EXECUTIVE SUMMARY

This characterization report summarizes the available information on the historical uses, current status, and sampling and analysis results of waste stored in single-shell tank 241-B-204. This report supports the requirements of the *Hanford Federal Facility Agreement and Consent Order*, Milestone M-44-09 (Ecology et al. 1996).

Tank 241-B-204 is one of 16 tanks located in the Hanford 200 East Area B Tank Farm. The tank went into service in the second quarter of 1952 and received lanthanum fluoride waste (224) from the B Plant lanthanum fluoride process. The transfers continued for one more quarter. In the fourth quarter of 1952 and the first quarter of 1953, the tank received B Plant flush waste. These were the last waste transfers into the tank. Other than removing 23 kL (6 kgal) of supernatant in 1974, no other transfer activity is recorded (Agnew et al. 1996). Tank 241-B-204 was removed from service in 1978, and it was declared an assumed leaker in 1984. Interim stabilization and intrusion prevention were completed in June 1984 and June 1985, respectively.

Table ES-1 describes tank 241-B-204, and Figure ES-1 shows a diagram of the tank. The tank has an operating capacity of 208 kL (55 kgal), and it currently contains an estimated 189 kL (50 kgal) of waste. The waste is estimated to be comprised of 185 kL (49 kgal) sludge, 4 kL (1 kgal) supernatant, and no saltcake or pumpable liquid. The sludge contains approximately 19 kL (5 kgal) of drainable interstitial liquid (Hanlon 1996).

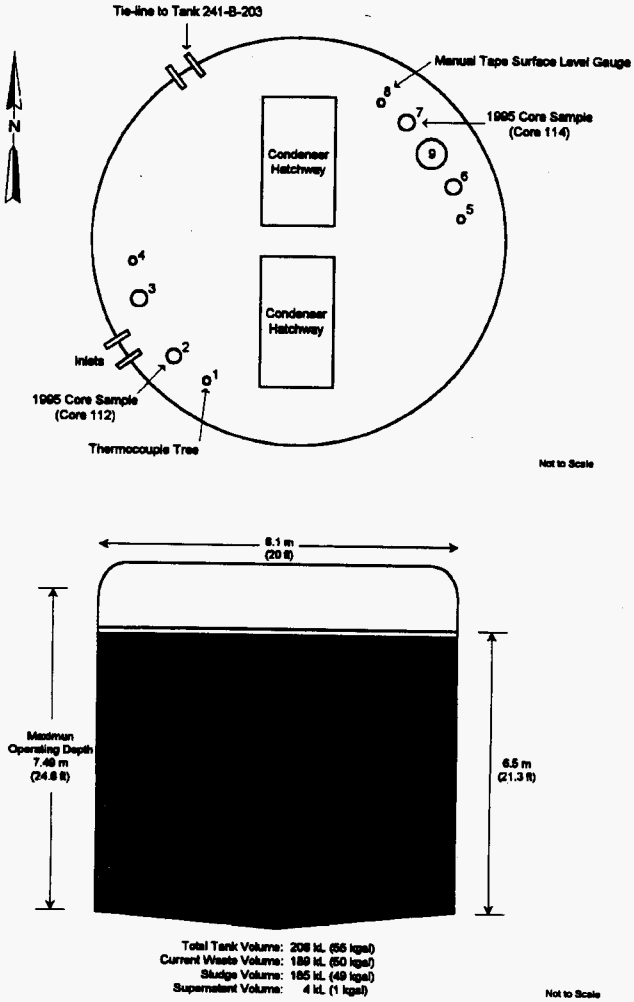
Table ES-1. Description and Status of Tank 241-B-204.

TANK DESCRIPTION	
Type	Single-shell
Constructed	1943 to 1944
In-service	1952
Diameter	6.1 m (20 ft)
Operating depth	7.50 m (24.6 ft)
Capacity	208 kL (55 kgal)
Bottom shape	Dish
Ventilation	Passive
TANK STATUS	
Waste classification	Noncomplexed
Total waste volume	189 kL (50 kgal)
Sludge volume	185 kL (49 kgal)
Drainable interstitial liquid volume	19 kL (5 kgal)
Supernatant volume	4 kL (1 kgal)
Waste surface level (1991 to 1996)	6.50 m (256 in.) to 6.51 m (256.25 in.)
Temperature (May 1975 to January 1996)	7.2 °C (45 °F) to 43 °C (110 °F)[1]
Integrity	Assumed leaker 1984
Watch List	None
SAMPLING DATES	
Push-mode core samples and tank headspace flammability	October 1995
SERVICE STATUS	
Declared inactive	1978
Interim stabilization	June 1984
Intrusion prevention	June 1985

Note:

[1]The high temperature of 43 °C is suspect.

Figure ES-1. Profile of Tank 241-B-204.



This report summarizes the analysis of the core samples taken in October 1995. The sampling event was performed to satisfy the requirements of the *Tank Safety Screening Data Quality Objective* (Dukelow et al. 1995). The sampling and analyses were performed in accordance with the *Tank 241-B-204 Push-Mode Sampling and Analysis Plan* (Sasaki 1995). The sampling effort involved taking two push-mode core samples of the tank waste from widely-spaced risers. Core 112 was taken from riser 2, and core 114 was taken from riser 7.

The safety screening data quality objective (DQO) requires analyses for fuel content using differential scanning calorimetry (DSC), percent water by thermogravimetric analysis (TGA), total alpha activity through alpha proportional counting, and bulk density. The safety screening DQO also requires a determination of the flammability of the tank headspace gases. To satisfy this requirement, vapor samples were taken prior to core sampling, and the flammability was measured as a percent of the lower flammability limit using a combustible gas meter. The sampling and analysis plan (SAP) also required analyses for lithium and bromide to check for contamination of the samples by the hydrostatic head fluid (HHF) used during sampling operations. Additional results for other metals and anions were obtained as a result of these analyses.

No exothermic reactions were observed during the DSC analysis. The mean values for weight-percent water, determined by TGA, were 77.1 for sludge and 89.1 for drainable liquid. All total alpha activity results were well below the safety screening DQO notification limit of 41 μCi/g. Sludge bulk density results were 1.19 g/mL, while that of the drainable

liquids was 1.05 g/mL. The flammability of tank 241-B-204 headspace was measured at zero percent of the lower flammability limit. The analytical results were well within the parameters listed in the safety screening DQO. Table ES-2 shows the average values for major analytes and analytes of interest.

The concentrations of individual radionuclides were measured in only one sample. Assuming that the sludge is homogeneous, a tank heat load of < 0.8 W (< 3 Btu/hr) was estimated. The historical tank content estimate (HTCE) heat load value was zero (Brevick et al. 1994a), and the heat load based on headspace temperature was 47.2 W (161 Btu/hr) (Kummerer 1994). Both estimates were well below the 11,700 W (40,000 Btu/hr) threshold differentiating high-heat from low-heat tanks (Bergmann 1991). The available temperature data for the tank support either heat load estimate.

Table ES-2. Major Analytes and Analytes of Concern.

Analyte	Mean Sludge Concentration	Sludge RSD (Mean)	Mean Supernate Concentration	Supernate RSD (Mean)	Total Inventory[1]
METALS	**μg/g**	**%**	**μg/mL**	**%**	**kg**
Bismuth	48,400	5.8	< 15.1	n/a	10,700
Chromium	3,240	5.7	154	2.7	715
Iron	3,810	12.1	< 7.53	n/a	839
Lanthanum	10,400	2.6	< 7.53	n/a	2,290
Manganese	14,800	2.7	< 1.51	n/a	3,270
Potassium	5,780	1.8	6,110	4.6	1,290
Sodium	26,200	2.3	28,000	2.2	5,880
ANIONS	**μg/g**	**%**	**μg/mL**	**%**	**kg**
Fluoride	7,080	9.5	6,240	6.0	1,580
Nitrate	52,900	7.4	45,900	3.8	11,800
Phosphate	3,620	8.8	2,060	12.4	805
RADIONUCLIDES	**μCi/g**	**%**	**μCi/mL**	**%**	**Ci**
Total alpha	0.264	7.2	9.98E-05	8.2	58.1
PHYSICAL PROPERTIES	**Sludge Mean**	**%**	**Supernate Mean**	**%**	
Weight percent water	77.1%	0.9	89.1%	0.2	173,000
Density	1.19 g/mL	2.0	1.05 g/mL	0.5	n/a

Notes:

RSD (Mean) (%) = 100 x standard deviation of the mean ÷ mean value

n/a = not applicable

[1]Total inventory = total sludge mass (220,000 kg) plus total supernate mass (3,970 kg).

1.0 INTRODUCTION

This tank characterization report presents an overview of single-shell tank 241-B-204 and its waste contents. It provides estimated concentrations and inventories for waste components based on the latest sampling and analysis activities in combination with background tank information. The characterization of tank 241-B-204 is based on the results of a core sampling event in October 1995. For information purposes, results from a 1978 sampling event are also included. Other 241-B-200 series tanks contain waste similar to that in tank 241-B-204. For additional information, refer to Heasler et al. (1994) for tank 241-B-201 and Dougherty and Tran (1995) for tank 241-B-202.

Tank 241-B-204 was removed from service in 1978. Interim stabilization was completed in June 1984, and intrusion prevention was completed in June 1985; therefore, the composition of the waste should not change appreciably until pretreatment and retrieval activities commence. The analyte concentrations reported in this document reflect the best composition estimates of the waste based on the available analytical data and historical models. This report supports the requirements of the *Hanford Federal Facility Agreement and Consent Order*, Milestone M-44-09 (Ecology et al. 1996).

1.1 PURPOSE

The purpose of this report is to summarize the information about the use and contents of tank 241-B-204. When possible, this information will be used to assess issues associated with safety, operations, environmental, and process development activities. This report also serves as a reference point for more detailed information about tank 241-B-204.

1.2 SCOPE

The October 1995 core sampling event for tank 241-B-204 supported the evaluation of tank waste according to the *Tank Safety Screening Data Quality Objective* (Dukelow et al. 1995). Safety screening analyses were performed on the two core samples as directed in the *Tank 241-B-204 Push Mode Core Sampling and Analysis Plan* (Sasaki 1995). These analyses were differential scanning calorimetry (DSC) to evaluate fuel level and energetics, thermogravimetric analysis (TGA) to determine moisture content, total alpha activity analysis to evaluate criticality potential, and bulk density. The flammability of the tank headspace gases was also measured as required by the safety screening DQO. The SAP also required analyses for lithium by inductively coupled plasma spectroscopy (ICP) and bromide by ion chromatography (IC) to account for any hydrostatic head fluid (HHF) contamination during the core sampling operation. Results for additional analytes were obtained during the ICP and IC analyses and are included in this report. Gamma energy analyses (GEA) and ^{90}Sr analysis were performed on one segment to gather information for the disposal of laboratory waste (Sasaki 1996b).

This page intentionally left blank.

2.0 HISTORICAL TANK INFORMATION

This section describes tank 241-B-204 based on historical information. The first part details the current condition of the tank. It includes discussions of tank design, transfer history, process sources contributing to the tank waste, and an estimate of the current contents based on the process history. It also includes events that may be related to tank safety issues, such as potentially hazardous tank contents or off-normal operating temperatures. The final part summarizes available surveillance data for the tank. Solid and liquid level data are used to determine tank integrity (leaks) and to provide clues to internal activity in the solid layers of the tank. Temperature data are provided to evaluate the heat generating characteristics of the waste.

2.1 TANK STATUS

As of January 31, 1996, tank 241-B-204 contained an estimated 189 kL (50 kgal) of waste classified as noncomplexed (Hanlon 1996). Liquid volume was determined photographically. Solids volume was determined using a manual tape surface level gauge. The estimated amounts of the waste phases in the tank are shown in Table 2-1.

Table 2-1. Estimated Tank Contents.[1]

Waste Form	Estimated Volume	
	kL	kgal
Total waste	189	50
Supernatant liquid	4	1
Sludge	185	49
Saltcake	0	0
Drainable interstitial liquid	19	5
Drainable liquid remaining	23	6
Pumpable liquid remaining	0	0

Note:
[1]Hanlon (1996)

Tank 241-B-204 was declared an assumed a leaker in 1984 with a leak volume of approximately 1,500 L (400 gal). Interim stabilization was completed in June 1984, and intrusion prevention was completed in June 1985. Tank 241-B-204 is a low heat load tank that is passively ventilated. It is not on any Watch Lists. All monitoring systems were in compliance with documented standards as of January 31, 1996 (Hanlon 1996).

2.2 TANK DESIGN AND BACKGROUND

The 241-B Tank Farm is a first generation tank farm. Built between 1943 and 1944, it consists of 12 2,006 kL (530 kgal) and four 208 kL (55 kgal) single-shell tanks (Leach and Stahl 1993). The tanks were designed for nonboiling waste with a maximum fluid temperature of 104 °C (220 °F). As with all first generation tank farms, equipment to monitor the waste is sparse. A typical B Farm 208-kL (55-kgal) tank contains risers that provide surface level access to the underground tank. The risers range from 10 cm (4 in.) to 30 cm (12 in.).

Tank 241-B-204 is constructed of 0.3-m (1-ft) thick reinforced concrete with a .64-cm (0.25-in.)-thick mild carbon-steel liner on the bottom and sides and a 30-cm (12-in.) thick flat concrete top (Brevick 1994a). Tank 241-B-204 is equipped with nine risers through the top of the tank. The risers range in diameter from 10 cm (4 in.) to 1.1 m (3.5 ft). The carbon-steel liner has a 7.49 m (24.6 ft) operating depth, is 6.1 m (20 ft) in diameter, and has a 15-cm (6-in.) deep-dished bottom with a 0.9 m (3 ft) radius knuckle. The tank is set on a reinforced concrete foundation. At the time of construction, the tank was waterproofed on the sides and top with tar and gunite. The tank is covered with approximately 3.5 m (11.5 ft) of overburden.

The four 200-series tanks on the B tank farm are at the same elevation. Tank 241-B-204 is connected to tank 241-B-203 by a 7.6-cm (3-in.) diameter line that enables waste transfers from one tank to the other.

Figure 2-1 shows the riser configuration. Table 2-2 lists tank 241-B-204 risers, their diameter, and a description of each. Figure 2-2 shows a cross section of the tank with the approximate waste level and a schematic of the tank equipment. Tank 241-B-204 has a construction manhole and eight grade-level risers (Alstad 1993). A thermocouple tree in riser 1 monitors the tank waste temperature, and a manual tape through riser 8 measures the surface level. Risers 2, 3, 6 and 7 (30 cm [12 in.] in diameter) and risers 4 and 5 (10 cm [4 in.] in diameter) access the two sides of the tank (Lipnicki 1995).

Figure 2-1. Riser Configuration for Tank 241-B-204.

2.3 PROCESS KNOWLEDGE

The following sections describe the transfer history of waste in tank 241-B-204, the process wastes that were transferred, and an estimate of current tank contents based on transfer history.

2.3.1 Waste Transfer History

Table 2-3 shows the waste transfer history for tank 241-B-204. B Plant 224 waste from the lanthanum fluoride process was transferred to tank 241-B-204 during the second and third quarters of 1952. In the fourth quarter of 1952 and the first quarter of 1953, tank 241-B-204 received B Plant flush waste. From the second quarter of 1952 to the first quarter of 1953, the overflow from tank 241-B-204 was cascaded to a crib (Brevick et al. 1994b). Approximately 185 kL (49 kgal) of waste was left in the tank after the final transfer in 1974. Tank 241-B-204 was removed from service in 1978.

Table 2-3. Summary of Tank 241-B-204 Waste Transfer History.[1]

Transfer	Waste Type Received	Time Period	Estimated Waste Volume[2]	
			kL	kgal
224-U (B Plant)	224	1952	943	249
B Plant	B Plant Flush	1952 - 1953	466	123

Notes:

[1]Agnew (1995)

[2]Waste volumes and types are best estimates based on historical data.

2.3.2 Historical Estimation of Tank Contents

An estimate of the current contents of tank 241-B-204 based on historical transfer data is available from the *Historical Tank Content Estimate for the Northeast Quadrant of the Hanford 200 East Area* (Brevick et al. 1994a). The HTCE predictions have not been validated and should not be used as a basis for decisions affecting the waste in tank 241-B-204. Historical data used for the estimate include the *Waste Status and Transaction Record Summary (WSTRS) for the Northeast Quadrant* (Agnew et al. 1996), the *Hanford Defined Waste: Chemical and Radionuclide Compositions* (Agnew 1995), the *Tank Layer Model (TLM) for the Northeast, Southwest, and Northwest Quadrants* (Agnew et al. 1995), and the *Hanford Tank Chemical and Radionuclide Inventories: HDW Model Rev. 3* (Agnew 1996). The Waste Status and Transaction Record Summary is a compilation of available waste transfer and volume status data. The Hanford Defined Waste

(HDW) document provides the assumed typical compositions for Hanford waste types. In most cases, the available data are incomplete thereby reducing the reliability of the transfer data and the modeling results derived from it. The TLM takes the Waste Status and Transaction Record Summary data, models the waste deposition processes and, using additional data from the HDW document (which may introduce more error), generates an estimate of the tank contents. Therefore, these model predictions can only be considered an estimate that requires further evaluation using analytical data.

The TLM states that tank 241-B-204 contains 185 kL (49 kgal) of 224 waste from the LaF_3 process (waste generated in the B-224 building) and 4 kL (1 kgal) of supernate (see Figure 2-3). The 224 sludge waste layer should contain the following: (1) very large quantities of iron, lanthanum, sodium, strontium, bismuth, fluoride, and nitrate, (2) a large quantity of carbonates, and (3) a trace amount of plutonium. The plutonium quantity may be enough to give this waste a slight activity. Table 2-4 shows the waste constituents and their concentrations.

[1]Agnew (1996)

[2]The HTCE predictions have not been validated and should not be used as the basis for decisions affecting the waste in tank 241-B-204.

[3]Small differences appear to exist among the inventory values in this column and the inventories calculated from the two sets of concentrations. The differences are being evaluated.

2.4 SURVEILLANCE DATA

Tank 241-B-204 surveillance consists of surface level measurements (liquid and solid) and temperature monitoring (inside the tank waste and headspace). The data provide the basis for determining tank integrity. Liquid level measurements may indicate the presence of a major tank leak. Solid surface level measurements indicate physical changes and consistency of the solid layers. Tank 241-B-204 does not have liquid observation wells or drywells.

2.4.1 Surface Level

The surface level of the waste is monitored daily with a manual tape through riser 8. The maximum allowed deviations from the 6.515 m (21.37 ft) baseline established for tank 241-B-204 are a 5.0 cm (2 in.) increase and a 5.0 cm (2 in.) decrease. Between 1991 and 1996, the surface level readings have ranged between 6.50 m (21.33 ft) and 6.51 m (21.36 ft). Figure 2-4 shows the tank volume history. The surface level on March 14, 1996, was 6.5 m (21.33 ft).

2.4.2 Internal Tank Temperatures

Tank 241-B-204 has a single thermocouple tree with 12 thermocouples for monitoring temperatures. Documentation describing the thermocouple tree design and the elevations of the thermocouples was not available. No temperature data are available prior to 1975, and there is a data gap between April 1982 and July 1989. Tank 241-B-204 temperatures currently are monitored semiannually. For plots of individual thermocouple readings, refer to Brevick et al. (1994b).

Between May 1975 and January 1996, the mean temperature was 17 °C (62.7 °F) with a minimum of 7.2 °C (45 °F) and a maximum of 43 °C (110 °F). On January 9, 1996, the high temperature was 17 °C (62.6 °F) recorded by thermocouple 9, and the low temperature was 14 °C (57.2 °F) recorded by thermocouple 12. Figure 2-5 shows a graph of high temperatures recorded between 1975 and 1996. Brevick et al. (1994b) classify the maximum temperature of 43 °C, recorded July 5, 1989, as an outlier. All tank 241-B-204 thermocouples and most thermocouples for other 241-B 200-series tanks show a similar high reading on that same date. Considering the temperature history of the tank and the nature of the tank waste, it seems unlikely that tank waste temperatures were actually as high as 43 °C. It is more likely that all the readings were subject to the same systematic error when they were collected.

Figure 2-4. Tank 241-B-204 Level History.

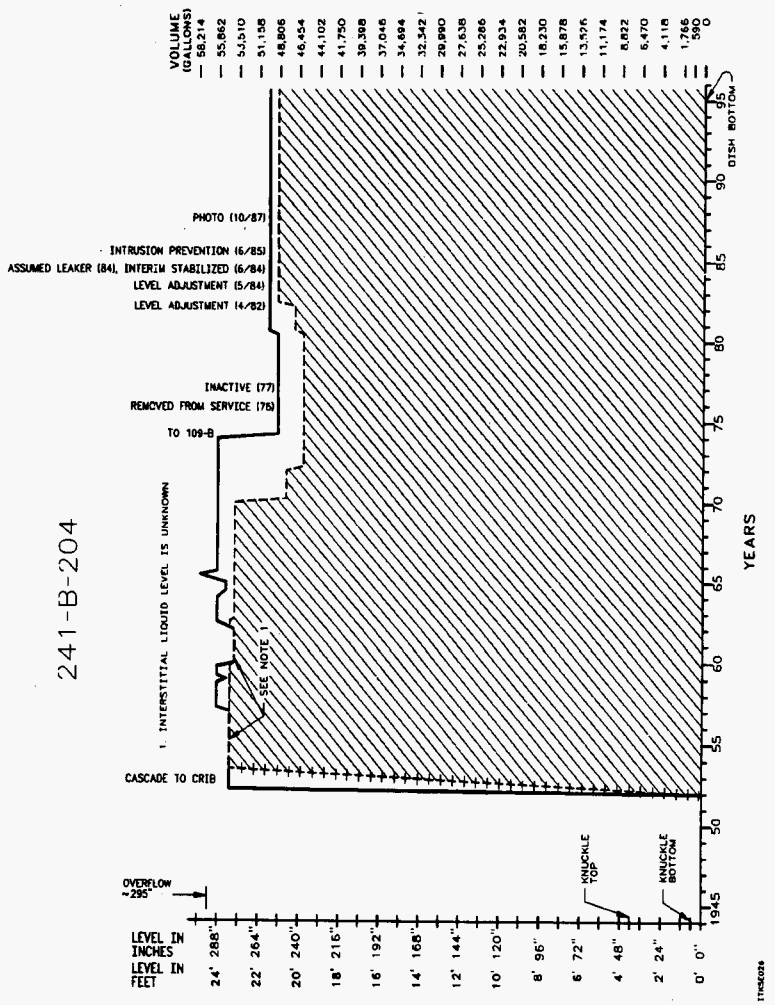

Figure 2-5. Tank 241-B-204 Weekly High Temperature Plot.

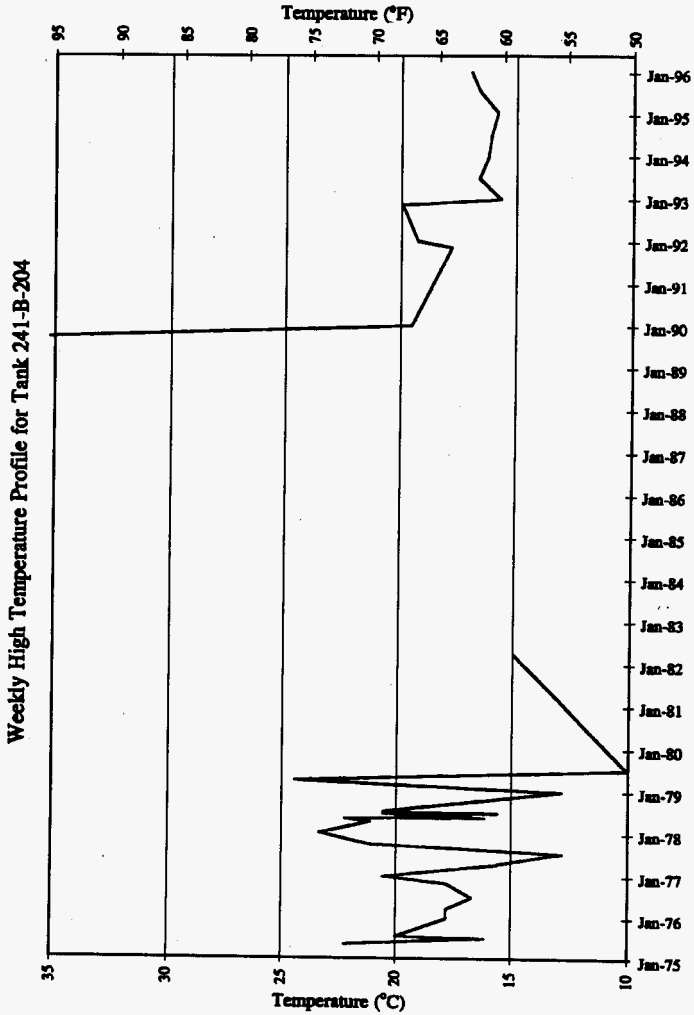

Note: The 1989 high temperature reading is classified as an outlier (Brevick et al. 1994b).

2.4.3 Tank 241-B-204 Photograph

Figure 2-6 is a montage of 1987 photographs of the tank 241-B-204 interior showing a thin supernate layer over a dark orange sludge. The in-tank photographs should correspond to the current tank contents since no transfers have taken place since the photographs were taken. The photographs show approximately 189 kL (50 kgal) of waste which equals a waste depth of about 6.4 m (21 ft). Picture quality is poor and the tank details are hazy; the inlet nozzle and temperature probe were overexposed because they were too close to the flash.

3.0 TANK SAMPLING OVERVIEW

This section describes the October 1995 sampling and analysis event for tank 241-B-204. Push-mode core samples were taken to satisfy the requirements of the safety screening DQO (Dukelow et al. 1995), and sampling and analysis were performed in accordance with the sampling and analysis plan (SAP) (Sasaki 1995). For further discussions of the sampling and analysis procedures, refer to the *Tank Characterization Reference Guide* (DeLorenzo et al. 1994).

3.1 DESCRIPTION OF SAMPLING EVENT

Two 14-segment push-mode core samples were collected from tank 241-B-204 between October 11 and October 19, 1995. Cores 112 and 114 were taken from risers 2 and 7, respectively. Water was used as the HHF during sampling operations. A tracer (lithium bromide) was added to the HHF to gauge contamination of the segments by the HHF. A field blank and a sample of the HHF were also taken. Prior to core sampling, the tank headspace was sampled to determine the flammable gas concentration as outlined in the safety screening DQO. This sampling was done through riser 2 at approximately 1 m (3.3 ft) above the waste surface (or 4 m [13 ft] below the top of the riser) (Sasaki 1996a).

All analyses were performed by the Westinghouse Hanford Company 222-S Laboratory in accordance with the SAP (Sasaki 1995). Table 3-1 summarizes the sampling and analysis requirements of the safety screening DQO (Dukelow et al. 1995). Table A-2 summarizes each core segment's riser number, sample depth, sample numbering, and drill string dose rate information.

Table 3-1. Integrated Data Quality Objective Requirements for Tank 241-B-204.

Sampling Event	Applicable DQOs	Sampling Requirements	Analytical Requirements
Push-mode core sampling	Safety screening (Dukelow et al. 1995)	Core samples from a minimum of two risers separated radially to the maximum extent possible	Energetics Moisture content Total alpha activity Density Flammable gas concentration

3.2 SAMPLE HANDLING

Cores 112 and 114 were received by the 222-S Laboratory between October 12 and October 20, 1995, and were extruded between October 16 and October 26, 1995. The top two segments of core 112 and the top segment of core 114 contained drainable liquid. Small amounts of liner liquid were also recovered for most samples. All remaining segments of the two cores were full of smooth, soft, black sludge. No separable organic layer was observed in any segments. One field blank and one HHF sample were delivered to the 222-S Laboratory with core 114. Both cores were subsampled at the half-segment level for analysis. Table A-3 tabulates the subsampling scheme, the subsegment masses, and visual characteristics of the segments.

3.3 SAMPLE ANALYSIS

The safety screening DQO required analyses for thermal properties by DSC, moisture by TGA, fissile content by total alpha analysis, and bulk density. In addition to the core sample analyses, the tank headspace flammability was measured prior to core sampling.

Bromide analysis by IC and lithium analysis by ICP were required by the SAP to determine the amount of HHF contamination in the samples. During these measurements, results for other metals and anions were obtained and reported as requested by the SAP.

A GEA and ^{90}Sr analysis were performed on one solid subsample to provide radionuclide content information for the disposal of laboratory waste. The sample analyzed was from the lower half solids of segment 14, core 112, because this sample had the highest measured total alpha result.

All reported analyses were performed in accordance with approved laboratory procedures. Table A-4 lists the sample numbers and applicable analyses. Table A-5 displays analytical procedures by title and number. No deviations or modifications were noted by the laboratory. The appropriate quality control checks were run in conjunction with all chemical and physical analyses. Section 5.1.2 assesses the quality control results.

3.4 DESCRIPTION OF HISTORICAL SAMPLING EVENT

There was one historical sampling event reported for tank 241-B-204. The sample was analyzed in 1978 and referenced as sample number 1974 (Horton 1978). Because the sample was collected and analyzed prior to May 1989, the data do not meet current quality assurance requirements. Therefore, no decisions regarding the waste in tank 241-B-204 should be based upon these historical data.

The specifics for this event such as the procedure, riser used, and depth at which the sample was taken are not available from historical records. The sample was received by the Chemical Analysis Laboratories at the 222-S Laboratory and was reported as black in color with a consistency of soft grease. Test results were reported on December 4, 1978. Both a water leach and an unspecified acid digestion method were performed on the sample. The results of the analyses revealed that the primary constituents by volume (percent) were sodium, nitrate, potassium, and carbonate. Appendix D shows the analytical results for this historical sample, and Section 5.2 compares the 1978 and 1995 analytical results.

4.0 ANALYTICAL RESULTS

This section summarizes the analytical results of the October 1995 sampling of tank 241-B-204. The sampling and analysis were performed as directed in the SAP (Sasaki 1995). This plan integrated all documents related to sampling and analytical requirements including applicable DQOs. Analysis of the two cores were performed at the Westinghouse Hanford Company 222-S Laboratory.

Table 4-1 shows the locations of the analytical results.

4.1 DATA PRESENTATION

This section summarizes the analytical results from the 1995 sampling of tank 241-B-204. The subsections below provide information about the chemical, physical, vapor, and HHF contamination check data. Data from the analysis of cores 112 and 114 were reported in *45-Day Safety Screening Results for Tank 241-B-204, Push Mode Cores 112 and 114* (Sasaki 1996a) and *Final Report for Tank 241-B-204, Push Mode Cores 112 and 114* (Sasaki 1996b).

4.1.1 Chemical Data Summary

Table 4-2 shows the mean concentration estimates and inventories for the sludge and drainable liquid results separately and as a total tank inventory. Data from the two cores were combined to derive the overall concentration means for all analytes, with the exception of the radionuclides analyzed by GEA. The overall means reported are weighted means and were calculated by taking a simple mean of all subsegment values for a particular segment, averaging the segment means for an individual core to derive a core mean, and averaging the two core means to obtain an overall mean. When 50 percent or more of the individual

Notes:

n/a = not applicable

[1]Radionuclide means are based on the results from one sample/duplicate pair taken from the lower half solids of segment 14, core 112.
[2]Relative standard deviation of the data is shown because only one sample/duplicate pair was analyzed.
[3]Weight-percent water overall means are based on results corrected for HHF contamination.

sample/duplicate measurements had detected results, the overall mean was reported as a detected value. Conversely, when results for more than 50 percent of the individual sample/duplicate results were nondetected, the overall mean was reported as a less than (<) value.

The GEA and ^{90}Sr were performed only on the lower half solids of segment 14, core 112. Consequently, the overall means for ^{241}Am, ^{60}Co, ^{137}Cs, ^{154}Eu, ^{155}Eu, and ^{90}Sr are based on the results from one sample/duplicate pair and may not represent the entire tank contents.

Table 4-2 shows the overall means in columns 2 and 5 for the sludge and supernate portions of the waste, respectively. Appendix B lists the original subsegment analytical data.

Relative standard deviations of the mean (RSD [Mean]), defined as 100 times the standard deviation of the mean divided by the tank mean. The standard deviation was computed using a nested analysis of variance model and restricted maximum likelihood methods. They are reported in columns 3 and 6 and were calculated only for analytes which had 50 percent or more of their individual sample/duplicate results above the detection limit.

The sludge inventory in column 4 was calculated by multiplying the overall mean by the sludge density (1.19 g/mL) and the sludge waste volume (185,000 L [49,000 gal]), then dividing by a unit conversion factor of 1E+06. The supernate inventory in column 7 was calculated by multiplying the overall mean by the supernate waste volume (4,000 L [1,000 gal]) and dividing by a unit conversion factor of 1E+06. Total inventory results in column 8 are the sum of the sludge and supernate inventories. Using the respective estimates for the sludge and supernate volumes and densities, the total sludge mass is estimated to be 220,000 kg, and the total supernate mass is estimated to be 3,970 kg.

4.1.2 Physical Data Summary

Thermal analyses were performed on tank 241-B-204 core samples to satisfy the requirements of the safety screening DQO (Dukelow et al. 1995) which dictated that TGA and DSC be performed on both solid and liquid phases of the waste samples. Density determinations were also performed.

4.1.2.1 Thermogravimetric Analysis. In a TGA, the mass of a sample is measured while its temperature is increased at a constant rate. A gas, such as nitrogen or air, is passed over the sample during the heating to remove any released gases. A decrease in the weight of a sample represents a loss of gaseous matter from the sample through evaporation or through a reaction that forms gas phase products.

Weight-percent water by TGA was performed by the 222-S Laboratory under a nitrogen purge using procedures LA-560-112, Rev. B-1 (Mettler[1]) and LA-514-114, Rev. C-1 (Perkin-Elmer[2]).

Table B-50 shows the TGA percent water data for tank 241-B-204. The HHF-corrected mean weight-percent water result for drainable liquid samples was 89.1 percent with an RSD of 0.2 percent. The HHF-corrected mean result for the sludge samples was 77.1 percent with an RSD of 0.9 percent. All weight-percent water sample means were calculated by equal weighting of the two cores, the segments, and the subsegments using values corrected for HHF contamination based on the bromide results. Sample S95T003260 was rerun because of an instrument error, and a triplicate was analyzed on sample S95T003278 because of the large discrepancy between the original and duplicate results. The laboratory did not encounter other problems.

4.1.2.2 Differential Scanning Calorimetry. In a DSC analysis, heat absorbed or emitted by a substance is measured while the substance is exposed to a linear increase in temperature. As the substance is being heated, a gas such as nitrogen is passed over the waste material to remove any gases being released. The onset temperature for an endothermic event (characterized by or causing the absorption of heat) or an exothermic event (characterized by or causing the release of heat) is determined graphically.

The DSC analyses were performed by the 222-S Laboratory under a nitrogen atmosphere using procedures LA-514-113, Rev. C-1 (Mettler™) or LA-514-114, Rev. C-1 (Perkin-Elmer™).

No exothermic reactions were observed, and the only endothermic transition exhibited was that associated with the evaporation of free and interstitial water. Because there were no exothermic reactions, the calculation of a 95 percent confidence interval as specified by the safety screening DQO (Dukelow et al. 1995) was not necessary. Table B-51 shows the DSC results and includes, for each sample, the temperature range and enthalpy for the single endothermic transition.

4.1.2.3 Density. Bulk density measurements were performed on solid samples using procedure LO-160-103, Rev. A-7. Specific gravity measurements were performed on the liquid samples using procedure LA-510-112, Rev. C-3. The mean density of the sludge was 1.19 g/mL, and that of the drainable liquid was 1.05 g/mL. Table B-52 shows the analytical data.

[1]Mettler is a registered trademark of Mettler Electronics, Anaheim, CA.

[2]Perkin-Elmer is a registered trademark of Perkins Research and Manufacturing Company, Inc., Canoga, Park CA.

4.1.3 Tank Headspace Flammability

The sampling of tank 241-B-204 headspace was performed prior to core sampling. The tank vapors were field tested using a combustible gas meter; the flammable vapor content was determined to be 0 percent of the lower flammability limit, indicating no flammability concerns. In addition, the concentrations of oxygen (20.7 percent), total organic vapors (1.4 ppm), and ammonia (2 ppm) were measured.

4.1.4 Hydrostatic Head Fluid Contamination Check

Hydrostatic head fluid was used in conjunction with the 1995 core samplings, and lithium bromide was used as a tracer in the HHF to estimate the degree of sample contamination. This check, through chemical analyses for lithium and bromide, was prescribed by the SAP (Sasaki 1995). The analytical results indicated that both elements were present in detectable quantities in all sludge subsegments and most drainable liquid samples (see Appendix C). Based on the bromide results, the HHF contamination was less than 2 percent for all samples. The HHF correction factors were applied to the weight-percent water analytical data for all subsegments; the HHF correction factors were not applied to any other analyte. The bromide values were chosen for the HHF correction factors because bromide is less likely than lithium to form insoluble compounds with tank waste. When lithium and bromide results were compared, the equivalents of lithium recovered were less than those for bromide in general. An overall mean and tank inventory were not calculated for these two analytes because they are not constituents of the tank waste.

This page intentionally left blank.

5.0 INTERPRETATION OF CHARACTERIZATION RESULTS

This section discusses the overall quality and consistency of the current sampling results for tank 241-B-204 and assesses and compares these results to historical information and program requirements.

5.1 ASSESSMENT OF SAMPLING AND ANALYTICAL RESULTS

This section evaluates sampling and analysis factors that may impact data interpretation. These factors are used to assess the overall data quality and consistency and to identify data limitations.

5.1.1 Field Observations

The safety screening DQO (Dukelow et al. 1995) requirement to sample from at least two widely-spaced risers was fulfilled. Therefore, a horizontal and vertical comparison of the analytical results was possible and gave an estimate of waste constituent distribution. No sampling problems were noted. All samples achieved 100 percent recovery.

5.1.2 Quality Control Assessment

The usual quality control assessment includes evaluating the appropriate standard recoveries, spike recoveries, duplicate analyses, and blanks that are performed in conjunction with the chemical analyses. All pertinent quality control tests were conducted on the 1995 core samples, enabling a full assessment of data accuracy and precision. The SAP (Sasaki 1995) established the specific criteria for the primary analytes (TGA, DSC, bulk density, total alpha activity, lithium, and bromide), and the remainder of the analytes were governed by the laboratory criteria (DOE 1995). Sample and duplicate pairs that had one or more quality control results outside the specified criteria are identified by footnoting the data in Appendices B and C.

The standard and spike recovery results provide an estimate of analysis accuracy. If a standard or spike recovery is above or below the given criterion, the analytical results may be biased high or low, respectively. The precision is estimated by the relative percent difference (RPD), which is defined as the absolute value of the difference between the primary and duplicate samples, divided by their mean, times one hundred. The lithium analyses had two low spike recoveries, a result of the lithium concentration in the sample being two orders of magnitude greater than the spike. When the sample concentration is more than four times larger than the spike, the error introduced in calculating the spike recovery becomes large and results in a poor recovery. The lithium analyses also had three high RPDs. Several spike recoveries and RPDs were outside the target level for total alpha

activity. This was caused by low sample activities and high dissolved solids in the samples and by possible self-shielding. Several standard recoveries, conducted with total alpha activity, were outside the SAP criterion; TGA had three RPDs, and bulk density had one RPD outside the limits. Finally, no sample exceeded the criterion for preparation blanks; therefore, contamination was not a problem.

In summary, almost all quality control results for the primary analytes listed above were within the boundaries specified in the SAP. The few discrepancies noted should not impact data validity or use. None of the remaining data in this report had quality control violations (ICP, IC, and GEA analytes).

5.1.3 Data Consistency Checks

Comparing different analytical methods can help to assess data consistency and quality. The quantity of data available enabled calculations of mass and charge balances and comparisons of the ICP phosphorus and sulfur results with the IC phosphate and sulfate results, respectively.

5.1.3.1 Comparison of Results from Different Analytical Methods. The following data consistency check compares phosphate and sulfate results from two analytical methods. A close correlation between the two methods strengthens the credibility of both results, whereas a poor correlation may bring the data reliability into question. Table 4-2 shows the analytical mean results.

For supernate, the ICP mean total phosphorous result was 680 μg/mL (equivalent to 2,090 μg/mL phosphate). The IC mean phosphate result was 2,060 μg/mL. The ICP and IC results agree with an RPD of only 1.4 percent.

For sludge, the analytical phosphorous mean result as determined by ICP was 2,320 μg/g (equivalent to 7,110 μg/g phosphate). The IC phosphate mean result was 3,620 μg/g, which yielded an RPD between the two phosphate results of 65 percent. The low IC phosphate value is caused by the inability of the water-leach sample-preparation procedure to solubilize the water-insoluble phosphate compounds prior to IC analysis. The acid-digestion procedure, which is used to dissolve the sludge prior to ICP analysis, is much more likely to yield soluble phosphate that is detected as total phosphorous. Comparing IC and ICP results for phosphate suggests that only 51 percent of the phosphate in the sludge is water soluble.

The mean total sulfur value for the supernate, as determined by ICP, was 134 μg/mL (equivalent to 401 μg/mL sulfate). The mean sulfate value, as determined by IC, was 785 μg/mL; the RPD for the two values is 64.8 percent. The poor agreement between the two sulfate values may be caused in part by the IC supernate samples being diluted to very near the method's detection limit for sulfate. Therefore, the poor agreement between the ICP and IC supernate sulfate values may be caused by inaccuracies associated with quantifying sulfate near the IC detection limit. In contrast, the ICP sulfur values tended to

fall between five and 10 times the ICP detection limit for sulfur. Therefore, the sulfate value calculated from the ICP sulfur results may be a better estimate of the sulfate concentration in the supernate than the IC sulfate value.

The mean ICP sulfur value for the sludge of 95.0 μg/g converts to 284 μg/g of sulfate. The IC sulfate mean result was 648 μg/g, which yielded an RPD of 78 percent between the two sulfate results. Again, the IC sulfate values for the diluted, water-digested samples were near the detection limit of sulfate and the ICP sulfur values tended to be between five and 10 times the ICP detection limit for sulfur. Furthermore, the water leach of the sludge may not have removed all sulfate from the sludge. Therefore, the sulfate value calculated from the ICP sulfur results may be a better estimate of the sulfate concentration in the sludge than the IC sulfate value.

5.1.3.2 Mass and Charge Balances. The principle objective in performing mass and charge balances is to determine whether the measurements are self-consistent. When calculating the balances, only the analytes detected at a concentration of 3,000 μg/g or greater were considered (see Table 4-2). Only the sludge portion of the waste was considered because it comprises 98 percent of the tank contents.

Except for sodium and potassium, all cations were assumed present in their most common hydroxide or oxide form, and the concentrations of the assumed species were calculated stoichiometrically (see Table 5-1). Because precipitates are neutral species, all positive charge was attributed to the sodium and potassium cations. The anionic analytes were assumed present as sodium/potassium salts and were expected to balance the positive charge exhibited by the cations (see Table 5-2). Phosphorus is assumed present as the soluble phosphate ion and the insoluble compound bismuth phosphate. The concentration of the insoluble phosphate was found by subtracting soluble phosphate, as determined by IC, from the total amount of phosphate calculated from total phosphorous by ICP. The concentrations of the cationic species, the anionic species, and the percent water were used to calculate the mass balance. The uncertainty estimates (RSDs) associated with each analyte are also given in the tables. Uncertainty estimates for the cation and anion totals and the overall uncertainty (see Table 5-3), were computed by a statistical technique known as the propagation of errors (Nuclear Regulatory Commission 1988).

The mass balance was calculated from the formula below. The factor 0.0001 is the conversion factor from μg/g to weight percent.

$$\begin{aligned}\text{Mass balance} &= \%\ \text{Water} + 0.0001 \times \{\text{Total Analyte Concentration}\} \\ &= \%\ \text{Water} + 0.0001 \times \{BiPO_4 + Bi_2O_3 + Cr(OH)_3 + FeO(OH) + La(OH)_3 \\ &\quad + MnO(OH) + Na^+ + K^+ + F^- + NO_3^- + PO_4^{-3}\}\end{aligned}$$

The total analyte concentrations calculated from the above equation is 203,000 μg/g. The sludge mean weight percent water obtained from TGA (see Table 4-2) is 77.1 percent or 771,000 μg/g. The mass balance resulting from adding the percent water to the total analyte concentration is 97.4 percent (see Table 5-3).

Table 5-1. Cation Mass and Charge Data.

Analyte	Concentration µg/g	Assumed Species	Concentration of Assumed Species µg/g	RSD (Mean) %	Charge µeq/g
Bismuth	7,680	$BiPO_4$	11,200	5.8	0
Bismuth	40,700	Bi_2O_3	45,400	5.8	0
Chromium	3,240	$Cr(OH)_3$	6,420	5.7	0
Iron	3,810	FeO(OH)	6,060	12.1	0
Lanthanum	10,400	$La(OH)_3$	14,200	2.6	0
Manganese	14,800	MnO(OH)	23,700	2.7	0
Potassium	5,780	K^+	5,780	1.8	148
Sodium	26,200	Na^+	26,200	2.3	1,140
Total			139,000	2.1	1,290

Table 5-2. Anion Mass and Charge Data.

Analyte	Concentration µg/g	Assumed Species	Concentration of Assumed Species µg/g	RSD (Mean) %	Charge µeq/g
Fluoride	7,080	F^-	7,080	9.5	373
Nitrate	52,900	NO_3^-	52,900	7.4	853
Phosphate	3,620	PO_4^{3-}	3,620	8.8	114
Total			63,600	6.3	1,340

Table 5-3. Mass Balance Totals.

Totals	Concentrations µg/g	RSD (Mean) %
Total from Table 5-1	139,000	2.1
Total from Table 5-2	63,600	6.3
Water %	771,000	0.9
Grand Total	974,000	0.9

The following equations demonstrate the derivation of total cations and total anions; the charge balance is the ratio of these two values.

Total cations (μeq/g) = $[Na^+]/23.0 + [K^+]/39.1 = 1{,}290$ μeq/g

Total anions (μeq/g) = $[F^-]/19.0 + [NO_3^-]/62.0 + [PO_4^{3-}]/31.7 = 1{,}340$ μeq/g

The charge balance obtained by dividing the sum of the positive charge by the sum of the negative charge was 0.96.

In summary, the above calculations yield reasonable mass and charge balance values (close to 1.00 for charge balance and 100 percent for mass balance), indicating that the analytical results and the assumptions used in interpreting them are generally self-consistent.

5.2 COMPARISON OF HISTORICAL WITH ANALYTICAL RESULTS

Based on the tank waste transfer history, tank contents have not changed since 1974. Therefore, it is possible to compare historical sludge sampling from 1978 and the sludge results from the 1995 core sampling event. The 1995 sampling was well documented and should be representative of the tank contents. No specific information was available about sample location, depth, or number of samples in the 1978 data so it is not known how representative these samples were. These data are not validated and are for comparison only. No decisions regarding the waste in tank 241-B-204 should be based on the 1978 data.

Table 5-4 compares the two data sets. The 1978 results were derived by summing the water soluble and acid (fusion) results for each analyte (see Appendix D). Only one plutonium value was available from the 1978 results. It is unknown whether this represents a sum of all plutonium isotopes or just one of them. When comparing to the 1995 total alpha activity result, it was assumed that plutonium was the only alpha emitter present, and that all plutonium was present as ^{239}Pu. The conversion factor of 0.0615 Ci/g was used to convert the 1978 plutonium result of 9.74E-06 g/g to 0.599 μCi/g total alpha.

As seen from the large RPDs, most analytes do not compare well. The percent water and density results compare very well indicating the liquid content of the tank has remained unchanged. Although the waste-water content might have been expected to decrease between the two sampling events because of 17 years evaporation, very little evaporation may have occurred because the thermal driver for evaporation is very small, and the tank is passively ventilated. The large differences between the results of the two sampling events may be caused by different sampling depths and locations and the possibility that 1978 results do not represent the tank waste and may not be valid.

Table 5-4. Comparisons of Sludge Data from the 1978 and 1995 Sampling Events for Tank 241-B-204.

Analyte	1978 Analytical Result[1,2]	1995 Mean Sludge Concentration[3]	Relative Percent Difference
METALS	**µg/g**	**µg/g**	**%**
Aluminum	88	65.3	29.6
Bismuth	62,000	48,400	24.6
Chromium	400	3,240	156
Iron	29,000	3,810	154
Lanthanum	20,100	10,400	63.6
Manganese	1	14,800	200

PHYSICAL PROPERTIES			**%**
Bulk density	1.14 g/mL	1.19 g/mL	4.3
Percent water	76.0 %	77.1 %	1.4

Notes:

[1]Brevick et al. (1994a)

[2]These data are not validated and are for comparison only.

[3]Sasaki (1996b)

[4]Calculated from total plutonium.

Table 5-5 compares the calculated mean concentrations for tank 241-B-204 sludge samples with those of tanks 241-B-201, 241-B-202, and 241-B-203. The HTCE estimates (Agnew 1996) identical sludge compositions for these four tanks.

Tank 241-B-201 was the first of the four tanks to receive waste. It received 224 waste in the first quarter of 1952; no other waste transfers were made into the tank. Tank 241-B-204 received 224 waste from the second quarter of 1952 to the third quarter of 1952 and B Plant flush water from the fourth quarter of 1952 to the first quarter of 1953. These wastes cascaded from tank 241-B-204 to tank 241-B-203, then to tank 241-B-202, then to a crib.

Because tanks 241-B-204 and 241-B-203 are adjacent tanks in a cascade, they are expected to be similar in composition. Table 5-5 shows the waste compositions of the tanks are similar. Almost all analytes are within ±30 percent of each other. The limited number of analytes for tank 241-B-202 also compare well with tank 241-B-204. There is less similarity between tanks 241-B-201 and 241-B-204. Because tank 241-B-201 was the first to receive 224 waste, the composition of the 224 waste stream at startup might vary from later waste. Also, higher concentrations of aluminum, cesium, and strontium suggest that some first cycle decontamination waste and cladding waste may have been mixed in with the 224 waste that went to tank 241-B-201.

5.3 TANK WASTE PROFILE

The visual description of the sludge samples from both risers was soft, damp, and black thereby indicating possible homogeneity within the sludge layer. The color of the drainable liquid samples varied. Information on the vertical disposition of the tank contents was available from the TLM (see Figure 2-3), indicating that the waste consists of several inches of supernatant covering approximately 250 inches of sludge (composed of a single waste type). Thus, the waste sample description and the TLM indicate that a thin supernate layer overlies the sludge layer and that the sludge layer may be vertically homogeneous.

Because vertical profiles of the tank waste were taken from two widely-spaced risers, an analysis of variance (ANOVA) was conducted on the 1995 samples to determine whether there were horizontal and/or vertical variations in the analyte concentrations. These calculations were performed only for analytes that had half or more of their individual measurements above the detection limit. The ANOVA generates a p-value that is compared with a standard significance level ($\alpha = 0.05$). If a p-value is below 0.05, there is sufficient evidence to conclude that the sample means are significantly different from each other and that the difference is not due to chance. However, if a p-value is above 0.05, there is not sufficient evidence to conclude that the samples are significantly different from each other.

Table 5-5. Comparison of B-200 Series Tank Compositions. (2 sheets)

Analyte	Tank 241-B-201[1]	Tank 201-B-202[2]	Tank 241-B-203[3]	Tank 241-B-204

[1]Heasler et al. (1994)
[2]Dougherty and Tran (1995)
[3]Jo et al. (1996)

For drainable liquid samples, the results of the ANOVA indicated that none of the 17 analytes tested showed concentration differences between the two cores. The sludge results indicated that only three of 29 analytes tested had concentration differences between the two cores: bismuth, silicon, and density (with p-values of 0.0026, 0.0034, and 0.0006, respectively). The test for vertical differences between the main segments was conducted only on the sludge samples because of the very limited vertical data from the drainable liquid results. Fourteen of the 29 analytes tested on the segment level, all metals, showed significant vertical concentration differences (p-values are given in parentheses): aluminum (< 0.001), calcium (< 0.001), cerium (0.033), chromium (< 0.001), lanthanum (0.006), manganese (< 0.001), nickel (< 0.001), phosphorus (< 0.001), potassium (< 0.001), silicon (< 0.001), sodium (0.003), strontium (< 0.001), sulfur (0.002), and zinc (< 0.001). For these analytes showing vertical differences, no obvious general trend of increasing or decreasing analyte concentration as a function of depth was apparent. Of these 14 analytes, only seven have mean concentrations above 0.1 weight percent and only lanthanum, manganese, and sodium have mean concentrations above 1 weight percent. Subsegment concentrations ranged from 0.67 to 1.44 weight percent for lanthanum, 0.88 to 1.92 weight percent for manganese, and 2.24 to 2.90 weight percent for sodium.

In summary, horizontal concentration differences in the tank waste do not appear to exist. Vertically, the results of the statistical tests for the sludge layer indicate about half the analytes showed some differences among the segments, but no obvious trends appeared in analyte concentration as a function of the sample point in the tank.

5.4 COMPARISON OF TRANSFER HISTORY WITH ANALYTICAL RESULTS

Table 5-6 shows the HTCE predictions for the contents of tank 241-B-204 and Table 4-2 shows the mean sludge concentrations from the 1995 core sampling event. This comparison is for information purposes only, because the HTCE values have not been validated and should not be used for decisions affecting the waste in tank 241-B-204.

The HTCE and analytical values generally did not agree well. Eighteen analytes were compared. Only five analytes (potassium, chloride, nitrate, density, and percent water) exhibited RPDs less than 50 percent; of these, only one (chloride) exhibited an RPD less than 10 percent. Six analytes (calcium, chromium, manganese, nitrite, oxalate, and total alpha) exhibited RPDs greater than 150 percent. The RPDs for the remaining analytes were between these two extremes.

Table 5-6 shows the anion mean sludge concentrations as determined using a water-leach sample preparation and IC; therefore, the results for the anions forming insoluble compounds, fluoride and phosphate, will be biased low. If the phosphate and sulfate values, as calculated from ICP results, are compared with the HTCE predictions, the agreement for those two species is somewhat better. The phosphate and sulfate values, as determined by ICP, are in parentheses.

Table 5-6. Comparison of HTCE Predictions with the 1995 Analytical Results for Tank 241-B-204. (2 sheets)

Analyte	HTCE Estimate[1,2]	1995 Mean Sludge Concentration[3]	Relative Percent Difference
METALS	**µg/g**	**µg/g**	**%**
Bismuth	9,170	48,400	136
Calcium	7,100	305	184
Chromium	130	3,240	185
Iron	14,600	3,810	117
Lanthanum	23,900	10,400	78.7
Manganese	154	14,800	196

Total alpha	0.0100[5]	0.264	185
PHYSICAL PROPERTIES			**%**
Bulk Density	1.38 g/mL	1.19 g/mL	14.8
Percent Water	55.5	77.1	32.6

Notes:

[1]Agnew (1996)

[2]These data are not validated and are for comparison only.

[3]Sasaki (1996b)

[4]Results in parentheses are calculated from ICP results.

[5]Calculated from total plutonium.

The original process flowsheets from the lanthanum fluoride process were reviewed (Schneider 1951), and the source terms for the HDW definition of 224 (lanthanum fluoride) waste were examined. Results of this investigation provided plausible explanations for the large discrepancies observed for some analytes between the two data sets.

The HTCE underestimates the concentrations of bismuth, chromium, and manganese. Sodium bismuthate ($NaBiO_3$) was used as the primary oxidant during efforts to oxidize plutonium for separation from fission products. Sodium dichromate ($Na_2Cr_2O_7$) was used as a holding oxidant to stabilize oxidized plutonium. It is possible that the HDW did not take into account the metals used in these oxidizing compounds. According to Schneider (1951), potassium permanganate ($KMnO_4$) was determined to be an acceptable substitute for sodium dischromate in laboratory tests. However, the use of potassium permanganate is not specifically documented in the process flowsheets. The elevated levels of manganese in the waste samples strongly suggest that potassium permangante was used.

The HTCE overestimated the concentration of iron. It appears the HDW source term is biased high. From the process flowsheets, iron was not expected to be present in the quantities predicted by the HTCE. The discrepancy is probably caused by overestimating iron from corrosion.

It appeared that the HTCE also overestimated the concentration of sodium. Sodium and nitrate are the soluble chemical species present in the greatest quantities, and their charges can be expected to balance each other more or less. This prediction was born out in the analytical results evidenced by the change balance (see Section 5.1.3.2). Of the 1,290 μeq/g of positive charge, 1,140μeq/g are attributed to sodium. Nitrate contributed 853 μeq/g to the anion total of 1,340 μeq/g. A comparison of the sodium and nitrate values gives a ratio of 1.34. The HTCE values should be similarly distributed. However, a ratio of the HTCE sodium and nitrate predictions on a μeq/g basis yields a value of 3.4. Consequently, it appears that a high bias in the HTCE sodium prediction does exist.

The reason for the poor agreement in fluoride concentrations is a deficiency in the analytical results. Because fluoride is measured by IC after a water digestion, only the soluble fluoride is measured. This does not compare with the HTCE fluoride value, which includes both soluble and insoluble fluoride.

The reason for the large HTCE prediction of oxalate is unknown. Organic material is not expected to be present in lanthanum fluoride in the high quantities estimated by the HTCE. In addition, the low radionuclide content of the waste is unlikely to produce large amounts of oxalate as an organic degradation product.

Finally, the HTCE prediction for weight percent water is too low. It is known from other samples of 224 waste (tanks 241-B-201, 241-B-202, 241-B-203, and 241-T-111) that the percent water in this waste type is 60 to 85 weight percent.

In summary, the problems that occur when estimating the composition of the 224 waste are probably caused by documentation which does not describe the waste as it currently exists. A more accurate estimate of the 224 waste probably could be derived by examining the analytical results from all tanks containing 224 waste.

5.5 EVALUATION OF PROGRAM REQUIREMENTS

The two tank 241-B-204 core samples analyzed at the 222-S Laboratory were taken to meet the requirements of the safety screening DQO (Dukelow et al. 1995). This section discusses the requirements of the DQO and compares the analytical data to defined concentration limits.

5.5.1 Safety Evaluation

Data criteria, identified in the safety screening DQO, are used to assess the waste safety and to check for unidentified safety issues. The DQO requires a vertical profile of the tank waste from two widely-spaced risers. This requirement was met. Of the five primary analyses required by the DQO, three have decision criteria thresholds which, if exceeded, could warrant further investigation to ensure tank safety. These three analyses include DSC to measure the fuel content, a determination of the total alpha activity to evaluate the criticality potential, and a measurement of the flammability of the tank headspace vapors.

The safety screening DQO has established a notification limit of -480 J/g (dry weight basis) for exothermic reactions detected during the DSC analysis. No exothermic reactions were observed in any tank 241-B-204 samples.

The safety screening DQO decision threshold for criticality screening is 1 g/L plutonium, or 41 μCi/g as specified in the SAP. All results were well below the limit, with 0.496 μCi/g being the largest single result. The highest 95 percent upper confidence level limit for these results was 1.00 μCi/g, far below the DQO limit.

The DQO notification limit for flammable gas concentration in the tank headspace is 25 percent of the lower flammability limit. Combustible gas meter readings taken at the time of sampling revealed the concentration of flammable gases to be 0 percent of the lower flammability limit.

In summary, the October 1995 core sampling event met all the requirements of the safety screening DQO. Table 5-7 lists the safety issues, the properties of concern and their notification limits, and the corresponding analytical results.

Table 5-7. Safety Screening Data Quality Objective Decision Variables and Criteria.

Issue	Primary Decision Variable	Decision Criteria Threshold	Mean Analytical Result
Ferrocyanide/Organics	Total fuel content	-480 J/g	No exothermic reactions
Criticality	Total alpha activity	41 μCi/g	0.264 μCi/g
Flammable gas	Flammable gas	25 percent of the lower flammability limit	0 percent of the lower flammability limit

Another factor in assessing tank waste safety is the heat generation and the temperature of the waste. Heat is generated in the tanks from radioactive decay. Radionuclides were only analyzed on one subsegment from one core. If the sludge is assumed to be homogeneous, a tank heat load of < 0.8 W (< 3 Btu/hr) is estimated from the analytical data. The HTCE prediction was zero (Brevick et al. 1994a), and the heat load, based on headspace temperature, was 47.2 W (161 Btu/hr) (Kummerer 1994). These estimates are well below the 11,700 W (40,000 Btu/hr) threshold differentiating high-heat from low-heat tanks (Bergmann 1991). Because an upper temperature limit has been exhibited (see Section 2.4.3), it may be concluded that any heat generated from radioactive sources throughout the year is dissipated.

Another safety related issue relates to the drying of wastes after they have been saltwell pumped. Tank 241-B-204 was not saltwell pumped, but it was interim stabilized in June 1984. The tank is not actively ventilated; therefore, the water loss from the waste is expected to be low. The sludge in tank 241-B-204 has a uniformly high water content (75 to 80 weight percent) which is similar to that measured in a sludge sample taken in 1978 prior to stabilization. There is a small amount of supernate (1 kgal) in the tank. Liquid level readings indicate a decrease in the liquid level of approximately 1.3 cm (0.5 in.) or approximately 370 L (100 gal) since the tank was stabilized.

6.0 CONCLUSIONS AND RECOMMENDATIONS

The waste in tank 241-B-204 has been sampled and analyzed according to the requirements listed in the *Tank Safety Screening Data Quality Objective* (Dukelow et al. 1995). The tank was core sampled using the push-mode method in October 1995. To assess tank safety, the safety screening DQO required analyses for energetics, weight percent water, density, total alpha activity, and the flammable gas concentration in the tank headspace. In addition, the SAP required the laboratory to perform ICP and IC analyses to determine the concentrations of lithium and bromide, indicators of contamination by the hydrostatic head fluid. The laboratory was also required to report all results generated by ICP and IC not just lithium and bromide (Sasaki 1996b). Finally, one subsegment was subjected to GEA and ^{90}Sr analysis to obtain information for the disposal of laboratory waste. All samples were analyzed at the Westinghouse Hanford Company 222-S Laboratory.

All analyses met the requirements of the safety screening DQO. No exothermic reactions were observed in the DSC analysis. Weight percent water was measured by TGA for the correction of the DSC results to a dry-weight basis; the overall mean (corrected for HHF contamination) was 77.1 wt% for the sludge and 89.1 wt% for the supernate. (Dry-weight corrections of the DSC results were not performed because no exotherms were observed.) The total alpha activity overall mean was 0.264 μCi/g, well below the DQO notification limit of 41 μCi/g. Finally, the concentration of flammable gas in the tank headspace was zero percent of the lower flammability limit. No quality assurance issues were identified that affected the interpretation of the analytical results. Based upon the decision criteria of the safety screening DQO, this tank may be categorized as "safe."

The heat load estimate based on analytical results was < 0.8 W (< 3 Btu/hr), the HTCE prediction was zero, and the heat load based on headspace temperature was 47.2 W (161 Btu/hr). Because the tank temperature is not continuously increasing, it may be concluded that any heat generated from radioactive sources throughout the year is dissipated.

Hydrostatic head fluid marked with a lithium bromide tracer was used during core sampling operations, and some contamination was detected in all samples; the maximum calculated HHF contamination was two weight-percent water. Corrections for the HHF contamination were applied to the weight-percent water measurements.

The results from the 1995 core samples show that the major cation constituents of the sludge are bismuth, chromium, iron, lanthanum, manganese, potassium, and sodium. Major anion constituents are fluoride, nitrate, and phosphate. Charge and mass balance calculations based on the 1995 sludge sample results indicate that the results appear to be reasonably self-consistent. The charge balance yielded a value of 0.96 (ideal = 1), and the mass balance was 97.4 percent (ideal = 100 percent). Analysis of variance of the analytical data revealed only minor horizontal heterogeneity and statistically significant vertical heterogeneity in the sludge layer.

Comparing the analytical results of the sludge from the 1995 core samples to 1978 historical results yielded mixed results. The sludge density and percent water values compare closely for the two data sets. However, many of the values for the chemical constituents, especially the major components, compare poorly. Because the details of the 1978 sampling event (such as riser number, sample depth, etc.) are unknown, and the 1995 results are an overall estimate for the entire tank, the two sets of samples may not be entirely comparable.

Between the HTCE estimate and the 1995 samples, only five analytes (potassium, chloride, nitrate, density, and percent water) compare favorably, and other major analytes (bismuth, sodium, fluoride, and phosphate) compare poorly. The poor fluoride and phosphate correlations may be due in part to the limitations of the water-leach sample preparation method used prior to the IC analysis of the 1995 samples. The water-leach sample preparation allows only a fraction of the insoluble fluoride and phosphate solids to be determined. The poor correlation of the other analytes between the HTCE and the 1995 core samples may indicate poor source term estimates for, or poor modeling of, those analytes in the HTCE.

APPENDIX A

SAMPLE INFORMATION FOR 1995 CORE SAMPLING

A.1 INTRODUCTION

Appendix A contains the sample information for tank 241-B-204 push-mode cores 112 and 114 collected in October 1995. Table A-1 shows the location of specific sample information in Tables A-2 through A-5. All data, except the core segment depths, are from Sasaki (1996b); core segment depths were obtained in a telephone conference from the core sampling cognizant engineer.

[1]Customer sample number

[2]"Sample length" is the distance the drill string was advanced for that core segment and is *not* necessarily the same as the length of the recovered core.

[3]Sample elevation is measured from the bottom centerline of the tank to the top of the segment; these values are approximate, and the uncertainty on these values is unknown.

Table A-3. Subsampling Scheme, Recovery, and Sample Description. (3 sheets)

Segment	Subsegment	Recovery	Description
Core 112 - Riser 2			
1	DL	150.1 g	DL was clear and yellow. No solids present. Estimated sample volume was 150 mL.
	LL	< 5 mL	
2	Whole	40.2 g	DL was opaque and dark gray/black. Three to four in. of solids extruded. Solids were wet and black and did not retain their shape. No facies present.
	DL	125.6 g	
	LL	122.5 g	
3	Upper ½	167.2 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. The top in. of upper ½ contained a slurry. No facies or DL.
	Lower ½	179.9 g	
	LL	< 5 mL	
4	Upper ½	183.3 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	186.1 g	
	LL	< 5 mL	
5	Upper ½	176.5 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies, DL, or LL.
	Lower ½	185.4 g	
6	Upper ½	188.3 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies, DL, or LL.
	Lower ½	175.0 g	
7	Upper ½	179.6 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies, DL, or LL.
	Lower ½	177.4 g	
8	Upper ½	182.8 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	184.0 g	
	LL	7.4 g	
9	Upper ½	190.2 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	176.9 g	
	LL	< 5 mL	
10	Upper ½	206.4 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	161.8 g	
	LL	< 5 mL	
11	Upper ½	194.5 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	183.6 g	
	LL	< 5 mL	

Table A-3. Subsampling Scheme, Recovery, and Sample Description. (3 sheets)

Segment	Subsegment	Recovery	Description
Core 112 - Riser 2 (continued)			
12	Upper ½	192.0 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	180.7 g	
	LL	< 5 mL	
13	Upper ½	184.0 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	191.7 g	
	LL	< 5 mL	
14	Upper ½	197.4 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	169.1 g	
	LL	< 5 mL	
Core 114 - Riser 7			
1	DL	125.5 g	DL was opaque and brownish gray. No solids were present. Estimated sample volume was 130 mL.
	LL	< 20 mL	
2	Upper ½	143.8 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge. Bottom 15 in. retained its shape but slumped slightly. Top 4 in. did not keep its shape. No facies or DL.
	Lower ½	178.7 g	
	LL	< 5 mL	
3	Upper ½	163.3 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	162.0 g	
	LL	< 10 mL	
4	Upper ½	171.9 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	172.8 g	
5	Upper ½	178.5 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	165.3 g	
	LL	< 10 mL	
6	Upper ½	163.5 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape for most segments. Top 2-3 in. were softer and did not retain their shape. No facies or DL.
	Lower ½	176.0 g	
	LL	< 10 mL	
7	Upper ½	189.3 g	19 in. of solids were extruded. Solids were a black, damp, and soft sludge that retained its shape. No facies or DL.
	Lower ½	167.0 g	
	LL	< 20 mL

APPENDIX B

ANALYTICAL RESULTS FROM 1995 CORE SAMPLING

This page intentionally left blank.

APPENDIX B

ANALYTICAL RESULTS FROM 1995 CORE SAMPLING

B.1 INTRODUCTION

Appendix B reports the chemical, radiochemical, and physical characteristics of tank 241-B-204 in table form and in terms of the specific concentrations of metals, ions, radionuclides, and physical properties.

Tables B-1 through B-53 list the following information: laboratory sample identification; sample origin (core/segment/subsegment); an original and duplicate result for each sample; a sample mean; a mean for the tank in which all cores, segments, and subsegments are weighted equally; a relative standard deviation of the mean (RSD [Mean]); and a projected tank inventory for the particular analyte using the weighted mean and the appropriate conversion factors. The projected tank inventory column is not applicable to the percent water, DSC, TGA, or bulk density data. The data are listed in standard notation for values greater than 0.001 and less than 100,000. Values outside these limits are listed in scientific notation.

A description of the units and symbols used in the analyte tables and the sources used in compiling the analytical data (Sasaki 1996b) are found in the List of Terms and Section 7.0, respectively. For information on sampling rationale, locations, and descriptions of sampling events, see Section 3.0 and Appendix A.

B.2 ANALYTE TABLE DESCRIPTION

Tables B-1 through B-50 describe the organization of the chemical species and radionuclide tables. Tables B-51 through B-53 contain the TGA, DSC, and density results; the organization of these tables is similar to the chemical species tables with only slight variations.

Column 1 lists the laboratory sample for which the analyte was measured.

Column 2 lists the core and segment from which each sample was derived. The first number is the core number; it is followed by a colon and the segment number.

Column 3 lists the name of the segment portion (subsegment) from which the sample was taken. This can be the entire segment (whole), the drainable liquid portion (DL), or the upper or lower half segment portions.

Columns 4 and 5 (Result and Duplicate) are self-explanatory. The "Mean" is the average of the result and duplicate values. All values, including those below the detection level (indicated by the less-than symbol, <), were averaged in calculating the sample means. If the result and duplicate values were both nondetected, the mean is expressed as a nondetected value. If one of the two values is nondetected and one is detected, or if both are detected, then the sample mean is reported as a detected value. The result and duplicate values and the result/duplicate means are reported in the tables exactly as found in the original laboratory data package. The means may appear to have been rounded up in some cases and rounded down in others. This is because the analytical results given in the tables may have fewer significant figures than originally reported not because the means were incorrectly calculated.

Column 7 is the overall (or analyte concentration) means for the waste in tank 241-B-204; they were calculated as follows:

The drainable liquid means were calculated by averaging the segment means within a core, then averaging the two core means to obtain an overall mean.

The estimated overall sludge mean based on segment level data were calculated in the following manner. The sample/duplicate results within a subsegment were averaged to obtain a subsegment mean, subsegment means were averaged to obtain a segment mean, then segment means were averaged to obtain a core mean, and finally the two core means were averaged to obtain the overall mean.

Column 8 (RSD [Mean]) is 100 times the standard deviation of the mean divided by the overall tank mean. The standard deviation of the mean was estimated using standard ANOVA statistical techniques. Relative standard deviations of the mean were not computed for analytes that had greater than 50 percent nondetected values. For analytes with 50 percent or more detected results, all data for a given analyte were used in the calculation.

Column 9 (projected inventory) is the product of the overall analyte concentration mean, the volume of tank waste (185 kL for the sludge and 4 kL for the drainable liquid), the bulk density of the waste (1.19 g/mL for the sludge and 1.05 g/mL for the drainable liquid), and the appropriate conversion factors.

The four quality control parameters assessed on the tank 241-B-204 samples were standard recoveries, spike recoveries, duplicate analyses (RPDs), and blanks. These were summarized in Section 5.1.2. Sample and duplicate pairs, in which any quality control parameters were outside their specified limits, are footnoted in column 6 of the following tables. Limits for quality control parameters were specified only for total alpha, TGA, DSC, specific gravity, bulk density, lithium, and bromide analyses because these were the analyses required by the applicable DQO.

Notes:

Temp. = temperature

[1]The range in parentheses is for the duplicate; the range in brackets is for the triplicate.

[2]The mean is corrected for hydrostatic head fluid contamination based on bromide results.

[3]The overall corrected mean is calculated based on "Corrected Mean" results.

[4]The percent water by thermogravimetric analysis was determined using a Mettler™ instrument.

[5]The percent water by thermogravimetric analysis was determined using a Perkin-Elmer™ instrument.

[6]The RPD was outside the quality control limit of ≤ 10 percent.

RESULTS OF HYDROSTATIC HEAD FLUID CONTAMINATION CHECK FOR SINGLE-SHELL TANK 241-B-204

This page intentionally left blank.

APPENDIX C

RESULTS OF HYDROSTATIC HEAD FLUID CONTAMINATION CHECK FOR SINGLE-SHELL TANK 241-B-204

C.1 INTRODUCTION AND ANALYTE TABLE DESCRIPTION

Appendix C reports the results of the HHF contamination check for the 1995 core sampling and analysis event. Lithium and bromide were measured to detect contamination of the waste samples by the HHF. Lithium was determined by ICP; bromide by ion chromatography. Because lithium may form insoluble compounds with the tank waste matrix, the HHF corrections to the percent water values were based on the bromide results.

Column 1 lists the laboratory sample identification number for each analyte. For sampling rationale, locations, and a description of the sampling event, see Section 3.0 and Appendix A.

Column 2 lists the core and segment from which each sample was derived. The first number is the core number; it is followed by a colon and the segment number.

Column 3 lists the name of the segment portion (subsegment) from which the sample was taken. This can be the entire segment (whole), the drainable liquid portion (DL), or the upper or lower half segment portions.

Columns 4 and 5 (Result and Duplicate) are self-explanatory.

Column 6 (Mean) is the average of the result and duplicate values. All values, including those below the detection level (indicated by the less-than symbol, <), were averaged in calculating the sample means. If the result and duplicate values were both nondetected, the mean is expressed as a nondetected value. If one of the two values is nondetected and one is detected, or if both are detected, then the sample mean is reported as a detected value. The result and duplicate values and the result/duplicate means, are reported in the tables exactly as found in the original laboratory data package. The means may appear to have been rounded up in some cases and rounded down in others. This is because the analytical results given in the tables may have fewer significant figures than originally reported, not because the means were incorrectly calculated.

The four quality control parameters assessed on the tank 241-B-204 samples were standard recoveries, spike recoveries, duplicate analyses (RPDs), and blanks. These were summarized in Section 5.1.2. Sample and duplicate pairs, in which any of the quality control parameters were outside their specified limits, are footnoted in column 6 of the following tables.

APPENDIX D

HISTORICAL SAMPLING RESULTS

D.1 INTRODUCTION

Table D-1 lists the analytical results from a historical sampling event performed in 1978. The sample, reference number 1974, was reported as black in color with a consistency of soft grease. No additional specifics were available from historical records. These historical data are not validated and are included for comparison only; decisions affecting the waste in tank 241-B-204 should not be based on these data.

Table D-1. Historical Sampling Results for Tank 241-B-204.[1]

Physical Data			
VIS-OTR: Black in color, with a consistency of soft grease			
Property	**Lab Value**		**Lab Units**
Water Solubility	26		%
Bulk Density	1.14		g/mL
H_2O	76		%
TOC	0.096		mol/L
Chemical Analysis			
Components	**Water Soluble**	**Acid (Fusion)**	**Lab Units**
Al*	0.0008	0.008	%
Bi^{3+}	< 0.0006	6.2	%
CO_3^{2-}	0.3	n/a	%
CrO^{4-}	0.08	n/a	%
Cl^-	0.07	n/a	%
F^-	n/r	0.2	%
Fe*	0.0008	2.9	%
Hg*	0.001	n/a	%
K^+	0.4	n/a	%
La^{3+}	0.01	2	%
Mn*	0.0001	n/a	%
Ni^{2+}	n/a	0.03	%
NO_2^-	0.3	n/a	%

Chemical Analysis (continued)			
Components	**Water Soluble**	**Acid (Fusion)**	**Lab Units**
NO_3^-	2.8	< 0.07	%
Na^+	1.4	n/a	%
OH^-	0.1	n/a	%
PO_4^{3-}	0.1	1.2	%
SO_4^{2-}	< 0.05	< 0.1	%
SiO_2^{2-}	0.004	0.3	%
Radiological Analysis			
Components	**Water Soluble**	**Acid (Fusion)**	**Lab Units**
U*	4.63E-08	9.71E-06	g/g
Pu*	1.16E-09	9.74E-06	g/g
Am*	n/r	n/a	n/a
$^{89/90}Sr$	0.004	4	μCi/g
^{137}Cs	0.005	0.007	μCi/g
^{155}Eu*	n/r	n/a	n/a

Notes:

* = All oxidation states

n/a = not applicable or not available

n/r = Analysis not requested
