The Advanced Photon Source

Facility Overview

The Advanced Photon Source (APS), a national user facility for synchrotron radiation research, is located at Argonne National Laboratory, approximately 25 miles southwest of Chicago, Illinois. The APS is considered a third-generation synchrotron radiation facility (specifically designed to accommodate insertion devices to serve as radiation sources) and is one of three such facilities in the world. Currently, it is the most brilliant source in the United States for research in such diverse fields as biology, medicine, materials science, chemistry, geology, agriculture and soil science, physics, and manufacturing technology.

Researchers use the APS either as members of Collaborative Access Teams (CATs) or as Independent Investigators (IIs). CATs are responsible for designing, building, and operating beamlines in one or more sectors, each sector consisting of an insertion-device (ID) beamline and a bending-magnet (BM) beamline. Each beamline is designed to accommodate a specific type of research program(s) and is optimized accordingly.

User Program

CAT members are entitled to use 75% of the available beam time to pursue CAT research goals. The remaining 25% of the available beam time must be made available to IIs, who are selected by the CAT through a proposal process determined by each CAT and approved by the APS. Prospective IIs submit proposals to the APS User Office, which screens each proposal for completeness, logs it in, arranges for review, then forwards it to the appropriate CAT(s). Proposal forms can be downloaded from the World Wide Web (WWW) at the following address: http://www.aps.anl.gov/xfd/communicator/useroffice/llprop_form.html. This document, the CAT Guide and Beamline Directory, was written to help prospective IIs determine which beamlines are suitable for their specific experiments. Further information can be obtained from the APS User Office or the individual CATs (contact information is provided on the inside back cover of this document).

Overview

SRI-CAT is organized into instrumentation developers and scientific members, with the developers coming primarily from the Experimental Facilities Division of the APS, as well as from Purdue University, University of Houston, National Institute of Science and Technology, Lawrence Berkeley National Laboratory, Stanford Synchrotron Radiation Laboratory, Cornell High Energy Synchrotron Source, and many Australian institutions managed by the Australian Nuclear Science and Technology Organization.

Research Focus

The principal mission of SRI-CAT is to develop new and unique forefront instruments and techniques to advance the use of synchrotron radiation. To that end, research programs involve the design, construction, and operation of standard and specialized insertion devices; diagnostics of radiation from these insertion devices; development of high-heat-load optics; the design, construction, and testing of various standard and modular beamline components; and the development of strategic instruments and techniques. Among those instruments/capabilities are the application of microbeam techniques, the development of scientific capabilities at high energies (>50 keV), the application of coherence-based techniques, the development of 0.5- to 4-keV scientific capabilities, the development of ultrahigh-resolution inelastic scattering techniques, and the application of nuclear coherent spectroscopy. The insertion-device beamline in sector 4 is currently being developed to provide variably polarized x-rays with energies from 0.5 keV to 100 keV and higher. In the low-energy range (0.5 keV to 3 keV), a helical undulator with grazing-angle reflective optics will be used; for energies above 3 keV, a standard APS undulator A with crystal optics will be used as the radiation source. These unique tunable polarization and energy capabilities on one beamline will provide scientists with the ability to cover all important absorption edges from M to K for magnetic spectroscopy experiments, spectro-microscopy, and resonant magnetic scattering.

Overview

The DND-CAT is a team of senior scientists and engineers formed jointly by the E.I. Du Pont de Nemours Co., Northwestern University, and the Dow Chemical Company to develop, build, and operate facilities dedicated to advancing x-ray research on new materials. The ability to characterize the increasing numbers of new and advanced materials with specifically engineered properties is closely coupled with the ability to analyze their molecular structure.

Research Focus

The scientific thrust of DND-CAT is concentrated in three main areas: the study of the atomic structure of bulk materials, the study of two-dimensional atomic structures (e.g., surfaces, interfaces, and thin films), and polymer science and technology.

Atomic Structure of Bulk Materials

In addition to crystallographic determinations of unknown compounds, this aspect of DND-CAT’s program concentrates on the determination of defects and local atomic arrangements in materials. For example, the arrangement of dopant atoms and other lattice defects in metals, catalysts, and semiconductors is under study. In addition, DND-CAT researchers are extensively studying catalysts under realistic conditions of high temperature and pressure. Catalysts of interest include supported metal and bimetallic catalysts (e.g., Pd, Pd-Re), zeolites, and catalysts for environmentally benign chlorofluorocarbons.

Study of Two-Dimensional Structures

The structure of surfaces at interfaces is a primary factor controlling the properties of materials in many technologically important applications. Some of these include catalysis, corrosion, tribology, crystal growth, and ion transport through biomembranes. DND-CAT researchers will use a custom-designed ultra-high-vacuum system to study buried interfaces, thin films, and surfaces to determine mechanisms of film growth, segregation at grain boundaries, surface melting, and other two-dimensional phenomena.

Polymer Science and Engineering

The third major area for DND-CAT is polymer physics, chemistry, and engineering. Areas of interest include solution characterization of polymers and their precursors, structure formation, polymer melt rheology, fiber formation, structure/property/processing relationships, and mechanical properties.

Midwest Universities CAT

Overview

The Midwest Universities CAT was organized in 1990. At present, its member institutions include Ames Laboratory/Iowa State University, University of Missouri at Columbia, Georgia Institute of Technology, Washington University, University of Wisconsin at Madison, University of Nebraska at Lincoln, Kent State University, State University of New York at Stony Brook, Michigan State University, and the Institut für Festkorperforschung Forschungszentrum Jülich GmbH. The main undulator line of the sector features a four-circle diffractometer for single-crystal work, a liquid surface reflectometer, and a new surface science chamber. In addition, a high-energy side station (30-120 keV) is currently under construction and will run in parallel with the main undulator line [3-22 keV for Si (111) monochromating crystals].

Research Focus

Research efforts are focused in the areas of magnetic scattering and spectroscopy, as well as in resonant- and nonresonant-scattering studies of magnetic materials. The technique of circular magnetic x-ray dichroism (CMXD) offers tremendous potential as a tool for studies of the electronic states associated with magnetic order in ferromagnetic materials of fundamental and technological interest. Resonant and nonresonant magnetic x-ray scattering measurements offer important and complementary means of determining magnetic structures in materials that are ill-suited, by reasons of size or chemical composition, to traditional neutron measurements (e.g., for magnetic structure studies of metastable phases and surfaces).

Research efforts in the surface-scattering program are centered on the study of the kinetics and growth of two-dimensional systems, the role of defects in epitaxy, ordered non-epitaxial overlayers, phase transitions, and investigations of liquid surfaces. The surface chamber constructed for this sector will enable surface-scattering investigations to expand into new areas: real-time growth characterization in a variety of growth environments, low-Z adsorbate systems, and two-dimensional surface kinetics. A liquid surface diffractometer will be used to probe the chemistry and physics of monolayer films at liquid surfaces, as well as of realistic models of biological membranes.

General scattering programs include microdiffraction techniques, coherent scattering, high-temperature processing of materials, studies of liquid crystals and polymers, and strain in thin films and interfaces.

Work on the high-energy side station will include techniques such as nonresonant magnetic scattering, radial distribution function analysis of disordered and partially ordered materials, and in situ time-resolved measurements of high-temperature materials processing.

MHATT-CAT

Center for Real-Time X-ray Studies

Overview

The Center for Real-Time X-ray Studies CAT (MHATT-CAT) was formed in 1989 as a university-industry partnership between the University of Michigan, Howard University, and Bell Laboratories (Lucent Technologies). MHATT-CAT's facilities include two fully instrumented beamlines (one based on an undulator and the other on a bend magnet) to exploit the unique characteristics of the APS. A high-speed communications network between the participating institutions and the APS is planned to facilitate the involvement of students in the MHATT-CAT collaboration and to maximize participation in research at national user facilities.

Research Focus

MHATT-CAT's research program is focused on time-dependent structural phenomena across a broad range of materials systems, including thin films, polymers, liquid crystals, and biomaterials. The undulator line serves as the host for microprobe studies of high-temperature superconductors, interconnects, and optical fibers; for the development of coherent x-ray scattering techniques; and for the application of ultrafast lasers. The sector is expected to develop into an international gathering point for scientists and engineers with strong interest in time-resolved structural studies.

Overview

The IBM-MIT-McGill CAT (IMM-CAT) was organized by individual scientists from the three institutions to build and operate a sector at the APS optimized for research involving dynamic phenomena in materials science, physics, chemistry, and recently, structural biology.

Research Focus

IMM-CAT’s research involves a broad range of topics emphasizing processes and phenomena that take place over time, such as the growth of thin films. Experiments conducted by CAT member scientists fall primarily into the following four areas:

1. Time-resolved x-ray-scattering studies of bulk phase transition kinetics.
2. Grazing-incidence scattering studies of surface structure and kinetics.
3. Scattering studies of the structure and kinetics of buried interfaces.
4. Studies of dynamics by x-ray intensity fluctuation spectroscopy and related coherent x-ray methods.

A primary goal is to aid the development and understanding of new materials, which may lead to improved products such as magnetic disk drives, computer chips, and computer displays, as well as improvements in processing techniques.

For example, the study of interfaces where layers of magnetic materials meet helps in the engineering of materials with more desirable magnetic properties for use in magnetic disks (used for information storage). Research into thin polymer films can lead to improved coatings, such as those used for lubricants in magnetic disk drives and for orienting liquid-crystal films in flat panel displays.

The construction of a bending-magnet beamline devoted to structural biology is under consideration.

CMC-CAT

Complex Materials Consortium CAT

Overview

The Complex Materials Consortium CAT (CMC-CAT) was organized by individuals who share a common research interest in complex materials and a strong dedication to the use of the unique properties of synchrotron radiation to structurally and functionally characterize them. This organization was subsequently formalized into a consortium containing the following institutional members: Exxon Research and Engineering Company, University of Pennsylvania, Brookhaven National Laboratory, Princeton University, University of California at Santa Barbara, Los Alamos National Laboratory, Oak Ridge National Laboratory, and the University of Tennessee.

Research Focus

Complex materials, broadly defined, are materials that possess unique and novel properties by virtue of the complexity of their molecules and/or the complexity of interaction between their molecules. These materials include polymers, surfactants, liquid crystals, biomaterials, membranes, and thin molecular films of hydrocarbons on solid or liquid surfaces. They also include novel synthetic materials such as fullerenes, fibers, polymer composites, and zeolites. A basic understanding of the molecular structure, morphology, and molecular dynamics of such materials, particularly under non-equilibrium conditions or at interfaces, is essential for the development and optimization of novel materials and processes for industry. It is equally important for obtaining a complete theoretical description of the equilibrium and non-equilibrium behavior of complex, multicomponent systems.

At the APS, CMC-CAT uses several experimental techniques to study complex materials on a variety of length and time scales. The techniques include small-angle and wide-angle x-ray scattering, x-ray diffraction, x-ray surface scattering, x-ray spectroscopy, magnetic scattering, and x-ray microtomography and imaging. The studies depend on novel technical developments such as ultrafast-high-resolution two-dimensional imaging detectors, high-speed data inversion and image-processing algorithms, and novel x-ray microfocusing devices. Using such techniques, CMC-CAT researchers study phenomena such as the dynamic response of polymers, membranes, fibers, and fluids to applied stresses; the kinetics of phase separation in mixed systems; the formation of pitting, corrosion, and protective layers on metals in electrolytic solutions; the formation of novel surface structures on catalysts undergoing reactions; the formation of cracks and voids in composite materials; and the flow of fluids through microporous solids such as oil-bearing rocks or sand.

Overview

The Materials Research CAT (MR-CAT) is composed of groups from four universities (University of Florida, Illinois Institute of Technology, Northwestern University, and University of Notre Dame), a major corporation (BP-Amoco) and a federal research laboratory (Argonne National Laboratory/Chemical Technology and Environmental Research Divisions).

Research Focus

The scientific program of MR-CAT focuses on the study of advanced materials in situ as a means of characterizing their structure and electronic properties, as well as understanding their preparation. The primary research techniques of wide- and small-angle scattering, diffraction (single-crystal and powder), absorption spectroscopy (XFS), reflectivity, standing waves, diffraction anomalous fine structure (DAFS), and time-dependent and microfocus techniques are being used to study the following in situ:

- structural phase changes, especially in non-equilibrium systems
- disordered systems (e.g., alloys and amorphous materials)
- growth, recrystallization, surfaces, and interfaces of electronic materials
- catalysts (in situ time-dependent studies)
- structure of static and dynamic confined liquids
- organic thin films and self-assembling systems
- polymers (e.g., dynamics of block copolymers, single-fiber studies)
Beamline 10-ID / MR-CAT

Scientific focus: Materials science and environmental science

Scientific programs: Spectroscopy of dilute environmental systems, combined techniques for in situ characterization of materials, and zone plate micro-focusing spectroscopy and imaging

Sectors 11 and 12

Basic Energy Sciences Synchrotron Radiation Center CAT

Overview

The Basic Energy Sciences Synchrotron Radiation Center CAT (BESSRC-CAT) includes scientists from the Chemistry and Materials Science Divisions at Argonne National Laboratory (ANL), researchers from the ANL geophysics program, and scientists from the Department of Physics at Northern Illinois University. Its two sectors are developed and instrumented to serve the research needs of users with particular interests in materials science, chemical science, atomic physics, solid-state physics, and geosciences. The facility's two sectors are equipped with seven separate instrumental stations. One sector consists of an undulator and bending magnet with four experiment stations. The other sector has an elliptical multipole wiggler and is split into three beamlines with three experiment stations.

Research Focus

Scientific areas of interest include time-resolved studies of photoexcited states in photosynthetic materials, real-time investigations of chemical reactions, and time-dependent studies of phase transformations in crystalline compounds. Structural studies of actinide materials, studies of ultra-small crystals, trace-element analysis, and surface and interface studies also form part of the research focus. Examples of studies conducted include radiation-induced surface modification, impurity clustering at grain boundaries, measurements of the electrical double layer at electrodes in electrochemical cells, concentration profiling at dissimilar interfaces, studies of the magnetic structure of ultra-thin films, and others.

BESSRC-CAT has an MOCVD system in the undulator beamline for in situ growth studies of oxides and GaN and also an MBE system on line for structural studies of surfaces and interfaces under UHV conditions. There is an extensive research program in the use of small-angle x-ray scattering and anomalous small-angle x-ray scattering with particular emphasis on time-resolved measurements. BESSRC-CAT has established a research program directed towards the use of high-energy diffraction techniques to study the structure of materials. Additionally, an extensive research program is directed towards the use of circularly polarized x-rays in the study of the magnetic properties of materials, i.e., using XMCD, magnetic Compton scattering, and magnetic scattering.

Overview

The Consortium for Advanced Radiation Sources (CARS) currently has four institutional members—The University of Chicago (the managing agent for CARS), Northern Illinois University, Southern Illinois University, and the Australian Nuclear Science and Technology Organization—and four national user groups—BioCARS for structural biology, GeoCARS for geophysical sciences, SoilEnviroCARS for soil/environmental sciences, and ChemMatCARS for chemistry and materials science. At present, CARS has developed or is developing five x-ray beamlines for use by the faculty and staff of its institutional members and national user groups for frontier research that exploits the unique characteristics of the APS as an x-ray source.

Research Focus

The scientific program and experiments carried out on CARS beamlines exploit the unique features of the x-rays emitted by both wiggler and undulator sources. Two main themes are (1) the study of samples with which x-rays interact very weakly because of their small size (area or volume), low concentration, large crystallographic unit cell dimensions, or necessity for monochromatic radiation of unusually narrow bandpass and (2) time-dependent studies of samples with which x-rays interact more strongly.

For BioCARS, the main thrust is to understand basic biological processes in structural terms. Experiments involve crystallographic studies of viruses, ribosomes, and other complexes with very large unit cells; studies of microcrystals; time-resolved crystallography; and phase determination by MAD techniques.

In GeoSoilEnviroCARS, research is designed to further knowledge of the composition, structure, and properties of earth and planetary materials and the processes they control. High-pressure research in both a diamond-anvil cell and a large-volume press; x-ray diffraction, scattering, and absorption spectrosopies from earth and planetary materials; and x-ray fluorescence microprobe analysis and microtomography should make possible major advances in understanding such diverse processes as earthquake development and nitrogen fixation in roots.

In ChemMatCARS, research focuses on several aspects of dynamic and structural condensed matter and materials chemistry. Research areas include surface and interfacial properties in soft condensed matter; molecular liquids and liquid metals; chemical crystallography with emphasis on dynamics of energy transfer, fast photochemical processes, and valence and element specific crystallography; the structure and properties of molecular aggregates; and interfacial and bulk properties of novel polymers and composites including supramolecular, mesoscopic, and nanometer structures.

Optics & Optical Performance
- Kohzu Seiki monochromator HLD-3
  - 3.1–22.5 keV energy range (for Si(111) and 25-mm offset)
  - 5°–40° angular range
  - 25–35 mm offset
cryo-cooled Si or water-cooled diamond modes
- Oxford/SESO vertically focusing mirror (A)
  - water cooling
  - white beam compatible
- Oxford/SESO water-cooled 2nd steering mirror (B)
- modes of operation:
  1) monochromator w/ or w/out mirror(s)
  2) white beam mirror operation
- high-energy-resolution monochromator
  - dE/E - 10^{-5}
  - used with Kohzu monochromator
- in-station optics
  - steering crystal or multilayer for surface science
  - microfocusing optics

Experiment Stations
- 15-ID-A
  - white beam first optics enclosure
- 15-ID-B
  - white beam station
crystallography
- 15-ID-C
  - pink beam station
  - surface science
- 15-ID-D
  - SAXS/WAXS

Overview

The High-Pressure Collaborative Access Team (HP-CAT) currently has three institutional members: the Carnegie Institution of Washington (managing member), Lawrence Livermore National Laboratory, and the University of Nevada, Las Vegas. These members pool resources and share expertise for the development, construction, and operation of sector 16. The purpose of HP-CAT is to provide its members with facilities for state-of-the-art educational and research activities and to assist the members and general users in operating these facilities; the goal is to advance high-pressure research with synchrotron radiation. The ultimate aim of HP-CAT is to set up a world-leading high-pressure research center at the APS and to make it accessible to the scientific community.

Research Focus

Extreme pressure conditions radically alter the properties of materials. With the recent advances and developments in the technology of pressure vessels, which can now reach several hundreds of gigapascal (1 GPa = 10 kbar), the pressure variable promises to add a whole new dimension in fundamental physics, chemistry, earth and planetary sciences, and material science and technology. HP-CAT is dedicated to the scientific exploration of these fields with a common focus on the high-pressure dimension.

In ultrahigh pressure research, the power of an integrated approach is far greater than the sum of individual techniques. Comprehensive understanding of high-pressure phenomena relies on the combination of complementary measurements. HP-CAT integrates x-ray diffraction and spectroscopy with samples at high pressures and variable temperatures (from cryogenic conditions to thousands of degrees). These techniques include single-crystal structure refinement using energy-dispersive x-ray diffraction, high-resolution angle-dispersive polycrystalline x-ray diffraction, high-resolution x-ray emission spectroscopy, x-ray absorption spectroscopy, nuclear resonance forward scattering, inelastic x-ray scattering, and Compton scattering. The structural, vibrational, electronic, and magnetic properties of materials can thus be measured in situ for identifying novel phenomena and transitions at high pressures.

Industrial Macromolecular Crystallography Association CAT

Overview

The Industrial Macromolecular Crystallography Association (IMCA) is a consortium of crystallographic groups from 12 companies with major pharmaceutical research laboratories in the United States. IMCA-CAT comprises both IMCA and the Center for Synchrotron Radiation Research (CSRRI) at the Illinois Institute of Technology. The 12 corporate members of IMCA are Abbott Laboratories; Bayer Corporation; Bristol-Myers Squibb Pharmaceutical Research Institute; Glaxo Wellcome Research Institute; Eli Lilly and Company; Merck and Company, Incorporated; Monsanto / Searle; Parke-Davis Pharmaceutical Research; Pharmacia and Upjohn, Incorporated; The Procter and Gamble Company; Schering-Plough Research Institute; and SmithKline Beecham Pharmaceuticals. IMCA-CAT is unusual in that a large fraction of research conducted by CAT members is expected to be proprietary. Member scientists function as competitors in the discovery research that arises from their data-collection efforts; however, they collaborate in methods development and collectively fund the operation of the beamlines.

Research Focus

Macromolecular crystallography is the primary research focus for IMCA, with the ultimate objective of facilitating the process of rational drug design. Traditional drug design methods involve testing thousands of compounds to determine biological activity. Rational drug design research attempts to elucidate biological processes in detail, which depends heavily on detailed knowledge of the atomic structure of the molecules involved. IMCA-CAT's insertion-device beamline is designed primarily for monochromatic and multiwavelength anomalous diffraction (MAD) experiments on small (<80 micrometer) protein crystals over an energy range of 6 to 20 keV. The bending-magnet line is designed mostly for monochromatic and MAD experiments on somewhat larger protein crystals over a similar energy range.

Biophysics CAT

Overview

The Biophysics CAT (Bio-CAT) is organized as a national research resource to be used primarily to study the structure of partially ordered biological molecules, complexes of biomolecules, and cellular structures under conditions similar to those present in living cells. The goal of this research is to determine the detailed mechanism of action of biological systems at the molecular level. The techniques used are x-ray fiber diffraction, x-ray scattering, x-ray absorption/emission spectroscopy, and advanced imaging techniques such as diffraction enhanced imaging. The research conducted at Bio-CAT’s beamlines complements that done by other APS CATs (specifically, those that emphasize protein crystallography: BioCARS, IMCA-CAT, and SBC-CAT).

Research Focus

Many biological macromolecules (e.g., enzymes) and complexes (e.g., viruses) can be crystallized and subjected to classic crystallographic analysis. However, in living cells, most biological systems are noncrystalline, and many biological structures cannot be studied in this manner because they cannot be crystallized, are transiently formed, or have structures or dynamical behaviors that change upon crystallization. For example, comparison of x-ray absorption spectra from crystalline and solution enzyme samples has shown that the processes of crystallization can change the microstructures sufficiently that crystallographic structural analysis alone would lead to incorrect interpretations of the enzymes’ mechanisms of action.

All biological systems have some degree of spatial or dynamic order; this order can be probed by noncrystallographic diffraction and x-ray absorption. Of key interest to Bio-CAT scientists are the structures of small ordered domains such as single muscle fibers and connective tissues and studies of the time dependence of structural changes that occur as biomolecular complexes carry out their functions. Key research areas involve biological processes and systems of direct biomedical importance such as enzymes (particularly metalloproteins), DNA-binding proteins, proteins involved in gene expression, cell membranes, nerve cells, immune system components, the processes of cell transport, and cell motility.

Structural Biology Center CAT

Overview

The Structural Biology Center CAT has constructed a national user facility at the APS for studies in macromolecular crystallography. Funded by the Department of Energy's Office of Biological and Environmental Research, the Structural Biology Center provides users with a full complement of instrumentation, ancillary facilities, software, and support staff to enhance the productivity of their research. The majority of beamtime is allocated to Independent Investigators through a proposal process, with a small amount of time reserved for research and development activities by SBC-CAT staff members.

Research Focus

The principal focus of the SBC-CAT research program is macromolecular crystallography. Designed as a rapid-throughput facility, the Structural Biology Center provides researchers with the ability to use both standard crystallographic techniques and multiple energy anomalous dispersion (MAD) phasing methods.

One current major program focuses on the study of macromolecular assemblies, with an emphasis on molecular recognition and interaction between macromolecules. Specific projects include molecular chaperones (bacterial and archael chaperonins 60, human hsc70 chaperone), protein/nucleic acid complexes (trp repressor/operator systems), and multimeric enzymes.

  - 6°–40° Bragg angle range
  - 1st crystals: Si(111), Si (220), Si(331)
  - 25 mm wide, common cooler carrier
  - 2nd crystals: Si(111), Si(220), Si(331)
  - exchangeable, 25 mm x 125 mm
  - 35 mm beam offset (nominal)

### Experiment Stations

- **19-BM-A**  
  - white beam first optics enclosure
- **19-BM-C**  
  - white beam optics enclosure
- **19-BM-D**  
  - monochromatic experiment station
  - kappa goniostat for macromolecular crystallography
  - guard slits
  - filter/shutter
  - detector support and positioner

### Detectors

- SBC1 3k x 3k CCD  
  - built by ANL-ECT
  - 210 mm x 210 mm active area
  - 1.8 sec readout

### Beamline Controls and Data Acquisition

- Multiprocessor SG1 workstation, plus two UNIX workstations for data acquisition and data processing
- 3 HP workstations running EPICS, VME for beamline and detector control
- PMAC motor controller, software by ANL-ECT
- GUI for beamline control, data acquisition, and detector control by ANL-ECT

### Beamline Support Equipment/Facilities

- Rosenbaum-Rock miniaturized kappa goniostat
- high-magnification-alignment cameras (two)
- Rosenbaum-Rock high-precision detector support and positioner
- liquid-nitrogen cryosystem sample cooler

Overview

The Pacific Northwestern Consortium CAT (PNC-CAT) includes a number of institutions in the Pacific Northwest regions of both the United States and Canada. Scientists from the lead institutions of the University of Washington, Pacific Northwest National Laboratories, and Simon Fraser University share several common research goals: specifically, a basic understanding of materials as related to their physical and chemical properties, the development of new strategies for environmental cleanup based on a fundamental understanding of the interaction of pollutants with the ambient environs, and structure-function properties of macromolecules.

Research Focus

Several innovative instruments, including an analytical x-ray microscope with 0.1-μm resolution and capability to measure diffraction, x-ray absorption fine structure (XAFS), and diffraction anomalous fine structure (DAFS), will enable investigators to characterize heterogeneous materials in new ways. These measurements can be combined with two- and three-dimensional imaging using absorption and phase contrast. UHV and MBE facilities are available for in situ investigations using surface diffraction and XAFS. Capabilities for time-resolved measurements in the nanosecond scale are planned. These techniques and instruments will be used to investigate materials science and environmental problems, on both a fundamental and applied level.

Southeast Regional CAT

Overview

SER-CAT, which represents institutions from the states of Alabama, Florida, Georgia, Kentucky, Missouri, North Carolina, South Carolina, Tennessee, and Virginia, as well as the Intramural Program of the National Institutes of Health, plans to build and operate a sector at the APS. The SER-CAT mission is to provide researchers from its member institutions with timely access to tunable, high-intensity x-rays for x-ray diffraction structural studies of biomolecules. SER-CAT plans to provide its users with a complete research facility, including a full complement of instrumentation, software, and support staff for high-throughput data collection and processing. SER-CAT also plans to provide 25% of its beam time to outside users through its Independent Investigator program via a proposal process.

Research Focus

The principal focus of the SER-CAT research program is macromolecular crystallography. The SER-CAT beamline designs are based on those of SBC-CAT; researchers will be able to use both traditional and multiple wavelength anomalous dispersion (MAD) techniques for structure determination and investigation.

The research interests of SER-CAT researchers are varied, ranging from DNA, protein and virus structures, to catalysts and basic materials science.

COM-CAT

Commercial CAT

Overview

The Commercial Beamline Collaborative Access Team (COM-CAT) will be specializing in the application of synchrotron radiation to industrial problems. COM-CAT plans to operate a general-purpose beamline as an analytical service laboratory, providing both materials analysis and data interpretation for problems that require synchrotron radiation techniques for their solution. Funds for beamline construction were provided by the State of Illinois. Beamline operations will ultimately be funded on a fee-for-service basis.

Research Focus

Analyses based on synchrotron radiation are generally applicable to problems in materials science. Industrial companies have used synchrotron facilities to examine a wide variety of materials, including polymers, catalysts, candidate drugs, and biomolecules. COM-CAT expects to provide a convenient means to use synchrotron analysis capabilities to industrial organizations who either do not have current access to a beamline or require rapid turnaround of samples.

COM-CAT will, in its initial stages, construct and operate a single undulator beamline. To provide as broad a range of analytical capabilities as possible, the experimental facilities will consist of three permanent stations devoted to spectroscopy, single-crystal diffraction, small-angle scattering, and x-ray fluorescence. Zone plates will be used when microfocusing is required. To maximize use of the available beam, each table will have a permanent basic configuration. To use a downstream station, the upstream tables will be lowered below the flight path of the x-ray beam.

COM-CAT is also involved in outreach to the general industrial community. It has organized a workshop on industrial applications of synchrotron radiation and will provide on-site introductions to synchrotron radiation for potential customers.

Overview

The UNI-CAT is a collaboration between scientists from the University of Illinois, the Oak Ridge National Laboratory, the National Institute of Standards and Technology, and UOP Research and Development. The UNI-CAT mission is to instrument and operate x-ray research facilities at the APS that provide advanced x-ray techniques to a diverse scientific community. This goal is achieved through the development of two sectors at the APS that are designed for cutting-edge x-ray studies in materials, physics, chemistry, biology, and geology. This is a multi-purpose scattering facility capable of high-resolution scattering with excellent energy resolution and beam-focusing optics. Special capabilities in the UNI-CAT sectors also include a dedicated surface/interface diffraction station equipped with a molecular-beam epitaxy and chemical-vapor deposition facility, an ultra-small-angle x-ray scattering apparatus, an x-ray microscope, a topography station, a dedicated insertion-device beamline for microfocus and coherent x-ray diffraction, instrumentation for time-resolved x-ray scattering experiments, and reactive environment x-ray absorption spectroscopy.

Research Focus

The primary research areas of UNI-CAT members encompass materials sciences and condensed matter physics, and include techniques such as structural crystallography, diffuse x-ray scattering, magnetic x-ray scattering, ultra-small-angle x-ray scattering, x-ray microscopy, millivolt resolution spectroscopy, surface and interface scattering, absorption spectroscopy, x-ray topography, microbeam techniques, coherent x-ray diffraction, and time-resolved techniques. These research tools permit UNI-CAT scientists and collaborators to explore fundamental structure/property relationships in bulk solids, at surfaces, and at internal interface boundaries.

Optics & Optical Performance
- 4–40 keV energy range
- collimating mirror
- double-crystal monochromator
- focusing mirror

Experiment Stations
- 33-BM-B
  - EXAFS topography station
- 33-BM-C
  - general purpose scattering station

Detectors
- NaI scintillation counters
- gas-filled proportional counters (Xe, Ar)
- ionization chambers

Beamline Controls and Data Acquisition
- Sun UNIX running EPICS with VME, SPEC

Beamline Support Equipment/Facilities
- topography station (33-BM-B)
- EXAFS table (33-BM-B)
- Huber 4-circle diffractometer (33-BM-C)

Beamline contact: Paul Zschack

Beamsline contact: Paul Zschack tel 630.252.0860 zschack@anl.gov
Beamline 33-ID / UNI-CAT

Scientific focus: Material Science and condensed matter physics

Scientific programs: Material science, ceramic science, phase transitions, surface science, thin-films structure and growth, and materials physics

Insertion Device Source Characteristics (nominal)

Optics & Optical Performance
- focused beam size 280 μm hor. x 100 μm vert.
- PSL double-crystal monochromator
  45 m from source
  4.0–40.0 keV energy range Si(111)
  $10^{-4}$ energy resolution (dE/E)
  20–35 nm beam offset
  liquid-nitrogen cooling
  variable sagittal focus
- vertical focusing mirror
  2.0–4.0 mrad angle of incidence
  Pt, Si, Rh coating stripes
  variable vertical focus
- harmonic rejection mirror
  2.0–4.0 mrad angle of incidence
  Pt, Si, Rh coating stripes

Experiment Stations
- 33-ID-D
  general purpose scattering
  USAXS station
- 33-ID-E
  surface and interface scattering station

Detectors
- NaI scintillation counters
- ionization chambers
- gas-filled proportional counters (Xe, Ar)

Beamline Controls and Data Acquisition
- Sun UNIX running EPICS with VME, SPEC

Beamline Support Equipment/Facilities
- Huber 4-circle diffractometer (33-ID-D)
- Newport 6-circle goniometer w/ kappa geometry (33-ID-D)
- USAXS (33-ID-D)
- UHV surface/interface scattering chamber (33-ID-E)

### Optics & Optical Performance
- Beamline under design
- Beam-splitting mirrors
- Monochromators

### Experiment Stations
- **34-ID-C**
  - Coherent beam diffraction station
- **34-ID-E**
  - Microbeam scattering station

### Detectors
- Various CCD cameras
- NaI scintillation counters

### Beamline Controls and Data Acquisition
- To be determined

### Beamline Support Equipment/Facilities
- Kappa diffractometer with surface science capability (34-ID-C)
- Microbeam scattering table (34-ID-E)
