Updated on the 20th of the month.
- *Weekly Coal Production*
Updated on Fridays by noon.
- *Quarterly Coal Report*
Updated 40 days after the end of the quarter.
- *Electric Power Monthly*
Updated during the second week of the month.
- *Monthly Energy Review*
Updated the second week of the month.
- *Short-Term Energy Outlook*
Updated 60 days after the end of the quarter.
- *Winter Fuels Report* (October through April)
Propane inventory data updated Wednesdays at 5 p.m. All other data updated Thursdays (Friday in event of a holiday) at 5 p.m.

Preface

The Electric Power Monthly (EPM) presents monthly electricity statistics for a wide audience including Congress, Federal and State agencies, the electric utility industry, and the general public. The purpose of this publication is to provide energy decisionmakers with accurate and timely information that may be used in forming various perspectives on electric issues that lie ahead. The EIA collected the information in this report to fulfill its data collection and dissemination responsibilities as specified in the Federal Energy Administration Act of 1974 (Public Law 93-275) as amended.

Background

The Electric Power Division, Office of Coal, Nuclear, Electric and Alternate Fuels, Energy Information Administration (EIA), Department of Energy prepares the EPM. This publication provides monthly statistics at the State, Census division, and U.S. levels for net generation, fossil fuel consumption and stocks, quantity and quality of fossil fuels, cost of fossil fuels, electricity retail sales, associated revenue, and average revenue per kilowatthour of electricity sold. In addition, data on net generation, fuel consumption, fuel stocks, quantity and

cost of fossil fuels are also displayed for the North American Electric Reliability Council (NERC) regions.

The EIA publishes statistics in the EPM on net generation by energy source; consumption, stocks, quantity, quality, and cost of fossil fuels; and capability of new generating units by company and plant.

Data Sources

The EPM contains information from seven data sources: Form EIA-759, "Monthly Power Plant Report"; Federal Energy Regulatory Commission (FERC) Form 423, "Monthly Report of Cost and Quality of Fuels for Electric Plants"; Form EIA-826, "Monthly Electric Utility Sales and Revenue Report with State Distributions"; Form EIA-900, "Monthly Nonutility Sales for Resale Report"; Form EIA-861, "Annual Electric Utility Report"; Form EIA-860, "Annual Electric Generator Report;" and Form EIA-867, "Annual Nonutility Power Producer Report." Copies of these forms and their instructions may be obtained from the National Energy Information Center. A detailed description of these forms is in Appendix B, "Technical Notes."

Reducing Nitrogen Oxide Emissions: 1996 Compliance with Title IV Limits

Introduction

A variety of Federal and State regulatory initiatives are aimed at reducing nitrogen oxide (NO_x) emissions from electricity generators. NO_x emissions are a concern because they contribute to the formation of acid rain and, either directly or through the creation of ozone, lead to harmful effects on human health. It has been determined that the combustion of fossil fuels is the major source of NO_x emissions. According to estimates made by the U.S. Environmental Protection Agency (EPA), highway vehicles accounted for 35 percent of the 22 million tons of NO_x emissions in the United States in 1995, and electric utilities accounted for 29 percent.¹

To address this issue, electric utilities began complying in 1996 with the first phase of the acid deposition control regulations established by the EPA under Title IV of the Clean Air Act Amendments of 1990 (CAAA90). This first phase places limits on NO_x emissions from 239 older coal-fired generating units. Overall, the utilities that operate the affected units achieved a 40-percent reduction in the emissions rates of the units and a total reduction of approximately 340,000 tons of NO_x emissions in 1996 from their 1990 levels. In most cases, the units were retrofitted with low-NO_x burners that control fuel and air mixing to limit NO_x formation.

The purpose of this article is to summarize the existing Federal NO_x regulations and the 1996 performance of the 239 Title IV generating units. It also reviews the basics of low-NO_x burner technology and presents cost and performance data for retrofits at Title IV units.

NO_x Emissions Reductions

Federal Standards for New Units

Federal regulations on NO_x emissions have been established by the EPA in response to a series of amendments

to the Clean Air Act. The initial Federal standards on NO_x emissions for newly constructed utility power plants were called New Source Performance Standards. They were developed as a result of Title I, "Air Pollution Prevention Control," of the Clean Air Act of 1970 and applied to generating units that were constructed or modified between August 17, 1971, and September 18, 1978. Limits were specified as an allowable rate, that is, pounds of NO_x emissions per million British thermal units (Btu) of fuel input to the electric boiler. The limits varied for plants based on the type of fossil fuel consumed and, for coal-burning plants, the rank of coal used, that is, lignite versus bituminous (Table 1). The standards for new utility power plants were modified in the revised New Source Performance Standards of the Clean Air Act Amendments of 1977, which apply to all plants constructed or modified after September 18, 1978.

In July 1997, the EPA proposed another change in the New Source Performance Standards. A final rule is scheduled to be issued by September 3, 1998. The proposed regulation is groundbreaking in that it mandates pollution limits per unit of electricity generated rather than the traditional approach of limits per Btu of fuel input. The EPA is basing the proposed revisions to the New Source Performance Standards on the performance that can be achieved by selective catalytic reduction (SCR) technology. SCR technology is a method by which ammonia vapor is used as a reducing agent and is injected into the flue gas stream.²

Federal Standards for Existing Units

Title IV, "Acid Deposition Control," of the CAAA90 required the EPA to establish NO_x emissions standards for older generating units. These standards go into effect in two phases. The first phase began in 1996. The affected units consisted of units named in Table A of Title IV, "Affected Sources and Units," or their

Table 1. Utility NO_x Emission Requirements

Category	Number of Boilers	Standard (pounds of NO _x /million Btu)	Date for Compliance
Group 1			
Phase I	115 Dry Bottom Wall-Fired ^a	0.50	1/1/1996
	124 Tangentially Fired ^b	0.45	1/1/1996
Phase II	308 Dry Bottom Wall-Fired	0.46	1/1/2000
	299 Tangentially Fired	0.40	1/1/2000
Group 2	145 Other Types	0.68-0.86 ^c	1/1/2000
NSPS Units	All units with capacities greater than 73 megawatts that began operation or were modified between 8/17/71 & 9/18/78	0.8 for lignite from North Dakota, South Dakota, or Montana; 0.7 for solid fossil fuel; 0.6 for other lignite; 0.3 for oil; 0.2 for gas	8/17/1971
	All units with capacities greater than 73 megawatts that began operation or were modified after 9/18/78	0.8 for lignite from North Dakota, South Dakota, or Montana; 0.6 for other lignite, bituminous, and anthracite and 65 percent NO _x removal; 0.5 for subbituminous and 65 percent for NO _x removal; 0.3 for oil; 0.2 for gas	9/18/1978
Proposed Revisions for NSPS	All new or reconstructed units constructed after 7/9/97 with capacities greater than 25 megawatts	1.35 lbs/mWh	7/9/97

^aDry bottom refers to the form of the ash leaving the boiler. In dry bottom boilers, the temperature remains below the ash melting point, and the ash remains in a solid, "dry" form. Wall-fired refers to the placement and orientation of burners in the combustion chamber. Burners in wall-fired boilers are perpendicular to the wall of the chamber, either all on one wall (front) or split between two facing walls (opposed).

^bTangentially fired boilers are spaced around the chamber and angled to produce a rotating flame within the chamber.

^cGroup 2 boilers consist of 36 Cell Burners with a limit of 0.68 lbs/mmBtu, 55 Cyclone Burners with a limit of 0.86 lbs/mmBtu, 26 Wet Bottom Wall-Fired Burners with a limit of 0.84 lbs/mmBtu and 28 Vertically Fired boilers with a limit of 0.80 lbs/mmBtu.

lbs = pounds.

mmBtu = million Btu.

mWh = megawatthour.

NSPS = New Source Performance Standards.

Source: Energy Information Administration from Code of Federal Regulations and the U.S. Environmental Protection Agency.

substitution units that have tangentially fired³ or dry bottom wall-fired⁴ boilers. The second phase will begin in 2000.

utilities to "over-control" the emissions of those units that can be controlled more easily and less expensively than others.)

A utility can choose to comply with the EPA Title IV NO_x standards in one of four ways:

3. A utility that cannot meet the standard emissions limit may apply for a less stringent alternative emissions limit if it uses the applicable emissions control technology. EPA's determination of an alternative limit will be based on evidence that control equipment was properly designed, installed, and operated during a demonstration period.

1. Meet the standard as specified for each boiler type.

2. Average the emissions rates of two or more boilers that have the same owner or operator. (This allows

³ Tangentially fired boilers have burners spaced around the chamber and angled to produce a rotating flame within the chamber.

⁴ Dry bottom refers to the form of the ash leaving the boiler. In dry bottom boilers, the temperature remains below the ash melting point, and the ash remains in a solid, "dry" form. Wall-fired refers to the placement and orientation of burners in the combustion chamber. Burners in wall-fired boilers are perpendicular to the wall of the chamber, either all on one wall (front) or split between two facing walls (opposed).

4. A utility can apply for Phase I NO_x extensions. Utilities with boilers affected in Phase I qualified for two types of extensions from the Phase I NO_x requirements: (1) EPA granted NO_x compliance extensions (extension period varies by unit) to utilities that could not install the necessary control technology in time to comply; and (2) EPA granted NO_x extensions for 1996 compliance to utilities with units at which sulfur dioxide (SO₂) flue gas desulfurization equipment was installed under SO₂ Phase I extension plans. Twenty-seven units qualified for these extensions. Of the 27 units that received 1996 extensions, 25 had to comply starting in 1997, compliance activities for 1 had to begin in August 1997, and 1 had to comply at the beginning of 1998.⁵ All of these units are now in compliance with the NO_x standard.

First Phase Title IV NO_x Emissions Reductions

There were 239 coal-fired units required to meet the provisions of the first phase of the CAAA90 Title IV emissions limitations for NO_x. Phase I applied to units that were affected by the Phase I requirements for SO₂ under Title IV and had tangentially fired or dry bottom wall-fired boilers. The EPA has estimated the cost of the Phase I NO_x reduction program to the electric power industry would be \$267 million per year.⁶

All 239 units required to meet the Phase I limits on NO_x emissions in 1996—144 Table A units and 95 substitution units—underwent verification of emissions rates, and all of them met their reduction requirements. There were 115 dry bottom wall-fired boilers and 124 tangentially fired boilers affected in the first year of the program (Table 2).

For utility units required to meet the Phase I Title IV NO_x emissions limitations, both emissions rates and total emissions in 1996 were below 1990 levels. Their 1996 emission rates were cut by 40 percent, from the 1990 average of 0.65 pounds of NO_x per million Btu of heat

input to an average of 0.39 pounds of NO_x per million Btu.⁷ Compliance at the 239 units resulted in emissions levels approximately 314,000 tons (33 percent) below 1990 levels.⁸

Table 2. Boilers Subject to Title IV Phase I NO_x Reductions in 1996

Boiler Type	Standard NO _x Emissions Limit (lb/mm Btu)	Number of 1996 Table A Units	Number of Substitution Units
Tangentially Fired	0.45	82	42
Dry Bottom Wall-Fired	0.50	62	53

Source: U.S. Environmental Protection Agency, Acid Rain Program, 1996 Compliance Report, EPA 430-R-97-025 (Washington, DC, June 1997), p. 16.

A 38-percent reduction of approximately 290,000 tons of NO_x was achieved by the 144 Table A units affected in 1996. For the 95 substitution units, emissions were reduced by 51,000 tons or 17.5 percent. Many of the substitution units were already lower emitters of NO_x than the Table A units; for example, some had already been meeting a New Source Performance Standard only moderately higher than the 1996 Phase I limits. In fact, in 1990, some of the substitution units were already below the applicable NO_x emissions rates required by Title IV in 1996.⁹

Although average emissions rates for the 239 Phase I units were 40 percent lower in 1996 than in 1990, the amount of NO_x actually released into the air was only about 33 percent lower.¹⁰ The difference resulted from higher fuel use by Table A units and substitution units. Without further reductions in emissions rates, NO_x emissions from these units can be expected to rise with increased utilization.

The 1996 Emissions Scorecard released by EPA's Acid Rain Division¹¹ indicates that for 141 of the 239 Phase I

units, low-NO_x burner technologies were used for compliance in 1996 (Figure 1). At 67 of those units, low-NO_x burners were coupled with a two-stage combustion process called "overfire air." At three other units, overfire air technologies alone were used for compliance. Overfire air technology diverts about 20 percent of combustion air at the burner level to air ports above the burner zone, reducing the oxygen availability at the burners.¹²

Experience With Low-NO_x Burner Retrofits

Retrofitting existing generating units with low-NO_x burners was most frequently chosen for compliance because it is an economical way to limit the formation of NO_x. NO_x is produced through oxidation of nitrogen gas (N₂) in the air and nitrogen chemically bound in the coal. The amount of NO_x formed when coal burns is a function of the nitrogen content of the coal, the flame temperature, the amount and distribution of air during combustion, and the flame structure.

Low-NO_x burners control fuel and air mixing to create larger and more branched flames, reduce peak flame temperatures and lower the amount of NO_x formed. The improved flame structure also improves burner efficiency by reducing the amount of oxygen available in the hottest part of the flame. In principle, there are three stages in a conventional low-NO_x burner: combustion, reduction, and burnout. In the initial stage, combustion occurs in a fuel-rich, oxygen-deficient zone where the NO_x is formed. A reducing atmosphere follows, where hydrocarbons are formed and react with the already formed NO_x. In the third stage, internal air staging completes the combustion. Additional NO_x formation occurs in the third stage, but it can be minimized by an air-lean environment. Low-NO_x burners can also be combined with overfire air technologies to reduce NO_x further.¹³

Wall-Fired Boilers

Three general categories of low-NO_x burners for wall-fired boilers are (1) delayed combustion low-NO_x burners, (2) external staged low-NO_x burners, and, (3) internal staged low-NO_x burners.¹⁴ In delayed combustion burners, the fuel is burned slowly with long, low-intensity flames. The slow combustion and long flames result in lower flame temperatures, inhibiting thermal NO_x formation. The slow combustion retards early fuel and air mixing, inhibiting the oxidation of nitrogen chemically bound in the fuel.¹⁵ External staged burners function similarly to conventional burners but are equipped with tertiary air ports for staging conditions.¹⁶ Internal staged low-NO_x burners also retain conventional flame shapes but stage the combustion of the fuel and air within the burner itself. Internal staged low-NO_x burner technologies are more efficient at reducing NO_x while maintaining lower levels of unburned carbon.

Burner Performance

To assess the success of low-NO_x burner technologies in reducing NO_x emissions, data for wall-fired boilers before and after retrofitting with low-NO_x burners were

obtained from open literature and several utilities. The baseline emissions rates for the boilers represented in the data range from 0.57 to 1.34 pounds of NO_x per million Btu before the retrofits, with a mean of 0.99 pounds per million Btu. After the retrofits, the controlled emissions rates range from 0.27 to 0.60 pounds of NO_x per million Btu with a mean of 0.47 pounds of NO_x per million Btu.

System Impacts

Retrofitting low- NO_x burners in wall-fired boilers (Figures 2a and b) involves removing the existing burners and providing more space for the installation of the low- NO_x burners. Normally, small modifications to the waterwall¹⁷ and major modifications to the windbox are required for improved air distribution. Low- NO_x burners are generally larger than conventional burners, and extensive bending of waterwall tubes usually is required to provide the additional space. For small

furnaces, installation of low- NO_x burners may cause flames to impinge on the opposite wall of the furnace. Derating of the unit load may be required to prevent flame impingement, which causes very high heat flux in furnace tubes, from occurring. Flames contain chemicals in highly active forms, such as free radicals, that can corrode the tube metal at high temperatures.

Extensive restructuring of the boiler configuration was required when retrofits were applied at Arizona Public Service Company's Four Corners Unit 4. Originally, Four Corners Unit 4 had 9 coal pulverizers serving 18 three-nozzle cell burners. The retrofit with low- NO_x burners required the following modifications:

- Conversion to 8 pulverizers and 48 low- NO_x burners arranged in 4 rows of 6 burners on each firing wall

Figure 2. Burner and Flame Configurations

Source: G. Lotta, "Experience with Low- NO_x Burners," *IEA Coal Research* (London, November 1997), p. 15.

¹⁷ The side(s) of a boiler made of tubes through which water flows.

- New lower furnace waterwall panels designed for a conventional, widened burner spacing
- Replacement of burner piping
- Installation of a new coal pulverizer and burner control system.

Operation of low-NO_x burners in wall-fired boilers tends to increase unburned carbon in the ash. Unburned carbon can occur in both the bottom ash and the fly ash. Unburned carbon in the fly ash is termed "loss on ignition." Loss on ignition increased from 15 percent to 19 percent of the total fly ash weight when low-NO_x burners were installed at the New England Power Company's Salem Harbor Unit 1. At Salem Harbor Unit 3, the loss on ignition level increased from 8 percent to 16 percent.

Increases in carbon monoxide and unburned carbon levels are attributed to imbalances in the distribution of air and fuel.¹⁸ These problems can be alleviated by operating the low-NO_x burners with systems that accurately regulate the fuel and air supplies.¹⁹ Carbon monoxide and unburned carbon levels are very site-specific and depend on factors such as load, coal characteristics, furnace configuration and operating conditions.²⁰

Other system impacts may include slagging in the lower furnace region. Because low-NO_x burners are operated with fuel-rich conditions, a reducing environment is created, and coal slagging is increased. Modifications to the windbox²¹ may be required to achieve optimal air flow and distribution for efficient combustion. Windbox modifications may result in major structural changes to the boiler unit.²²

Low-NO_x burners are effective at reducing thermal NO_x formation because they reduce the high-temperature

flame regions that are characteristic of conventional burners. High temperatures in the flame zone promote slagging on the furnace walls. Therefore, the operation of low-NO_x burners can help reduce the rate of furnace slagging. This was evident during the operation of the low-NO_x burners at Four Corners Unit 4, where the furnace exit gas temperatures decreased, upper furnace heat absorption increased by 31 to 66 percent, and boiler efficiency increased by approximately 1 percent.²³

During the retrofit of the low-NO_x cell burner technology at Dayton Power and Light's Stuart Station Unit 4, a few burners were modified to prevent high levels of carbon monoxide and hydrogen sulfide formation. Corrosion rates increased on the furnace walls, and chromitized coating was applied to the walls to prevent such damages. No significant modifications were made during the retrofit of West Penn Power's Hatfield's Ferry Unit 2. Overall, no major modifications to the boiler configuration were required for the retrofit of the low-NO_x cell burner.²⁴ The cost of retrofitting a unit with low-NO_x burners varies (Table 3).

Systems with Overfire Air

Some wall-fired boilers combine the low-NO_x burner technology with an overfire air technology that creates two stages for combustion. The two-stage combustion requires a primary and a secondary source of combustion air. The secondary air nozzles are located above the burners. This system results in more complete burnout of the fuel and formation of N₂ rather than NO_x.

Table 3 shows cost data for retrofits at Public Service of New Hampshire's Schiller Station Units 4, 5, and 6. Estimated cost data indicate that the total capital costs associated with the installation of low-NO_x burner and overfire air systems depend on the following modification requirements:

1. Replacement or modification of existing burners
2. Installation of control and management systems for the low-NO_x burner and overfire air technology
3. Modifications to the fan and primary flow elements
4. Replacement of ignitors and scanners.²⁵

Tangentially Fired Boilers

Low-NO_x burner technology for tangentially fired boilers differs from that for wall-fired boilers because of differences in firing configurations between the two boiler types (Figure 2c). The most commonly applied low-NO_x burner technology in U.S. coal-fired boilers, the low-NO_x concentric firing system, is specifically designed for tangentially fired boilers. Three systems are available, Levels I, II, and III.

Unlike the technologies for wall-fired units, overfire air plays a more integrated role in the low-NO_x burner technologies applied to tangentially fired units. Level I is the only low-NO_x concentric firing system that does not use separated overfire air. Level II incorporates separated overfire air and Level III uses both separated

and close-coupled overfire air. In all three designs, protection against waterwall corrosion is achieved by diverting the combustion air toward the wall of the furnace. The close-coupled overfire air in the low-NO_x concentric firing system Level III is integrated into the existing windbox by exchanging the highest coal nozzle with the air nozzle immediately below it. Thus, the top row supplies overfire air, and the next lowest row is for coal burners.

Burner Performance

Low-NO_x concentric firing system retrofits require the replacement of all fuel and air nozzles; however, no major changes in the structure, windbox, or waterwall are needed. Retrofit applications of the low-NO_x concentric firing system Level I have shown significant control of NO_x emissions in tangentially fired boilers.

Performance data for the low-NO_x concentric firing system Level I technology were collected from open literature and several utilities. To protect proprietary data, the names and unit-specific information on units obtained from utilities are not provided. For the units studied, the controlled levels ranged from 0.34 to 0.55 pounds per million Btu. The reductions in emissions after the retrofits ranged from 10 to 48 percent. The

²⁵ David South, Energy Resources International, Unpublished Data, 1997.

control efficiencies for low-NO_x burners in tangentially fired units are lower than those reported for wall-fired boilers. Because the baseline emissions for tangentially fired units are lower than those in wall-fired units, the reductions to meet emissions standards are smaller.

Systems with Overfire Air

Low-NO_x concentric firing system Level II is operated with separated overfire air. Both close-coupled overfire air and separated overfire air are integrated into the low-NO_x concentric firing system Level III. With separated overfire air, more air at higher velocities can be introduced for better mixing. The Level III configuration allows for greater control and flexibility of air and fuel staging.

Several other low-NO_x burner and overfire air technologies are available for tangentially fired boilers, but they have not been widely applied. For example, the clustered concentric tangential firing system is an advancement of the low-NO_x concentric firing system, using burners that are grouped together. This design develops a more fuel-rich combustion environment than is produced in the low-NO_x concentric firing system.

Cost estimates were obtained for the low-NO_x burner and overfire air retrofits at two unnamed sites as well as for Public Service Company of Colorado's Valmont Unit 5 and Cherokee Unit 4 (Table 3). The estimates for the unnamed plants were provided by vendors.

Future Developments

Low-NO_x burners are one of the technologies that can be used for controlling NO_x emissions. New State and Federal standards for ozone will require additional reductions in NO_x emissions. Currently, both the standards and the NO_x control technologies are evolving. New NO_x emissions limits may come from a requirement that was issued by the EPA on October 11, 1997, which requires State Implementation Plans to meet the current Federal 1-hour ozone standard of 120 parts per billion. The EPA intends to publish a supplemental

notice of proposed rulemaking in early 1998 clarifying the requirement for ozone reduction. Part of the supplement will be a discussion of the interaction between the State Implementation Plan requirement and the CAAA90 Title IV requirements.²⁶

The State Implementation Plan requirement was issued by the EPA in response to a petition from the Ozone Transport Assessment Group (OTAG).²⁷ The OTAG petition called for the EPA to allow States to adopt a range of emissions levels to help meet ozone standards. OTAG also called for an intraregional emissions trading system. A final rulemaking is due in September 1998.

Additional NO_x emissions limits for utilities may come from the NO_x Budget Program of the Ozone Transportation Commission (OTC), or from Section 126 of the Clean Air Act, which allows any State or political subdivision to petition the EPA for a finding that "any major source or group of stationary sources emits or would emit" any air pollutant in violation of Title I of the Clean Air Act. EPA will issue a notice of proposed rulemaking based on the petitions of a number of eastern States by September 30, 1998, and will take final action by April 30, 1999.

The OTC, which represents the State Environmental Directors of the Ozone Transport Region,²⁸ designed the NO_x Budget Program with the goal of reducing region-wide emissions as part of the efforts by each State in the Ozone Transport Region to attain the national ambient air quality standards for ground-level ozone. These reductions are to occur in two phases, the first beginning in May 1999 and the second in May 2003.²⁹ From May through September 1999, the first period of the program, the region-wide seasonal NO_x budget cap is 219,000 tons. The cap will remain in place until 2003, the start of the second phase of the program, when it will be reduced to 143,000 tons of NO_x across the region. Each budget source will be allocated NO_x allowances from the State in which it is located, on either an annual or multi-year basis.

Another new ozone standard was released by EPA in July 1997 in response to a court order to tighten air quality rules. Although it is more stringent, at 80 parts

²⁶ Federal Register, CFR 40 Part 52, p. 9.

²⁷ OTAG was started in 1994 by the Environmental Council of the States and EPA to address the ozone standards under the Clean Air Act. Data showed significant movement or transport of ozone around the country, making it impossible for local regulators to address the problem individually.

²⁸ The OTC comprises Maine, New Hampshire, Vermont, Massachusetts, Connecticut, Rhode Island, New York, New Jersey, Pennsylvania, Maryland, Delaware, the northern counties of Virginia, and the District of Columbia.

²⁹ U.S. Environmental Protection Agency, "Ozone Transport Commission NO_x Budget Program: An Overview," obtained from the Acid Rain Division Website: www.epa.gov/acidrain/otc/ovrww.html

per billion rather than 120, the new standard is an 8-hour rather than a 1-hour standard. By 2000, States will be required to have designated areas for complying with the new standard. By 2003, implementation plans will be required.³⁰

As operators have gained more experience with low-NO_x burners, they have developed more effective

operating procedures to limit additional maintenance and costs. The cost and performance data for new technologies for controlling NO_x to comply with the proposed new standards are also likely to evolve with experience.

³⁰ Steven Rapp, U.S. Environmental Protection Agency, personal conversation, October 7, 1997.

Monthly Update

Nonutility Sales for Resale—February 1998

Total estimated sales of electricity for resale by nonutility power producers in the United States were 17 billion kilowatthours for February 1998. This reflected a level of sales for resale that was 5 percent lower than the level in February 1997, as well as a 10-percent decrease from January 1998.

Utility Generation and Retail Sales—February 1998

Generation. Total U.S. net generation of electricity was 265 billion kilowatthours, slightly above the amount reported in February 1997. The energy source with the largest quantitative increase in generation compared with February of last year was petroleum. Generation from petroleum-fired plants during the month was 28 percent above the level reported a year ago.

Sales. Total sales of electricity to ultimate consumers in the United States during February 1998 were 248 billion kilowatthours, 1 billion kilowatthours less than the level reported at this time in 1997. Compared with February 1997, retail sales of electricity in the industrial sector showed the largest increase at 2 billion kilowatthours (3 percent) followed by the commercial sector at an increase of 1 billion kilowatthours (1 percent). Sales of electricity in the residential sector were lower by 3 billion kilowatthours (3 percent).

Utility Fuel Receipts, Costs, and Quality—January 1998

Coal. January 1998 receipts of coal at electric utilities totaled a record 79 million short tons, up 7 million

short tons from the prior year level. This increase in receipts was the result of a more urgent need to replace coal consumed due to the lower level of coal stocks on hand at electric utilities at the start of the January 1998 as compared to January 1997. At the national level, beginning-of-month bituminous coal stocks had decreased to the 91 million short ton level as compared to 106 million short tons in January 1997. Deliveries of coal to electric utilities located in the West South Central Census division continue to be affected by rail congestion problems. Several coal-fired plants in this census division are operating with a minimum level of coal stocks. A drop in nuclear and hydroelectric generation in January 1998 from prior year levels were factors affecting the use of fossil fuels by electric utilities.

Petroleum. Receipts of petroleum totaled 10 million barrels, up slightly from January 1997 levels. The average weighted cost of Number 6 fuel oil was \$2.36 per million Btu as compared to \$3.06 per million Btu in January 1997.

Gas. Receipts of gas in January 1998 totaled 165 billion cubic feet (Bcf), up from 134 Bcf reported in January 1997. This increase was primarily due to a drop in the cost of gas from the prior year level. In January 1997, fears of a supply shortage at the start of the winter months caused a dramatic rise in natural gas prices and a corresponding decrease in receipts. The average cost of gas delivered to electric utilities in January 1998 was \$2.75 per million Btu as compared to \$4.08 per million Btu in January 1997.

Electricity Supply and Demand Forecast for 1998¹

The EIA prepares a short-term forecast for electricity that is published in the *Short-Term Energy Outlook*. This page provides that forecast for the current year along with explanations behind the forecast.²

- Electricity demand in 1998 is projected to grow in each of the five demand sectors. The overall total for 1998 is forecast at 2.4 percent above 1997 levels, which is higher than the 1.3 percent growth rate experienced in 1997.
- Residential demand for electricity in 1998 is projected to increase by 2.6 percent over 1997. This is due to the expected second and third quarter increase in cooling demand over the same period in 1997, when temperatures were milder than normal.
- Commercial sector demand is forecast to rise by 3.0 percent in 1998 and can be attributed mainly to expanding employment and favorable economic conditions. Industrial demand is projected to grow by 1.6 percent in 1998 reflecting the continuing growth in industrial output.
- Electricity generation at U.S. utilities is expected to grow at the rate of 1.3 percent, just slightly below the growth rate experienced in 1997. Nonutility generation is projected to rise by 4.2 percent, mainly due to capacity additions.
- Assuming that weather will be normal in 1998, hydropower generation by electric utilities is expected to decrease by 10.7 percent from the abnormally high levels seen in 1996 and 1997. These levels resulted from increased availability of hydroelectric generation due to high runoff conditions in the Pacific Northwest, created by above-average rainfall in both years.
- Nuclear power generation is expected to increase by 3.0 percent as it recovers from the negative growth seen in 1997, as many of the downed nuclear plants go back on line (but not back up to peak 1996 levels).
- Net imports of electricity from Canada are forecast to be 2.5 percent above last year's level. This ends a downward trend which began after the record high levels of imports seen in 1994.

¹Energy Information Administration, *Short-Term Energy Outlook: 2nd Quarter 1998*, DOE/EIA-0202 (98/2Q) (Washington, DC, April 1998).

See next page for footnotes

- 1 Values are estimates based on a cutoff sample; see Technical Notes for a discussion of the sample design for Form EIA-900.
- 2 Values for 1998 are estimates based on a cutoff model sample; see Technical Notes for a discussion of the sample design for the Form EIA-759; 1997 estimates have been adjusted to reflect the Form EIA-759 census data and are final; see Technical Notes for adjustment methodology.
- 3 Includes petroleum coke.
- 4 Represents total pumped storage facility production minus energy used for pumping. Pumping energy used at pumped storage plants for February 1998 was 1,781 million kilowatt-hours.
- 5 The February 1998 petroleum coke consumption was 134,698 short tons.
- 6 The February 1998 petroleum coke stocks were 358,158 short tons.
- 7 Values for 1998 are estimates based on a cutoff model sample; see Technical Notes for a discussion of the sample design for the Form EIA-826; values for 1997 have been revised and are preliminary. Retail revenue and retail average revenue per kilowatt-hour do not include taxes such as sales and excise taxes that are assessed on the consumer and collected through the utility. Retail sales and net generation may not correspond exactly for a particular month for a variety of reasons (i.e., sales data may include purchases of electricity from nonutilities or imported electricity). Net generation is for the calendar month while retail sales and associated revenue accumulate from bills collected for periods of time (28 to 35 days) that vary dependent upon customer class and consumption occurring in and outside the calendar month.
- 8 Includes public street and highway lighting, other sales to public authorities, sales to railroads and railways, and interdepartmental sales.
- 9 Values are preliminary for 1998 and final for 1997.
- 10 The January 1998 petroleum coke receipts were 120,679 short tons.
- 11 Average cost of fuel delivered to electric generating plants; cost values are weighted values.
- 12 January 1998 petroleum coke cost was 90.7 cents per million Btu.
- 13 Includes small amounts of coke-oven, refinery, and blast-furnace gas.

* = For detailed data, the absolute value is less than 0.5; for percentage calculations, the absolute value is less than 0.05 percent.

NM = This value may not be applicable or the percent difference calculation is not meaningful.

Notes: * = means the absolute value of the number is less than 0.5. *Totals may not equal sum of components because of independent rounding. *Percent difference is calculated before rounding. *kWh=kilowatt-hours, and Mcf=thousand cubic feet. *Monetary values are expressed in nominal terms.

Industry Developments

California Successfully Starts Deregulated Electricity Market

After a 3-month delay caused by computer problems and the need for additional testing of the system, California opened its electricity market to competition. On March 31, 1998, the 10 million customers of Southern California Edison Company (SCE), Pacific Gas & Electric Company (PG&E), and San Diego Gas & Electric Company (SDG&E), that represent 70 percent of electricity customers and 80 percent of electricity consumption in California, were allowed to choose their electricity service provider (ESP). However, according to the Los Angeles Times, fewer than 40,000 of the 10 million eligible customers have decided to switch to a new ESP. Of the large commercial and industrial customers that account for two-thirds of electricity consumption in California, approximately 10 percent have switched to a new ESP.

Currently, municipal utilities and their customers are not participating in the deregulated market system. Municipals will be given the option to join the system and open their service areas to competition in 2 years.

The electricity market system now in place in California is operated by two new entities, the *California Power Exchange (PX)* and the *Independent System Operator (ISO)*. The primary function of the PX is to set the price of electricity based on the supply and demand bids for electricity received through an auction market. The ISO is responsible for the operation of the transmission network and to ensure system reliability. Though separate entities, a large amount of coordination between the PX and the ISO is required for efficient and reliable operation of the system.

The PX is a non-profit corporation set up to provide an "efficient, competitive energy auction that meets the load requirements of PX customers at market prices." It will set the price of electricity, referred to as the *Market Clearing Price (MCP)*, on an hourly basis, based on demand and supply bids from those wanting to buy and sell power to the PX. Auctions will be conducted to set the MCP of electricity for two distinct markets, the Day-Ahead market and the Hour-Ahead market. In the Day-

Ahead market, participants bid supply and demand commitments for the next 24 hours of market operation. The Day-Ahead market starts at 6:00 a.m. on the day ahead of the trading day, and closes at 1:00 p.m. the same day. Closing is conditioned upon the ISO accepting the final day-ahead schedule. The Hour-Ahead market, which is scheduled to begin later in the year, will allow participants to buy and sell electricity closer to the delivery schedule in order to fine-tune their commitments made in the Day-Ahead market.

Not all power transactions are bid through the PX. While SCE, PG&E, and SDG&E "must buy from and sell all" their generation through the PX from March 1998 through March 2002, independent power producers, municipal generators, aggregators, and electric utilities located outside of California will have the option of using the PX. They can either buy and sell electricity through the PX or sell it directly to a customer. However, transactions conducted outside the PX auction market must still go through a Scheduling Coordinator who will coordinate the transaction with the ISO in order to secure transmission access and maintain system reliability. If the ISO determines that the schedule submitted by the PX will result in congestion¹ on the transmission system, the ISO can change the MCP of electricity through "adjustment bids" that will serve to either increase or decrease electricity supply or demand as needed. All rules and service charges of the PX will be regulated by the Federal Energy Regulatory Commission.

The ISO is the control area operator for the transmission systems of SCE, PG&E, and SDG&E. It ensures that all buyers and sellers of electricity have access to the transmission system. Previously in California, each of the investor-owned electric utilities operated a control area in which they had to balance the generation and consumption of power. In the new market, the ISO will control the dispatch of generation, provide access for transmission, maintain system reliability, manage transmission schedules, and provide real-time balancing of load and generation for the entire system. The ISO will work with the PX to ensure that the day-ahead schedule is feasible for the transmission system, and ensure that existing transmission contracts receive

¹ Power flow exceeds transmission capacity.

priority in using the transmission system. To ensure system reliability, the PX and other Scheduling Coordinators will provide information to the ISO that will include schedules of operation for individual generating units. Information will also be provided to the ISO on schedules for delivery of generated power, including the point in the transmission system from which electricity will be delivered. Based on this data, the ISO will be able to determine if adjustments will be necessary to avoid congestion on the transmission system. While the PX will operate in a forward-looking mode to schedule electricity transactions, the ISO will manage the market in a real-time mode to ensure balance in energy supply and demand.²

Though the ISO will manage the transmission system, each electric utility will continue to own their transmission and distribution networks. However, all users of the transmission system will pay a fee for services that are required to maintain the system and to ensure system reliability. These ISO support services or 'ancillary' services will include automatic generation control (needed to balance generation with demand for generation), spinning reserve (synchronized generating capacity that is not online but immediately available), non-spinning reserve (generating capacity with less than 10 minutes of response time), and replacement reserve (generating capacity available within 60 minutes). They will be provided through a competitive market where market participants will make bids through the PX for the necessary reserves that are required by the ISO. Other ancillary services that the ISO will provide include Reactive Power (to maintain system voltage), and Generation Black Start (to provide for recovery during a major outage).³

Maryland Lawmakers Veto Electric Deregulation In 1998 Session

Within days of the Maryland State Senate approving a bill that would have allowed electric competition in the State starting July 3, 2000, the 188 member General Assembly voted against the measure and eliminated any hope that the issue could be resolved during the 1998 session.

Though most state lawmakers had not expected deregulation to be up for a vote during the current session, the

legislation took an unexpected turn in early April when the State Senate approved a bill that would have opened Maryland's electric market to competition. According to *The Washington Post*, the quick action by the State Senate "caught the utilities off guard and surprised some industry watchers." Apparently, electric utilities in the state have been working with the Maryland Public Service Commission (MPSC) to come up with a comprehensive legislative package that also would have allowed competition to start in July, 2000. However, some state lawmakers believed that the MPSC "is too close to the utilities" and that it has not moved fast enough on the issue of deregulation. An opportunity for the Senate to force the issue came when the House of Delegates passed a bill that allowed the Baltimore Gas & Electric Company (BG&E) to create a holding company for unregulated subsidiaries. The Senate Finance Committee then amended the House bill to require that "all or a portion" of electric customers in Maryland be allowed to choose their electric supplier by July 2000. The bill was then passed by the Maryland State Senate and was widely applauded by power marketers and large commercial and industrial consumers of electricity. However, enactment was contingent on the General Assembly passing additional legislation that would address issues that include state and local taxation, energy conservation, pollution control, ensuring affordable electric rates for low-income consumers, and regulation of transactions between a utility and its holding company.⁴

The vote against the legislation by the General Assembly not only halted deregulation for the time being, but also killed an attempt by BG&E to create a holding company. Another attempt at passing an electric deregulation bill is expected during the 1999 session of the General Assembly.

Enron to Leave California Residential Sales Market

Enron Corporation (Enron) has announced that it will no longer pursue residential electricity customers in California due to a poor response from consumers and the fact that the business will not be as profitable as the company had once thought. The loss of Enron from the deregulated electric market in California is a serious blow to competition in the State. Enron was one of the

² California Power Exchange, PX Primer, "The Basics: How the PX Works," extracted from the Internet at <http://www.calpx.com/index.htm> (extracted on April 16, 1998).

³ L. Moore and J.H. Anderson, "Introduction To The New California Power Market," extracted from the Internet at <http://www.calpx.com> (extracted on April 24, 1998).

⁴ C. Babington and M.M. Hamilton, "Md. Senate Approves Electric Deregulation," *The Washington Post*, April 3, 1998.

marketers of electricity to enter the State and offer an alternative to the monopolies once held by the three investor-owned electric utilities, Pacific Gas & Electric Company, Southern California Edison Company, and San Diego Gas & Electric Company.

According to the *Wall Street Journal (WSJ)*, Enron had signed up only 30,000 residential customers, a number that is considerably less than what the company had originally thought it could sign. Besides a lack of response by residential customers to its marketing plea, Enron stated its dislike for the Competitive Transition Charge (CTC). The CTC, which according to the *WSJ* accounts for approximately one-third of an average customer's bill, is a charge that is paid to electric utilities to cover their stranded costs. These are investments in plants or contracts that would have been recovered in a regulated environment through a rate of return but would not be recovered in an unregulated or competitive environment. Enron noted that a 3-month delay in deregulation in California, and well publicized problems with some electric marketers in the State "contributed to customers lack of interest" in switching energy service providers.

Enron will continue to seek commercial and industrial customers, an area where it has been quite successful. It

has recently signed an electricity contract with the California State college system. Consumer advocates in California pointed out that Enron's decision reinforces their thinking that the "small electricity user will see few of the benefits of a competitive industry."⁵

Nevada Power and Sierra Pacific Resources to Merge

The Nevada Power Company and Sierra Pacific Resources have announced their intention to merge into a new holding company called Sierra Pacific Resources (SPR). SPR will serve 800,000 electric, 100,000 gas, and 65,000 water customers located in Nevada and in the Lake Tahoe area of California through its subsidiaries that include the Nevada Power Company and Sierra Pacific Power Company. Company officials expect merger related savings from the elimination of duplicate corporate programs and greater efficiencies in operations to total approximately \$350 million over a 10-year period. Regulatory approval is required from the Nevada Public Utilities Commission, the Federal Energy Regulatory Commission, and the Securities and Exchange Commission, and is expected to take about 1 year.⁶

¹ Includes fuel oils nos. 1, 2, 4, 5, and 6, crude oil, kerosene, and petroleum coke

² Includes supplemental gaseous fuel

³ Includes biomass, wind, photovoltaic, and solar thermal energy sources

NA This estimated value is not available due to insufficient data or inadequate anticipated data/model performance

NA = Not available

Notes: *Values for electric utilities for 1998 are estimates based on a cutoff model sample--see Technical Notes for a discussion of the sample design for the Form EIA-759. Values for electric utilities for 1997 have been adjusted to reflect the Form EIA-759 census data and are final--see Technical Notes for adjustment methodology. Values for electric utilities for 1996 and prior years are final. *Values for nonutilities (Form EIA-867) for 1996 and prior years are final, and for 1997 are preliminary. *Totals may not equal sum of components because of independent rounding.

Sources: Energy Information Administration, Form EIA-759, "Monthly Power Plant Report"; Form EIA-867, "Annual Nonutility Power Producers Report."

1996	453,333	289,982	16,115	29,382	118,869	-936

¹ Includes lignite, bituminous coal, subbituminous coal, and anthracite.

² Includes fuel oil Nos. 2, 4, 5, and 6, crude oil, kerosene, and petroleum cokes.

³ Pumping energy used for pumped storage plants for February 1998 was 1,781 million kilowatthours.

Notes: *Values for 1998 are estimates based on a cutoff model sample--see Technical Notes for a discussion of the sample design for the Form EIA-759. Values for 1997 have been adjusted to reflect the Form EIA-759 census data and are final--see Technical Notes for adjustment methodology. Values for 1996 and prior years are final. *Totals may not equal sum of components because of independent rounding.

* = For detailed data, the absolute value is less than 0.5, for percentage calculations, the absolute value is less than 0.05 percent

NM = This estimated value is not available due to insufficient data or inadequate anticipated data/model performance, information may not be applicable, or the percent difference calculation is not meaningful

Notes: *Values for 1998 are estimates based on a cutoff model sample--see Technical Notes for a discussion of the sample design for the Form EIA-759. Values for 1997 have been adjusted to reflect the Form EIA-759 census data and are final. *Negative generation denotes that electric power consumed for plant use exceeds gross generation. *Totals may not equal sum of components because of independent rounding. *Percent difference is calculated before rounding.

* = For detailed data, the absolute value is less than 0.5, for percentage calculations, the absolute value is less than 0.05 percent

NM = This estimated value is not available due to insufficient data or inadequate anticipated data/model performance; information may not be applicable, or the percent difference calculation is not meaningful

Notes: Values for 1998 are estimates based on a cutoff model sample—see Technical Notes for a discussion of the sample design for the Form EIA-759. Values for 1997 have been adjusted to reflect the Form EIA-759 census data and are final. Negative generation denotes that electric power consumed for plant use exceeds gross generation. Totals may not equal sum of components because of independent rounding. Percent difference is calculated before rounding. Other energy sources include geothermal, wood, wind, waste, and solar.

¹ Includes anthracite silt stored off-site.

² Includes subbituminous coal.

Notes: *Values for 1998 are estimates based on a cutoff model sample—see Technical Notes for a discussion of the sample design for the Form EIA-759. Values for 1997 have been adjusted to reflect the Form EIA-759 census data and are final—see Technical Notes for adjustment methodology. Values for 1996 and prior years are final. *Totals may not equal sum of components because of independent rounding. *Mcft=thousand cubic feet.

Alaska	NM	NM	NM	1	-27.5
Hawaii	937	998	1,013	-6.0	-7.4
U.S. Total	49,687	49,837	46,402	-3	7.1

* = For detailed data, the absolute value is less than 0.5, for percentage calculations, the absolute value is less than 0.05 percent

NM = This estimated value is not available due to insufficient data or inadequate anticipated data/model performance; information may not be applicable, or the percent difference calculation is not meaningful

Notes: *Values for 1998 are estimates based on a cutoff model sample—see Technical Notes for a discussion of the sample design for the Form EIA-759. Values for 1997 have been adjusted to reflect the Form EIA-759 census data and are final. *Totals may not equal sum of components because of independent rounding. *Percent difference is calculated before rounding. *Data do not include petroleum coke. *The February 1998 petroleum coke stocks were 358,158 short tons. *Stocks are end-of-month stocks at electric utilities

Receipts and Cost of Fossil Fuels at U.S. Electric Utilities

January 1998 Receipts and Cost Data

At the time of publication, all submissions for the FERC Form 423, "Monthly Report of Cost and Quality of Fuels at Electric Plant," had been received.

Table 26. U.S. Electric Utility Receipts of and Average Cost for Fossil Fuels, 1988 Through January 1998

Period	Coal ¹		Petroleum				Gas		All Fossil Fuels ²
	Receipts (thousand short tons)	Cost (cents/ 10 ⁶ Btu)	Heavy Oil ³		Total		Receipts (thousand Mcf)	Cost (cents/ 10 ⁶ Btu)	Cost (cents/ 10 ⁶ Btu)
			Receipts (thousand barrels)	Cost (cents/ 10 ⁶ Btu)	Receipts (thousand barrels)	Cost (cents/ 10 ⁶ Btu)			
1988	727,775	146.6	230,234	248.8	236,924	243.9	2,362,721	226.3	164.3

¹ Includes lignite, bituminous coal, subbituminous coal, and anthracite

² The weighted average for all fossil fuels includes both heavy oil and light oil (Fuel Oil No. 2, kerosene, and jet fuel) prices. Data do not include petroleum coke

³ Heavy oil includes Fuel Oil Nos. 4, 5, and 6, and topped crude fuel oil

⁴ Data for 1998 are preliminary. Data for 1997 are final

Notes: Totals may not equal sum of components because of independent rounding. As of 1991, data are for electric generating plants with a total steam-electric and combined-cycle nameplate capacity of 50 or more megawatts. Data for 1988-1990 are for steam-electric plants with a generator nameplate capacity of 50 or more megawatts. Mcf=thousand cubic feet. Monetary values are expressed in nominal terms

Notes: Data for 1998 are preliminary. Data for 1997 are final. Totals may not equal sum of components because of independent rounding. Data are for electric generating plants with a total steam-electric and combined-cycle nameplate capacity of 50 or more megawatts. Includes small quantities of coke-oven, refinery, and blast-furnace gas. Mcf=thousand cubic feet.

1998	284,735	142,824	164,855	16,129	521,742

¹ Includes public street and highway lighting, other sales to public authorities, sales to railroads and railways, and interdepartmental sales.

Notes: *Values for 1998 are estimates based on a cutoff model sample; see Technical Notes for a discussion of the sample design for the Form EIA-826. Values for 1997 have been revised and are preliminary. Values for 1996 and prior years are final. *Values for 1996 in the commercial and industrial sectors for Maryland, the South Atlantic Census Division, and the U.S. Total reflect an electric utility's reclassification for this information by Standard Industrial Classification Code (SIC). *Retail sales and net generation may not correspond exactly for a particular month for a variety of reasons (i.e., sales data may include purchases of electricity from nonutilities or imported electricity). Net generation is for the calendar month while retail sales and associated revenue accumulate from bills collected for periods of time (28 to 35 days) that vary dependent upon customer class and consumption occurring in and outside the calendar month. *Totals may not equal sum of components because of independent rounding.

¹ Includes public street and highway lighting, other sales to public authorities, sales to railroads and railways, and interdepartmental sales.

Notes: *Values for 1998 are estimates based on a cutoff model sample; see Technical Notes for a discussion of the sample design for the Form EIA-826. Values for 1997 have been revised and are preliminary. *Retail sales and net generation may not correspond exactly for a particular month for a variety of reasons (i.e., sales data may include purchases of electricity from nonutilities or imported electricity). Net generation is for the calendar month while retail sales and associated revenue accumulate from bills collected for periods of time (28 to 35 days) that vary dependent upon customer class and consumption occurring in and outside the calendar month. *Totals may not equal sum of components because of independent rounding.

¹ Includes public street and highway lighting, other sales to public authorities, sales to railroads and railways, and interdepartmental sales.

Notes: *See technical notes for CV methodology. *It should be noted that such things as large changes in retail sales, reclassification of retail sales, or changes in billing procedures can contribute to unusually high coefficients of variations.

¹ Includes public street and highway lighting, other sales to public authorities, sales to railroads and railways, and interdepartmental sales.

Notes: *Values for 1998 are estimates based on a cutoff model sample, see Technical Notes for a discussion of the sample design for the Form EIA-826. Values for 1997 have been revised and are preliminary. *Retail sales and net generation may not correspond exactly for a particular month for a variety of reasons (i.e., sales data may include purchases of electricity from nonutilities or imported electricity). Net generation is for the calendar month while retail sales and associated revenue accumulate from bills collected for periods of time (28 to 35 days) that vary dependent upon customer class and consumption occurring in and outside the calendar month. *Totals may not equal sum of components because of independent rounding.

¹ Includes public street and highway lighting, other sales to public authorities, sales to railroads and railways, and interdepartmental sales.

Notes: Values for 1998 are estimates based on a cutoff model sample. See Technical Notes for a discussion of the sample design for the Form EIA-826. Values for 1997 have been revised and are preliminary. Retail sales and net generation may not correspond exactly for a particular month for a variety of reasons (i.e., sales data may include purchases of electricity from nonutilities or imported electricity). Net generation is for the calendar month while retail sales and associated revenue accumulate from bills collected for periods of time (28 to 35 days) that vary dependent upon customer class and consumption occurring in and outside the calendar month. Totals may not equal sum of components because of independent rounding.

¹ Includes public street and highway lighting, other sales to public authorities, sales to railroads and railways, and interdepartmental sales.

Notes: *Values for 1998 are estimates based on a cutoff model sample, see Technical Notes for a discussion of the sample design for the Form EIA-826. Values for 1997 have been revised and are preliminary. Retail sales and net generation may not correspond exactly for a particular month for a variety of reasons (e.g., sales data may include purchases of electricity from nonutilities or imported electricity). Net generation is for the calendar month while retail sales and associated revenue accumulation from bills collected for periods of time (28 to 35 days) that vary dependent upon customer class and consumption occurring in and outside the calendar month. *Totals may not equal sum of components because of independent rounding.

¹ Other energy sources include geothermal, solar, wood, wind, and waste

* Less than 0.05

Notes: *Data for 1997 are final. *Totals may not equal sum of components because of independent rounding. *Net generation for jointly owned units is reported by the operator. *Negative generation denotes that electric power consumed for plant use exceeds gross generation. *Station losses include energy used for pumped storage. *Generation is included for plants in test status. *Nuclear generation is included for those plants with an operating license issued authorizing fuel loading/low power testing prior to receipt of full power amendment. *Central storage is a common area for fuel stocks not assigned to specific plants. *Mcf=thousand cubic feet and bbls=barrels. *Holding Companies are: AEP is American Electric Power, APS is Allegheny Power System, ACE is Atlantic City Electric, CSW is Central & South West Corporation, CBS is Commonwealth Energy System, DMV is Delmarva, ECU is Eastern Utilities Associates Company, GFS is General Public Utilities, MSU is Middle South Utilities, NEES is New England Electric System, NU is Northeast Utilities, SC is Southern Company, TU is Texas Utilities.

¹ The January 1998 petroleum cake receipts were 120,579 short tons and the cost was 90.7 cents per million Btu.

² Monetary values are expressed in nominal terms.

³ The entry includes at least one delivery at a price of 1,000 cents per million Btu or greater. High price is frequently caused when fixed costs are averaged into a small quantity.

* Less than 0.05.

Notes: *Data for 1998 are preliminary. *Totals may not equal sum of components because of independent rounding. *Data are for electric generating plants with a total steam-electric and combined-cycle nameplate capacity of 50 or more megawatts. *Millionthousand cubic feet and thousand barrels.

¹ Other energy sources include geothermal, solar, wood, wind, and waste.

* = For detailed data, the absolute value is less than 0.5; for percentage calculations, the absolute value is less than 0.05 percent.

NM = This value is not available due to insufficient data, inadequate anticipated data/model performance, the percent difference calculation is not meaningful.

Notes: *Totals may not equal sum of components because of independent rounding. *Net generation for jointly owned units is reported by the operator. *Negative generation denotes that electric power consumed for plant use exceeds gross generation. *Station losses include energy used for pumped storage. *Generation is included for plants in test status. *Nuclear generation is included for those plants with an operating license issued authorizing fuel loading/low power testing prior to receipt of full power amendment. *Central storage is a common area for fuel stocks not assigned to specific plants. *Mcf=thousand cubic feet and bbls=barrels. *Data for 1997 are final. *Holding Companies are: AEP is American Electric Power, APS is Allegheny Power System, ACE is Atlantic City Electric, CSW is Central & South West Corporation, CES is Commonwealth Energy System, DMV is Delmarva, EU is Eastern Utilities Associates Company, GPS is General Public Utilities, MSU is Middle South Utilities, NEES is New England Electric System, NU is Northeast Utilities, SC is Southern Company, TU is Texas Utilities.

General Information

Articles

Feature articles on electric power energy-related subjects are frequently included in this publication. The following articles and special focus items have appeared in previous issues.

June 1990	Petroleum Fuel-Switching Capability in the Electric Utility Industry
April 1991	U.S. Wholesale Electricity Transactions
April 1992	Electric Utility Demand-Side Management
April 1992	Nonutility Power Producers
August 1992	Performance Optimization and Repowering of Generating Units
February 1993	Improvement in Nuclear Power Plant Capacity Factors
October 1993	Municipal Solid Waste in the U.S. Energy Supply
November 1993	Electric Utility Demand-Side Management and Regulatory Effects
November 1994	The Impact of Flow Control and Tax Reform on Ownership and Growth in the U.S. Waste-to-Energy Industry
July 1995	Nonutility Electric Generation: Industrial Power Production
August 1995	Steam Generator Degradation and Its Impact on Continued Operation of Pressurized Water Reactors in the United States
September 1995	New Sources of Nuclear Fuel
November 1995	Relicensing and Environmental Issues Affecting Hydropower
May 1996	U.S. Electric Utility Demand-Side Management: Trends and Analysis
June 1996	Upgrading Transmission Capacity for Wholesale Electric Power Trade
May 1998	Reducing Nitrogen Oxide Emissions: 1996 Compliance with Title IV Limits

Appendix B

Technical Notes

Data Sources

The *Electric Power Monthly (EPM)* is prepared by the Electric Power Division, Office of Coal, Nuclear, Electric and Alternate Fuels (CNEAF), Energy Information Administration (EIA), U.S. Department of Energy. Data published in the EPM are compiled from seven data sources. Those forms are: the Form EIA-759, "Monthly Power Plant Report," the Form EIA-900, "Monthly Nonutility Sales for Resale Report," the FERC Form 423, "Monthly Report of Cost and Quality of Fuels for Electric Plants," the Form EIA-826, "Monthly Electric Utility Sales and Revenue Report with State Distributions," the Form EIA-861, "Annual Electric Utility Report," the Form EIA-860, "Annual Electric Generator Report," and the Form EIA-867, "Annual Nonutility Power Producer Report."

Form EIA-759

The Form EIA-759 is a cutoff model sample of approximately 360 electric utilities drawn from the frame of all operators of electric utility plants (approximately 700 electric utilities) that generate electric power for public use. Data will be collected on an annual basis from the remaining operators of electric utility plants. The new monthly data collection is from all utilities with at least one plant with a nameplate capacity of 25 megawatts or more. (Note: includes all nuclear units). However, the few utilities that generate electricity using renewable fuel sources other than hydroelectric are all included in the sample. The Form EIA-759 is used to collect monthly data on net generation; consumption of coal, petroleum, and natural gas; and end-of-the-month stocks of coal and petroleum for each plant by fuel-type combination. Summary data from the Form EIA-759 are also contained in the *Electric Power Annual (EPA)*, *Monthly Energy Review (MER)*, and the *Annual Energy Review (AER)*. These reports present aggregate data estimates for electric utilities at the U.S., Census division, and North American Electric Reliability Council Region (NERC) levels.

Instrument and Design History. Prior to 1936, the Bureau of the Census and the U.S. Geological Survey collected, compiled, and published data on the electric power industry. In 1936, the Federal Power Commission (FPC) assumed all data collection and

publication responsibilities for the electric power industry and implemented the FPC Form 4. The Federal Power Act, Sections 311 and 312, and FPC Order 141 define the legislative authority to collect power production data. The Form EIA-759 replaced the FPC Form 4 in January 1982. As of the January 1996 reporting period, the Form EIA-759 was changed to collect data from a cutoff model sample of plants with a nameplate capacity of 25 megawatts or more.

Data Processing. The Form EIA-759, along with a return envelope, is mailed to respondents approximately 4 working days before the end of the month. The completed forms are to be returned to the EIA by the 10th day after the end of the reporting month. After receipt, data from the completed forms are manually logged in and edited before being keypunched for automatic data processing. An edit program checks the data for errors not found during manual editing. The electric utilities are telephoned to obtain data in cases of missing reports and to verify data when questions arise during editing. After all forms are received from the respondents, the final automated edit is submitted. Following verification of the data, text and tables of aggregated data are produced for inclusion in the EPM. Following EIA approval of the EPM, the data are made available for public use, on a cost-recovery basis, through custom computer runs, data tapes, or in publications.

FERC Form 423

The Federal Energy Regulatory Commission (FERC) Form 423 is a monthly record of delivered-fuel purchases, submitted by approximately 230 electric utilities for each electric generating plant with a total steam-electric and combined-cycle nameplate capacity of 50 or more megawatts. Summary data from the FERC Form 423 are also contained in the EPA, MER, and the *Cost and Quality of Fuels for Electric Utility Plants - Annual*. These reports present aggregated data on electric utilities at the U.S., Census division, and State levels.

Instrument and Design History. On July 7, 1972, the FPC issued Order Number 453 enacting the New Code of Federal Regulations, Section 141.61, legally creating the FPC Form 423. Originally, the form was used to collect data only on fossil-steam plants, but was

amended in 1974 to include data on internal combustion and combustion turbines. The FERC Form 423 replaced the FPC Form 423 in January 1983. The FERC Form 423 eliminated peaking units, which were previously collected on the FPC Form 423. In addition, the generator nameplate capacity threshold was changed from 25 megawatts to 50 megawatts. This reduction in coverage eliminated approximately 50 utilities and 250 plants. All historical FPC Form 423 data in this publication were revised to reflect the new generator nameplate capacity threshold of 50 or more megawatts reported on the FERC Form 423. In January 1991, the collection of data on the FERC Form 423 was extended to include combined-cycle units. Historical data have not been revised to include these units. Starting with the January 1993 data, the FERC began to collect the data directly from the respondents.

Data Processing. The FERC processes the data through edits and each month provides the EIA with a diskette containing the data. The EIA reviews the data for accuracy. Beginning with May 1994 data, an additional quality check began in which coal data are compared with data prepared by Resource Data International, Inc., of Boulder, Colorado. Following verification of the data, text and tables of aggregated data are produced for inclusion in the *EPM*. After the *EPM* is cleared by the EIA, the data become available for public use, on a cost-recovery basis, through custom computer runs or in publications.

Form EIA-826

The Form EIA-826 is a monthly collection of data from approximately 260 of the largest primarily investor-owned and publicly owned electric utilities. A model is then applied to estimate for the entire universe of U.S. electric utilities. The electric power sales data are used by the Federal Reserve Board in their economic analyses.

Instrument and Design History. The collection of electric power sales, revenue, and income data began in the early 1940's and was established as FPC Form 5 by FPC Order 141 in 1947. In 1980, the report was revised with only selected income items remaining and became the FERC Form 5. The Form EIA-826 replaced the FERC Form 5 in January 1983. In January 1987, the Form EIA-826 was changed to the "Monthly Electric Utility Sales and Revenue Report with State Distributions." It was formerly titled, "Electric Utility Company Monthly Statement." The Form EIA-826 was revised in January 1990, and some data elements were eliminated. In 1993, EIA for the first time used a model sample for the Form EIA-826. A stratified-random sample, employing auxil-

iary data, was used for each of the 4 previous years. (See previous issues of this publication, and (Knaub, 12) for details.) The current sample for the Form EIA-826, which was designed to obtain estimates of electricity sales and revenue per kilowatthour at the State level by end-use sector, was chosen to be in effect for the January 1993 data.

Frame. The frame for the Form EIA-826 was originally based on the 1989 submission of the Form EIA-861 (Section 1.4), which consisted of approximately 3,250 electric utilities selling retail and/or sales for resale. Note that for the Form EIA-826, the EIA is only interested in retail sales. Updates have been made to the frame to reflect mergers that affect data processing. Some electric utilities serve in more than one State. Thus, the State-service area is actually the sampling unit. For each State served by each utility, there is a utility State-part, or "State-service area." This approach allows for an explicit calculation of estimates for sales, revenue, and revenue per kilowatthour by end-use sector (residential, commercial, industrial and other) at State, Census division, and the U.S. level. Regressor data came from the Form EIA-861. (Note that estimates at the "State level" are for sales for the entire State, and similarly for "Census division" and "U.S." levels.)

The preponderance of electric power sales to ultimate consumers in each State are made by a few large utilities. Ranking of electric utilities by retail sales on a State-by-State basis revealed a consistent pattern of dominance by a few electric utilities in nearly all 50 States and the District of Columbia. These dominant electric utilities were selected as a model sample. These electric utilities constitute about 8 percent of the population of U.S. electric utilities, but provide three-quarters of the total U.S. retail electricity sales. The procedures used to derive electricity sales, revenue, revenue per kilowatthour, and associated coefficient of variation (CV) estimates are provided in the Form EIA-826 subsection of the Formulas Data Section. See (Knaub, 12) for a study of CV estimates for this survey.

Data Processing. The forms are mailed each year to the electric utilities with State-parts selected in the sample. The completed form is to be returned to the EIA by the last calendar day of the month following the reporting month. Nonrespondents are telephoned to obtain the data. Imputation, in model sampling, is an implicit part of the estimation. That is, data that are not available, either because it was not part of the sample or because the data are missing, are estimated using a model. The data are edited and entered into the computer where additional checks are completed. After all forms have been received from the respondents, the final automated

edit is submitted. Following verification, tables and text of the aggregated data are produced for inclusion in the EPM. After the EPM receives clearance from the EIA, the data are made available for public use through custom computer runs, data tapes, or in publications (EPA, AER) on a cost-recovery basis.

Form EIA-900

The Form EIA-900, "Monthly Nonutility Sales for Resale Report," is a cutoff model sample drawn from the frame for the Form EIA-867, "Annual Nonutility Power Producer Report." Members of the Form EIA-867 frame with nameplate capacity greater than or equal to 50 megawatts constitute the sample for the Form EIA-900. Unlike the Form EIA-867 which gathers data on a number of topics, however, the Form EIA-900 currently is used to collect data on only one element, sales by nonutilities for resale through the power grid.

Instrument and Design History. The Form EIA-900 was implemented to collect monthly data, starting with January 1996. The reason for its inception was to fill, in part, a "data gap" that existed on a monthly basis when comparing utility sales to end users (from the Form EIA-826) with utility generation (from the Form EIA-759). This data gap occurred because utility sales data include electricity purchased from nonutilities and because of other factors such as transmission losses and imports/exports. In light of sampling and nonsampling error, a more complete description of events may be gleaned by including results based on the Form EIA-900.

Data Processing. The Form EIA-900 is mailed to all operating Form EIA-867 respondent facilities with more than 50 megawatts of total operating capacity. In 1996, there were approximately 380 respondents for the Form EIA-900. Data submission is allowed by Internet e-mail, postal mail, telephone or facsimile (FAX) transmission. In the near future, the EIA plans to allow touchtone data entry. At first submission, the number for the one datum element collected is compared to a previously submitted number, through the use of an interactive edit. Later, batch edits are applied. One edit is used to compare total sales, generation, line losses and imports/exports to determine if the results are reasonable. Another edit is applied on an individual, annual basis, to compare 12 month totals for the Form EIA-900 submissions to the corresponding Form EIA-867 submissions.

Form EIA-861

The Form EIA-861 is a mandatory census of electric utilities in the United States. The survey is used to collect information on power production and sales data from approximately 3,250 electric utilities. The data collected are used to maintain and update the EIA's electric utility frame data base. This data base supports queries from the Executive Branch, Congress, other public agencies, and the general public. Summary data from the Form EIA-861 are also contained in the *Electric Sales and Revenue*, the *Electric Power Annual*, the *Financial Statistics of Selected Publicly Owned Electric Utilities*, the *Financial Statistics of Selected Investor-Owned Electric Utilities*, the AER, and, the *Annual Outlook for U.S. Electric Power*. These reports present aggregate totals for electric utilities on a national level, by State, and by ownership type.

Instrument and Design History. The Form EIA-861 was implemented in January 1985 to collect data as of year-end 1984. The Federal Administration Act of 1974 (Public Law 93-275) defines the legislative authority to collect these data.

Data Processing. The Form EIA-861 is mailed to the respondents in February of each year to collect data as of the end of the preceding calendar year. The data are manually edited before being entered into the interactive on-line system. Internal edit checks are performed to verify that current data total across and between schedules, and are comparable to data reported the previous year. Edit checks are also performed to compare data reported on the Form EIA-861 and similar data reported on the Forms EIA-826; EIA-412, "Annual Report of Public Electric Utilities," and FERC Form 1, "Annual Report of Major Electric Utilities, Licensees, and Others." Respondents are telephoned to obtain clarification of reported data and to obtain missing data.

Form EIA-860

The Form EIA-860 is a mandatory census of electric utilities in the United States that operate power plants or plan to operate a power plant within 10 years of the reporting year. The survey is used to collect data on electric utilities' existing power plants and their 10-year plans for constructing new plants, generating unit additions, modifications, and retirements in existing plants. Data on the survey are collected at the

generating unit level. These data are then aggregated to provide totals by energy source (coal, petroleum, gas, water, nuclear, other) and geographic area (State, NERC region, Federal region, Census division). Additionally, at the national level, data are aggregated to provide totals by prime mover. Data from the Form EIA-860 are also summarized in the *Inventory of Power Plants in the United States* and the EPA, and as input to publications (AER) and studies by other offices in the Department of Energy.

Instrument and Design History. The Form EIA-860 was implemented in January 1985 to collect data as of year-end 1984. The Federal Energy Administration Act of 1974 (Public Law 93-275) defines the legislative authority to collect these data.

Data Processing. The Form EIA-860 is mailed to approximately 900 respondents in November or December to collect data as of January 1 of the reporting year, where the reporting year is the calendar year in which the report was filed. Effective with the 1996 reporting year, respondents have the option of filing Form EIA-860 directly with the EIA or through an agent, such as the respondent's regional electric reliability council. Data reported through the regional electric reliability councils are submitted to the EIA electronically from the North American Electric Reliability Council (NERC). Data for each respondent are preprinted from the applicable data base. Respondents are instructed to verify all preprinted data and to supply missing data. The data are manually edited before being keypunched for automatic data processing. Computer programs containing additional edit checks are run. Respondents are telephoned to obtain correction or clarification of reported data and to obtain missing data, as a result of the manual and automatic editing process.

Form EIA-867

The Form EIA-867 is a mandatory survey of all existing and planned nonutility electric generating facilities in the United States with a total generator nameplate capacity of 1 or more megawatts. In 1992, the reporting threshold of the Form EIA-867 was lowered to include all facilities with a combined nameplate capacity of 1 or more megawatts. Previously, data were collected every 3 years from facilities with a nameplate capacity between 1 and 5 megawatts. Planned generators are defined as a proposal by a company to install electric generating equipment at an existing or planned facility. The proposal is based on the owner having obtained (1) all environmental and regulatory approvals, (2) a contract for the electric energy, or (3) financial closure

on the facility. The Form consists of Schedules I, "Identification and Certification"; Schedule II, "Facility Information"; Schedule III, "Standard Industrial Classification Code Designation"; Schedule IVA, "Facility Fuel Information"; Schedule IVB, "Facility Thermal and Generation Information"; Schedule V, "Facility Environmental Information"; and Schedule VI, "Electric Generator Information."

Submission of the Form EIA-867 is required from all facilities that have a combined facility nameplate capacity of 1 megawatt or more. Schedule V, "Facility Environmental Information" is only required of those facilities of 25 megawatts or more.

The form is used to collect data on the installed capacity, energy consumption, generation, and electric energy sales to electric utilities and other nonutilities by facility. Additionally, the form is used to collect data on the quality of fuels burned and the types of environmental equipment used by the respondent. These data are aggregated to provide geographic totals for selected States and at the Census division and national levels. Since the Form EIA-867 data are considered confidential, suppression of some data is necessary to protect the confidentiality of the individual respondent data. See "Confidentiality of the Data" in this section for further information.

Instrument and Design History. The Form EIA-867 was implemented in December 1989 to collect data as of year-end 1989. The Federal Energy Administration Act of 1984 (Public Law 93-275) defines the legislative authority to collect these data.

Data Processing. The Form EIA-867 is mailed to the respondents in January to collect data as of the end of the preceding calendar year. Static data for each respondent are preprinted from the previous year, and the respondents are instructed to verify all preprinted information and to supply the missing data. The completed forms are to be returned to the EIA by April 30. The response rate for all facilities for which addresses were confirmed was 100 percent. The data are manually edited before being keyed for automatic data processing. Computer programs containing additional edit checks are run. Respondents are telephoned to obtain corrections or clarifications of reported data and to obtain missing data as a result of the manual and automated editing.

Formulas/Methodologies

The following formula is used to calculate percent differences.

$$\text{Percent Difference} = \left(\frac{x(t_2) - x(t_1)}{x(t_1)} \right) \times 100,$$

where $x(t_1)$ and $x(t_2)$ denote the quantity at year t_1 and subsequent year t_2 .

Form EIA-826

The Form EIA-826 data are collected at the utility level by sector and State. When a utility has sales in more than one State, the State data that may be required are dependent upon the sample selection that was done for each State independently. Data from the Form EIA-826 are used to determine estimates by sector at the State, Census division, and national level for the entire corresponding State, Census division, or national category. Form EIA-861 data were used as the frame from which the sample was selected, and also as regressor data.

The sample consists of approximately 260 electric utilities. This includes a somewhat larger number of State-service areas for electric utilities. Estimation procedures include imputation to account for non-response. Nonsampling error must also be considered. The nonsampling error is not estimated directly, although attempts are made to minimize it.

State-level sales and revenue estimates are calculated. Also, a ratio estimation procedure is used for estimation of revenue per kilowatthour at the State level. These estimates are accumulated separately to produce the Census division and U.S. level estimates.

The coefficient of variation (CV) statistic, usually given as a percent, describes the magnitude of sampling error that might reasonably be incurred. The CV, sometimes referred to as the relative standard error, is the square root of the estimated variance, divided by the variable of interest. The variable of interest may be the ratio of two variables (for example, revenue per kilowatthour), or a single variable (for example, sales).

The sampling error may be less than the nonsampling error. Nonsampling errors may be attributed to many sources, including the response errors, definitional difficulties, differences in the interpretation of questions, mistakes in recording or coding data obtained, and other errors of collection, response, or coverage. These nonsampling errors also occur in complete censuses. In a complete census, this problem may become unmanageable. One indicator of the magnitude of possible nonsampling error may be gleaned by examining the history of revisions to data for a survey (Table B2).

Coefficients of variation are indicators of error due to sampling. (CVs do not account for nonsampling errors, such as errors of misclassification or transposed digits. However, estimates of CVs, although not designed to measure nonsampling error, are affected by them). In fact, large CV estimates found in preliminary work with these data have often indicated nonsampling errors, which were then identified and corrected. Using the Central Limit Theorem, which applies to sums and means such as are applicable here, there is approximately a 68-percent chance that the true sampling error is less than the corresponding CV. Note that reported CVs are always estimates, themselves, and are usually, as here, reported as percents. As an example, suppose that a revenue-per-kilowatthour value is estimated to be 5.13 cents per kilowatthour with an estimated CV of 1.6 percent. This means that, ignoring any nonsampling error, there is approximately a 68-percent chance that the true average revenue per kilowatthour is within approximately 1.6 percent of 5.13 cents per kilowatthour (that is, between 5.05 and 5.21 cents per kilowatthour). There is approximately a 95-percent chance of a true sampling error being 2 CVs or less.

The basic approach used is shown in (Royall, 6) with additional discussion of variance estimation in (Royall and Cumberland, 7), (Royall and Cumberland, 8), and (Knaub, 5). From (Royall, 6), for sales or revenue for any sector at the State level, if we let x represent an observation from the Form EIA-861, y represents an observation from the Form EIA-826, and $\hat{y}$ represents an estimated value for data not collected, then

$$y_i = bx_i + x_i^T e_{0i},$$

$$\hat{y}_i = \hat{b}x_i,$$

$$\hat{b}(\gamma) = \left[\sum_{k=1}^n x_k^{1-2\gamma} y_k \right] / \left[\sum_{k=1}^n x_k^{2-2\gamma} \right]$$

Here, n is the Form EIA-826 sample size for that State, and b is the factor ('slope') relating x to y in the linear regression. γ is taken to be $\frac{1}{2}$ (see (Knaub, 5)), although more research (Knaub, 9) could refine this. For the Form EIA-826, $\gamma = \frac{1}{2}$ has certainly been shown to be adequate (see (Knaub, 5), page 878, Table 1). The variance formula for V_d found in (Royall and Cumberland, 7 and 8) performs well for sales and for revenue. For revenue per kilowatthour, the model covariance comes from notes provided by Professor Poduri S.R.S. Rao (Rao, 10) of the University of Rochester and the Energy Information Administration. Aggregate level CV estimates for revenue per kilowatthour are calculated as supported by (Hansen,

Hurwitz and Madow, 11). Details are published in (Knaub, 12).

Additional information or clarification can be addressed to the Energy Information Administration as indicated in the "Contacts" section of this publication.

Form EIA-900

The Form EIA-900 data are collected at the facility level, which is roughly the nonutility equivalent of plant level. Like the Form EIA-826, cutoff model sampling and estimation are employed, however, the estimation formula are modified by use of a second regressor. It was found that more variability occurred under the single regressor model than was generally found in the case of the Form EIA-826, but that through the use of nameplate capacity as a second regressor, results were greatly improved. Increasing variance as regressor values increase (heteroscedasticity), a phenomenon which caused us to use a value for gamma greater than zero in the case of the Form EIA-826, is at least as important a consideration here, and further study to increase efficiency may be performed. A paper, "Weighted Multiple Regression Estimation for Survey Model Sampling," has been accepted for publication in the Internet statistics journal, InterStat at <http://interstat.stat.vt.edu/intersta.htm>. This paper explains a great deal of the background and methodology involved in providing a satisfactory estimator in this case. It appears at the Web site given above, under May 1996 (Knaub, 13).

Form EIA-759

Data for the Form EIA-759 are collected at the plant level. Estimates are then provided for geographic levels. Consumption of fuel(s) is converted from quantities (in short tons, barrels, or thousand cubic feet) to Btu at the plant level. End-of-month fuel stocks for a single generating plant may not equal beginning-of-the-month stocks plus receipts less consumption, for many reasons, including the fact that several plants may share the same fuel stock.

Like the Form EIA-900, cutoff model sampling and estimation are employed, using the same multiple regression model. Once again, as described under the corresponding subsection on the Form EIA-900, details of the estimation of totals and variances of totals are published on the Internet in a paper entitled "Weighted Multiple Regression Estimation for Survey Model Sampling (Knaub, 13)."

At the fuel and State level (i.e., lowest aggregate level), there are a number of cases where the minimal sample size of three is not met, when using a 25 MW cutoff. Imputation of historic values for the smallest plants is used to supplement actual values for the largest ones. However, at the NERC level, this is not necessary. Data element totals for each NERC region, by fuel type, are estimated using model sampling. These samples are composed solely of data reported for the plants actually in the sample. The national level estimate from this is then considered our best estimate, and all other estimates are apportioned accordingly.

As a final adjustment based on our most complete data, use is made of final Form EIA-759 annual census, when available. The annual census for Form EIA-759 data by State and energy source are compared to the corresponding monthly Form EIA-759 values. The ratio of these two values in each case is then used to adjust each corresponding monthly value.

FERC Form 423

Data for the FERC Form 423 are collected at the plant level. These data are then used in the following formulas to produce aggregates and averages for each fuel type at the State, Census division, and U.S. level. For these formulas, receipts and average heat content are at the plant level. For each geographic region, the summation Σ represents the sum of all plants in that geographic region. Additionally,

- For coal, units for receipts (R) are in tons, units for average heat content (A) are in Btu per pound, and the unit conversion (U) is 2,000 pounds per ton;
- For petroleum, units for receipts (R) are in barrels, units for average heat content (A) are in Btu per gallon, and the unit conversion (U) is 42 gallons per barrel;
- For gas, units for receipts (R) are in thousand cubic feet (Mcf), average heat content (A) are in Btu per cubic foot, and the unit conversion (U) is 1,000 cubic feet per Mcf.

$$\text{Total Btu} = \sum_i (R_i \times A_i \times U),$$

where i denotes a plant; R_i = receipts for plant i ; A_i = average heat content for receipts at plant i ; and, U = unit conversion;

$$\text{Weighted Average Btu} = \frac{\sum_i (R_i \times A_i)}{\sum_i R_i}$$

where I denotes a plant; R_i = receipts for plant I ; and, A_i = average heat content for receipts at plant I .

The weighted average cost in cents per million Btu is calculated using the following formula:

$$\text{Weighted Average Cost} = \frac{\sum_i (R_i \times A_i \times C_i)}{\sum_i (R_i \times A_i)}$$

where I denotes a plant; R_i = receipts for plant I ; A_i = average heat content for receipts at plant I ; and C_i = cost in cents per million Btu for plant I .

The weighted average cost in dollars per unit is calculated using the following formula:

$$\text{Weighted Average Cost} = \frac{U \sum_i (R_i \times A_i \times C_i)}{10^3 \sum_i R_i}$$

where I denotes a plant; R_i = receipts for plant I ; A_i = average heat content for receipts at plant I ; U = unit conversion; and, C_i = cost in cents per million Btu for plant I .

Form EIA-861

Data for the Form EIA-861 are collected at the utility level from all electric utilities in the United States, its territories, and Puerto Rico. Form EIA-861 data in this publication are for the United States only. These data are then aggregated to provide geographic totals at the State, NERC region, Census division, and national level. Sources and disposition of data are also provided by utility class of ownership and retail consumer class of service. Average revenue (nominal dollars) per kilowatthour of electricity sold is calculated by dividing total annual retail revenue (nominal dollars) by the total annual retail sales of electricity.

Average revenue per kilowatthour is defined as the cost per unit of electricity sold and is calculated by dividing retail electric revenue by the corresponding sales of electricity. The average revenue per kilowatthour is calculated for all consumers and for each sector (residential, commercial, industrial, and other sales).

Electric utilities typically employ a number of rate schedules within a single sector. These alternative rate

schedules reflect the varying consumption levels and patterns of consumers and their associated impact on the costs to the electric utility for providing electrical service. The average revenue per kilowatthour reported in this publication by sector represents a weighted average of consumer revenue and sales within that sector and across sectors for all consumers.

The electric revenue used to derive the average revenue per kilowatthour is the operating revenue reported by the electric utility. Operating revenue includes energy charges, demand charges, consumer service charges, environmental surcharges, fuel adjustments, and other miscellaneous charges.

Electric utility operating revenues cover, among other costs of service, State and Federal income taxes and taxes other than income taxes paid by the utility. The Federal component of these taxes are, for the most part, "payroll" taxes. State and local authorities tax the value of plant (property taxes), the amount of revenues (gross receipts taxes), purchases of materials and services (sales and use taxes), and a potentially long list of other items that vary extensively by taxing authority. Taxes deducted from employees' pay (such as Federal income taxes and employees' share of social security taxes) are not a part of the utility's "tax costs," but are paid to the taxing authorities in the name of the employees. These taxes are included in the utility's cost of service (for example, revenue requirements) and are included in the amounts recovered from consumers in rates and reported in operating revenues.

Electric utilities, like many other business enterprises, are required by various taxing authorities to collect and remit taxes assessed on their consumers. In this regard, the electric utility serves as an agent for the taxing authority. Taxes assessed on the consumer, such as a gross receipts tax or sales tax, are called "pass through" taxes. These taxes do not represent a cost to the utility and are not recorded in the operating revenues of the utility. However, taxing authorities differ as to whether a specific tax is assessed on the utility or the consumer—which, in turn, determines whether or not the tax is included in the operating revenue of the electric utility.

Form EIA-860

Data from the Form EIA-860 are submitted at the generating unit level and are then aggregated to provide total capacity by energy source and geographic area. In addition, at the national level, data are aggregated by prime mover.

Estimated values for net summer and net winter capability for electric generating units were developed by use of a regression formula. The formula is used to estimate values for existing units where data are missing and for projected units. It was found that a zero-intercept linear regression works very well for estimating capability based on nameplate capacity. The only parameter then is the slope ($\hat{\beta}$) that is used to relate capacity to capability as follows: $\hat{y} = \hat{\beta}x$, where $\hat{y}$ is the estimated capability, and x is the known nameplate capacity. There will be a different value for $\hat{\beta}$ for different prime movers and for summer and winter capabilities and it will also depend upon the age of the generator. For more details see the *Inventory of Power Plants*.

Form EIA-867

Gross electricity generation data from the Form EIA-867, reported by generator, are aggregated to provide totals by energy source and geographic area. Nonutility power producers report gross electricity generated on the Form EIA-867, unlike electric utilities that report net generation on various EIA and FERC forms. Nonutilities generally do not measure and record electrical consumption used solely for the production of electricity. Nonutility generators and associated auxiliary equipment are often an integral part of a manufacturing or other industrial process and individual watt-hour meters are not generally installed on auxiliary equipment.

Estimated values for net generation from nonutility power producers were developed by EIA using gross generation, prime mover, fuels, and type of air pollution control data reported on the Form EIA-867. The difference between gross and net generation is the electricity consumed by auxiliary equipment and environmental control devices such as pumps, fans, coal pulverizers, particulate collectors, and flue gas desulfurization (FGD) units. The difference between gross and net generation is sometimes called parasitic load. In smaller power plants rotating auxiliaries are almost always electric motors. In large power plants that produce steam, rotating auxiliaries can be powered by either steam turbines or electric motors and sometimes both because of cold startup requirements.

This methodology for estimating net generation from gross generation is based on determining typical energy consumption for auxiliary electrical equipment associated with electrical generators. For instance, wind turbines have none of the auxiliaries common to a coal-burning power plant such as a coal pulverizers, fans, and emission controls. On the other hand,

windfarms do consume electricity since automatic, computer-based control systems are used to control blade pitch and speed thereby affecting generator electricity output.

Shown below are the conversion factors used to estimate net generation by nonutility generators. The factors are typical of a modern electric power plant but could vary significantly between individual plants. Net generation is calculated by multiplying the appropriate conversion factor by the reported gross electrical generation.

Prime Mover Type	Gross-to-Net Generation Conversion Factor
Gas (Combustion) Turbine	.98
Steam Turbine	.97*
Internal Combustion	.98
Wind Turbine	.99
Solar-Photovoltaic	.99
Hydraulic Turbine	.99
Fuel Cell	.99
Other	.97

*Factor reduced by .01 if the facility has flue gas particulate collectors and another .03 if the facility has flue gas desulfurization (FGD) equipment. Facilities under 25 megawatts and burning coal in traditional boilers (e.g., not fluidized bed boilers) are assumed to have particulate and FGD equipment.

These conversion factors were estimated by the staff of the Office of Coal, Nuclear, Electric and Alternate Fuels, Energy Information Administration. The primary reference used in developing the conversion factors was *Steam, Its Generation and Use*, 40th Edition, Babcock & Wilcox, Barberton, Ohio.

Average Heat Content

Heat content values (Table B1) collected on the FERC Form 423 were used to convert the consumption data from the Form EIA-759 into Btu. Respondents to FERC Form 423 represent a subset of all generating plants (steam plants with a capacity of 50 megawatts or larger), while Form EIA-759 respondents generally represent generating plants with a combined capacity of 25 or more megawatts. The results, therefore, may not be completely representative.

Quality of Data

The CNEAF office is responsible for routine data improvement and quality assurance activities. All operations in this office are done in accordance with formal standards established by the EIA. These standards are

the measuring rod necessary for quality statistics. Data improvement efforts include verification of data-keyed input by automatic computerized methods, editing by subject matter specialists, and follow-up on nonrespondents. The CNEAF office supports the quality assurance efforts of the data collectors by providing advisory reviews of the structure of information requirements, and of proposed designs for new and revised data collection forms and systems. Once implemented, the actual performance of working data collection systems is also validated. Computerized respondent data files are checked to identify those who fail to respond to the survey. By law, nonrespondents may be fined or otherwise penalized for not filing a mandatory EIA data form. Before invoking the law, the EIA tries to obtain the required information by encouraging cooperation of nonrespondents.

Completed forms received by the CNEAF office are sorted, screened for completeness of reported information, and keyed onto computer tapes for storage and transfer to random access data bases for computer processing. The information coded on the computer tapes is manually spot-checked against the forms to certify accuracy of the tapes. To ensure the quality standards established by the EIA, formulas that use the past history of data values in the data base have been designed and implemented to check data input for errors automatically. Data values that fall outside the ranges prescribed in the formulas are verified by telephoning respondents to resolve any discrepancies.

Conceptual problems affecting the quality of data are discussed in the report, *An Assessment of the Quality of Selected EIA Data Series: Electric Power Data*. This report is published by the Energy Information Administration (Office of Statistical Standards). See item 2 in Appendix A.

Data Precision

Monthly sample survey data have both sampling and nonsampling errors. Sampling errors may be expected since all data are not collected and, therefore, must be mathematically estimated. (Note that the annual series for a monthly sample is not subject to sampling error because it is a census). Nonsampling errors are the result of incorrect allocation of data (for example, transcriptions or misclassifications) and can be difficult to control and estimate. A study of coefficients of variance and data revisions was conducted so that the appropriate levels of precision, based on the accuracy and completeness of the data from which the estimates

are derived, is provided in this report for average revenue per kilowatthour of electricity sold. It was judged that three significant digits are justified for average revenue per kilowatthour of electricity sold at the U.S. level except for monthly data prior to 1990 where two significant digits are more appropriate.

Data Imputation

It may become necessary (as in March and April 1996 FERC Form 423 data) to impute for some data, even if a 100-percent census is normally collected without incident. In such cases, a modeling approach, similar to what is done for the Form EIA-826, can be implemented. The estimation methodologies for model sampling and model imputation are identical.

Data Editing System

Data from the form surveys are edited on a monthly basis using automated systems. The edit includes both deterministic checks, in which records are checked for the presence of required fields and their validity; and statistical checks, in which estimation techniques are used to validate data according to their behavior in the past and in comparison to other current fields. When all data have passed the edit process, the system builds monthly master files, which are used as input to the EPM.

Confidentiality of the Data

In general, the data collected on the forms used for input to this report are not confidential. However, data from the Form EIA-900, "Monthly Sales for Resale," and from the Form EIA-867, "Annual Nonutility Power Producers," are considered confidential and must adhere to EIA's "Policy on the Disclosure of Individually Identifiable Energy Information in the Possession of the EIA" (45 Federal Register 59812 (1980)).

Rounding Rules for Data

Given a number with r digits to the left of the decimal and $d+t$ digits in the fraction part, with d being the place to which the number is to be rounded and t being the remaining digits which will be truncated, this number is rounded to $r+d$ digits by adding 5 to the $(r+d+1)$ th digit when the number is positive or by subtracting 5 when the number is negative. The t digits are then truncated at the $(r+d+1)$ th digit. The symbol for a rounded number truncated to zero is (*).

Data Correction Procedure

The Office of Coal, Nuclear, Electric and Alternate Fuels has adopted the following policy with respect to the revision and correction of recurrent data in energy publications:

1. Annual survey data collected by this office are published either as preliminary or final when first appearing in a data report. Data initially released as preliminary will be so noted in the report. These data will be revised, if necessary, and declared final in the next publication of the data.
2. All monthly and quarterly survey data collected by this office are published as preliminary. These data are revised only after the completion of the 12-month cycle of the data. No revisions are made to the published data before this.
3. The magnitudes of changes due to revisions experienced in the past will be included in the data reports, so that the reader can assess the accuracy of the data.
4. After data are published as final, corrections will be made only in the event of a greater than one percent difference at the national level. Corrections for differences that are less than the before-mentioned threshold are left to the discretion of the Office Director. Note that in this discussion, changes or revisions are referred to as "errors."

In accordance with policy statement number 3, the mean value (unweighted average) for the absolute values of the 12 monthly revisions of each item are provided at the U.S. level for the past 4 years (Table B2). For example, the mean of the 12 monthly absolute errors

(absolute differences between preliminary and final monthly data) for coal-fired generation in 1995 was 49. That is, on average, the absolute value of the change made each month to coal-fired generation was 49 million kilowatthours.

The U.S. total net summer capability, updated monthly in the EPM (Table 1), is based solely on new electric generating units and retirements which come to the attention of the EIA during the year through telephone calls with electric utilities and on the Form EIA-759, "Monthly Power Plant Report," and may not include all activity for the month. Data on net summer capability, including new electric generating units, are collected annually on the Form EIA-860, "Annual Electric Generator Report." Preliminary data for net summer capability are published in the *Electric Power Annual* (EPA). Final data are published in the *Inventory of Power Plants*. With respect to net summer capability published in the EPM, the EIA examines the accuracy of that data by comparing the annual total value with the final annual total value published in the IPP.

NERC Aggregation

Beginning in January 1986, NERC region totals for the Form EIA-759 are aggregates based on membership of the individual electric utilities in NERC. Prior to January 1986, NERC region totals were aggregates defined by the physical location of the power plants generating electricity.

Use of the Glossary

The terms in the glossary have been defined for general use. Restrictions on the definitions as used in these data collection systems are included in each definition when necessary to define the terms as they are used in this report.

Table B1. Average Heat Content of Fossil-Fuel Receipts, January 1998

Glossary

Ampere: The unit of measurement of electrical current produced in a circuit by 1 volt acting through a resistance of 1 ohm.

Anthracite: A hard, black lustrous coal, often referred to as hard coal, containing a high percentage of fixed carbon and a low percentage of volatile matter. Comprises three groups classified according to the following ASTM Specification D388-84, on a dry mineral-matter-free basis:

	Fixed Carbon Limits		Volatile Matter	
	GE	LT	GT	LE
Meta-Anthracite	98	-	-	2
Anthracite	92	98	2	8
Semianthracite	86	92	8	14

Average Revenue per Kilowatthour: The average revenue per kilowatthour of electricity sold by sector (residential, commercial, industrial, or other) and geographic area (State, Census division, and national). Is calculated by dividing the total monthly revenue by the corresponding total monthly sales for each sector and geographic area.

Barrel: A volumetric unit of measure for crude oil and petroleum products equivalent to 42 U.S. gallons.

Baseload: The minimum amount of electric power delivered or required over a given period of time at a steady rate.

Baseload Capacity: The generating equipment normally operated to serve loads on an around-the-clock basis.

Baseload Plant: A plant, usually housing high-efficiency steam-electric units, which is normally operated to take all or part of the minimum load of a system, and which consequently produces electricity at an essentially constant rate and runs continuously. These units are operated to maximize system mechanical and thermal efficiency and minimize system operating costs.

Bcf: The abbreviation for 1 billion cubic feet.

Bituminous Coal: The most common coal. It is dense and black (often with well-defined bands of bright and

dull material). Its moisture content usually is less than 20 percent. It is used for generating electricity, making coke, and space heating. Comprises five groups classified according to the following ASTM Specification D388-84, on a dry mineral-matter-free (mmf) basis for fixed-carbon and volatile matter and a moist mmf basis for calorific value.

	Fixed Carbon Limits		Volatile Matter Limits		Calorific Value Limits Btu/lb	
	GE	LT	GT	LT	GE	LE
LV	78	86	14	22	-	-
MV	69	78	22	31	-	-
HVA	-	69	31	-	14000	-
HVB	-	-	-	-	13000	14000
HVC	-	-	-	-	10500	13000

LV = Low-volatile bituminous coal

MV = Medium-volatile bituminous coal

HVA = High-volatile A bituminous coal

HVB = High-volatile B bituminous coal

HVC = High-volatile C bituminous coal

Boiler: A device for generating steam for power, processing, or heating purposes or for producing hot water for heating purposes or hot water supply. Heat from an external combustion source is transmitted to a fluid contained within the tubes in the boiler shell. This fluid is delivered to an end-use at a desired pressure, temperature, and quality.

Btu (British Thermal Unit): A standard unit for measuring the quantity of heat energy equal to the quantity of heat required to raise the temperature of 1 pound of water by 1 degree Fahrenheit.

Capability: The maximum load that a generating unit, generating station, or other electrical apparatus can carry under specified conditions for a given period of time without exceeding approved limits of temperature and stress.

Capacity: The full-load continuous rating of a generator, prime mover, or other electric equipment under specified conditions as designated by the manufacturer. It is usually indicated on a nameplate attached to the equipment.

Capacity (Purchased): The amount of energy and capacity available for purchase from outside the system.

Census Divisions: The nine geographic divisions of the United States established by the Bureau of the Census, U.S. Department of Commerce, for the purpose of statistical analysis. The boundaries of Census divisions coincide with State boundaries. The Pacific Division is subdivided into the Pacific Contiguous and Pacific Noncontiguous areas.

Circuit: A conductor or a system of conductors through which electric current flows.

Coal: A black or brownish-black solid combustible substance formed by the partial decomposition of vegetable matter without access to air. The rank of coal, which includes anthracite, bituminous coal, subbituminous coal, and lignite, is based on fixed carbon, volatile matter, and heating value. Coal rank indicates the progressive alteration from lignite to anthracite. Lignite contains approximately 9 to 17 million Btu per ton. The contents of subbituminous and bituminous coal range from 16 to 24 million Btu per ton and from 19 to 30 million Btu per ton, respectively. Anthracite contains approximately 22 to 28 million Btu per ton.

Coincidental Demand: The sum of two or more demands that occur in the same time interval.

Coincidental Peak Load: The sum of two or more peak loads that occur in the same time interval.

Coke (Petroleum): A residue high in carbon content and low in hydrogen that is the final product of thermal decomposition in the condensation process in cracking. This product is reported as marketable coke or catalyst coke. The conversion factor is 5 barrels (42 U.S. gallons each) per short ton.

Combined Pumped-Storage Plant: A pumped-storage hydroelectric power plant that uses both pumped water and natural streamflow to produce electricity.

Commercial Operation: Commercial operation begins when control of the loading of the generator is turned over to the system dispatcher.

Compressor: A pump or other type of machine using a turbine to compress a gas by reducing the volume.

Consumption (Fuel): The amount of fuel used for gross generation, providing standby service, start-up and/or flame stabilization.

Contract Receipts: Purchases based on a negotiated agreement that generally covers a period of 1 or more years.

Cost: The amount paid to acquire resources, such as plant and equipment, fuel, or labor services.

Crude Oil (including Lease Condensate): A mixture of hydrocarbons that existed in liquid phase in underground reservoirs and that remains liquid at atmospheric pressure after passing through surface separating facilities. Included are lease condensate and liquid hydrocarbons produced from tar sands, gilsonite, and shale oil. Drip gases are also included, but topped crude oil (residual oil) and other unfinished oils are excluded. Liquids produced at natural gas processing plants and mixed with crude oil are likewise excluded where identifiable.

Current (Electric): A flow of electrons in an electrical conductor. The strength or rate of movement of the electricity is measured in amperes.

Demand (Electric): The rate at which electric energy is delivered to or by a system, part of a system, or piece of equipment, at a given instant or averaged over any designated period of time.

Demand Interval: The time period during which flow of electricity is measured (usually in 15-, 30-, or 60-minute increments.)

Electric Plant (Physical): A facility containing prime movers, electric generators, and auxiliary equipment for converting mechanical, chemical, and/or fission energy into electric energy.

Electric Utility: An enterprise that is engaged in the generation, transmission, or distribution of electric energy primarily for use by the public and that is the major power supplier within a designated service area. Electric utilities include investor-owned, publicly owned, cooperatively owned, and government-owned (municipals, Federal agencies, State projects, and public power districts) systems.

Energy: The capacity for doing work as measured by the capability of doing work (potential energy) or the conversion of this capability to motion (kinetic energy). Energy has several forms, some of which are easily convertible and can be changed to another form useful for work. Most of the world's convertible energy comes

from fossil fuels that are burned to produce heat that is then used as a transfer medium to mechanical or other means in order to accomplish tasks. Electrical energy is usually measured in kilowatthours, while heat energy is usually measured in British thermal units.

Energy Deliveries: Energy generated by one electric utility system and delivered to another system through one or more transmission lines.

Energy Receipts: Energy generated by one electric utility system and received by another system through one or more transmission lines.

Energy Source: The primary source that provides the power that is converted to electricity through chemical, mechanical, or other means. Energy sources include coal, petroleum and petroleum products, gas, water, uranium, wind, sunlight, geothermal, and other sources.

Fahrenheit: A temperature scale on which the boiling point of water is at 212 degrees above zero on the scale and the freezing point is at 32 degrees above zero at standard atmospheric pressure.

Failure or Hazard: Any electric power supply equipment or facility failure or other event that, in the judgment of the reporting entity, constitutes a hazard to maintaining the continuity of the bulk electric power supply system such that a load reduction action may become necessary and a reportable outage may occur. The imposition of a special operating procedure, the extended purchase of emergency power, other bulk power system actions that may be caused by a natural disaster, a major equipment failure that would impact the bulk power supply, and an environmental and/or regulatory action requiring equipment outages are types of abnormal conditions that should be reported.

Firm Gas: Gas sold on a continuous and generally long-term contract.

Fossil Fuel: Any naturally occurring organic fuel, such as petroleum, coal, and natural gas.

Fossil-Fuel Plant: A plant using coal, petroleum, or gas as its source of energy.

Fuel: Any substance that can be burned to produce heat; also, materials that can be fissioned in a chain reaction to produce heat.

Fuel Emergencies: An emergency that exists when supplies of fuels or hydroelectric storage for generation are at a level or estimated to be at a level that would threaten the reliability or adequacy of bulk electric

power supply. The following factors should be taken into account to determine that a fuel emergency exists: (1) Fuel stock or hydroelectric project water storage levels are 50 percent or less of normal for that particular time of the year and a continued downward trend in fuel stock or hydroelectric project water storage level are estimated; or (2) Unscheduled dispatch or emergency generation is causing an abnormal use of a particular fuel type, such that the future supply or stocks of that fuel could reach a level which threatens the reliability or adequacy of bulk electric power supply.

Gas: A fuel burned under boilers and by internal combustion engines for electric generation. These include natural, manufactured and waste gas.

Generation (Electricity): The process of producing electric energy by transforming other forms of energy; also, the amount of electric energy produced, expressed in watthours (Wh).

Gross Generation: The total amount of electric energy produced by the generating units at a generating station or stations, measured at the generator terminals.

Net Generation: Gross generation less the electric energy consumed at the generating station for station use.

Generator: A machine that converts mechanical energy into electrical energy.

Generator Nameplate Capacity: The full-load continuous rating of a generator, prime mover, or other electric power production equipment under specific conditions as designated by the manufacturer. Installed generator nameplate rating is usually indicated on a nameplate physically attached to the generator.

Geothermal Plant: A plant in which the prime mover is a steam turbine. The turbine is driven either by steam produced from hot water or by natural steam that derives its energy from heat found in rocks or fluids at various depths beneath the surface of the earth. The energy is extracted by drilling and/or pumping.

Gigawatt (GW): One billion watts.

Gigawatthour (GWh): One billion watthours.

Gross Generation: The total amount of electric energy produced by a generating facility, as measured at the generator terminals.

Heavy Oil: The fuel oils remaining after the lighter oils have been distilled off during the refining process.

Except for start-up and flame stabilization, virtually all petroleum used in steam plants is heavy oil.

Horsepower: A unit for measuring the rate of work (or power) equivalent to 33,000 foot-pounds per minute or 746 watts.

Hydroelectric Plant: A plant in which the turbine generators are driven by falling water.

Instantaneous Peak Demand: The maximum demand at the instant of greatest load.

Integrated Demand: The summation of the continuously varying instantaneous demand averaged over a specified interval of time. The information is usually determined by examining a demand meter.

Internal Combustion Plant: A plant in which the prime mover is an internal combustion engine. An internal combustion engine has one or more cylinders in which the process of combustion takes place, converting energy released from the rapid burning of a fuel-air mixture into mechanical energy. Diesel or gas-fired engines are the principal types used in electric plants. The plant is usually operated during periods of high demand for electricity.

Interruptible Gas: Gas sold to customers with a provision that permits curtailment or cessation of service at the discretion of the distributing company under certain circumstances, as specified in the service contract.

Kilowatt (kW): One thousand watts.

Kilowatthour (kWh): One thousand watthours.

Light Oil: Lighter fuel oils distilled off during the refining process. Virtually all petroleum used in internal combustion and gas-turbine engines is light oil.

Lignite: A brownish-black coal of low rank with high inherent moisture and volatile matter (used almost exclusively for electric power generation). It is also referred to as brown coal. Comprises two groups classified according to the following ASTM Specification D388-84 for calorific values on a moist material-matter-free basis:

	Limits Btu/lb.	
	GE	LT
Lignite A	6300	8300
Lignite B	-	6300

Maximum Demand: The greatest of all demands of the load that has occurred within a specified period of time.

Mcf: One thousand cubic feet.

Megawatt (MW): One million watts.

Megawatthour (MWh): One million watthours.

MMcf: One million cubic feet.

Natural Gas: A naturally occurring mixture of hydrocarbon and nonhydrocarbon gases found in porous geological formations beneath the earth's surface, often in association with petroleum. The principal constituent is methane.

Net Energy for Load: Net generation of main generating units that are system-owned or system-operated plus energy receipts minus energy deliveries.

Net Generation: Gross generation minus plant use from all electric utility owned plants. The energy required for pumping at a pumped-storage plant is regarded as plant use and must be deducted from the gross generation.

Net Summer Capability: The steady hourly output, which generating equipment is expected to supply to system load exclusive of auxiliary power, as demonstrated by tests at the time of summer peak demand.

Noncoincident Peak Load: The sum of two or more peak loads on individual systems that do not occur in the same time interval. Meaningful only when considering loads within a limited period of time, such as a day, week, month, a heating or cooling season, and usually for not more than 1 year.

North American Electric Reliability Council (NERC): A council formed in 1968 by the electric utility industry to promote the reliability and adequacy of bulk power supply in the electric utility systems of North America. The NERC Regions are:

ASCC - Alaskan System Coordination Council
ECAR - East Central Area Reliability Coordination Agreement
ERCOT - Electric Reliability Council of Texas
FRCC - Florida Reliability Coordinating Council
MAIN - Mid-America Interconnected Network
MAAC - Mid-Atlantic Area Council
MAPP - Mid-Continent Area Power Pool
NPCC - Northeast Power Coordinating Council
SERC - Southeastern Electric Reliability Council
SPP - Southwest Power Pool
WSCC - Western Systems Coordinating Council

Nuclear Fuel: Fissionable materials that have been enriched to such a composition that, when placed in a nuclear reactor, will support a self-sustaining fission chain reaction, producing heat in a controlled manner for process use.

Nuclear Power Plant: A facility in which heat produced in a reactor by the fissioning of nuclear fuel is used to drive a steam turbine.

Off-Peak Gas: Gas that is to be delivered and taken on demand when demand is not at its peak.

Ohm: The unit of measurement of electrical resistance. The resistance of a circuit in which a potential difference of 1 volt produces a current of 1 ampere.

Operable Nuclear Unit: A nuclear unit is "operable" after it completes low-power testing and is granted authorization to operate at full power. This occurs when it receives its full power amendment to its operating license from the Nuclear Regulatory Commission.

Other Gas: Includes manufactured gas, coke-oven gas, blast-furnace gas, and refinery gas. Manufactured gas is obtained by distillation of coal, by the thermal decomposition of oil, or by the reaction of steam passing through a bed of heated coal or coke.

Other Generation: Electricity originating from these sources: biomass, fuel cells, geothermal heat, solar power, waste, wind, and wood.

Other Unavailable Capability: Net capability of main generating units that are unavailable for load for reasons other than full-forced outage or scheduled maintenance. Legal restrictions or other causes make these units unavailable.

Peak Demand: The maximum load during a specified period of time.

Peak Load Plant: A plant usually housing old, low-efficiency steam units; gas turbines; diesels; or pumped-storage hydroelectric equipment normally used during the peak-load periods.

Peaking Capacity: Capacity of generating equipment normally reserved for operation during the hours of highest daily, weekly, or seasonal loads. Some generating equipment may be operated at certain times as peaking capacity and at other times to serve loads on an around-the-clock basis.

Percent Difference: The relative change in a quantity over a specified time period. It is calculated as follows: the current value has the previous value subtracted from it; this new number is divided by the absolute value of

the previous value; then this new number is multiplied by 100.

Petroleum: A mixture of hydrocarbons existing in the liquid state found in natural underground reservoirs, often associated with gas. Petroleum includes fuel oil No. 2, No. 4, No. 5, No. 6; topped crude; Kerosene; and jet fuel.

Petroleum Coke: See Coke (Petroleum).

Petroleum (Crude Oil): A naturally occurring, oily, flammable liquid composed principally of hydrocarbons. Crude oil is occasionally found in springs or pools but usually is drilled from wells beneath the earth's surface.

Plant: A facility at which are located prime movers, electric generators, and auxiliary equipment for converting mechanical, chemical, and/or nuclear energy into electric energy. A plant may contain more than one type of prime mover. Electric utility plants exclude facilities that satisfy the definition of a qualifying facility under the Public Utility Regulatory Policies Act of 1978.

Plant Use: The electric energy used in the operation of a plant. Included in this definition is the energy required for pumping at pumped-storage plants.

Plant-Use Electricity: The electric energy used in the operation of a plant. This energy total is subtracted from the gross energy production of the plant; for reporting purposes the plant energy production is then reported as a net figure. The energy required for pumping at pumped-storage plants is, by definition, subtracted, and the energy production for these plants is then reported as a net figure.

Power: The rate at which energy is transferred. Electrical energy is usually measured in watts. Also used for a measurement of capacity.

Price: The amount of money or consideration-in-kind for which a service is bought, sold, or offered for sale.

Prime Mover: The motive force that drives an electric generator (e.g., steam engine, turbine, or water wheel).

Production (Electric): Act or process of producing electric energy from other forms of energy; also, the amount of electric energy expressed in watthours (Wh).

Pumped-Storage Hydroelectric Plant: A plant that usually generates electric energy during peak-load periods by using water previously pumped into an elevated storage reservoir during off-peak periods when excess generating capacity is available to do so. When additional generating capacity is needed, the water can

be released from the reservoir through a conduit to turbine generators located in a power plant at a lower level.

Pure Pumped-Storage Hydroelectric Plant: A plant that produces power only from water that has previously been pumped to an upper reservoir.

Qualifying Facility (QF): This is a cogenerator or small power producer that meets certain ownership, operating and efficiency criteria established by the Federal Energy Regulatory Commission (FERC) pursuant to the PURPA, and has filed with the FERC for QF status or has self-certified. For additional information, see the Code of Federal Regulation, Title 18, Part 292.

Railroad and Railway Electric Service: Electricity supplied to railroads and interurban and street railways, for general railroad use, including the propulsion of cars or locomotives, where such electricity is supplied under separate and distinct rate schedules.

Receipts: Purchases of fuel.

Reserve Margin (Operating): The amount of unused available capability of an electric power system at peak load for a utility system as a percentage of total capability.

Restoration Time: The time when the major portion of the interrupted load has been restored and the emergency is considered to be ended. However, some of the loads interrupted may not have been restored due to local problems.

Restricted-Universe Census: This is the complete enumeration of data from a specifically defined subset of entities including, for example, those that exceed a given level of sales or generator nameplate capacity.

Retail: Sales covering electrical energy supplied for residential, commercial, and industrial end-use purposes. Other small classes, such as agriculture and street lighting, also are included in this category.

Running and Quick-Start Capability: The net capability of generating units that carry load or have quick-start capability. In general, quick-start capability refers to generating units that can be available for load within a 30-minute period.

Sales: The amount of kilowatthours sold in a given period of time; usually grouped by classes of service, such as residential, commercial, industrial, and other. Other sales include public street and highway lighting,

other sales to public authorities and railways, and interdepartmental sales.

Sales for Resale: Energy supplied to other electric utilities, cooperatives, municipalities, and Federal and State electric agencies for resale to ultimate consumers.

Scheduled Outage: The shutdown of a generating unit, transmission line, or other facility, for inspection or maintenance, in accordance with an advance schedule.

Short Ton: A unit of weight equal to 2,000 pounds.

Spot Purchases: A single shipment of fuel or volumes of fuel, purchased for delivery within 1 year. Spot purchases are often made by a user to fulfill a certain portion of energy requirements, to meet unanticipated energy needs, or to take advantage of low-fuel prices.

Standby Facility: A facility that supports a utility system and is generally running under no-load. It is available to replace or supplement a facility normally in service.

Standby Service: Support service that is available, as needed, to supplement a consumer, a utility system, or to another utility if a schedule or an agreement authorizes the transaction. The service is not regularly used.

Steam-Electric Plant (Conventional): A plant in which the prime mover is a steam turbine. The steam used to drive the turbine is produced in a boiler where fossil fuels are burned.

Stocks: A supply of fuel accumulated for future use. This includes coal and fuel oil stocks at the plant site, in coal cars, tanks, or barges at the plant site, or at separate storage sites.

Subbituminous Coal: Subbituminous coal, or black lignite, is dull black and generally contains 20 to 30 percent moisture. The heat content of subbituminous coal ranges from 16 to 24 million Btu per ton as received and averages about 18 million Btu per ton. Subbituminous coal, mined in the western coal fields, is used for generating electricity and space heating.

Substation: Facility equipment that switches, changes, or regulates electric voltage.

Sulfur: One of the elements present in varying quantities in coal which contributes to environmental degradation when coal is burned. In terms of sulfur content by weight, coal is generally classified as low (less than or

equal to 1 percent), medium (greater than 1 percent and less than or equal to 3 percent), and high (greater than 3 percent). Sulfur content is measured as a percent by weight of coal on an "as received" or a "dry" (moisture-free, usually part of a laboratory analysis) basis.

Switching Station: Facility equipment used to tie together two or more electric circuits through switches. The switches are selectively arranged to permit a circuit to be disconnected, or to change the electric connection between the circuits.

System (Electric): Physically connected generation, transmission, and distribution facilities operated as an integrated unit under one central management, or operating supervision.

Transformer: An electrical device for changing the voltage of alternating current.

Transmission: The movement or transfer of electric energy over an interconnected group of lines and associated equipment between points of supply and points at which it is transformed for delivery to consumers, or is delivered to other electric systems. Transmission is considered to end when the energy is transformed for distribution to the consumer.

Transmission System (Electric): An interconnected group of electric transmission lines and associated

equipment for moving or transferring electric energy in bulk between points of supply and points at which it is transformed for delivery over the distribution system lines to consumers, or is delivered to other electric systems.

Turbine: A machine for generating rotary mechanical power from the energy of a stream of fluid (such as water, steam, or hot gas). Turbines convert the kinetic energy of fluids to mechanical energy through the principles of impulse and reaction, or a mixture of the two.

Watt: The electrical unit of power. The rate of energy transfer equivalent to 1 ampere flowing under a pressure of 1 volt at unity power factor.

Watt-hour (Wh): An electrical energy unit of measure equal to 1 watt of power supplied to, or taken from, an electric circuit steadily for 1 hour.

Wheeling Service: The movement of electricity from one system to another over transmission facilities of inter-vening systems. Wheeling service contracts can be established between two or more systems.

Year to Date: The cumulative sum of each month's value starting with January and ending with the current month of the data.
