Key Words Spent Nuclear Fuel Cold Vacuum Drying Facility Final Safety Analysis Report

Abstract The Cold Vacuum Drying (CVD) Facility Annex B Final Safety Analysis Report is part of the overall Spent Nuclear Fuel Project FSAR which is a multi volume document. This volume contains information specific to the CVD Facility. All topics have been addressed in this volume in accordance with DOE STD 3009 94 Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports.

ANNEX B

COLD VACUUM DRYING FACILITY
FINAL SAFETY ANALYSIS REPORT

HNF-3553
Revision 0

November 1999
This page intentionally left blank
EXECUTIVE SUMMARY

BE 1 FACILITY BACKGROUND AND MISSION

The U.S. Department of Energy (DOE) established the Spent Nuclear Fuel (SNF) Project to address safety and environmental concerns associated with deteriorating SNF presently stored under water in the Hanford Site K Basins, which are located in the 100 K Area near the Columbia River. Recommendations for a series of projects to construct and operate systems and facilities to manage the safe removal of K Basins fuel were made in WHC-EP-0830, *Hanford Spent Nuclear Fuel Recommended Path Forward,* and its subsequent update, WHC-SD-SNF-SP-005, *Hanford Spent Nuclear Fuel Project Integrated Process Strategy for K Basins Fuel.* The integrated process strategy recommends the following steps:

- Fuel preparation activities at the K Basins, including removing the fuel elements from their K Basins canisters, separating fuel particulate from fuel elements and fuel fragments greater than 0.25 in. in any dimension, removing excess sludge from the fuel fragments by means of flushing, as necessary, and packaging the fuel into multi-canister overpacks (MCOs);

- Transportation of MCOs loaded with SNF from the K Basins to the Cold Vacuum Drying Facility (CVDF), a new facility in the 100 K Area.

---

Removal of free water from the fuel performed at the CVDF by draining of bulk water from the MCO and subsequent vacuum drying to remove remaining bulk water and sufficient portions of the hydration water, evacuation and backfilling of the MCO with an inert gas (helium), followed by sealing and leak testing of the MCO.

Dry shipment of fuel from the CVDF to the Canister Storage Building (CSB), a new facility in the 200 East Area.

Interim storage of the MCOs in the CSB until a suitable long-term repository is established.

The SNF Project Final Safety Analysis Report (FSAR) is a multi-volume document. Volume 1 contains SNF Project information applicable to all project facilities. Volume 2 contains information specific to the CSB. This volume, Volume 3, contains information specific to the CVDF. This volume represents the CVDF design as of June 7, 1999.

The purpose of Volume 3 is to provide the basis for authorization to operate the CVDF. The scope of this report includes the operating and support structures and equipment required for receipt cold vacuum drying, and preparation for dry shipment of the MCOs to the CSB. All topics identified in DOE-STD-3009-94, Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports, are addressed, including descriptions of site and facility design, hazard and accident analyses, safety-class and safety-significant equipment, derivation of technical safety requirements, prevention of inadvertent criticality, and other areas of facility design and operational programs. This report also follows the guidance presented and approved in HNF-SD-SNF-DB-003, Spent Nuclear Fuel Project Path Forward.

---

BE 2 FACILITY OVERVIEW

The CVDF is a new facility located to the west of the K Basins in the 100 K Area of the Hanford Site. The CVDF includes four adjoining areas: the process bay area, the process support area, the process water tank room, and the administrative building. The process bay area (60 ft by 150 ft) contains four operational process bays and one unused bay. The process bay area has been constructed using a steel frame with attached concrete panels, and each functional process bay contains a second-level mezzanine. Immediately adjacent and contiguous to the process bay area is the process support area (20 ft by 150 ft), a steel-framed, two-story metal building that encloses the traffic corridor, process bay support rooms, and the second floor mechanical equipment room. Immediately adjacent to the process bay area on the north side is a single-story concrete and structural steel building that encloses the process water tank room (20 ft by 60 ft), and a single-story, preengineered metal building that encloses office and change room functions.

Each operational process bay contains a process equipment skid, a safety-class helium system, a process hood, and a process bay recirculation heating, ventilation and air conditioning (HVAC) system. Each process equipment skid contains a vacuum and purge system and a tempered water (annulus) system.

The CVDF interfaces with the 100 K Area, Hanford Site infrastructure services, and the CSB. The CVDF operation interfaces with K Basins operations by receiving cask–MCO packages for processing. Water removed from the MCO and water used for system flushes is cleaned and transported by tanker truck to the K West Basin for further processing.

---

Service water (filtered river water) is supplied to the CVDF fire protection system from the 100 K Area service water system. Potable water is supplied to the CVDF from the 100 K Area sanitary water loop. A feed line from Site utilities supplies the CVDF electrical systems. Security fire response, and medical services are provided as sitewide services. The CVDF also interfaces with the CSB operation when the cask-MCO packages are shipped to the CSB after the cold vacuum drying process has been completed.

BE 3 FACILITY HAZARD CLASSIFICATION

A final hazard categorization of the CVDF facility was determined from the results of the final accident analyses performed for the facility. These analyses provided an estimate of the material at risk for the hazard categorization performed in accordance with DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480 23 Nuclear Safety Analysis Reports*, Attachment 1 and with the guidance of HNF-PRO-704, *Hazard and Accident Analysis Process*, Appendix B.

Consistent with DOE-STD-1027-92, the CVDF is classified as a hazard category 2 nuclear facility and is based on the material at risk chosen to bound the material at risk from the worst-case unmitigated thermal runaway accident. These CVDF material quantities were compared against the threshold quantities contained in DOE-STD-1027-92.

---

BE 4 SAFETY ANALYSIS OVERVIEW

The scope of the hazard analysis included all normal, intended CVDF operations for MCO receipt, cold vacuum drying, and preparation for dry shipment to the CSB. The analysis included reviews of draft operations, flow diagrams, and the facility final design. CVDF operations considered were those involved with bringing the transportation cask containing an MCO into the facility on the transporter, removing the cask lid, hooking up the processing equipment to the MCO, conducting the cold vacuum drying processing activities, conducting a series of final dryness tests, inerting the MCO with helium, disconnecting the processing equipment, replacing the cask lid, and transporting the MCO from the facility.

The hazard analysis involved the identification of hazard sources, hazardous conditions, potential accident scenarios and their initiators, and preliminary assessments of event frequencies and consequences. Hazards were identified by form and location and represent a complete spectrum of events that could occur throughout the facility.

The high-risk events that pose a challenge to offsite and onsite radiological dose evaluation guidelines were selected from the hazard analysis for further quantitative evaluation as design basis accidents (DBAs). These accidents are presented in detail in Chapter B3.4. Each DBA analyzed represents a bounding case for a category of hazards and accidents. The following six major DBA events are evaluated:

- Gaseous release
- Liquid release
- MCO external hydrogen explosion
- MCO internal hydrogen explosion
- MCO thermal runaway reaction
- MCO overpressurization
Four receptors were evaluated in the DBA analysis

- Hanford Site boundary receptor (offsite) defined at a distance of 10,090 m (33,100 ft) from the CVDF
- Collocated worker receptor (onsite), defined at a distance of 100 m (328 ft) from the CVDF
- Near bank of the Columbia River receptor (onsite), defined at a distance of approximately 650 m (2,130 ft) from the CVDF
- 100 Area Fire Station receptor (onsite) defined at a distance of approximately 3,750 m (12,300 ft) from the CVDF

Consequences to the Hanford Site boundary receptor and collocated worker receptor were compared against defined release limits and risk evaluation guidelines and were used for the selection of safety-class and safety-significant features, respectively. Consequences for receptors at the near bank of the Columbia River and at the 100 Area Fire Station also were calculated for the purpose of identifying any additional measures considered necessary to reduce the dose to individuals at these receptor locations. No additional safety features have been identified based on the consequences calculated for these locations. Safety-class preventive features and safety-significant preventive and mitigative features identified for the DBAs serve to reduce the dose consequences at all of the receptor locations.

BE 5 ORGANIZATIONS

Fluor Daniel Hanford, Incorporated is responsible to the DOE for the planning, integrating, and managing of SNF Project activities, including programs, projects, and operations.
Fluor Daniel Hanford is supported by subcontractors, including Duke Engineering and Services Hanford, Incorporated. Organizational responsibilities related to the SNF Project are summarized in the executive summary of Volume 1 and described in detail in Chapter 170 of that volume.

BE 6 SAFETY ANALYSIS CONCLUSIONS

The safety analysis conclusions for the CVDF DBAs are presented in detail in Chapter B30, Section B3 4 2 of this volume and are summarized as follows.

**Gaseous release** The bounding unmitigated scenario for this accident category describes a pressurized release of helium gas and entrained contaminated particulate through a process line leak. The unmitigated consequences of this event do not exceed the offsite release limits but do exceed the onsite risk evaluation guidelines. No safety-class features are required to mitigate this event. Safety-significant features selected to mitigate this event include portions of the process general supply/exhaust HVAC system and process bay local exhaust HVAC and process vent system and differential pressure alarms for the process bays and process water tank room. Mitigated consequences of this event are well below both offsite release limits and onsite risk evaluation guidelines. For a detailed description of safety features selected to prevent or mitigate other events within this accident category, see Section B3 4 2 1.

**Liquid release** The bounding unmitigated scenario for this accident category describes a pressurized leak of water and entrained contaminated particulate from the process water conditioning piping. The unmitigated consequences of this event do not exceed the offsite release limits but do exceed the onsite risk evaluation guidelines. No safety-class features are required to mitigate this event. Safety-significant features selected to mitigate this event include portions of the process general supply/exhaust HVAC system (ductwork and high-efficiency particulate air [HEPA] filters for the process water tank room) and the process water tank room differential pressure alarm. Mitigated consequences of this event are well below both offsite release limits.
and onsite risk evaluation guidelines. For a detailed description of safety features selected to prevent or mitigate other events within this accident category, see Section B3.4.2.2

**MCO external hydrogen explosion** The bounding unmitigated scenario for this accident category describes accumulation of hydrogen outside an MCO when it is vented from the MCO into the local exhaust process ventilation system and mixed with air, followed by ignition and explosion of the hydrogen gas. The unmitigated consequences of this event do not exceed the offsite release limits but do exceed the onsite risk evaluation guidelines. No safety-class features are required to prevent or mitigate this event. Safety-significant features selected to prevent this event include portions of the process bay local exhaust HVAC and process vent system (ductwork and HEPA filters) and special tools to limit the cask vent flow rate. Because the selected safety features prevent and mitigate this event, both offsite release limits and onsite evaluation guidelines are satisfied. For a detailed description of safety features selected to prevent or mitigate other events within this accident category, see Section B3.4.2.3

**MCO internal hydrogen explosion** The bounding unmitigated scenario for this accident category describes the ignition and explosion of a hydrogen–air mixture inside an MCO. The unmitigated consequences of this event do not exceed the offsite release limits but do exceed the onsite risk evaluation guidelines. No safety-class features are required to prevent or mitigate this event. However, some safety-class features preventing the MCO thermal runaway reaction and overpressurization events (i.e., multiple safety functions to detect process upsets, the safety-class helium system, portions of the tempered water [annulus] system) also prevent this accident, but in a safety-significant role. Because the designated safety features prevent and mitigate this event, both offsite release limits and onsite risk evaluation guidelines are satisfied. For a detailed description of safety features selected to prevent or mitigate other events within this accident category, see Section B3.4.2.4

**MCO thermal runaway reaction** The bounding scenario for this accident category describes an accident that is initiated by a reduction of heat removal from an MCO.
This condition results in the uncontrolled escalation of the chemical reaction within the MCO, resulting in high temperatures there. If unmitigated, the high temperatures of this scenario could lead to a continuous release of gas and contaminated particulate for an extended period of time. The unmitigated consequences of this event challenge the offsite release limits and exceed the onsite risk evaluation guidelines. Safety-class features selected to prevent this event include safety features to detect process upsets, the safety-class helium system purge and isolation, and portions of the tempered water (annulus) system. Because these safety-class features prevent this event, both offsite release limits and onsite risk evaluation guidelines are satisfied. For a detailed description of safety features selected to prevent or mitigate other events within this accident category, see Section B3.4.2.5

**MCO overpressurization** The bounding unmitigated scenario for this accident category describes overpressurization of an isolated MCO with no pressure relief. The pressure in an isolated MCO increases with the formation of hydrogen gas as a product of the uranium-water reaction. The MCO internal pressure continues to increase until the MCO pressure boundary is breached or until the fuel or water are completely consumed. The overpressurization leads to a pressurized release of gas and contaminated particulate followed by an extended period of slow continuous release driven by the continued oxidation of the uranium inside the MCO. The unmitigated consequences of this event exceed both the offsite release limits and onsite risk evaluation guidelines. Safety-class features selected to prevent this event include multiple safety features to detect process upsets, the safety-class helium system, the 30 lb/in² gauge vent line, the 150 lb/in² gauge rupture disk, and portions of the tempered water (annulus) system. These safety-class features reduce the frequency and mitigate the occurrence of this event to well within the offsite release limits. Additional safety significant features for confinement and filtration are identified to mitigate the onsite consequences to well below the onsite risk evaluation guidelines. For a detailed description of other safety features selected to prevent or mitigate other events within this accident category, see Section B3.4.2.6.
The following safety-class and safety-significant features are relied upon in the facility safety bases:

- Vacuum purge system
  - Isolation valves with instrument air filters (safety class)
  - Deionized water isolation valves with instrument air filters (safety class)
  - Isolation piping and flex hoses (safety class)
  - MCO connectors (safety class)
  - Pressure instruments (safety class)
  - 30 lb/in² vent path (safety class)

- General-service helium system
  - Safety relief valves (two) (safety class)
  - MCO helium flow transmitter trip (safety significant)
  - Isolation valve with instrument air filters (safety class)
  - Isolation piping (safety class)

- Process water conditioning system
  - Ion exchange modules (safety class)
  - Isolation valve with instrument air filters (safety class)
  - Isolation piping and flex hose (safety class)
  - Process water transfer line in process bays (safety significant)

- Process bay local exhaust HVAC and process vent system
  - Exhaust fans and plenum (safety significant)
Annex B — Cold Vacuum Drying Facility

- HEPA filter (safety significant)
- Ductwork (safety significant)
- Low flow alarm switch (safety significant)
- Hood isolation damper (fail closed) (safety significant)
- Cask venting orifice (safety significant)
- Cask vent jumper tool (safety significant)
- Cask venting valve (safety significant)
- Cask venting flow interlock (safety significant)
- MCO vent jumper tool (safety significant)

- Process general supply/exhaust HVAC system
  - HEPA filter (safety significant)
  - Exhaust ductwork (safety significant)
  - Isolation dampers (process bays) (safety significant)

- Process bay recirculation HVAC system
  - Isolation dampers (outside air inlets) (safety significant)

- Reference air system
  - Reference air header (safety significant)
  - Differential pressure alarms (safety significant)

- Instrument air system
  - Instrument air reservoirs (safety significant)
  - Air reservoir pressure gauges (safety significant)
Standby electrical power
  
  - Diesel generator (safety significant)
  - Local exhaust restart circuit (safety significant)

BE 7 SAFETY ANALYSIS REPORT ORGANIZATION

The CVDF FSAR is based on the format and content guidance of DOE-STD-3009-94\(^7\) and the requirements of DOE Order 5480 23, *Nuclear Safety Analysis Reports*\(^7\). This report also includes content guidance from NRC Regulatory Guide 3 26, *Standard Format and Content of Safety Analysis Reports for Fuel Reprocessing Plants*,\(^8\) as a result of the DOE regulatory policy described in HNF-SD-SNF-DB-003.\(^4\)

B1 0 SITE CHARACTERISTICS

B1 1 INTRODUCTION

The Cold Vacuum Drying Facility (CVDF) is located in the 100 K Area of the U.S. Department of Energy (DOE) Hanford Site. The CVDF will be used to remove free water from spent nuclear fuel (SNF) taken from the K West (KW) and K East (KE) fuel storage basins and to vacuum dry the SNF before it is transferred to the Canister Storage Building in the 200 East Area. This chapter describes the characteristics of the 100 K Area, including the site on which the CVDF is located, and supports the hazard analysis and accident analyses presented in Chapter B3. A detailed description of the CVDF structures and systems is provided in Chapter B2. This chapter and Chapter 10 of the SNF Project Final Safety Analysis Report (FSAR) contain information related to regional and Hanford Site characteristics.

B1 2 REQUIREMENTS

The requirements that establish the basis for siting the CVDF are identified in Section 1.2 of the SNF Project FSAR. Some of the requirements listed in Section 1.2 of the SNF Project FSAR were not in existence at the time the CVDF was designed. The impact of these later orders and standards is reflected in WHC-SD-SNF-DB-010, Cold Vacuum Drying System Natural Phenomena Hazards. A discussion of U.S. Nuclear Regulatory Commission (NRC) equivalency requirements is provided in Section 1.2 of the SNF Project FSAR.

In addition to the requirements identified in Section 1.2 of the SNF Project FSAR, the following industry standards are applicable to the CVDF safety basis:

- ASCE 7-95, 1995, Minimum Design Loads for Building and Other Structures

B1 3 SITE DESCRIPTION

The following sections address the geography, demography, and regional land and water use of the area encompassed by, and surrounding, the 100 K Area. The information contained in these sections was obtained primarily from DOE/EIS-0245F, Management of Spent Nuclear Fuel from the K Basins at the Hanford Site, Richland, Washington.
B1 3 1 Geography

**B1 3 1 1 Hanford Site Vegetation**  Section 1 3 1 1 of the SNF Project FSAR provides information applicable to all SNF Project facilities

**B1 3 1 2 Hanford Site Facilities**  Section 1 3 1 2 of the SNF Project FSAR provides information applicable to all SNF Project facilities

**B1 3 1 3 Boundaries for Evaluation of Accident and Effluent Release Limits**  As stated in Section 1 3 1 3 of the SNF Project FSAR, activities at the 100 K Area are within the DOE-controlled zone. DOE has directed that consequences of accident releases to collocated workers and to the public (offsite receptor) be calculated at the following four locations (Sellers 1996) (see Section B3 4 1 2)

- Receptors located 100 m from the CVDF
- Receptors located at the near bank of the Columbia River (about 650 m, the nearest point of uncontrolled public access)
- Receptors located at the fire station (about 3,750 m to the east-southeast)
- Receptors located at the Hanford Site boundary (about 10,000 m to the west of the K West Basin)

Consequences of accident releases from the CVDF to collocated workers are calculated in Section B3 4 2 at 100 m from the point of release in accordance with approved procedures. Routine and accidental releases to the public (offsite receptor) are calculated at the Hanford Site boundary (North Wahluke Slope) shown in Figure B1-1. This Hanford Site boundary is also the location of the controlled area boundary, as the term is defined in Title 10 Code of Federal Regulations Part 72 'Licensing Requirements for the Independent Storage of Spent Nuclear Fuel and High-Level Radioactive Waste' (10 CFR 72), Section 72 106 "Controlled Area of an ISFSI or MRS."

Doses at the near bank of the Columbia River were calculated for the purpose of identifying any additional measures considered necessary to reduce the dose to individuals at this receptor location as stated in Section B3 4 1 2. For Highway 240 to the south and west, DOE and its contractors can control access during emergency and accident conditions. This access control meets the requirements of 10 CFR 72 106(b). Before changes to the Site boundaries are placed into effect by the proper authorities, the calculations in this FSAR will be reviewed (and reanalyzed if required) in accordance with DOE Order 5480 21 "Unreviewed Safety Questions"
B1 3 2 Demography

Section 1 3 2 of the SNF Project FSAR provides a description of the onsite and offsite demography.

B1 4 ENVIRONMENTAL DESCRIPTION

B1 4 1 Meteorology

Section 1 4 1 of the SNF Project FSAR provides meteorology information applicable to all SNF Project facilities.

The specific air transport factors used for accident consequence analyses, and the basis for their calculation and use, are discussed in detail in HNF-SD-SNF-TI-059, A Discussion on the Methodology for Calculating Radiological and Toxicological Consequences for the Spent Nuclear Fuel Project at the Hanford Site, and in Section B3 4 1 2. To support the accident analyses of Section B3 4 2, air transport factors (X/Q and X/Q'), representing the dilution of a contaminant by atmospheric turbulence and diffusion as the contaminant travels downwind, were calculated (HNF-SD-SNF-TI-059). The symbol X/Q is the ratio of the average air concentration at the receptor to the average release rate at the release point. It is used to assess potential radiological dose and noncorrosive chemical concentration at downwind locations. The symbol X/Q' is the normalized peak air concentration at the center of a puff divided by the quantity released, and is used to assess the consequences to a receptor for corrosive chemicals. The X/Q's for the analyses were calculated using joint frequency distribution data so as to be exceeded only 0.5% of the time (99.5% percentile) for each sector, or to be exceeded only 5% of the time (95% percentile) for data from all sectors combined (the greater of the two calculated values is used in the analyses).

The GXQ computer code, Version 4.0 (WHC-SD-GN-SWD-30002), was used to generate X/Q and X/Q' values. GXQ incorporates the methods described in NRC Regulatory Guide 1 145 Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants. The specific air transport factors used for accident consequence analyses, and the basis for their calculation and use, are discussed in detail in HNF-SD-SNF-TI-059 and in Section B3 4 1 2. Also see supporting information in Table B3-7 for the atmospheric transport factors used in accident analyses for the CVDF. Supporting information is also provided in Section 1 4 1 2 8 of the SNF Project FSAR.

The wind rose data (Figure B1-2 and Figure B1-3) indicate that winds from the west sector occur most frequently (nearly 16% of the time). That is, the emissions are transported toward the east sector. Winds out of the west-northwest and west-southwest also occur with a relatively high frequency (12% and 10%, respectively). Information provided in these figures corresponds to the data presented in HNF-SD-SNF-TI-059.
B1 4 2 Hydrology

Section 1 4 2 of the SNF Project FSAR provides Hanford Site hydrology information that is applicable to all SNF Project facilities.

B1 4 2 1 Surface Water Section 1 4 2 1 of the SNF Project FSAR provides surface water information.

B1 4 2 2 Vadose Zone Section 1 4 2 2 of the SNF Project FSAR provides a definition of the vadose zone.

B1 4 2 3 Aquifers The 100 Area aquifer systems are discussed in Section 1 4 2 3 of the SNF Project FSAR.

B1 4 3 Geology

A description of the Hanford Site geology which applies to all SNF Project facilities, is provided in Section 1 4 3 of the SNF Project FSAR.

B1 4 3 1 Physiographic Setting of the Hanford Site See Section 1 4 3 1 of the SNF Project FSAR for information on the physiographic characteristics applicable to the CVDF.

B1 4 3 2 Stratigraphy See Section 1 4 3 2 of the SNF Project FSAR for information on the stratigraphy of the Pacific Northwest and the Hanford Site that is applicable to the CVDF.

B1 4 3 3 History of Cataclysmic Flooding in the Pasco Basin See Section 1 4 3 3 of the SNF Project FSAR for information on cataclysmic floods that is applicable to the CVDF.

B1 4 3 4 Geologic Structures of the Columbia Basin and Hanford Site See Section 1 4 3 4 of the SNF Project FSAR for information on geologic structures that is applicable to the CVDF.

B1 4 3 5 Geology of the 100 K Area The 100 K Area and vicinity is underlain by the Columbia River Basalt Group and intercalated Ellensburg Formation, the Ringold Formation, the Hanford formation and Holocene deposits. The 100 K Area is near the axis of the Wahluke syncline. The Columbia River Basalt Group lies approximately 527 ft beneath the 100 K Area. Overlying the Columbia River Basalt Group is the Ringold Formation (Figure B1-4).

The Ringold Formation is about 493 ft thick and consists of the fluvial gravels and sands of units A, B, C and E lacustrine and fluvial overbank deposits, and paleosols (Figures B1-4, B1-5, and B1-6). Unit A, the lowermost unit, is approximately 7 m (23 ft) thick and consists of fluvial gravel facies grading upward into sand associations. Overlying unit A is the Lower Mud unit. The Lower Mud unit is approximately 105 ft thick. Unit B is approximately 92 ft thick and consists predominantly of sand. Overlying unit B is a 209-ft-thick sequence of muds and sandy
muds typically displaying characteristics of paleosols and fluvial overbank deposits. The sequence has three parts: an upper and a lower part that are predominantly silt to sandy silt and a middle section of gravelly sand. The uppermost unit of the Ringold Formation at the 100 K Area is the coarse-grained unit E, which is predominantly composed of the fluvial gravel and fluvial sand facies. The unconfined portion of the uppermost aquifer system occurs in this unit at the 100 K Area. The known thickness of unit E ranges from 64 to 141 ft.

The Hanford formation at the 100 K Area is a wedge that decreases in thickness toward the Columbia River. It is approximately 120 to 130 ft thick. The Hanford formation pinches out from southeast to northwest across the 100 K Area. The gravel-dominated facies predominates in the Hanford formation throughout the 100 K Area. Boulder gravel is often found in the upper 20 to 50 ft. The sand-dominated facies occurs locally in a few intervals, but it is not thick enough or extensive enough to correlate from borehole to borehole. The silt-dominated facies has not been identified in the 100 K Area.

Holocene deposits in the study area are dominated by Columbia River deposits and eolian deposits. Columbia River deposits consist of gravels and coarse-grained sands deposited in channels and silts and fine sands deposited in the overbank area. Eolian deposits consist dominantly of less than 3 ft of silty, fine-grained sands that blanket much of the area except in locations where they were removed for construction purposes. In many locations eolian deposits are only a thin blanket (less than 1 ft thick).

The 100 K Area is geologically different than surrounding areas (100 B, 100 C, and 100 N Areas) because the Ringold Formation is exposed, not only along the banks of the Columbia River, but also from the river to 1,200 ft or more away from the river to the southeast.

The Wahluke syncline is the principal structural unit that contains the 100 Areas and the CVDF. The Wahluke syncline is an asymmetric and relatively flat-bottomed structure similar to the Cold Creek syncline. The northern limb dips gently (approximately 5°) to the south. The steepest limb is adjacent to the Umtanum Ridge-Gable Mountain structure.

The 100 K Area lies along the axis of the Wahluke syncline. The bedrock basalt surface tilts gently to the south in the area north of the 100 K Area. The basalt is tilted steeply to the north along the north flank of the Gable Butte portion of the Umtanum-Gable Mountain anticline.

The 100 K Area is about 1.2 mi north of the Umtanum-Gable Mountain thrust fault. The Umtanum-Gable Mountain fault is a reverse to thrust fault that extends over 62 mi along the north side of the Umtanum-Gable Mountain anticline. The Central Fault on the Gable Mountain segment of the Umtanum-Gable Mountain anticline is a capable fault (NUREG-0892, Supplement No. 1) and is 8 mi east of the 100 K Area.

**B1 4 3 6 Tectonic Development of the Hanford Site** See Section 1 4 3 6 of the SNF Project FSAR for information on geologic structures and faults that relate to Hanford Site seismic hazard.
analysis that is applicable to the CVDF. Also see WHC-SD-W236A-TI-002 Probabilistic Seismic Hazard Analysis DOE Hanford Site Washington.

B1 4 3 7 Contemporary Stress and Strain See Section 1 4 3 7 of the SNF Project FSAR for information on earthquake activity, contemporary stress measurements and subsidence history that is applicable to the CVDF.

B1 4 3 8 Geologic Hazards

B1 4 3 8 1 Seismic Hazard Assessment The major source of earthquakes at the Hanford Site is swarm activity in the syncline of the Yakima Fold Belt. There are three general areas of significant swarm activity: the Wooded Island swarm area, the Coyote Rapids swarm area, and the Saddle Mountains swarm area.

The Coyote Rapids swarm area is located at the horn of the Columbia River between the 100 K and 100 N Areas. It occurs over no known geologic structure. The CVDF is located in the southern portion of this swarm. The swarm lies at the intersection of two paleoslopes that make a northeast-southwest trough extending from Spokane, Washington to the Columbia Gorge. This zone may be an old basement weakness zone, but there is no known reason for the swarm to occur in its present position. The largest earthquake recorded on the Hanford Site has a magnitude of 3.8 and was a part of the Coyote Rapids swarm area.

The mean seismic hazard curves for the 100 K Area are shown in Figures B1-7 and B1-8 and illustrate the contributions of individual folds to the hazard. The relative contribution of crustal and Cascadia Subduction sources at the 100 K Area is illustrated in Figure B1-9 and the relative contribution of the three crustal sources for the same location is shown in Figure B1-10.

The performance category 3 horizontal and vertical equal-hazard response spectra were developed for the CVDF site. These spectra are shown at 5% damping for performance category 3 in Figure B1-11. They are the enveloping spectra for the 200 Areas and the 100 K Area. More detail and additional damping values are presented in WHC-SD-W236A-TI-002. As stated in WHC-SD-SNF-DB-010, performance category 3 projects follow the requirements of DOE Order 5480.28 Natural Phenomena Hazards Mitigation as a minimum and supporting standard DOE-STD-1020-94, Natural Phenomena Hazards Design and Evaluation Criteria for Department of Energy Facilities, Chapter 2 and Appendix C. Equal-hazard 5% damped horizontal and vertical response spectra are anchored at 0.26 g horizontal. In-structure response spectra are generated for structures, systems, and components (SSCs) supported by the CVDF structure. This information is provided in Chapter B4.0 for the design of the CVDF SSCs.

B1 4 3 8 2 Volcanic Hazard Assessment Information about the volcanic hazards applicable to all SNF Project facilities is provided in Section 1 4 3 8 2 of the SNF Project FSAR.
B1 4 3 8 3 Subsurface Stability The CVDF is constructed on flood sediments, the youngest sediments being approximately 13,000 years old. There are no areas of potential surface or subsurface subsidence, uplift, or collapse except for the low geologic deformation. With the exception of the loose, surficial, wind-deposited silt, soils are competent and form good foundations. Geotechnical studies have been completed in and around the 100 K Area (WHC-SD-NR-ER-093, Redpath 1994). The water table is approximately 75 ft below ground surface in the relatively compact and moderately well cemented unit of the Ringgold Formation.

B1 5 NATURAL PHENOMENA THREATS

Table B1-1 (Table 1 of WHC-SD-SNF-DB-010) summarizes the natural phenomena design loads to be used for the design of safety-class SSCs for the CVDF. The industry codes and standards used for the design, fabrication, and procurement of safety-significant SSCs are shown in Table B4-3. The design codes used for general service equipment follow industry acceptable design codes and standards. These SSCs are designed to codes, standards, regulations, and orders, as listed in Section 1.2 of the SNF Project FSAR. Each of these phenomena and the bases for the analysis values have been discussed in Section 1.4 of the SNF Project FSAR.

B1 6 EXTERNAL HUMAN-GENERATED THREATS

This section identifies and investigates specific potential human-generated threats to CVDF operation. Threats to the CVDF from human activities that are not known at this time will be evaluated when identified by the Unreviewed Safety Question process.

B1 6 1 Aircraft Activity

The methodology used in the aircraft activity analysis is provided in Section 1.6.1 and Figure 1-35 of the SNF Project FSAR. There are twelve active airports within a 35-mi radius of the CVDF (Beary 1997). Ten of these are small airports that serve only general aviation aircraft and are within 24 mi of the CVDF. The Richland Airport, 27 mi southeast of the CVDF, primarily supports general aviation operations, but two commercial freight carriers per day land and take off from the airport’s runways. The nearest airport with significant commercial and military air activity is the Tri-Cities Airport, 34 mi southeast of the CVDF.

DOE-STD-3014-96, Accident Analysis for Aircraft Crash into Hazardous Facilities, provides the methodology to conservatively evaluate and assess the significance of aircraft crash risk on facility safety. The CVDF meets the standard’s guidelines for applicability because it contains enough radioactive material to be classified as a hazard category 2 nuclear facility according to the criteria established in DOE-STD-1027-92, Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23 Nuclear Safety Analysis Reports.

<sup>g</sup> NFPA 780 1995  Lightning Protection Systems National Fire Protection Association Quincy Massachusetts
The approach used in DOE-STD-3014-96 includes the methodology to evaluate the frequency of aircraft impact into the facility. If the frequency of aircraft impact, calculated according to the methodology given in the standard, exceeds $10^{-6}$/yr, the analysis proceeds to a consideration of whether those aircraft that have a high impact frequency could actually cause damage resulting in potential releases from the facility. Using that methodology, the frequency of aircraft impact into the CVDF has been assessed (Beary 1997).

The methodology provided in DOE-STD-3014-96 considers two contributors to the overall frequency of aircraft crashes: (1) the frequency of crashes resulting from nearby airport activity (i.e., takeoffs and landings) and (2) the frequency of crashes during overflights of the facility. Only runways within about 24 mi of the facility are included on the crash location probability tables given in Appendix B of DOE-STD-3014-96. Activities on runways at greater distances are not considered potential contributors to the frequency of a crash at the facility location for any category of aircraft. For calculating the frequency of crashes from aircraft flying over the site, DOE-STD-3014-96 provides DOE site-specific frequency data, in crashes per square mile per year centered at the site for various classes of aircraft.

As stated above, there are 10 active airports within a 24-mi radius of the CVDF (Beary 1997). All operations at these airports involve general aviation aircraft. The nearest airports serving commercial or military aircraft are the Richland Airport, 27 mi southeast of the CVDF and the Tri-Cities Airport, 34 mi southeast. Table B1-2 lists the 10 airports within 24 mi of the CVDF and their distances from and orientation to the facility.

For both the nearby airports and the overflight activities, DOE-STD-3014-96 bases the calculation of frequency of aircraft crash into a facility on a "four factor formula" that considers the following:

1. The number of aircraft operations at nearby airports and overflying the site ($N$).
2. The probability that an aircraft will crash ($P$).
3. The conditional probability that, given a crash, the aircraft crashes into a one-square-mile area where the facility is located ($f(x,y)$).
4. The site-specific effective area of the facility ($A_{eff}$).

The formula is applied individually to each category of aircraft for both the nearby airports and the overflight activities. The overall frequency of aircraft crashes into the facility is the sum of the frequencies calculated for all categories of aircraft and for all operational modes.
The distances and orientations of the runways for the 10 nearby airports were compared to tables in Appendix B of DOE-STD-3014-96 to identify which of the flight sources contribute to the frequency that an aircraft will crash in a one-square-mile area in the vicinity of the CVDF. All of the airports exclusively support general aviation. The screening revealed that only the landing operations on runways 18 and 36 at the Mattawa Air Strip and on runway 27 at Desert Aire contribute to the crash frequency for nearby airport operations for the CVDF.

The Mattawa Air Strip reports 1,250 operations per year, and Desert Aire has approximately 12 operations per week or 624 operations per year. It was assumed that the operations were equally distributed between runways and that there are an equal number of takeoffs and landings. Table 1 of DOE-STD-3014-96 gives a crash rate for landings of representative fixed wing general aviation aircraft of \( 2 \times 10^{-5} \) per landing.

The conditional probability \( f(x,y) \), that a general aviation aircraft attempting to land on one of these runways will crash into a one-square-mile area containing the CVDF was taken from Table 5 of DOE-STD-3014-96. The values are \( 8.7 \times 10^{-5} \) for Mattawa runway 18, \( 1.8 \times 10^{-4} \) for Mattawa runway 36, and \( 5.6 \times 10^{-5} \) for Desert Aire runway 27.

Multiplying the number of operations per year, \( N \), the crash rate per operation, \( P \), and the conditional probability per square mile, \( f(x,y) \), gives a factor \( NPf(x,y) \), representing the contribution for each airport for general aviation operations. The values for the three flight
sources can be summed at this point because all involve the same category of aircraft (general aviation) and the same flight phase (landing). The value of NPf(x,y) for operations for the Mattawa runways is

\[
NPf(x,y)_1 = 2 \times 10^{-5} \frac{\text{crashes}}{\text{landing}} \left( \frac{1.25}{4} \frac{\text{landings/yr}}{\text{runway}} \times (8.7 \times 10^{-5} + 1.8 \times 10^{-4}) \frac{\text{impacts}}{\text{mi}^2} \right)
\]

\[
= 1.67 \times 10^{-6} \frac{\text{impacts/yr}}{\text{mi}^2}
\]

The value of NPf(x,y) for operations at Desert Aire runway is

\[
NPf(x,y)_2 = 2 \times 10^{-5} \frac{\text{crashes}}{\text{landing}} \left( \frac{624}{4} \frac{\text{landings/yr}}{\text{runway}} \times 5.6 \times 10^{-5} \frac{\text{impacts}}{\text{mi}^2} \right)
\]

\[
= 1.75 \times 10^{-7} \frac{\text{impacts/yr}}{\text{mi}^2}
\]

This factor will ultimately be multiplied by the effective area of the facility to give the contribution of operations at that airport to the overall annual frequency of aircraft crashes into the facility.

To evaluate the frequency of crashes that impact the CVDF from overflight operations, Tables 14 and 15 of DOE-STD-3014-96 give generic values of NPf(x,y) in crashes per square mile per year centered at various DOE sites, including the Hanford Site, for five categories of aircraft. The values are based on the historic record for aircraft crashes in the continental United States.

The site-specific values of NPf(x,y) for overflight operations given for the Hanford Site by aircraft category are as follows:

- General aviation \(1 \times 10^{-4}\) crashes/yr/mi\(^2\)
- Air carrier \(1 \times 10^{-7}\) crashes/yr/mi\(^2\)
- Air taxi \(1 \times 10^{-6}\) crashes/yr/mi\(^2\)
- Large military \(1 \times 10^{-7}\) crashes/yr/mi\(^2\)
- Small military \(4 \times 10^{-8}\) crashes/yr/mi\(^2\)

For both the nearby airport and the overflight operations, the NPf(x,y) for each category of aircraft is multiplied by an effective area, \(A_{\text{eff}}\), representing the ground surface area within which an unobstructed aircraft, were it to crash within the area, would impact the facility, either by flying or skidding into the facility. The effective area depends not only on the length, width, and
height of the facility, but also on the aircraft's wingspan, the flight path angle, the heading angle relative to the heading of the facility, and the length of the skid. Therefore, an effective area is calculated for each category of aircraft.

Formulas for calculating the effective area of the facility are given in Appendix B of DOE-STD-3014-96. The effective area has two terms: the effective fly-in area \( A_f \), and the effective skid area \( A_s \)

\[
A_{\text{eff}} = A_f + A_s
\]

and

\[
A_f = (WS + R) H\cot \phi + \frac{2 LWWS}{R} + LW
\]

\[
A_s = (WS + R) S
\]

where

- \( WS \) = aircraft wingspan
- \( R \) = length of the diagonal of the facility \((L^2 + W^2)^{0.5}\)
- \( H \) = facility height (35 ft for the CVDF)
- \( \cot \phi \) = mean of the cotangent of the aircraft impact angle
- \( L \) = facility length (180 ft for the CVDF)
- \( W \) = facility width (110 ft for the CVDF)
- \( S \) = aircraft skid distance (mean value)

The CVDF dimensions used in the calculation include the helium tanks outside the facility but not the administration wing. The values of \( WS \), \( \cot \phi \), and \( S \) are given in Tables 16, 17, and 18 of DOE-STD-3014-96 for the categories of aircraft. For the military aviation categories, different values for the mean of \( \cot \phi \) and the mean skid distance are given for takeoff and landing. DOE-STD-3014-96 recommends using the takeoff values for the calculations involving overflight operations. Table B1-3 presents the calculated effective areas for the CVDF for all the classes of aircraft.

Multiplying the \( NPf(x, y) \) factors for both the nearby airport and the overflight operations by the effective impact areas gives the annual frequency of impact into the facility for each class of aircraft. These values are given in Table B1-4.

</table>
The major contributor to the frequency of aircraft impact into the CVDF is general aviation aircraft during in-flight operations. The overall frequency of aircraft impact from all sources is \(4.6 \times 10^{-4} \text{ /yr}\). \(\text{DOE-STD-3014-96}\) specifies that if the total impact frequency, calculated according to the method given in the standard, is less than \(10^{-4} \text{ /yr}\), the safety risk is below the level of concern. Therefore, it is not necessary to further calculate the probability that the impact will lead to a release from the facility or the consequences of such a release.

For rotary wing aircraft, see Section 1.6.1 of the SNF Project FSAR.

Medical evacuation helicopters' closest approach to the CVDF will be a landing pad at the 100 Area fire station, which is about 2.1 mi from the CVDF.

**B1.6.2 Other Transportation Accidents**

A discussion of the guidance for evaluating transportation accidents is provided in Section 1.6.2 of the SNF Project FSAR.

Figure B1-12 shows a rail spur that passes by the CVDF. This spur has not been used recently and will not be used in support of SNF Project activities. The switch that would route trains on the spur is normally locked in the position that would route trains away from the CVDF (see K Basins FSAR HNF-SD-WM-SAR-062).

Accidents that might occur on State Highway 240, such as explosions or toxic chemical releases, are judged to present a negligible risk to the CVDF because of the distance between the facility and the highway. At its closest approach, the distance is about 6 mi. NRC Regulatory Guide 1.78, *Assumptions for Evaluating the Habitability of a Nuclear Power Plant Control Room During a Postulated Hazardous Chemical Release*, provides useful guidance on evaluating chemicals stored or situated at distances greater than 5 mi from the facility. It states that they need not be considered because if a release occurs at such a distance, atmospheric dispersion will dilute and disperse the incoming plume to such a degree that there should be sufficient time for the operators to take appropriate action. In addition, the probability of the plume remaining within a given sector for a long time is quite small.

NRC Regulatory Guide 1.78 also provides useful guidance for the evaluation of potential accidents involving hazardous chemicals that might be shipped past the CVDF on Route 4 North and the Hanford Site railroad. NRC Regulatory Guide 1.78 does not require control room habitability analysis for shipments less frequent than 10/yr for truck traffic, 30/yr for rail traffic, or 50/yr for barge traffic. Neither the truck nor rail guidelines are exceeded for shipments of a quantity that could present a risk to the CVDF. Section B3.3 addresses this hazard from the perspective of safety of CVDF workers and capability to maintain the facility in a safe state. Barge shipment on the Columbia River does not routinely occur above the Port of Benton barge facility as discussed in Section 1.3.1 of the SNF Project FSAR.
B1 7 NEARBY FACILITIES

Accidents in certain facilities in the 100 Areas have the potential to impact the CVDF and its operations, as discussed in Section B1 7 1 Conversely, certain nearby facilities can potentially be affected by accidents in the CVDF, as discussed in Section B1 7 2

Threats to the CVDF from nearby facilities that are not known at this time will be evaluated when identified This also applies to those activities that have been identified but that may change significantly in terms of a potential increased risk to the facility These will be evaluated when identified by the Unreviewed Safety Question process

B1 7 1 Potential Effects from Nearby Facilities

Potential hazards to the CVDF from onsite or offsite hazardous operations or facilities are examined under three general classifications

1. Nonreactor nuclear and nonnuclear industrial facilities within 5 mi of the CVDF
2. Nuclear reactors within a 50-mi radius of the CVDF
3. Military activities

If the CVDF habitability is challenged by an event at a nearby facility, the appropriate actions (i.e., notifications, take-cover, emergency shutdown, evacuation) will be defined in the CVDF emergency response plan and emergency response procedures See Section B15 4 6 and Section 15 4 6 of the SNF Project FSAR for additional information on protective actions

B1 7 1 1 Hazards to the Cold Vacuum Drying Facility from Nonreactor Nuclear Facilities

B1 7 1 1 1 K Basins The greatest risk for release of radionuclides in the 100 Areas exists with the K Basins The basins are in the 105-KE and 105-KW reactor buildings The storage basins were modified and reactivated to provide interim storage for N Reactor fuel Details on these modifications are provided in the K Basins FSAR, HNF-SD-WM-SAR-062

The KW Reactor was shut down in February 1970 and the KE Reactor one year later, in February 1971 The stored fuel, except for a few loose pieces, was shipped to the 200 East Area for processing The storage basins were then idle but were kept filled with water The area water system was shut down, except for a small portion periodically activated to provide a reservoir of water for sanitary and fire protection systems, process water for other activities, and makeup water for the fuel storage basins

N Reactor spent fuel currently stored in the K Basins was destined for chemical processing in the Plutonium-Uranium Extraction (PUREX) Facility However, in December 1992, DOE directed that the PUREX Facility be shut down and deactivated because it was no longer needed to support the nation's weapons-grade plutonium production
In addition to the storage of N Reactor fuel, a small amount of single pass reactor (SPR) fuel is also stored in the K Basins. The KW Basin has 98 kg, 87 pieces, of unidentified initial $^{235}\text{U}$ enrichment SPR SNF of 1.25 wt% $^{235}\text{U}$ or less encapsulated in canisters. The KE Basin has 396 kg, 138 pieces, of less than or equal to 0.95 wt% $^{235}\text{U}$ fuel stored in 3 canisters and 2 open containers (see K Basins FSAR, HNF-SD-WM-SAR-062). The KW Basin received approximately 3.5 metric tons of uranium of SPR fuel from cleanout of the PUREX Facility in 1996.

The K Basins FSAR covers the handling (including load-in and load-out), encapsulation, storage of N Reactor fuel, and storage of small amounts of SPR fuel in the modified fuel storage basins. During normal operation, there are no releases of significant quantities of radioactive materials to the environment. Contaminated or potentially contaminated building service floor drains within the basins' boundaries have been intercepted and routed to a liquid effluent sump for return to the basins. Unused or unnecessary drains have been plugged and sealed with concrete. An epoxy sealant has been applied to the floor and walls of the KW Basin to further limit leakage. An epoxy sealant was applied to the discharge chute area of the KE Basin after leak repair in 1983. The existing underbasin leakage collection systems composed of an asphalt membrane and a pipeline to a dispersion tile field have been intercepted outside the facility. If leakage occurred contaminated effluents would be collected, routed to a sump and pumped back to the facility or to a radioactive waste holding tank. Leakage from the discharge chute area of the basins is not intercepted by the underbasin leakage collection system. Basin water is passed through an ion exchange medium to remove fission products.

Design basis accidents at the K Basins are discussed in Section 3.4.2 of the K Basins FSAR. Several credible accidents at the K Basins have been determined such as the dropping of heavy loads in the basin, drop of a cask–MCO during cask removal, and drops impacting basin drain lines.

The unmitigated dose from these accidents exceeds both guidelines and limits. There are no mitigated dose consequences because safety-class design features and administrative controls prevent basin leakage from occurring.

Another DBA includes ignition of a fuel element in an MCO basket which exceeds the evaluation guidelines for the onsite receptor at 100 m for an unmitigated dose. Design of the MCO basket stiffback grapple precludes raising the basket above the basin water level and prevents this accident from occurring.

As described in HNF-SD-SNF-SAD-002, the Integrated Water Treatment System (IWTS) filters water from the fuel retrieval system (FRS) and maintains basin water quality for dose minimization and water clarity. The IWTS supplies treated water for fuel removal processes and other uses in the basin.
K Basin DBAs involving the IWTS include (1) fire and explosion hazards and (2) spray releases. Preliminary results indicate that the onsite (100 m, east) unmitigated dose is exceeded. This event has an estimated extremely unlikely frequency of occurrence and potential dose consequences are orders of magnitude lower when credit is taken for the safety-significant designation of the annular filter vessel radiation monitoring system used to mitigate the filter backwash accident scenario.

Preliminary results from a spray release initiated by a rupture in an IWTS pressurized process line indicate the onsite (100 m, east) unmitigated release is also exceeded. This event is considered an unlikely operational accident. Actions taken for mitigating the spray release consequences during filter vessel backwash were evaluated and result in a significantly lower dose.

The radiological dose consequences for the unmitigated hydrogen deflagration are less than the evaluation guidelines. Safety-significant equipment reduces dose consequences by several magnitudes. Mitigated dose consequences for the IWTS spray release are less than the evaluation guidelines.

Additional K Basin DBAs are discussed in Section 3.4.2 of the K Basins FSAR. Mitigated dose consequences of all K Basin DBAs are less than the evaluation guidelines. If CVDF habitability is challenged by K Basin accidents, actions (e.g., notifications, take-cover, emergency shutdown, evacuation) will be performed in accordance with the CVDF emergency plan and emergency response procedures. Facility requirements for operator actions to reach a safe and stable state and permit evacuation are described in Section B4.3.1.4.

**B1 7112 N Reactor** The N Reactor was a 4,000 MW thermal, graphite-moderated, pressurized, light-water-cooled, dual-purpose reactor capable of producing plutonium and, as a by-product, provided steam for the Energy Northwest (formerly the Washington Public Power Supply System) Hanford Generating Project (HGP). The reactor operated from 1963 through 1987. The N Basin received SNF from the reactor and was equipped with the capability to inspect, store and prepare the SNF for shipping. The reactor block was unloaded of fuel and all remaining spent fuel was removed from the N Basin in 1989. A cease preservation directive was received from DOE in 1991.

The N Reactor is currently being maintained in a surveillance and maintenance mode referred to as the "quiescent state." Deactivation of N Reactor and associated facilities, involving removal and disposal of radioactive and hazardous materials has been completed.

Risks at the N Reactor were segmented as to those associated with the N Basin and those associated with the N Reactor complex. The nature of the hazards (quantities, form, and location), their vulnerabilities, and the controls appropriate to maintain the N Basin hazards in an acceptable condition are addressed in BHI-00866, *N Basin Deactivation Project Hazardous Baseline*. This report identifies no N Basin hazards vulnerabilities that require reliance on either...
active mitigative or protective measures adequate facility structural integrity exists to safely control hazards. The report identifies no risks that could impact K Basins or CVDF operation.

Intrusive activities taking place during N Basin deactivation involved the removal and disposition of radioactively contaminated and activated material, basin sludge and basin water. Removal of high-exposure hardware and activated fuel fragments from the basin has been completed. Sludge characterization and removal is nearly complete and removal of basin water has been completed. Removal of basin sludge is currently scheduled to be completed before the SNF movement to the CVDF begins. If the status of the N Reactor changes, potential impacts to the CVDF will be re-evaluated.

**B1 7 1 1 3 Single-Pass Reactors** Eight single-pass water-cooled graphite-moderated reactors were used for plutonium production B, C, D, DR, F, KE, KW and H. The KE and KW Reactors were similar to the other SPRs but had larger reactor blocks in terms of physical size and the number of process tubes and control rods. Operation of the SPRs began with the startup of B Reactor in 1944 and ended with the shutdown of KE in 1971. The risk of these reactors to workers and the public is addressed in WHC-EP-0619 *Risk Management Study for the Retired Hanford Site Facilities Volume 2 Risk Evaluation Work Procedure for the Retired Hanford Site Facilities*. While this report concludes that significant risk and risk management problems exist with these facilities, the risks are associated with worker safety primarily related to the potential for falls and electrical shock. This study considered the radiological hazards associated with the significant amount of $^{60}$Co and $^{14}$C contained in the defueled reactor blocks and associated equipment. It did not give specific attention to the radionuclide inventory in the soils resulting from the following operations:

- Disposal of solid waste
- Disposal of liquid waste
- Leakage and overflow from cooling water retention basin
- Use of cribs and trenches to divert reactor coolant contaminated by fuel failures

The most significant release mechanisms from these soil sources is desorption of the immobile contaminants from the aquifer matrix and subsequent infiltration from the contaminated soils into the underlying groundwater. This groundwater eventually discharges into the Columbia River where it can contaminate sediments and has the potential to cause adverse impacts on local biota with possible food-chain effects on humans offsite (DOE/RL-90-33 and DOE/RL-91-46). More direct access to this groundwater in the vicinity of the reactors will not exist during CVDF operation as institutional controls will remain in place during this relatively short period. Most, if not essentially all of the contamination is now buried beneath the ground surface. These sites are permanently marked as radiation zones with concrete markers and warning signs, and the material is isolated from accessible areas. As such, the greatest risk of direct human exposure is to onsite workers who are involved in collecting environmental samples and conducting remedial activities (DOE/RL-90-33). Neither of these exposure paths represents a risk to SNF Project operation.
The DOE record of decision for disposal of these reactor facilities states that the preferred alternative is to place the reactors in safe storage for up to 75 years and then move the reactor blocks, in one piece, to a burial facility in the 200 West Area. The safe storage activities for the C Reactor were started in 1996 and completed in 1999. The reactor building was removed and the remaining reactor block cocooned (made inaccessible). If the status of the SPR changes (i.e., active decontamination and decommissioning), potential impacts to the CVDF will be re-evaluated.

B1 7 1 2 Hazards to the 100 K Area Facilities from Nonnuclear Hanford Site Facilities

B1 7 1 2 1 Water Treatment Facilities Sodium hypochlorite has replaced the chlorine water treatment at the 183-KE Water Treatment Facility and the 100 N Water Treatment Plant. The new water treatment process no longer presents a potential hazard to 100 K Area facilities operators.

B1 7 1 2 2 Hanford Generating Project The HGP, located adjacent to the N Reactor, was operated by Energy Northwest. The HGP consisted of two 430 Mwe low-pressure turbine generators that received steam from the N Reactor. It also included associated equipment normally found in a steam power station. The HGP condensers and auxiliary cooling systems were supplied by raw water pumped from the Columbia River and discharged back to the river. Operation of the HGP ceased with the shutdown of the N Reactor. Energy Northwest has decided not to repower the HGP from another source. The HGP contains no hazardous materials that represent a risk to SNF Project operation. Eight potential discrete locations of contaminated soils were associated with HGP operation (DOE/RL-91-46). For the same reasons provided above with regard to similar contaminated soils at the SPR sites, these potential contaminated soil locations do not represent a risk to SNF Project operation.

B1 7 1 2 3 200 Area Facilities A number of nonnuclear industrial facilities operating in the 200 Areas pose the potential for accidental fires, explosions, or releases of toxic fumes. These facilities include the Essential Materials Warehouse (Building 275-EA), oil and paint storage buildings, fabrication shops, gas cylinder storage buildings, the spare parts and electrical warehouse, B Plant storage buildings, maintenance facilities, gasoline service stations, and the powerhouse complexes in each area (284-E and 284-W). The most significant inventory of hazardous material in the 200 Areas exists in Building 275-EA. The worst case chemical release postulated involves evaporation of 2,450 kg of 1,1,1-trichloroethane. With the 8 m separation between this warehouse and the 100 K Area facilities, the inventory represents no threat to the CVDF or the K Basins. Additional hazards information from 200 Area facilities is provided in Section A1 7 of the Canister Storage Building FSAR, Annex A.

B1 7 1 3 Hazards to the Cold Vacuum Drying Facility from Nuclear Reactors Three recently shut down reactors, the N Reactor, Fast Flux Test Facility, and the Critical Mass Laboratories, do not pose a threat to the 100 K Area facilities. The N Reactor is undergoing decontamination and decommissioning, the Fast Flux Test Facility is in standby mode and may...
operate again in the future, and the Critical Mass Laboratories in the 200 East Area north of the PUREX Facility are currently being used as tank farm office areas.

The N Reactor was a 4 000 MW dual-purpose pressure tube, light-water cooled, graphite-moderated reactor (UNI-M-90). It is located in the 100 N Area, 2 4 mi from the 100 K Area site. The N Reactor began operating in 1963 producing plutonium for the defense program and steam for electrical power generation. The reactor was shut down in 1987 for safety improvements and then subsequently defueled and placed in cold standby in 1988. It is currently being decontaminated and decommissioned. Current plans are to remove the reactor building structures for the production reactors down to the reactor block and then cocoon the reactor block for 75-year safe storage.

The Fast Flux Test Facility is a 400 MW sodium-cooled mixed-oxide-fueled, fast reactor used for testing breeder reactor fuels, materials, and components. The Fast Flux Test Facility is currently in standby status, with the fuel removed from the core. Sodium is kept circulating in the loops at 400 °F until a decision is made to either restart the reactor for future missions or deactivate and decommission it. The facility is located in the 400 Area, 18 mi from the 100 K Area site.

The only operating nuclear reactor on the Hanford Site is Washington Nuclear Plant 2 (WNP-2) operated by Energy Northwest. The location of the Energy Northwest facilities is shown in Figure B1-1. WNP-2 is an operating commercial nuclear power plant using a boiling-water reactor steam supply system. The design power level was increased to 3,486 MW in 1995 (Docket No 50-397). The reactor was designed by the General Electric Company and is designated as a BWR/5 with a Mark II containment.

According to the requirements of Title 10, Code of Federal Regulations, Part 100 Reactor Site Criteria (10 CFR 100), the following are the maximum allowable doses for WNP-2:

<table>
<thead>
<tr>
<th>Location</th>
<th>Duration</th>
<th>Whole body dose</th>
<th>Thyroid</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exclusion area boundary</td>
<td>2 hours</td>
<td>250 mSv (25 rem)</td>
<td>3 000 mSv (300 rem)</td>
</tr>
<tr>
<td>Low population zone</td>
<td>30 days</td>
<td>250 mSv (25 rem)</td>
<td>3 000 mSv (300 rem)</td>
</tr>
</tbody>
</table>

The exclusion area boundary for WNP-2 is 1.2 mi and the low population zone distance is 3 mi. The K Basins and CVDF are located approximately 17 mi from WNP-2. Using the atmospheric diffusion guidance provided in NRC Regulatory Guide 1 3 Assumptions Used for Evaluating the Potential Radiological Consequences of a Loss of Coolant Accident for Boiling Water Reactors to estimate the dose reduction as a function of distance, it was determined that the 2-hour and 30-day doses at the 100 K Area would be reduced by a factor of 30. Review of the site-specific meteorology provided in the WNP-2 FSAR (Docket No 50-397) shows there...
would be no significant reduction for the change in wind direction. The factor of 30 reduction for distance would result in a whole body dose of 8.3 mSv (0.83 rem) and a thyroid dose of 100 mSv (10 rem).

The expected dose that would be received at the 100 K Area site, if a loss of coolant accident occurs, would be significantly less. NRC Regulatory Guide 1.3 requires an assumption that 25% of the radioactive iodine and all of the noble gases are released to the containment. In fact, the emergency core cooling system would prevent most of these releases, as little fuel damage would occur as a result of the loss of coolant accident.

Energy Northwest plans to add an independent spent fuel storage installation on its leased property. The independent spent fuel storage installation would be licensed based on the requirements of 10 CFR 72. According to 10 CFR 72.106, an individual located at the independent spent fuel storage installation's controlled area boundary shall not receive a dose greater than 50 mSv (5 rem). At the 100 K Area site, this would result in a dose not exceeding 1.7 mSv (0.17 rem).

B1 7.1.4 Hazards to the 100 K Area Facilities from Industrial Facilities off the Hanford Site

There are no oil or gas pipelines in the vicinity of the K Basins and CVDF. The nearest major natural gas pipeline to the CVDF site is about 34 mi away. A 20-in gas transmission line of the Northwest Pipeline Corporation is located east and essentially parallel to U.S. Highway 395 between Pasco and Ritzville, Washington. A second pipeline system consisting of parallel 36-in and 42-in lines, owned by Pacific Gas Transmission Company, passes through Wallula, approximately 65 mi from the site (Hosler 1996). These distances eliminate any potential hazard to plant operations from a natural gas fire or explosion due to industrial pipelines.

The nearest petroleum product storage tanks are located 47 mi from the site. These are 23-million-gallon capacity tanks at the Chevron Pipeline Company, and 21-million-gallon capacity tanks at the Tidewater Barge Lines. There are no plans to use a third petroleum storage facility at the Port of Pasco (Hosler 1996).

No other nonnuclear industrial facilities or operations have been identified that may impact 100 K Area facilities operations.

B1 7.1.5 Hazards to the 100 K Area Facilities from Military Facilities

The Yakima Training Center is a subinstallation under the command of Fort Lewis (Tacoma, Washington). Further information is given in the Final Environmental Impact Statement — Ft. Lewis Military Installation (DOA 1979). The southeastern boundary of the Yakima Training Center is located about 12 mi from the 100 K Area site (Figure B1-13). The Yakima Training Center is used for military maneuvers and weapons training and is the only significant military activity in the vicinity of the Hanford Site.

The only weapon currently in use at the Yakima Training Center known to present a potential hazard to the Hanford Site is the Multiple Launch Rocket System (MLRS). With a
range of approximately 16 mi; the MLRS could potentially impact the 100 K Area site. However, the MLRS is only fired from the perimeter of the Yakima Training Center into a centrally located impact zone. The safety fan for the MLRS is shown in Figure B1-13. The MLRS is fired away from the Hanford Site and is only fired with dummy warheads. Given this information, additional safety features and the administrative controls in place at the Yakima Training Center, a weapons accident having an impact on the Hanford Site is very improbable.

A more probable hazard to Hanford Site facilities is a scenario in which a fire starts within the Yakima Training Center boundary and spreads to the Hanford Site. Exploding artillery shells, sparks from tracked vehicles or other machines, and careless smoking by troops might start brush fires that, under adverse meteorological conditions, could spread rapidly beyond the Yakima Training Center boundaries. Range fires were considered with other potential hazards in the hazards analysis and Chapter B3-0 and were not found to adversely impact the CVDF.

B1 7.2 Potential Effects of the Cold Vacuum Drying Facility on Nearby Facilities

Potential CVDF accidents are discussed in Section B3-4.2. CVDF hazard assessments as discussed in Section B15-4.2 will use these potential accidents to help develop the CVDF emergency response plan and procedures, as discussed in Section 15-4 of the SNF Project FSAR and Section B15-4.

The CVDF hazard assessments for emergency planning for the CVDF will characterize the potential consequences to workers, the public, and the environment for each postulated accident. The hazard assessments will also determine the emergency planning zone as well as the emergency class protective actions and the observable indications and criteria (emergency action levels) corresponding to the range of potential accidents.

The hazard assessments will also include information to determine potential impacts to nearby facilities. This information will be made available to nearby facilities for determination of appropriate actions to be included in their emergency response plans and procedures. Information contained in CVDF emergency response plans and procedures will also include notifications evacuation potential operations impacts radiation threats to workers and other information relevant to nearby facilities. Prompt and accurate emergency notifications will be performed in accordance with DOE O 1511 Comprehensive Emergency Management System DOE O 232 1A, Occurrence Reporting and Processing of Operations Information applicable Federal, state or local requirements and special agreements with offsite agencies or tribal governments to mitigate the consequences and to protect the health and safety of workers, the public, and the environment.
B1 8 VALIDITY OF EXISTING ENVIRONMENTAL ANALYSES

No significant discrepancies have been identified between the site characteristic assumptions made in this chapter and those made in the SNF Project Environmental Impact Statement (DOE/EIS-0245F)

B2 0 FACILITY DESCRIPTION

B2 1 INTRODUCTION

The Spent Nuclear Fuel (SNF) Project Cold Vacuum Drying Facility (CVDF) mission is to remove free water from metallic uranium SNF and to prepare the SNF for storage in an inert atmosphere (helium). The SNF will be packaged into water-filled multi-cylinder overpacks (MCOs) and removed from the 100 K Area K East and K West fuel storage basins at the U.S. Department of Energy (DOE) Hanford Site in southeastern Washington State. Removal of free water is necessary to halt water-induced corrosion of exposed uranium surfaces (which results in the generation of hydrogen gas and pressurization of the MCO) and to allow the MCOs and their SNF payloads to be safely transported to the Hanford Site 200 East Area and stored within the SNF Project Canister Storage Building (CSB).

The CVDF is located within a few hundred yards of the 100 K Area fuel storage basins just southwest of the 165KW Power Control Building and the 105KW Reactor Building. The CVDF site is in close proximity to all of the required utilities and is within the 100 K Area inner security boundary. The site area required for the facility and vehicle circulation is approximately 20 acres. Access is provided by the main entrance to the 100 K Area using existing roadways.

Removal of free water from the MCOs reduces the potential for fuel-water corrosion reactions that could lead to MCO overpressurization at the CSB. The cold vacuum drying process involves the draining of bulk water from the MCO and subsequent vacuum drying to remove remaining bulk water and sufficient portions of the hydration water. The MCO is evacuated and backfilled with an inert gas (helium). The MCO is then sealed and leak tested before transport to the CSB within a sealed transportation cask.

The CVDF provides the required process systems, supporting equipment, and facilities needed to support the CVDF mission. The CVDF also contains equipment to prepare process water removed from the MCO for transport to the K West Basin and to package solid waste generated by the cold vacuum drying process for disposal. Four process bays contain process equipment, with an unequipped fifth bay.

The MCO remains within a shipping cask on a trailer during all CVDF activities. The trailer design includes a platform that serves as a work station for CVDF operators and provides direct access to cask–MCO process interface connections on the top of the MCO. Access to the lower port of the cask is available through a hole in the lower stabilizer of the trailer.

This chapter provides facility and operating descriptions for the CVDF to support assumptions used in the hazard and accident analyses. These descriptions focus on all major facility features necessary to understand the hazard and accident analyses, not just safety structures, systems, and components (SSCs). The level of detail used in this chapter is based on the significance of the preventive and mitigative features identified and the degree of complexity.
of the systems described. The descriptions provide an understanding of the facility and processes in sufficient detail that a general understanding of the facility can be achieved without extensive consultation of the references cited.

Chapter B30 describes the hazards and accident analyses and safety classifications of the SSCs for the CVDF. Chapter B40 describes the safety-class and safety-significant SSCs in greater detail and also identifies safety controls (the technical safety requirements).

B2 2 REQUIREMENTS

This section lists the requirements that establish the safety basis of the CVDF. The intent is to provide only the requirements that are specific for this chapter and pertinent to the safety basis. The basic process safety and quality assurance requirements, criteria, and data for the CVDF systems and facility are provided in HNF-SD-SNF-DRD-002, *Spent Nuclear Fuel Project Cold Vacuum Drying Facility Design Requirements*. HNF-SD-SNF-DRD-002 also establishes the operational readiness documentation required for testing, operation, maintenance, decontamination, and decommissioning. Specific codes, standards, and requirements applicable to the CVDF are defined in HNF-SD-SNF-RD-001, *Spent Nuclear Fuel Project Standards/Requirements Identification Document*. The specific codes, standards, and requirements applicable to the MCO are identified in HNF-SD-SNF-SARR-005, *Multi-Canister Overpack Topical Report*. Likewise, the specific codes, standards, and requirements applicable to the transport cask are identified in HNF-SD-TP-SARP-017, *Safety Analysis Report for Packaging Onsite Multi-Canister Overpack Cask*.

The design of the CVDF is governed by federal regulations, DOE directives (orders) and standards, Washington State regulations, Hanford Site standards, and various industry standards and guidelines. WHC-SD-SNF-SD-020, *K Basin Spent Nuclear Fuel Cold Vacuum Drying Facility Functions and Requirements* summarizes the requirements of the CVDF and identifies federal, state, and local regulations and laws that are applicable to the CVDF. HNF-SD-SNF-DRD-002 provides functional design and performance requirements for the CVDF.

The following requirements are applicable to the safety basis for the facility:

- **Title 10 Code of Federal Regulations Part 830, Nuclear Safety Management**. Section 830.120, "Quality Assurance Requirements" (10 CFR 830.120). This rule requires that a sufficient quality assurance program be in place.

- **Title 10 Code of Federal Regulations Part 835, "Occupational Radiation Protection"** (10 CFR 835). This rule provides requirements for radiation protection programs.

- DOE Order 5480 23, *Nuclear Safety Analysis Reports* This order provides nuclear safety analysis report content requirements.

- DOE Order 5480 24, *Nuclear Criticality Safety* This order requires that the CVDF design maintain criticality safety mandated spacing requirements during all design basis accidents. The design also incorporates applicable and appropriate results, requirements, and recommendations of HNF-2151, *Criticality Safety Evaluation Report for Multi-Canister Overpack Loading and Handling at the K Basins*.

- DOE Order 5480 28, *Natural Phenomena Hazards Mitigation* This order is used to define design requirements for seismic events and straight wind.

- DOE Order 6430 1A, *General Design Criteria* This order for nonreactor nuclear facilities presents the main reference standards and guides for facility and system design. Division 13, "Special Facilities," Section 1300, "General Requirements," provides overall general design requirements applicable to all SSCs. The contractor will maintain the design configuration, including compliance to DOE Order 6430 1A, throughout facility operations.

- DOE-STD-1020-94, *Natural Phenomena Hazards Design and Evaluation Criteria for Department of Energy Facilities* This standard provides the methodology for design of the CVDF for natural phenomena hazard events and is implemented via WHC-SD-SNF-DB-010, *Cold Vacuum Drying System Natural Phenomena Hazards*.

- DOE-STD-1021-93, *Natural Phenomena Hazards Performance Categorization Guidelines for Structures Systems and Components* This standard is used to define the specific performance category for SSCs.

- DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480 23 Nuclear Safety Analysis Reports* This standard is used to determine hazard categories for nuclear facilities.

In this regard, the standard provides more detailed information on the performance of accident analyses for hazard category 2 and 3 facilities. The standard also establishes additional requirements for the establishment of defense in depth and the identification of safety-significant SSCs.

In Letter 95-SFD-167, *Implementation of K Basins Spent Nuclear Fuel Project (SNFP) Regulatory Policy* (Sellers 1995), DOE established the requirement for new SNF Project facilities to achieve "nuclear safety equivalency" to comparable U.S. Nuclear Regulatory Commission (NRC)-licensed facilities. The SNF Project identified the NRC requirements that were needed in addition to existing and applicable DOE requirements to establish nuclear safety equivalency. These NRC requirements and the process used to identify them are documented in HNF-SD-SNF-DB-003 *Spent Nuclear Fuel Project Path Forward Additional NRC Requirements* and in WHC-SD-SNF-DB-010. An assessment of CVDF compliance with SNF Project NRC equivalency criteria is documented in Letter FDH-9950119 *Compliance with DOE 6430 1A and Nuclear Regulatory Commission Equivalency Requirements in Cold Vacuum Drying Project* (Williams 1999a). An update to the assessment is documented in Letter FDH-9953137A R3 *Contract Number DE-AC06-96RL13200 – U.S. Department of Energy Richland Operations Office Review Comments for DOE Order 6430 1A and U.S. Nuclear Regulatory Commission Equivalency Requirements for the Cold Vacuum Drying Facility* (Williams 1999b). Table B4-4 provides a summary of compliance with the additional NRC equivalency items.

**B2.3 FACILITY OVERVIEW**

This section includes a brief overview of the CVDF configuration and the basic processes performed therein. The CVDF provides a facility for draining the water from and drying the SNF-filled MCOs after they have been removed from the K Basins. Removal of free water using a cold vacuum drying process from the MCOs will prevent MCO overpressurization during the projected storage period at the CSB (HNF-SD-SNF-T1-040). The CVDF is designed to be a temporary facility. Removing the entire K Basins inventory of SNF is expected to take two to five years. The design life for the facility and equipment is a minimum of five years. This design life establishes the basis for procurement of equipment and necessary spares. With selective replacement of equipment, the operation of the facility can be extended as future needs dictate.

**B2.3.1 Facility Description**

The CVDF is designed to DOE Order 6430 1A. Furthermore, the process building is designated a nonreactor nuclear facility under Section 1300 "Special Facilities." The administrative building is a nonnuclear facility rated for office/business use in accordance with the *Uniform Building Code* (UBC) (ICBO 1994). The building code requirements are met as defined in the UBC (ICBO 1994) for a Group H-7 occupancy for the process bay and support.
Annex B — Cold Vacuum Drying Facility

areas and a Group B occupancy for the administrative building. See Figure B2-1 for the layout of the four main areas of the CVDF and Figure B2-2 for a side view of the facility.

B2 3 2 Cold Vacuum Drying Facility Hazards

A hazard category classification of the CVDF is presented in Chapter B3 with the assessment that the CVDF is a hazard category 2 nuclear facility. This classification was determined in accordance with DOE-STD-1027-92.

The CVDF hazard analysis is documented in HNF-SD-SNF-HIE-004, Cold Vacuum Drying Facility Hazard Analysis Report. The main inventory of hazardous material in the CVDF is the radiological content of the MCOs. The CVDF does not house chemical process systems.

Other hazardous materials identified in the MCO include pyrophoric metals and hydrides, oxidizers, and hydrogen. In addition, hazardous materials in the process bays and surrounding areas include diesel fuel and other combustible materials. The specific characteristics of those hazards are identified in detail in HNF-SD-SNF-HIE-004. The CVDF fire hazard analysis (SNF-4268) concluded that no release of radioactive material to the environment from the cask and MCO would result from any of the CVDF fire scenarios. As described in Section B3.4.2.3.5, a release to the environment from a flammable explosion in a high-efficiency particulate air (HEPA) filter is maintained below guidelines by a technical safety requirement based on the amount of radionuclides allowed to accumulate on the filter before changeout.

When fully loaded, each MCO houses five (Mark IV fuel ≤ 0.95 wt% \(^{235}\)U enrichment) or six (Mark IA fuel >0.95 wt% \(^{235}\)U enrichment) baskets, each basket containing prescribed amounts of SNF and incidental fuel corrosion products that have been retrieved from the K Basins. See Figure B2-3 for a sketch of a typical MCO and cask package. The following paragraphs contain physical descriptions of the fuel currently in the K Basins, give a fuel burnup summary, and provide details of the chemical and radionuclide inventories of SNF.

HNF-SD-SNF-SARR-005 identifies the restrictions and limitations on fuel contents of the MCOs. A summary discussion of MCO contents is provided in Section B2.5.2.

N Reactor fuel to be processed at the CVDF is Mark IA, Mark IB, Mark IC, Mark IV or Mark IVB fuel. There is, however, a small amount of single-pass reactor fuel currently in the K Basins. The single-pass reactor fuel drying is not covered in these analyses. An addendum to the SNF Project Final Safety Analysis Report (FSAR) will be prepared to address processing of this type of fuel prior to its being loaded into an MCO, processed at the CVDF, and stored in the CSB.

N Reactor fuel assemblies consist of two concentric tubes made of uranium metal coextruded into Zircaloy-2 cladding. The several basic types of fuel assemblies are differentiated by their uranium enrichment. Mark IV fuel assemblies have a preirradiation enrichment of...
0 947 wt% $^{235}\text{U}$ in both tubes and an average uranium weight of 50 lb. The Mark IV assemblies have an outside diameter of 2.42 in and lengths of 17.4, 23.2, 24.6, or 26.1 in. Mark IA fuel assemblies have a preirradiation enrichment of 1.25 wt% $^{235}\text{U}$ in the outer element and 0.947 wt% $^{235}\text{U}$ in the inner element. The Mark IA assemblies have an average uranium weight of 35.9 lb. Mark IA fuel assemblies have an outside diameter of 2.40 in and lengths of 14.9, 19.6, 20.9, or 26.1 in. Mark IB and Mark IVB fuel assemblies have preirradiation enrichments of 0.71 wt% $^{235}\text{U}$ and Mark IC fuel assemblies have a preirradiation enrichment of 0.95 wt% $^{235}\text{U}$. There are no special handling requirements for these fuel types. The Mark IB and Mark IC fuel assemblies are placed in Mark IV baskets. The Mark IVB fuel has the same dimensions and weights as the 26.1-in-long Mark IV fuel. A diagram of a typical Mark IV fuel assembly is provided in Figure B2-4.

Exposure level or fuel burnup and time since discharge determine the radionuclide content of a fuel assembly or group of assemblies. The K Basins inventory of N Reactor fuel is composed of elements that experienced a range of exposure levels. The exposure levels ranged from unburned fuel (0 MWd) to approximately 6,000 MWd per metric ton of uranium. This level is related to the weight fraction of the isotope $^{240}\text{Pu}$ that exists within the total quantity of plutonium in a particular fuel element. The $^{240}\text{Pu}$ content is commonly used to indicate fuel burnup and ranges from approximately 0 wt% $^{240}\text{Pu}$ up to 16.72 wt% $^{240}\text{Pu}$ for the N Reactor fuel in inventory.

Accountability records have been used as the basis for estimating the radionuclide content of N Reactor fuel. The accountability record run data include discharge date, fuel type, $^{240}\text{Pu}$ content, and other information for 497 groups of fuel elements (the groups are also known as keys). Each group or key includes elements of the same type with the same burnup, that were discharged from the reactor at the same time. The mass of uranium associated with each group varies from 7 kg to 67.4 metric tons of uranium. The accountability database that forms the inventory basis is shown in Appendix A of HNF-SD-SNF-TI-009. The Basin Material Design Basis Feed Description for Spent Nuclear Fuel Project Facilities.

The chemical content of the fuel on a preirradiation basis is derived by applying the reported preirradiation concentration range to the total uranium (4,630,000 lb), zirconium (320,000 lb), and braze fill (6,600 lb) in N Reactor fuel. In the post-irradiation fuel, a fraction of the $^{235}\text{U}$ has been fissioned, generating fission products. A small quantity of the $^{238}\text{U}$ has been converted to plutonium, and other elements in the fuel, cladding, and fuel element hardware have been activated by exposure to the neutron bombardment.

B2.3.3 Cold Vacuum Drying Facility Operations Summary

CVDF operations start with the receipt of the cask-MCO trailer at a process bay. The shipping documentation package is verified. Operators raise the process bay door to allow backing the tractor-trailer into a predetermined position in the bay. The tractor is driven out of
the process bay and the bay door is closed. Bay confinement is then reestablished. The security system is activated for the bay.

During transport to the CVDF, the MCO is vented to the cask headspace. Internal cask pressure is expected to increase as a result of hydrogen gas generation, and temperature is expected to increase as a result of radioactive decay heat, solar heating, and water-uranium corrosion reactions. Cask venting is performed by means of special venting hardware and flex lines connected to a cask lid port and the CVDF process bay local exhaust heating, ventilation, and air conditioning (HVAC) and process vent system. After venting, the cask lid is removed by a process bay overhead crane, the process hood seal ring assembly is installed onto the cask, and the MCO is prepared for process operations. See Section B2.5.1 for an overview of the cold vacuum drying process.

MCO processing is performed per operating procedures at a controlled water temperature in the cask-MCO annulus. Normal processing includes bulk water removal, helium purging, evacuation with and without helium purge, initial pressure rebound testing, extended operation under vacuum at the base pressure of the system, final pressure rebound testing, integrated leak testing of the MCO mechanical seals, and backfilling with helium. Normal processing is conducted between 40 °C and 50 °C. There are minimal manual operator actions in the process sequences. Field operator actions such as connecting the MCO process connectors, the deionization/helium rinse, blowdown after draining, and tempered water connections are required. Control room operators are responsible for acknowledging alarms and directing the monitoring and control system (MCS) and safety-class instrumentation and control (SCIC) system when to initiate a processing sequence. Valve state changes, water temperature control, and other process parameter changes are performed by the MCS.

There are two normal operator interfaces, the MCS computers and the SCIC system mode switch, both located in the control room (room 107). The SCIC system mode switch defines the MCO process mode and directly feeds this information into the MCS. While most sequences are held for operator permissions, some sequences occur based solely on SCIC system mode (e.g., keeping hydrogen concentration low in the MCO and process water conditioning [PWC] system receiving tanks).

Following the cold vacuum drying process and MCO testing, the cask-MCO trailer is prepared for shipment to the CSB. This operation is as follows:

- The cask-MCO is brought to approximately room temperature
- The MCO is pressurized with helium, sealed, and leak tested
- The cask annulus is drained and dried and the cask lid is reinstalled
- The cask-MCO trailer is reconnected to the tractor and released for shipment to the CSB
The CVDF can process up to four MCOs at any one time (one for each active process bay). However, the PWC system is designed to service one MCO at a time, so priority determination and scheduling are important.

### B2 3 4 Cold Vacuum Drying Facility Confinement

Confinement provides retention of radiological and chemical materials in specified areas. Confinement features in use at the CVDF can be divided into two categories: (1) process confinement for the SNF, and (2) ventilation confinement of gases in the CVDF.

#### B2 3 4 1 Spent Nuclear Fuel Confinement

During transportation to the CVDF, confinement for the SNF consists of (1) the MCO and (2) the transportation cask. At the CVDF, the tractor-trailer is decoupled, leaving the trailer with the loaded cask-MCO in one of the four processing bays. At this time, the cask lid is removed temporarily breaching SNF confinement for the water-filled MCO and a process hood is installed over the cask-MCO to reestablish secondary confinement via ventilation control.

#### B2 3 4 2 Cold Vacuum Drying Facility Confinement

Confinement in the CVDF is presented in two categories: primary and secondary.

##### B2 3 4 2 1 Primary Confinement

Primary confinement acts as a barrier separating the SNF material contained in the MCO and the process piping from the surrounding secondary confinement systems. The primary confinement of airborne and liquid effluents from the SNF is provided by the MCO (see Section B2 5 2 for a discussion of the design of the MCO and transportation cask) and isolation piping.

##### B2 3 4 2 2 Secondary Confinement

Secondary confinement controls movement of material released from the primary confinement system. During MCO processing, normal vent paths and exhausts are vented to secondary confinement. Some accident scenarios release contamination within the secondary confinement, which is captured and vented through a HEPA-filtered exhaust system. Secondary confinement consists of the process bay local exhaust HVAC and process vent system and the CVDF structure in conjunction with the process general supply/exhaust HVAC system. The process bay local exhaust HVAC and process vent system handles all potentially contaminated air flows from the process hood, process vents from the vacuum purge system (VPS) and tempered water (annulus) system cask venting the safety-class helium (SCHe) system and the VPS and PWC system piping beyond the isolation valves. During normal operations, the process general supply/exhaust HVAC system maintains a negative differential pressure within potentially contaminated areas of the CVDF (process bays, transfer corridor and associated process support rooms, the mechanical room, and the process water tank room). Differential pressure indicators are provided throughout the facility. This system also supplies conditioned air to and exhausts from the process support areas and the process water tank room. Each process bay has a HEPA-filtered recirculation system that is controlled individually to maintain temperature control and air quality with outside makeup air. The spare
process bay (bay 1) is not normally ventilated but has an installed connection to the process general supply/exhaust HVAC system

See Section B2 6 for a more detailed discussion of facility confinement and building HVAC

B2 3.5 Cold Vacuum Drying Facility Systems

Table B2-1 contains a list of CVDF systems. The system descriptions in this section are presented in the same order as they are given in the table. Table B2-1 identifies the Chapter B2 0 section that addresses the system, identifies the system number, and provides the system abbreviation.

B2 4 FACILITY STRUCTURE

The CVDF is approximately 230 ft in length, 80 ft in width, and 35 ft in height. The CVDF has the following four main areas:

- Process bay area
- Process support area
- Process water tank room
- Administrative building

The process bay area (60 ft wide by 150 ft long by 35 ft high) contains five process bays (one is a spare bay without services). The process support area (20 ft by 150 ft) includes a transfer corridor and adjacent rooms, along with a second-floor mechanical room, and is constructed as a two-story steel frame building with an exterior wall of metal siding. The process water tank room (20 ft by 40 ft) adjoins the north wall of process bay 1. It is constructed as a single-story, steel-frame building with 10-in.-thick exterior walls of precast concrete panels. The administrative building, adjacent to process bay 5, is a single-story, preengineered metal building with an exterior wall of insulated metal panels. All roof decks are metal. The CVDF exhaust stack (48 ft high and 30 in. in diameter) is located 17 ft from the west wall of the process support area.

Each process bay (excluding the spare bay) contains a second-level mezzanine. The process bay area design consists of a steel frame with attached concrete panels to facilitate decontamination and demolition.

The construction of the CVDF is in accordance with DOE Order 6430 1A, with egress requirements conforming to NFPA 101 Life Safety Code The process bay area is designated a nonreactor nuclear facility under DOE Order 6430 1A Section 1300 "Special Facilities " The administrative building is a nonnuclear facility rated for office and business use in accordance with the UBC (ICBO 1994) The building code requirements are met as defined in the UBC (ICBO 1994) for a Group H-7 occupancy for the process bay and process support areas and a Group B occupancy for the administrative building The exterior walls of the CVDF are prestressed concrete panels for the process bay area and process water tank room and insulated metal panels for the process support area and the administrative building

This section provides an overview of the facility and auxiliary structures, including construction details (e.g., basic floor plans, equipment layout, construction materials, controlling dimensions and dimensions significant to the hazard and accident analysis activity). This information supports an overall understanding of the facility structures and the general arrangement of the facility as it pertains to hazard and accident analyses. See Figure B2-5 for the CVDF first-floor layout, Figure B2-6 for the CVDF second-floor layout, Figure B2-7 for architectural exterior elevations, and Figure B2-8 for the process bay sections. The following subsections describe the process bay area (the process bays), the process support area (transfer corridor, mechanical equipment room), the process water tank room, and the administrative building (lunch/conference room, offices, control room, electrical and mechanical rooms, change rooms).

### B2 4.1 Process Bay Area

Each of the four active process bays (process bays 2 through 5) contained within the process bay area is designed to enclose a cask-MCO trailer without the tractor attached and to provide the operational space necessary to meet the functions of the cold vacuum drying process. Process bay area design provides radiological separation and shielding between process bays and ventilation confinement within each process bay. The spare process bay (bay 1) does not contain any process equipment and does not have a mezzanine. The bay does contain equipment and

connections for transferring processed water from the PWC system to a transport vehicle to return to the K Basins.

The process bay area design is a steel frame and prestressed concrete panel system that has a process bay width of approximately 30 ft and a nominal length of 60 ft. The height of the process bays is nominally 32 ft, which is dictated by the physical and functional requirements for all of the operations necessary. The exterior walls are 10-in-thick precast concrete panels. The interior walls are 8-in concrete panels up to a height of 23 ft. The panels are precast and prestressed, and the vertical joints are caulked. The remaining 9 to 12 ft above the interior precast concrete wall to the sloped roof is constructed of gypsum wallboard coped around the beams and sealed. The floor is sloped to a sump. An overhead telescoping metal door is provided for trailer entry into each process bay. Bay 1 has a roll-up door. A U-shaped mezzanine is provided in each process bay to support the HVAC system, to provide access to the process hood, and to provide support for activities at the top of the MCO. The mezzanine floor is constructed of steel plates. The roof is built-up membrane roof over rigid insulation adhered to a steel plate deck.

Each process bay includes an overhead bridge crane with a capacity of 2 tons. The crane is designed in accordance with the criteria included in CMAA 74, Specifications for Top Running and Under Running Single Girder Electric Overhead Traveling Cranes Utilizing Under Running Trolley Hoist. The bridge, trolley, and hoist are driven by electric motors and are capable of operation from the mezzanine level.

Access to the process bay area is via the process support area. Individual process bay access and egress control is through a vestibule with personnel doors to the transfer corridor and the process support rooms.

Each process bay provides ground floor space for the following:

- Enclosing a cask trailer without the tractor attached
- Personnel circulation and functional space around the cask trailer
- Process equipment skid including vacuum drying and tempered water equipment
- Access to the working level of the cask trailer
- Bridge crane control to remove the cask lid, install the process hood, and perform maintenance on equipment
- A supply cabinet and storage locker
- Electrical control panels
Access to the working level of the cask is accomplished using the mezzanine level, which has space for the following:

- Access to the working level of the cask trailer for process connections to the MCO
- HVAC equipment
- Process hood

## B2.4.2 Process Support Area

The process support area includes the transfer corridor and adjacent rooms on the first floor and the mechanical room on the second floor.

The two-story process support area is 28 ft high and 20 ft wide along the entire 150-ft length of the west side of the process bay area. Ventilation for both floors of the process support area is provided by the process general supply/exhaust HVAC system (see Section B2.6.2.5).

The process support area is built on a concrete foundation and is separated from the process bay area by concrete panel walls. The process support area structure is attached to the process bay area structure. The other interior walls in this area are gypsum wallboard on a metal frame construction. The exterior wall of the process support area is insulated metal siding. The second floor is 4-in-thick concrete on a metal deck supported by the structural steel frame. The standing beam fiberglass-batt insulated metal roof is supported by the structural steel frame.

The transfer corridor (corridor 116) runs the length of the process bay area along the west end of each process bay and ends at the process water tank room. This corridor is contiguous with the rooms at the south end of the administrative building. Individual process bay access control is provided through a vestibule specific to each process bay. In addition to the process bay access vestibules, corridor 116 provides access to process support area rooms 117, 120, 123, 126, and 129.

The process bay access vestibules (rooms 118, 121, 124, 127, and 130) function as ventilation boundaries between the controlled process bay and the uncontrolled transfer corridor. They are approximately 19 ft by 12 ft.

A single personnel decontamination room (room 117) serves all process bays via the transfer corridor. The personnel decontamination room provides clear standing space for the decontamination process, storage of decontamination materials and detection equipment, and one decontamination shower.
A swipe-count room (room 123) is provided to analyze and store samples taken from process bays or areas that have the potential for contamination. This room provides desk space for preparing testing reports, file space for storage of records, space for counting equipment, and wall space for mounting gas bottle equipment.

A deionized water equipment and air compressor room (room 120), with approximately 120 ft² of enclosed floor space, is located in the process support area.

A security system equipment room (room 126), with approximately 120 ft² of enclosed floor space, is located in the process support area.

The mechanical equipment room (room 207) (20 ft by 150 ft) is located on the second floor of the process support area above the transfer corridor, process bay change rooms, and other support rooms. Building ventilation equipment for the process bay local exhaust HVAC and process vent system and the process general supply/exhaust HVAC system are located in this room, along with chilled water system equipment.

**B2.4.3 Process Water Tank Room**

Water removed from an MCO has the potential to be contaminated, therefore, the water will be stored in a tank located in the isolated process water tank room with controlled access until it is transferred to K West Basin. The process water tank room (room 132) is located directly adjacent to the CVDF process bay area and process support area. This room is located adjacent to process bay 1. The process water tank room is approximately 20 ft wide, 40 ft long, and 13 ft high. The room is built on a concrete foundation and is separated from the process bay area by concrete interior walls. The process water tank room structure is attached to the process bay area structure. The exterior wall of the process water tank room is precast concrete. The process water tank room floor has an elevation of 2 ft below the rest of the CVDF and is designed with elevated doorways to contain liquid leaks.

**B2.4.4 Administrative Building**

The administrative building is the normal CVDF personnel entry point and provides space for a lunch and conference room, quality assurance and process engineer office, shift manager's office, radiological control technician and radiation monitoring office, control room, electrical and telecommunications room, fire riser and mechanical room, men's and women's rest rooms, men's and women's change rooms, and access and egress control and control monitoring of the process bays.

The administrative building is approximately 50 ft wide by 60 ft long by 12 ft high. This area is separated from the adjacent process support area by a 2-hour fire-rated wall. The adjacent process bay area wall is a precast panel that has fire resistance equivalent to a 2-hour fire-rated
The interior walls of the administrative building are gypsum wallboard on a metal frame. The exterior walls are standard (butler-rib type) insulated metal siding and the roof over this area is also a standing seam, batt-insulated, metal roof.

The lunch and conference room is room 105. A quality assurance and process engineering office is in room 104, and the shift manager's office is room 103.

The radiological control technician and radiation monitoring office (room 106) has space for associated instrumentation equipment, storage space for radiological control equipment, and wall space for mounting gas bottle equipment.

The control room (room 107) has space for process bay control functions including computer monitoring stations, MCS programmable logic controller (PLC) cabinet space, SCIC system annunciator and mode control panels, security monitors (two) and duress alarm panel, and HVAC control computer.

The electrical and telecommunication room (room 108) provides space for electrical and telecommunication systems and equipment.

The fire riser and mechanical room (room 110) provides space for a fire protection system alarm check valve riser and mechanical accessories and other support equipment.

Separate change room facilities for men and women employees include rest rooms, shower facilities, storage lockers and benches, and space for supplies storage. These are rooms 111, 112, 113, and 114.

**B2 4 5 Cold Vacuum Drying Facility Design Basis**

As discussed in Chapters B3 0 and B4 0, the CVDF SSCs are classified as either safety class, safety significant, or general service. The CVDF building structures are classified as general service and designed to appropriate natural phenomena hazard loads and conditions as described in WHC-SD-SNF-DB-010.

The CVDF building structures are assigned to natural phenomena hazard performance categories 1, 2, or 3 as defined in DOE-STD-1020-94. The process bay area is performance category 3 to protect the safety-class components located in the process bays. The process support area and the process water tank room are performance category 2. The administrative building is performance category 1. The control room is not required to be manned after natural phenomena events and therefore can be designed to the lower performance category.

The design basis natural phenomena loads and conditions applied to the CVDF performance category 3 structural design are tabulated in Chapter B1 0 and in Table 1 of WHC-SD-SNF-DB-010. This information is duplicated in Table B2-2.

Note: The wind speed criteria are based on recent revision of the Washington Nuclear Plant 2 tornado criteria by the U.S. Nuclear Regulatory Commission.

*DOE Order 5480 28 Natural Phenomena Hazards Mitigation U.S. Department of Energy, Washington, D.C.
*NFPA 780 1995 Lightning Protection Systems National Fire Protection Association, Quincy, Massachusetts
Performance category 1 and performance category 2 criteria also are defined in
WHC-SD-SNF-DB-010. Seismic design for performance categories 1 and 2 uses UBC
(ICBO 1994) zone 2B. Standard occupancy rules are used for performance category 1
facilities and essential facilities rules for performance category 2 facilities. The design
basis wind speed for performance categories 1 and 2 is 70 m/h. Volcanic ashfall is not
considered for performance categories 1 and 2. The design basis snow load for performance
categories 1 and 2 is 20 lb/ft².

The CVDF structure provides protection from seismic events, high winds, and tornado
winds. The process bay is performance category 3 enclosures for seismic and wind
protection. The process support area and the process water tank room are performance
category 2. Equipment within these enclosures is qualified to the appropriate performance
category requirements to not fail and impact the safety equipment required to accomplish
and maintain a safe shutdown of the process.

There are distinct structural boundaries between performance category 2 and performance
category 3 structural interfaces. Performance category 3 SSCs are isolated from the effects
of other SSC failures such that the performance category 3 safety functions can still be
accomplished under design basis conditions. The performance category 3 process bay area is
isolated from the performance category 2 process support area and the performance
category 2 process water tank room by the design of the connecting walls and structural
attachments.

Seismic design for performance category 3 projects follow DOE Order 5480.28 and
Chapter 2 and Appendix C of supporting standard DOE-STD-1020-94. In-structure response
spectra were generated for SSCs supported by the structure. Performance category 1 and 2
SSCs use the UBC (ICBO 1994) zone 2B, as discussed in DOE-STD-1020-94. Standard occupancy
rules are used for performance category 1 and essential facilities rules for performance
category 2.

There is no operating basis earthquake for the CVDF. The administrative building, which
is performance category 1, is structurally decoupled from the process bay area and is
designed to fail away from the process bay area during a performance category 3 event.

The members and attachments of the administrative building are not strong enough to
withstand performance category 3 forces. They are designed to be stronger against movement
in the north direction than in the south direction so when they fail it is to the south away
from the process bay area.

Straight wind load and missile load criteria are given in Chapter 10 of the SNF Project
FSAR and in Chapter 30 of WHC-SD-SNF-DB-010. Tornado missiles have been eliminated
from the CVDF requirements per WHC-SD-SNF-DB-010. The CVDF performance category 3
structures have been designed for tornado hazards in accordance with NUREG-0800: Standard
Review Plan Section 3.3.2 "Tornado Loading." The performance category 3 structures have
been designed to comply with these criteria as a design basis and therefore will be able to
withstand design basis seismic, wind, and tornado events.

Design basis accident loads, response spectra, and design requirements for ashfall are given
in Chapter 10 of the SNF Project FSAR and in Section 2.2 of WHC-SD-SNF-DB-010.
The design basis river flood level, assuming a 25% breach of Grand Coulee Dam, is 460 ft. The elevation of the CVDF is 476 ft above mean sea level. The CVDF structures are designed to resist earth and groundwater loads in accordance with DOE Order 6430 1A and DOE-STD-1020-94 as administered using the guidance of HNF-PRO-097, Engineering Design and Evaluation. Dynamic earth pressures were considered in the design of performance category 3 below-grade structures. The CVDF structures are designed for both dead loads and live loads in accordance with DOE Order 6430 1A and DOE-STD-1020-94 as administered by the guidance of HNF-PRO-097. The snow-load criterion, as specified in WHC-SD-SNF-DB-010, is the criterion given in Chapter 8 of ASCE-7-95, Minimum Design Loads for Buildings and Other Structures.

Neither DOE nor NRC have developed specific requirements for dealing with lightning. NFPA 780, Lightning Protection Systems, is recommended as guidance by DOE and NRC and has been applied for lightning protection for the CVDF.

The paved areas, concrete floor, and parking slabs of the CVDF are capable of supporting a tractor-trailer with an approximate weight of 105,000 lb. All concrete design complies with American Concrete Institute requirements as defined in ACI-301, Specifications for Structural Concrete for Buildings. Except for the process bays, floors throughout the facility have finishes appropriate to an area's function and flexibility requirements. In the process bays, concrete floors have 100% epoxy-coated surfaces that can be easily decontaminated.

The CVDF location was chosen based on a site selection evaluation that was done to determine the optimal site on which to build (Swenson 1996). The CVDF structural design was selected to facilitate demolition of the facility and recycling of the structural materials when the CVDF mission is completed.

Safety Considerations

The main structures of the CVDF provide the following functions: secondary confinement in conjunction with the HVAC exhaust systems (except the administrative building), radiation protection (as low as reasonably achievable [ALARA] exposure from cask-MCO and contaminated effluents), fire protection, natural phenomena and hazard mitigation (seismic, tornado and high winds, floods), and worker safety hazards protection (industrial safety and industrial hygiene).

B2.5 PROCESS DESCRIPTION

This section contains information on the CVDF processes and systems. Section B2.5.1 provides a summary-level integrated process description. The remaining sections contain CVDF system process descriptions. The intent of this information is to provide an understanding of normal operations of the facility.
The purpose of cold vacuum drying is to remove free water from the MCO. Free water and certain loosely bound waters of hydration will be removed by cold vacuum drying. More strongly bound waters of hydration and chemically bonded forms of water will not be removed by the cold vacuum drying process. A generalized drawing of the types of water contained within an MCO and the processes to be used for removal of these waters is provided in Figure B2-9. The chemically bound water that remains following cold vacuum drying continues to decompose via radiolysis, causing pressure to increase in the sealed MCO during storage (HNF-1523). In HNF-SD-SNF-TI-040, MCO Internal Gas Composition and Pressure During Interim Storage, it was determined that the amount of bound water remaining after completion of cold vacuum drying will not be sufficient to result in overpressurization of an MCO during storage at the CSB. This FSAR addresses the safety of the CVDF drying process and does not address the potential pressurization of the MCO after the MCO leaves the CVDF for transfer to the CSB.

B2.5.1 Cold Vacuum Drying Process Overview

The following process overview summarizes process functions performed from MCO receipt through final testing and shipping. CVDF system and equipment operating procedures guide all processing activities. CVDF personnel receive facility- and procedure-specific training. Figure B2-10 provides a block diagram of the cold vacuum drying process. Figure B2-11 shows the progression of water removal from an MCO during the cold vacuum drying process. The simplified diagram of cold vacuum drying process systems (Figure B2-12) serves as a preliminary overview of the process systems that are utilized during MCO cold vacuum drying. HNF-1851, Cold Vacuum Drying Residual Free Water Test Description, provides more detailed information on the process parameters, and their bases, associated with the cold vacuum drying process discussed in the remainder of this section.

B2.5.1.1 Multi-Canister Overpack Transport Receipt

Prior to cask-MCO receipt via tractor-trailer, CVDF operators ensure required systems and equipment are operational and facility technical safety requirements are met. For receipt, the SCIC system is in (1) BYPASS. The shipping package is verified for quality assurance acceptability. Upon receipt, the trailer is positioned in the process bay and the cask-MCO trailer is disconnected. The tractor is driven out, the telescoping door is closed, and the trailer is leveled. Radiation surveys are performed and exposure rates are posted. Security systems are established. The mezzanine bridge and work platform hand rails are configured for personnel safety.

B2.5.1.2 Cask Venting and Lid Removal

The cask-MCO is shipped with the MCO filtered process exit port valve in the open position, which allows the cask headspace to pressurize and collect hydrogen during shipping. Prior to cask lid removal, process vent lines are evacuated, the cask headspace is sampled (primarily for hydrogen concentration) and the cask undergoes helium pressurization and venting. Hydrogen is sampled during process validation using a sample cartridge that is sent to a lab for analysis and trending. The sample results are used for design confirmation and are not required in order to continue with the cold vacuum drying process.
The cask lid is removed using an overhead process bay bridge crane. The process vent plug valve on the MCO is then closed manually.

**B2 5 1 3 Process Hood-Seal Ring Installation** Installation of process connections are made after moving the process hood into place and removing the process port covers from the MCO. As received from the K Basins, the long axial process tube port valves is in the closed position while the filtered process exit port is received in the open position but is closed prior to installation of the hood/seal ring. The process hood-seal ring is lowered onto the top of the MCO using the process bay crane. When in position, the ring is bolted to the top of the cask. Following installation, two air-inflated seals provide annulus water confinement between the cask and the MCO. The process hood open-faced ventilation inlet is incorporated into the process hood structure. A flex hose connects the open-faced ventilation inlet with the process bay local exhaust HVAC and process vent system. The process hood also provides staging locations for the MCO VPS process connectors. A portion of the seal ring (leak test fixture) also encloses the main MCO seal ring area. Vacuum is applied during the cold vacuum drying process to remove residual water on the upper seal ring to facilitate helium leak testing at the conclusion of cold vacuum drying processing. Figure B2-13 shows the system interfaces with the MCO, and Figure B2-14 shows a detailed view of the process hood and seal ring installation on the MCO.

**B2 5 1 4 Vacuum Purge System Hookup and Venting** The process connectors are designed to provide connections to both the VPS and the helium systems through flex piping. Following installation, the process connectors are pressurized with helium and a leak test is performed. When leak-tight conditions are verified, the VPS system is purged with helium and vented to reduce residual air in the suction lines. The MCO process vent plug valve is then opened and helium pressurization and venting cycles are performed to reduce the hydrogen concentration in the MCO headspace. Pressurization and venting of the MCO headspace occurs prior to starting the drain cycle.

**B2 5 1 5 Multi-Canister Overpack Tempered Water System Hookup, Heatup and Drain, and Purge/Flush** For MCO heatup and drain, the SCIC system position switch is moved to (2) HEATUP. The gas-operated valves for the PWC line are interlocked closed to prevent premature draining of the MCO. Tempered water (annulus) system connections are established with the cask through the lower cask port and upper tempered water seal ring. Recirculating tempered water flows through the cask annulus from the bottom to the top at a flow rate of 15 to 20 gal/min and pressure of 20 to 35 lb/in² gauge. Prior to commencement of the drain a period of time is allowed for the MCO to “soak” so that the MCO contents can warm up and the water in the tempered water annulus can reach its operating range between 40 °C and 50 °C. Following the “soak,” the MCS is instructed to begin the draining sequence. The process water receiver tanks are purged (also referred to as a PWC prepurge) with helium to remove oxygen in the tanks. The SCIC system is activated by key switch to enter the (3) DRAIN mode. This action allows the MCS to begin the drain sequence. The MCO drains through the long process tube port to the PWC system. The drained water is treated by the PWC system, stored in a holding tank, and ultimately returned to the K Basins. While the water is draining, the helium supply system pressurizes the MCO through the MCO filtered process exit port. Draining takes...
HFN-3553 REV 0
Annex B — Cold Vacuum Drying Facility

approximately 30 minutes to remove the water from the MCO. Upon detection of water suction breakthrough (large increase of PWC system inlet pressure) the drain lineup remains unchanged for several minutes to remove residual water. The SCIC system position switch is moved to (4) PURGE/FLUSH. This automatically initiates a SCHe line purge of the long process tube to clear collected water in the line. After the SCHe line purge, the MCS starts a PWC system line flush with deionized water. The MCO pressure is normally maintained via helium through the filtered process exit port. The deionized water rinse runs deionized water to the receiver tanks. After the deionized water flush, helium is used to perform a PWC postpurge of the PWC system tanks to remove hydrogen that may have collected during the drain sequence. The process helium supply to the MCO is valved to flow from the MCO long process tube port, through the MCO, and out the filtered process exit port to the process vent system. This is the normal flow path for all drying mode operations.

B2 5 1 6 Vacuum Purge Drying Operation After draining and purge/flush, the SCIC system key switch is moved to the (5) DRYING mode. The gas-operated valves for the deionized water line are interlocked closed by the SCIC system to ensure against inadvertent water addition. During normal operations, the MCS automatically controls the drying operation. Verification is made that the MCO is being pressurized with process helium supplied via the MCO long process tube port and out the HEPA filter and filtered process exit port prior to the vacuum purge drying operation. The initial vacuum drying sequence dries the MCO contents using the VPS vacuum pump and condenser. The vacuum pump is used to remove noncondensable gases from the MCO cavity while a condenser is used to condense water vapors. Drying operations alternate positive pressure and vacuum drying modes with a limit of less than 8 hours for the first vacuum cycle and then 4 hours for all successive pressure and vacuum cycles. If during the drying process the 8-hour vacuum timer limit is reached, the SCIC repressurizes the MCO with a 4-hour minimum helium pressurization and purge. During vacuum pumping at pressures greater than a specified value, a small helium purge is normally added for hydrogen dilution. When the condenser differential temperature has reached a minimal setting for several minutes, the MCS isolates the condenser via the condenser isolation valves because the amount of water being removed from the MCO is relatively small. At this time, the process may proceed to the no-purge vacuum check.

B2 5 1 7 No-Purge Vacuum Check A no-purge vacuum check is performed after VPS condenser delta temperature reaches a minimal setting. With the VPS condenser valved out and the helium purge isolated, MCO pressure must decrease to less than 8 torr within 5 minutes. If 8 torr is not reached in 5 minutes, then the MCO is returned to the normal drying sequence, and the no-purge vacuum check is performed every hour while under vacuum. If the pressure decreases to less than 0.5 torr for a minimum of 15 minutes, the pressure rebound pretest is conducted. If not, the system is returned to the vacuum purge drying cycle.

B2 5 1 8 Pressure Rebound Pretest If the no-purge vacuum check is passed, a pressure rebound pretest is performed with the vacuum pump isolated. If the MCO pressure rises less than 0.4 torr over a 10-minute period, the test continues. If not, the system is returned to the vacuum purge drying cycle.
B2 5 1 9 Initial Pressure Rebound Test If the pressure rebound pretest is passed, a 1-hour pressure rebound test is conducted to indicate whether free water remains within the MCO. The pressure rebound test is performed after the MCO has undergone a 4-hour helium repressurization (thermal reset). This test is run from the vacuum system base pressure (expected to be less than 0.5 torr) with the MCO isolated. The tempered water inlet temperature must be maintained between 40 °C and 50 °C. Vacuum pressure and tempered water temperatures (inlet and outlet) are recorded. If the pressure increases at an average rate greater than 2.4 torr/h, the test fails and more vacuum purge drying is necessary.

B2 5 1 10 Proof of Dryness Demonstration Following a successful pressure rebound test, the SCIC system switch is placed in the (6) PROOF mode. The gas-operated valves for the VPS line continue to be interlocked closed to ensure against inadvertent water addition. The tempered water temperature is maintained between 40 °C and 50 °C. The goal of this step is to maintain the MCO under vacuum less than 18 torr for a minimum cumulative period of 8, 20, or 28 hours for no scrap basket, one scrap basket, or two scrap baskets respectively. Should the pressure increase above 18 torr, the MCS will automatically start a helium purge. An increase in pressure indicates an offgasing of hydrates, a leak of air or helium, additional free water in the MCO being released, or potential offgasing from other sources. The residual gas monitoring system (see Section B2 5 3 3) may be used to determine the source of pressure. The system can be returned to the vacuum purge drying cycle, or recovery procedures can be initiated if proof of dryness is not shown.

B2 5 1 11 Final Pressure Rebound Test The final pressure rebound test is used to confirm that bulk water was not reintroduced during the vacuum drying cycle. When the proof-of-dryness demonstration has been completed, the MCO is isolated from potential water sources (the vacuum pump and condenser systems), the VPS line gas-operated valves continue to be interlocked from the previous (6) PROOF mode position, and the pressure rebound test is repeated a final time. The test is successful if the pressure increases at an average rate that does not exceed 2.4 torr/h (HNF-1851). Following a successful test, drying is complete and the MCO is pressurized with helium. These data are important for long-term storage of SNF and are designated as Office of Civilian Radioactive Waste Management data.

B2 5 1 12 Multi-Canister Overpack cooldown The MCO requires cooling to approximately room temperature before final preparation for shipping. Cooldown is achieved by starting cooling water flow through the tempered water system cooler with the heaters off. After a mandatory hold is completed, the MCO helium pressure is verified and the MCO process port valves are closed sequentially.

B2 5 1 13 Multi-Canister Overpack Helium Leak Test and Preparation of Cask for Departure MCO process connectors are disconnected. A mass spectrometer leak detector (MSLD) leak check is performed on the MCO process ports and MCO main seal. The annular space between the MCO and the cask is drained to the PWC system and then the cask–MCO annular space is isolated from the tempered water system. The cask–MCO annulus is purged with instrument air to dry. The MCO helium MSLD and auxiliary vacuum system leak test are performed to verify that the MCO leak rate is <1 x 10^-5 standard cm^3/sec. The process hood-seal...
ring is removed, the cask and MCO exposed top surfaces are dried and cleaned, and radiation and contamination surveys are performed. The cask lid is installed. The trailer is prepared for transport, standard pretrip inspections conducted, and the cask, along with the MCO quality assurance package, is released for transfer to the CSB.

**B2 5 2 Cask-Multi-Canister Overpack Systems**

**Summary Description**

The transportation cask, trailer, and MCO are not part of the CVDF but are described in the following subsections because of the integral function they provide to the overall CVDF processing activities. The physical interfaces between the CVDF and the cask and MCO are as follows:

- Process bay local exhaust HVAC and process vent system (Section B2 6 2 4)
- PWC system (Section B2 5 7 1)
- Vacuum and purge system (Section B2 5 3)
- Deionized water system (Section B2 9 5)
- General-service helium system (Section B2 5 4 1)
- SCHe system (Section B2 5 4 2)
- Tempered water (annulus) system (Section B2 5 8 1)
- CVDF structure (process bay) (Section B2 4)
- Instrument air (Section B2 9 2)

A simplified diagram showing the CVDF system interfaces with an MCO is presented in Figure B2-13.

**B2 5 2 1 Transportation Cask and Trailer**

A design description of the transportation cask and trailer is provided in HNF-SD-TP-SARF-017. Additional details describing the interface between the MCO, transportation cask, trailer, and the CVDF are provided in HNF-SD-SNF-DRD-002.

SNF is received at the CVDF packaged in an MCO that is transferred from either the K East or K West Basin in a cask loaded on a tractor-trailer. The MCO, containing fuel and flooded with water, remains in the cask and on the trailer throughout processing in the CVDF. The trailer is disconnected from the tractor before processing activities are started. The trailer design includes platforms that serve as work stations for CVDF operators and provides direct access to cask-MCO process interface connections.

**B2 5 2 1 1 Transportation Cask**

The transportation cask (i.e., cask) is a category 1 package (NRC Regulatory Guide 7 11, Table 1). Therefore, NUREG/CR-3854, *Fabrication Criteria for Shipping Containers*, indicates that the design, fabrication, and testing of the cask containment boundary are performed to the intent of the requirements of the *Boiler and Pressure
Vessel Code, Section III, Subsection NB, Class 1 (ASME 1995) The containment boundary design follows the criteria from Section III of the code The structural analyses criteria meet Section III requirements However, the cask is not code stamped

Fabrication of the cask is in accordance with the guidelines of NUREG/CR-3854 All welds and weld joints meet NUREG/CR-3019, Recommended Welding Criteria for Use in the Fabrication of Shipping Containers for Radioactive Materials criteria and were examined in accordance with the Boiler and Pressure Vessel Code, Section III, Subsection NB (ASME 1995) All containment welds are radiographed per the Boiler and Pressure Vessel Code, Section III, Subsection NB-5000

Inspections and containment leak testing of the cask were performed per Boiler and Pressure Vessel Code, Section III (ASME 1995), and ANSI N14.5, Radioactive Materials — Leakage Tests on Packages for Shipment during fabrication

The cask is a vertical, cylindrical, stainless steel vessel The overall packaging assembly, including the lifting device, has an outside diameter of approximately 44 in and an overall height of 190 in The cask consists of a forged, stainless steel cylinder with an integrally welded stainless steel bottom head that is 6-in thick

The cask lid is forged stainless steel The lid is bolted to the cask body with 12 bolts that are arranged on a circle A single, butyl rubber O-ring seal forms the confinement boundary between the cask body and lid Lid installation is guided by two alignment pins that are integral to the cask body Two lifting brackets are welded to the cask lid for lifting of the cask and the lid A 4-in diameter trunnion is welded to each lifting bracket

The cask also has two vent ports and one drain port The vent ports are on the exterior of the cask lid, while the drain port is positioned in the side of the cask body The drain port is closed with quick-disconnect couplings The drain port has a cover that is bolted onto the cask with four bolts One vent port is closed with a quick-disconnect coupling that has a cover that is bolted onto the lid with four bolts The other vent port is closed with a head cap screw and has a cover that is threaded into the lid with a "snout"

B25212 Trailer The trailer serves as a support mechanism for the cask—MCO during the vacuum drying process It is a three-axle trailer and is attached to a standard tractor The trailer was procured as a commercial-grade item

The tiedown system on the trailer is a fixed system, which is an integral part of the conveyance system The conveyance system is based on a custom double-drop semi-trailer designed specifically to secure and transfer the cask The cask is transferred in the vertical position and fits into the cask support device, an approximately 15-in-deep well located beneath the deck of the trailer Approximately 118 in above the deck of the trailer, the cask is secured by a cask tiedown device mounted onto a fixed-frame constructed of structural tube members that are braced to the trailer deck with four structural tube members The tiedown system is
constructed of a rectangular, structural steel tubing (ASTM A500-96, Grade B) frame that is welded to the transport trailer bed. The cask tie-down device is designed as a hinged clam-shell ring where each half section pivots about a fixed hinge pin and is secured with three hex head bolts. The inside diameter of the clamping ring is constructed of 6061-T6 aluminum and equipped with a neoprene abrasion pad that forms a tight fit with the cask. Attached to the clamping ring are four cask hold-down brackets, equally spaced around the circumference, that restrain vertical movement of the cask.

The overall length of the trailer is 40 ft, its overall width is 10 ft, and its overall height with cask in place is 17 ft, 6 75 in. The trailer has a work platform that is permanently attached to it. The work platform can be used to work around the top of the cask and MCO while at the CVDF. The trailer also provides access to the bottom drain port.

**B2 5 2 2 Multi-Canister Overpack** Full MCO design details and design requirements, as well as detailed discussions of fuel inventories that are to be contained within the MCOs, are presented in HNF-SD-SNF-SARR-005. Additional information on the design of the MCO is provided in HNF-SD-TP-SARP-017. The information summarized below is to describe for the reader the basic design of an MCO and the anticipated fuel inventory contained therein.

The MCO is a single-use container that consists of a cylindrical shell, five or six fuel baskets, a shield plug, and design features necessary for maintaining the structural integrity of the container while it provides SNF criticality control and fuel drying capability. HNF-S-0426, *Specification for Spent Nuclear Fuel, Multi-Canister Overpack*, implements the functional requirements documented in WHC-SD-SNF-FRD-016, *Spent Nuclear Fuel Multi-Canister Overpack Technical Functions and Requirements*, which defines the MCO, and thus establishes the minimum essential requirements that the MCO design must meet. A diagram of a typical MCO assembly (with five fuel baskets) is provided in Figure B2-15.

The MCO provides confinement of SNF and maintains the SNF in a critically safe configuration. NRC requirements (NUREG-1536) for a Title 10, *Code of Federal Regulations*, Part 72 "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel and High-Level Radioactive Waste" (10 CFR 72) licensed facility would allow for application of either Subsection NB or NC, 3 IV 1 b(1)(b) of the Boiler and Pressure Vessel Code (ASME 1995). The MCO's structural design has been developed and the MCOs have been manufactured and code stamped in accordance with the Boiler and Pressure Vessel Code, Section III Subsection NB.

Key parameters required for maintaining confinement include the differential temperatures established in the MCO during processing. The maximum temperature difference between the outside of the MCO shell and the center of the shield plug must be less than or equal to 100 °C (180 °F) and less than or equal to 5 °C (9 °F) radially within the MCO shell wall. These parameters limit thermal expansion and preserve the integrity of the MCO mechanical seal.
Thermal analysis has shown that these key parameters are never approached during any of the MCO processing steps (HNF-SD-SN-SARR-005). The normal temperature range for the non-pressure her annulus water ensures the differential temperatures are well within the limiting values. Consequently, there is no requirement for operational controls to ensure that the differential temperature parameters are not exceeded.

Several types of fuel elements are contained in an MCO that will be processed through the CVDF: Mark IA, Mark IB, Mark IC, Mark IV, and Mark IVB. These types of fuel elements are contained within baskets, which are in turn contained within an MCO. The MCO fuel baskets are categorized into two major types: intact fuel element baskets and scrap fuel baskets. The Mark IA fuel and scrap baskets are designed in accordance with the Boiler and Pressure Vessel Code, Section III, Subsection NG (ASME 1995), under the component safety group as guided by NUREG/CR-3854. Mark IA fuel has a higher $^{235}$U enrichment than Mark IV fuel. Structural integrity is required of the Mark IA basket center post for criticality control whereas structural integrity for criticality control is not required for the Mark IV fuel basket. Therefore, the more stringent Section III, Subsection NG requirements are applied to the construction of the Mark IA fuel and scrap baskets. The remaining fuel elements will be handled in accordance with the requirements of Chapter C6.0 of Annex C, the K Basins FSAR.

There are four different basket types that may be contained within an MCO:

- **Type 1**—Holds 48 intact Mark IA fuel elements
- **Type 2**—Holds 54 intact Mark IV fuel elements and does not need an exclusion void
- **Type 3**—Holds Mark IA fuel fragments
- **Type 4**—Holds Mark IV fuel fragments and does not need the exclusion void

Type 1 and Type 3 baskets contain a center post to provide a critically favorable geometry in the baskets and the MCO.

The MCO has a shield design that protects workers from gamma rays and neutrons emanating from the inside of the MCO. The shield plug provides access to the interior of the MCO via four penetrations (Figure B2-16). The penetrations accommodate two process ports (ports 2 and 3), a safety-class rupture disk port (port 4), and a spare port (port 1). The two process ports have valve mechanisms to accommodate connections to external equipment. These process ports connect internally to two process paths. One process path (port 3) connects to a long process tube that extends down the MCO axis to the bottom and the second process path (port 2) extends to internal filters mounted on the shield plug's underside. A third path (port 4) extends from the rupture disk to the space between the bottom of the shield plug and the top of the guard plate. The long process pipe and the guard plate are fitted with debris screens. The connections leading to the long process tube or the filtered process exit port are designed to be easily differentiated by a worker looking at either the top or bottom of the shield plug.
The shield plug features an integrally machined axisymmetric lifting ring with a 12-ton lifting capacity when gripped with six equally spaced grippers. The ring facilitates handling of the MCO at the CSB.

The MCO has an internal filter to support the vacuum drying outflows from the MCO. The filter is installed between the shield plug bottom and the guard plate. The internal filter prevents fuel particulate corrosion products from leaving the MCO (thereby reducing dose in the facility) and reduces the risk of external contamination during breaking of CVDF process piping connections. The internal filter is a HEPA filter and adequate flow capacity is achieved through the filter to support operating needs. The filter does not meet the testing provisions of DOE Order 6430 1A because its efficiency cannot be tested after the shield plug is installed. The filter is not relied upon to perform a safety function. No credit has been taken for the presence or function of this filter in the accident analysis.

**Safety Considerations**

The cask functions to provide a flooded shipping container for MCO transport from the K Basins to the CVDF and to provide radiation shielding, a safety-significant function for worker safety. While at the CVDF, the cask provides the safety-class function of maintaining a water-filled annulus for heat transfer purposes.

The MCO provides criticality control functions for the Mark IA fuel. Within a closed cask, the MCO is designed to withstand a 30-min, 802 °C (1,475 °F) fire and still meet the radioactive material release criteria of Title 10, Code of Federal Regulations, Part 71, “Packaging and Transportation of Radioactive Material” (10 CFR 71), Section 71.51(a)(2) (HNF-SD-TP-SARP-017).

B2.5.3 Vacuum and Purge System

The cold vacuum drying process drying mode uses the VPS to place the MCO contents under vacuum and to perform inert helium gas purging using a cycle of helium flow, evacuation, and inert gas backfill/pressure stages. While in process, the VPS operation includes monitoring and testing stages to demonstrate acceptable equipment and MCO conditions. The acceptable conditions must be met before the process is allowed to begin or continue. The vacuum and purge system consists of several subsystems that function together. See Figure B2-17 for the process systems flow diagram.

**Summary Description**

The VPS process equipment is designed in a modular fashion consisting of one process hood and piping assembly and one process equipment skid.
The process equipment skid is an assembly of vacuum pump, water pump, residual gas monitoring (RGM) system, tanks, heaters, pipes, valves, instruments, instrumentation wiring, and electrical distribution wiring mounted on a frame that rests on the floor of a process bay. A mezzanine is located above the process equipment skid at the appropriate height to access the top of the MCO. A process hood and piping assembly serves as the key interface between the MCO and the process equipment skid. The process hood consists of a stainless steel slot hood designed to be bolted to a seal ring subassembly and, in turn, to the MCO and cask. See Figure B2-14 for a diagram of the process hood and seal ring installation on the MCO. Included with the hood and piping assembly are process connectors (containing valve operators) designed to be bolted directly to the MCO and to serve as a piping connection and tool for opening and closing process port valves in the shield plug. The process hood provides protection to operators by capturing radioactive particulate matter that may be released from the MCO while attachments of the process connectors are made or broken. The process hood also provides a location for the temporary storage of the process connectors while not in use. The seal ring subassembly is designed to be bolted to the top of the MCO and shield cask and to seal the interstitial space between the MCO and cask. The seal ring subassembly also has connections to facilitate manual refill of the cask-MCO annulus. Process piping associated with the assembly is mounted on a stand attached to the mezzanine and includes pipe, valves, and instrumentation.

VPS operating limits and normal operating conditions are provided in Table B2-3.

The use of stainless steel VPS piping and valves ensures that there will be negligible corrosion over the design life of the CVDF. A corrosion allowance of 0.06 in is specified in the ASME code data reports for the VPS equipment.

The process equipment skid occupies a space 18 ft east-west, 6 ft north-south, and 10 ft high. The skids are located 3 ft from the north wall of each process bay, centered between the east and west walls. The process hood support stand is 10 ft east-west, 3.5 ft north-south, and...
7 ft high, centered east-west and is attached to a base frame located near but isolated from the north mezzanine overhanging each process bay.

Figure B2-18 provides an overhead view of the location of a cask-MCO trailer in a process bay in relation to the process skid, process hood/seal ring and support, and mezzanine. Figure B2-19 shows a side view of the process skid (skid mezzanine, and process hood and support) in a typical process bay.

The vacuum and purge system consists of the following subsystems:

- **VPS** — The VPS consists of a single four-stage vacuum pump piping, valves, and pressure control valves and piping for helium purge gas supply and venting.
- **Heat trace system** — The heat trace system is used to minimize condensation in piping ahead of the VPS condenser and collection tank.
- **RGM system** — The RGM system consists of instrumentation and gas monitoring equipment that monitors the operating pressures and gas concentrations.
- **Helium MSLD and auxiliary vacuum system** — The helium MSLD and auxiliary vacuum system measures the pressure boundary leak rate of the MCO following the cold vacuum drying process.

The tempered water (annulus) system is on the process equipment skid but is treated as a separate process system in this document (see Section B2 5 8 1).

**B2 5 3 1 Vacuum Purge System**

The VPS has 11 major interfaces with the other CVDF systems. The interface systems, in addition to the cask-MCO, are as follows:

1. Electrical power distribution system (Section B2 8 1)
2. SCIC system (Section B2 5 9 2)
3. Deionized water system (Section B2 9 5)
4. Instrument air system (Section B2 9 2)
5. Facility structure (skid and process hood support stand) (Section B2 4 1)
6. Chilled water system (Section B2 5 8)
7. General-service helium system (Section B2 5 4 1)
8. SCHe system (Section B2 5 4 2)
9. Process bay local exhaust HVAC and process vent system (Section B2 6 2 4)
10. PWC system (Section B2 5 7 1)
11. MCS (Section B2 5 9 1)

The MCO is connected to VPS hardware via flexible hoses that run from the MCO process connectors to valves on the process hood support stand. Helium is supplied to the MCO interior through two separate paths (depending on the process mode). The MCO venting flow is through...
the MCO vent port, which is provided with HEPA filters inside the MCO shield plug. The flow then travels to the condenser and condenser tank, or is bypassed around the condenser under some vacuum conditions. The flow then proceeds through the vacuum pump to the process vent system that discharges to the HEPA-filtered process bay local exhaust HVAC and process vent system.

A 1-in VPS line is connected to each of two of the MCO ports. One of the lines (long process tube port) connects to the general-service helium system and deionized water line and also has connections to the SCHe system. The other line (filtered process exit port) provides the pathway directly to the VPS equipment with appropriate connections to the SCHe system. In general, the VPS consists of an RGM, a condenser (which can be bypassed after most of the water is removed from the MCO), a condenser water collection tank routed to the PWC system, a helium line to provide pressurization to remove MCO water, and a four-stage roots vacuum pump that connects to the process vent. When water has been drained from the MCO, a valve to the vacuum pump is opened and pump-down is initiated to remove the remaining water in the MCO fuel. At various stages the water/gas content of the MCO is monitored with the RGM and the condenser captures water vapor before it reaches the vacuum pump.

The VPS is designated general service but certain components are designated safety class. The safety-class components discussed in Chapter B4 0 are designed to function under worst-case internal and external environmental conditions. The VPS safety-class components that are credited with performing their safety function in a seismic event are seismically qualified to performance category 3 criteria. The VPS is protected from high winds by the CVDF structure. All VPS safety-class isolation valves have remotely activated operators and fail closed upon loss of control air, control signal, or electric power.

General service VPS tanks, valves, components, instrumentation, and controls are designed and qualified for performance category 1 as defined in DOE-STD-1020-94. Structural components and equipment anchorage are designed to be performance category 2 on the process equipment skid and performance category 3 on the process hood support stand.

The VPS has sufficient designed testability features to permit the periodic measurement and calibration of all setpoints and adjustments that affect the manner in which the VPS performs. Periodic testing of VPS SSCs is dictated by the requirements of the individual components according to the respective manufacturer's recommended schedule and practice or industry standards and is administered by controlled procedures.

The majority of VPS operation is automatically controlled by the MCS, but manual operations in the process sequences include field operator actions (e.g., connecting the MCO valves operating manual block valves, connecting quick-disconnect valves) and control room operator actions (e.g., acknowledging alarms, operating the SCIC system mode key switch). Operators direct the MCS to initiate a preprogrammed sequence in the MCS once conditions have been satisfied. Valve state changes, gas supply pressure control, process status notifications, and system alarm notifications are performed by the MCS or the SCIC system.
**B2.5.3.2 Heat Trace System** The heat trace system is installed on the VPS piping in each of the four process equipment skids and on the process hoods to minimize condensation and icing in piping ahead of the VPS condenser and collection tank. The heat trace system consists of (1) self-regulating heat cable made up of two bus wires, a semi-conductive polymer core of which resistance varies with temperature, and an insulating jacket, (2) connection accessories, and (3) local on-off thermostatic control. The heat trace cable has a fluoropolymer jacket over braid and is controlled from a local controller with resistance temperature detector input.

**B2.5.3.3 Residual Gas Monitoring System** The RGM system, during drying, provides continuous online monitoring of MCO offgas composition to assist in evaluation of fuel drying effectiveness and sends data to the MCS, which initiates an alarm if there are gas concentrations outside of process limits. The CVDF contains four RGM subsystems, one in each process bay. Most of the RGM subsystem is enclosed in a case and mounted on the VPS process equipment skid. RGM subsystem components consist of a pump, ionizer, filter, collector, and quadrupole-type mass spectrometer with associated piping, valves, instruments, alarms, and controllers.

The residual gas sample is drawn from the MCO vent line and analyzed for hydrogen, nitrogen, oxygen, argon, helium, water vapor, krypton, and xenon. Sample gases are discharged from the RGM system by a vacuum pump through a vent line to the CVDF process bay local exhaust HVAC and process vent system.

Normal RGM system operation interfaces with the MCS. Results of this monitoring are used along with pressure and temperature measurements of MCO gases to evaluate (1) adequacy of the vacuum conditioning process in removing water from the MCO fuel, (2) any air inleakage to the system, (3) the gas constituents of the MCO, and (4) presence of radioactive gas species. The system is designated as performance category 1.

**B2.5.3.4 Helium Mass Spectrometer Leak Detection System** The helium MSLD and auxiliary vacuum system are used to measure MCO leak tightness at the conclusion of the cold vacuum drying process to verify that the MCO is ready for interim storage. This system consists of a helium MSLD system, auxiliary vacuum pump, piping, valves, and instrumentation to measure the pressure boundary leak rate of the MCO following the cold vacuum drying process.

**Safety Considerations**

The VPS piping and valves perform confinement isolation functions between the MCO process connectors and isolation valves located on the process hood support stand, are classified as safety class and are designed to performance category 3 standards. Because the VPS is directly connected to the MCO, there is a potential for radioactive contamination throughout the system piping and components.

All of the VPS safety-class components required for process instrumentation and required to accomplish MCO isolation during process upset conditions are included in the process hood support stand. The safety-class components consist of the following:

---

*November 1999*
Fail close MCO isolation valves with instrument air line filters mounted on the process hood support stand

- Pressure transmitters, pressure indicators, and flow indicating transmitters mounted on the process hood support stand

- MCO 30 lb/in² gauge rupture disk and associated vent path to a local exhaust duct

- Piping inside isolation valves

A safety-class vent path mitigates the effects of a pressurized release from the MCO due to a postulated overpressurization event. The vent path originates from the MCO process ports number 2 (filtered process exit port) and number 4 (150 lb/in² gauge rupture disk). The primary vent path is accomplished via the 30 lb/in² gauge rupture disk on the MCO port number 2 process connector. A check valve with a 30 lb/in² gauge cracking/reseal pressure setting, is located downstream of the rupture disk. The primary vent path discharges to the process bay local exhaust HVAC system via a tie-in downstream of the process hood's bubble-tight isolation damper. A secondary vent path is provided for the MCO through port number 4 and its associated 150 lb/in² gauge rupture disk. This secondary vent path is not directly tied into the process bay local exhaust HVAC system. A diagram of the safety-class vent configuration for the cask-MCO is provided in Figure B2-13.

The deionized water flush line has gas-operated isolation valves with interlocks to isolate the MCO from the deionized water source for times other than when the MCO is undergoing preparations for cold vacuum drying, MCO draining, and PWC system line flushing. The PWC has interlocks to prevent draining during the (2) HEATUP mode.

The seal ring subassembly has safety-class connections to facilitate manual refill of the cask-MCO annulus, should a loss of annulus water occur.

B2 5.4 Helium Systems

Two helium systems are provided in the CVDF. The helium supply is normally from a commercial tube trailer. A backup supply is provided from the SCHe system gas cylinders. Each helium system is described in the following subsections.

B2 5.4.1 General-Service Helium System

Summary Description

The function of the general-service helium system is to provide pressurized helium for process operations, process support activities, and process safety functions (when available). Helium is an inert gas with good thermal conductivity and is used in process operations to provide
enhanced thermal conduction, to purge the MCO of hydrogen and other gasses, to pressurize the MCO to preclude oxygen ingress, and to provide an inert backfill of the MCO when drying is complete. The general-service helium system is used to provide thermal conductivity within the MCO and to enhance fuel corrosion reaction heat removal, to inert process vessels, to purge various process lines, to pressurize the MCO headspace during draining, and to provide an inert gas to pressurize the labyrinth seals on vacuum pumps.

The general-service helium system also provides (1) a non-safety-class helium supply to the SCHe system (see Section B2.5.4.2) (2) helium flow information to the SCIC system (see Section B2.5.9.2), and (3) safety-class isolation of the MCO. The general-service helium system is designed to supply helium in sufficient quantities and pressure to support simultaneous process operations in all process bays.

The general-service helium system is located both inside and outside the CVDF. Two leased helium tube trailers are parked on a concrete pad located on the west side of the CVDF. Only one helium tube trailer is used to supply helium to the facility at any one time. A helium pipe penetrates the west wall and connects to a helium header running north-south along the full length of the east wall of the transfer corridor. Figure B2-20 shows the general-service helium system delivery to the CVDF process bays. Branch piping connects each process bay to the helium header and flexible piping is used to distribute the helium to the process equipment skid, the process hood and support stand, the VPS, and the SCHe system. Within the process hood and support stand, the general-service helium system is connected to the VPS lines connected to the long process tube and the filtered process exit port.

In addition to piping, the general-service helium system includes pressure regulators, pressure and flow indicators, and control valves. System control and alarm functions are provided by the MCS (see Section B2.5.9.1). Check valves are used to prevent backflow from one process bay reaching the other process bays. The two tube transporters provide, at a minimum, a two-week supply of helium at the maximum process demand rate. Continuous operation is provided by allowing an empty tube transporter to be disconnected and replaced while helium is drawn from the other.

The general-service helium system has redundant safety-class safety relief valves designed to relieve pressure in the event of pressure regulator failure, as well as a general service safety relief valve.

Safety Considerations

The general-service helium system has safety-class components that provide for isolation of the MCO (e.g., redundant fail-closed isolation valves with associated instrument air filters and flexible tubing connections) and safety-class safety relief valves. The general-service helium system also has redundant safety-class instrumentation for process operation, identification of process upset conditions and initiation of SCIC system functions.
B2 5 4 2 Safety-Class Helium System

Summary Description

The SCHe system is a dedicated safety system that actuates upon SCIC signal trip, which can be automatic or manual, or upon loss of power or air. The key function of the SCHe system is to pressurize and purge the MCO with sufficient helium pressure and flow to preclude flammable concentrations of hydrogen and oxygen.

The SCHe system is capable of performing the following functions: (1) remove hydrogen and/or oxygen to maintain the MCO at less than the lower flammability limit, (2) maintain positive pressure in the MCO to preclude or limit oxygen ingress, (3) pressurize the MCO to provide enhanced thermal conductivity within the MCO, and (4) provide a pressure regulated vent flow path.

There are independent and identical SCHe systems for each process bay, the following description is applicable to all systems. Each process bay SCHe system consists of four parallel purge systems: two on the VPS line going to the MCO long process tube and two on the VPS line going to the MCO filtered process exit port. Each purge system consists of helium supply bottles, pressure regulating valves, rupture disks, and fail-open electropneumatically operated isolation valves with associated piping and instrumentation. The four lines form two redundant purge, vent, and pressurization paths for the MCO.

Each of the four SCHe system trains in a process bay has two sources of helium, a 240 ft³ (at standard temperature and pressure) helium bottle, and the normal helium tube trailers associated with the general-service helium system. The safety-class bottles provide the helium supply should the non-safety-class process tube trailer be unavailable. Figure B2-19 shows a side view of a process bay with the location of SCHe bottles in relation to the process skid. Figure B2-21 shows an overhead view of the location of the SCHe bottles in relation to the process skid within a process bay.

Pressure control settings are used to preferentially use general-service helium from the tube trailers. Under nonfaulted conditions, this preserves the SCHe system purge bottle supply and reduces the need for SCHe system bottle refill. Double check valves and a pressure regulator on the general-service helium supply to the SCHe are set slightly higher than the regulator for the SCHe bottles. This pressure differential allows helium to preferentially flow from the normal process supply as long as its pressure remains above the pressure setpoint for the SCHe bottles. When general-service helium is not available, the SCHe bottle supply would not be affected (safety-class separation criteria) and would be utilized upon an SCIC system purge initiation. When the SCHe system is actuated, the two paths connected to the VPS line connected to the MCO long process tube provide helium to the MCO. The two paths connected to the VPS line connected to the MCO filtered process exit port provide a vent path. This feature is achieved by the differential pressure balance between the two system configurations and the pressure control valves in the pathway to the process vent. The two SCHe supply lines to the long process tube...
are set at staggered pressures so that helium is drawn first from one bottle and then the other. The two vent lines are set at equal pressures so that both provide helium for long-term pressurization. The return gas flow then backfeeds into the SCHe system lower pressure supply headers, through pressure regulators, and into the process bay local exhaust HVAC and process vent system. A 125 lb/in$^2$ safety-class rupture disk is provided for each SCHe line. The rupture disk is located between the pressure control valve and the check valve.

Under faulted conditions the pressure control arrangement provides purge flow through any single-line break. Under the condition of a pipe break between a safety-class isolation valve and the MCO, the flow of helium is as follows:

- **Process line break on the MCO long process tube side with little or no bulk water in the MCO**: Purge flow is through the MCO from the MCO HEPA filter supply side (the 4 lb/in$^2$ gauge helium purge flow is sufficient to overcome the differential pressure of the HEPA filter). MCO pressure is maintained slightly positive with flow of helium through the line break and/or out the process vent, depending on the size of the leak.

- **Process line break on the MCO long process tube side with bulk water in the MCO**: The water is pushed through the broken line until the pressure of the purge gas is overcome by the static head of the water column in the long process tube. At this point, the MCO is maintained at a positive pressure to preclude oxygen ingress.

- **Process line break on the MCO HEPA filter side with little or no water in the MCO to preclude air ingress**: Purge is through the MCO from the MCO long process tube side out the line break.

- **Process line break on the MCO HEPA filter side with bulk water in the MCO**: The SCHe system pressure overcomes the backpressure of the long process tube filled with water or the MCO is vented to allow hydrogen (at low initial concentrations) to disperse into the process bay.

The SCHe system interfaces include the general-service helium system, electrical and instrument air supply process bay local exhaust HVAC and process vent system, process hood support stand, MCS, building structure and SCIC system (the MCS cannot operate any of the SCHe isolation valves because all control functions come from the SCIC only).

**Safety Considerations**

The SCHe system provides safety functions for several of the design basis accidents described in Chapter B3. Local safety-class SCHe system bottle pressure gauges are provided at each SCHe system bottle, to provide indication of SCHe operability. Other instruments in the SCIC system which form part of the pressure boundary, are safety class for confinement purposes only.
The SCHe system isolation valves are designed to fail open, therefore, a loss of electrical power or instrument air will actuate the SCHe system purge and vent processes.

Sufficient purge flow volume and time under pressure is provided to allow time to initiate and complete recovery operations (e.g., isolation of the MCO at the shield plug valves). The "SCIC ISO & PURGE" trip alarm in the control room signals that the SCHe system has actuated.

A redundant relief path for the SCHe system is made up of safety-class regulators and 125 lb/in² gauge safety-class rupture disks. This relief path is for a high pressure failure caused by non-safety pressure regulators.

The SCHe system's functional requirements, performance criteria, and capability to perform the required safety functions are evaluated in more detail in Chapter B4.

B2.5.5 Condensate Collection Systems

Summary Description

Condensate from the process bay recirculation HVAC systems and the process general supply/exhaust HVAC system (condensate from the HVAC cooling coils) is routed via copper piping to condensate collection tanks. A condensate collection tank is hung underneath the mezzanine of each of the process bays containing a process bay recirculation HVAC system, and the condensate collection tank for the process general supply/exhaust HVAC system is located in the transfer corridor. The condensate collection tanks have sight glasses for visual inspection of liquid levels in the tanks, tank vents, and capped tank drains. Water in the collection tanks may be sampled and verified to determine appropriate disposition. Water can be transferred to the PWC system or drained via a flexible hose to an appropriate disposal container.

Safety Considerations

The condensate collection system is classified as general service.

B2.5.6 Effluent Drains Systems

Summary Description

Each process bay is equipped with an effluent collection system, with the major components of the system consisting of a floor sump and a drain. The process bay sumps are serviced by a sump drain pipe that leads to a retention basin. The function of the effluent drains system is to collect primarily fire suppression water in sumps in each of the five process bays from which they can be drained to a 20,000-gal below-grade retention basin located west of the CVDF.
In the case of a spill in any process bay, the sumps will hold up to 200 gal of liquid each.

The sumps are located in the center of each bay's floor. The floor is sloped toward the sumps to facilitate drainage in the case the fire suppression system operates. The sump drain pipe has a drain valve at each sump, and there is an inlet valve at the interface between sump drain pipe and the retention basin. These valves (which are normally closed) are manually opened except for situations involving fire. In case of actuation of the fire suppression system in a process bay, the sump drain valve for that specific bay automatically opens to allow the water flow of the fire sprinklers to pass through the sump and into the retention basin.

In the case of fire sprinkler actuation, water from the retention basin is sampled to determine an appropriate method of disposal. Water may be discharged from the retention basin to the ground. This disposal to the soil column is regulated under State Waste Discharge Permit ST 4508, which the Washington State Department of Ecology issued to the DOE Richland Operations Office. Rules governing the quantity and quality of water that can be discharged are described in SNFP Process Standard 409, Discharge to Ground.

Safety Considerations

The effluent drain system is classified as general service.

B2.5.7 Process Water Systems

This section discusses the systems that will treat, sample, and temporarily store process water drained from the MCOs in the CVDF.

B2.5.7.1 Process Water Conditioning System

Summary Description

The PWC system contains two receiver tanks (a total capacity of approximately 300 gal), pumps, filters, and ion exchangers that remove particulate matter and dissolved ions from the process water. The PWC system is designed to service one MCO at a time. The PWC system vacuum source is a water jet ejector that requires a water circulation loop. The PWC system continuously circulates water through the ejector, thus having a continuous source of vacuum for draining MCOs, VPS condenser tanks, the tempered water (annulus) system, or the cask-MCO annulus (unless the system is shut down for maintenance). The MCS controls all non-safety automatic functions and alarming of the PWC system. The SCIC has interlocks and trip control of the PWC-to-MCO isolation valves, provides a control room alarm for prepurge and postpurge failures, and a seismic trip to the PWC pumps. See Section B2.5.9.2 for more details.
Normal operations of the PWC system include draining water, processing collected water through the ion exchange modules (IXMs), and transferring processed water to a 5,000 gal facility storage tank (tank PWC-TK-4001 in the process water tank room). System valving can be used to direct flow via the following pathways: PWC system water recirculation from the receiver tanks through the ejector back to the receiver tanks, IXM flow back to the receiver tanks, and IXM flow through the filter to the PWC system holding tank. See Figure B2-17 for the process systems flow diagram. A layout of the process water tank room (showing the PWC skid, receiver tanks, particulate filter, samplers, IXMs, and storage tank) is provided in Figure B2-22.

The PWC system is powered by two (one running and one standby) motor-driven pumps capable of pumping 45 gal/min at a head of 140 ft of water. The ejector is capable of pulling at least 5 gal/min of liquid at a head of 17 ft of water. The pump discharges into a primary receiver tank through a water jet ejector. Operation of the PWC system vacuum pumping and receiving system includes control and monitoring of the pump operation, flow loop performance, receiver tank conditions, and suction line performance. Three-way flow control valves are aligned to operate one pump at a time.

The PWC system impurity removal section consists of a flow branch for feeding process water through one of the two IXMs (one is available on standby to allow for rerouting of process water if the other IXM must be isolated from operation). After cleanup, flow is then directed to a separate particulate filter prior to water transfer to the PWC storage tank. Automatic sampling is done before and after the water passes through the IXMs and after it passes through the particulate filter.

The IXMs are self-shielding, single-use, disposable water treatment units used for the removal of radionuclides from the water at the CVDF. The IXMs are self-contained units that consist of six carbon steel tanks connected to a common inlet and outlet. During IXM construction, the tanks are encased within a block of concrete. While the IXMs are in service, the concrete serves as shielding for internal radiation that emanates from the radionuclides entrapped within.

Control of process water to the IXMs is through a flow valve controlled by a flow-indicating controller. Normally, flow is continuously fed through the IXMs. High-differential pressure alarms are triggered if the IXMs begin to plug. Operating experience will determine what differential pressure to set. IXM loading with transuranics is administratively controlled as determined by sample analysis and likely requires IXM changeout prior to reaching the differential pressure limit. After the process water has passed through the IXMs, the treated water can be returned to the receiver tanks for recirculation through the water conditioning process or directed for final transfer of processed water to the facility storage tank.

An IXM typically remains in service until the differential pressure across the IXM reaches a setpoint or until administrative transuranic loading limits are reached. At that time, the IXM is disconnected from the CVDF piping and transported to a disposal location. Roof hatches are
incorporated into the CVDF design and an IXM can be changed out using a crane. Changeout of IXMs through the roof hatches was identified in the hazard analysis (HNF-SD-SNF-HIE-004) but not analyzed because IXM replacement is not expected during the lifetime of the facility (SNF-5197). The IXM will be monitored during initial process operations in order to trend filter loading. These data are necessary to establish IXM changeout requirements. Any potential future IXM removal and replacement will be analyzed for safety consequences.

PWC system operating limits and normal operating conditions are shown in Table B2-4.

*This is an administrative limit based upon economic and regulatory constraints for transuranic material.*

The use of stainless steel PWC system piping and valves ensures that there will be negligible corrosion over the design life of the CVDF. A corrosion allowance of 0.06 in is specified in the ASME code data book for the VPS equipment.

**Safety Considerations**

The PWC isolation valves and associated piping are safety class. The PWC system has a safety-significant line to the receiver tanks and the remaining components are general service. The tanks in the IXMs are critically favorable by design. See Section B2 7 3 for additional details on criticality protection.
The PWC system filter and IXMs have shielding incorporated in their design.

The PWC system provides confinement of contaminated effluents in the process water, radiation protection from the effluents, worker safety hazards protection, criticality control, and natural phenomena hazard mitigation. The PWC tanks are inerted with helium from the general-service helium system before the MCO is drained to purge any air from the tanks and after draining to purge hydrogen from the tanks.

The water storage tank (PWC-TK-4001) is equipped with level indication and has an overflow pipe to allow for excess water in the storage tank to collect on the floor of the process water tank room.

**B2 5 7 2 Conditioned Water Shipping System**

**Summary Description**

The function of the conditioned water shipping system is to provide transportation of purified process water from the CVDF back to the K Basins integrated water treatment system for final treatment. The conditioned water shipping system consists of a pump (located in the process water tank room, pipe (from the process water tank room to spare bay 1), and flex hose to connect to a tanker truck. After process water storage tank sample results are verified, a tanker truck is backed into process bay 1 (room 131) and a transfer line is connected to the tanker truck using a flex line and quick disconnect. The tanker truck has a HEPA-filtered vent. Water is pumped from the PWC storage tank to the tanker truck using the storage tank pump. The water level in the storage tank is monitored.

**Safety Considerations**

The conditioned water shipping system is classified as general service. Any conditioned process water released from the tanker truck while it is in spare bay 1 is contained by the CVDF process bay sump. Specialty equipment is used to remove spills in the process bay to the PWC system.

**B2 5 7 3 Contaminated Water Sampling and Analysis System**

**Summary Description**

The contaminated water sampling and analysis (SMP) system is a subsystem of the PWC system. The SMP system is used to take water samples before process water is fed into the PWC system IXMs, after water exits the IXMs, and after water exits the particulate filter.

The SMP system contains sampling devices that are directly controlled by the MCS shielded collection bottles and instrumentation and controls that sample water from the process stream of the PWC system. See Figure B2-17 for the process systems flow diagram.
The collection bottles are periodically removed and sent to a laboratory for analysis. The results of the analysis determine the quantity of radionuclides removed from the MCOs, the radionuclides contained in the IXMs, and the water quality being transferred to the process water storage tank. The PWC impurity removal operation consists of a flow branch for feeding process water through IXMs and a particulate filter. Three samplers are provided and operate whenever flow is registered through the IXMs. The MCS controls the sample rate by sending a momentary sample initiation signal to the samplers.

**Safety Considerations**

The SMP system is classified as general service. The SMP system provides confinement of contaminated effluents from the process water, radiation protection from the effluents, and worker safety hazard protection.

**B2 5 8 Cooling Water Systems**

This section discusses the MCO tempered water (annulus) system and other associated water heating and cooling systems.

**B2 5 8 1 Tempered Water (Annulus) System**

**Summary Description**

The function of the tempered water (annulus) system is to maintain the MCO at the proper operating temperatures during processing. This includes heating the MCO before draining and cooling the MCO after processing.

The tempered water (annulus) system is a closed-loop system that provides tempered water (10 °C to 50 °C [50 °F to 122 °F] and 15 to 20 gal/min) to the annulus between the MCO and the cask (see Figures B2-17 and B2-23) and provides a means for controlling the temperature of the MCO contents. Pressure in the tempered water (annulus) system is approximately 20 to 35 lb/in² gauge. The tempered water is heated or cooled depending on the step in the drying process and is recirculated through the annulus with a water pump. The water level in the annulus is monitored by the SCIC system and the MCS on both supply piping and return piping.

Two water lines are connected to the cask-MCO, one near the bottom of the cask, which serves as the tempered water inlet, and one in the cask-MCO seal ring, which serves as the annulus outlet. The inlet line consists of a rigid, supported, vertical double-walled pipe with a double flex line lower section. The double flex line has a cask connection fitting that is mated to the cask-MCO. The upper end of the line connects to the process flange hood. Double containment is provided to an elevation above the top of the SNF contained within the MCO.
An inflatable seal-ring assembly forms part of the hydraulic boundary between the cask and the MCO. The cask–MCO seal ring is considered a part of the tempered water (annulus) system but is attached to the process hood. The seal ring’s function is to form a water- and air-tight seal in two locations: (1) between the cask shell and the seal ring on a horizontal plane and (2) between the MCO and the seal ring on a vertical plane. The center of the seal ring is open to allow process system connection access to the ports on the top of the MCO. Rubber seal ring bladders are inflated by the instrument air system after the process hood-seal ring assembly is bolted into place.

The tempered water is heated by an electric heater and chilled by the tempered water cooler. Chilled water to the cooler is supplied from the tempered water cooling system described in Section B2.5.8.2. The tempered water (annulus) system supply pressure to the cask–MCO annulus is controlled using a pressure control valve, and the pump discharge pressure is monitored.

A pump receiver tank is provided (TW-TK-3*12). The water level in this tank is monitored and has a high-level alarm.

**Safety Considerations**

The tempered water (annulus) system has three safety functions: (1) maintain water in the cask–MCO annulus, (2) maintain safe cask–MCO inlet water temperature, and (3) provide cask–MCO water level low-level alarm and indication. All of these functions are required throughout the cold vacuum drying process until the final pressure rebound test is completed.

The tempered water provides redundant safety-class temperature instrumentation on the inlet of the tempered water (annulus) system. The instrumentation trips the SCIC on high temperature and removes power from the tempered water heater. The water level in the annulus is monitored on the supply and return piping. The equipment design for maintaining the water level is passive; however, level alarms are provided to the SCIC system for annunciation in the control room if levels become low. The SCIC system has two independent temperature switches that will trip the tempered water heater when its setpoint is exceeded. The level alarm and temperature trip, which provide process parameter indication in the control room, are provided to the MCS. The annulus level alarm is annunciated on the SCIC annunciator panel in the control room.

The tempered water (annulus) system is designed to isolate the effects of failures on the non-safety portion of the piping. This includes line breaks, seismic activity damage, or process deviations. Water must be maintained in the annulus to provide a means to dissipate the heat generated in the MCO until the MCO is dried and passes its final pressure rebound test.

Recovery refill of the cask–MCO annulus is first attempted by use of a special tool (jumper between the deionized water line and the cask refill port). If deionized water is unavailable (the deionized water system is inoperable) to the tempered water (annulus) system, operators can refill...
the annulus manually with water, using a funnel, through a fill port and valve in the outlet line attached to the cask–MCO seal ring. A refill vent port is also provided to facilitate this manual refill operation by providing a visual indication of water level near the top of the supply line. Two parallel antisiphon valves are connected between the safety-class portion of the inlet and outlet piping of the deionized water system to prevent water from being inadvertently siphoned from the annulus in the event there is a line break in the piping.

The tempered water (annulus) system line from the connection flange on the process hood and extending to the lower port connection on the SNF cask is qualified as safety class B2 5 8 2 Tempered Water Cooling System

Summary Description

The tempered water cooling system provides cooling water to the tempered water (annulus) system cooling coils (see Figure B2-23). The cooling water provides the tempered water (annulus) system with the ability to cool the cask–MCO assembly during the MCO cooldown. The key process requirement for the tempered water cooling system is that it supplies cooling water of a designated temperature at a designated flow rate to the tempered water cooler.

The tempered water cooling system is used to supply cooling water at 10 °C (50 °F) and 20 gal/min to a tempered water (annulus) system cooler (see Figure B2-23). The system cools the tempered water recirculation loop during the cask–MCO cooling operational phase. The cooling water source is a closed water loop supplied by a heat exchanger and two pumps. The chilled water system removes the heat from the closed loop. The chilled water for the tempered water cooler is supplied by an intermediate cooling loop interfaced with the chilled water system through a process heat exchanger. The intermediate loop consists of a circulation loop with spare pumps. The cooling circuit provides cooling to the MCOs in each of the four process bays at any given time. Up to four MCOs can be processed, and the system is designed to remove 73 kW (250,000 Btu/h) (SNF-2356). The temperature of the water supply to the MCO annulus is controlled by the MCS except for the SCIC high temperature trip.

Pressure in the tempered water cooling system at 50 lb/in² gauge is greater than pressure in the tempered water (annulus) system at 20 to 35 lb/in² gauge. Pressures are higher in the cooling coils such that contamination spread into the cooling water system would be minimized during a postulated coil leak.

Safety Considerations

The tempered water cooling system is classified as general service.
B2 5 8 3 Chilled Water System

Summary Description

The chilled water system is designed to serve the cooling loads of the HVAC systems and the tempered water cooling system. The chilled water system includes packaged chiller units, circulating pumps, and associated piping, instrumentation, and controls. See Figure B2-24 for the layout of the major components of the chilled water system in the mechanical room.

The chilled water system serves the cooling coils in the process bay recirculation HVAC supply systems, the process general supply/exhaust HVAC system, and the process heat exchanger for tempered water cooling. The chilled water system has two fully redundant pumps. Two-way control valves are used on each cooling coil distribution loop. The chilled water refrigeration subsystem is comprised of two partially redundant, split-system, air-cooled water chillers with remote condensing units. Each chiller has a dedicated primary pump, piped in parallel to provide standby protection. The refrigerant system incorporates a chiller sequencing controller, staged compressors, bypass flow line, and back pressure valves to accommodate varying chilled water demand. Two chillers operate via a common sequencing panel and each system circulates chilled water at a constant volumetric rate. Check valves restrict backflow of water and a safety relief valve directs excess water through a drain line to the floor for collection via the effluent drain system.

Safety Considerations

The chilled water system is classified as general service.

B2 5 8 4 Vacuum Purge System Chilled Water System

Summary Description

The VPS chilled water system is used to supply chilled water at design temperature and flow rate to the VPS condenser and to the VPS condenser rundown tank cooling jacket (see Figure B2-25). A flow control valve controls the flow of water without MCS intervention. The chilled source is a closed, water-propylene glycol loop. The chilled water supply for the VPS condensers is a dedicated, low-temperature chiller (one chiller package for the four process bays with no redundancy). This chiller is capable of supplying water to all condensers. The water is supplied to the process skids via flexible hoses.

Safety Considerations

The VPS chilled water system is classified as general service.
B2 5 9 Instrumentation and Control Systems

This section discusses the instrumentation and control systems for the CVDF. These systems consist of the following:

- MCS
- SCIC
- Automatic temperature control (ATC) (the ATC is the control system for the CVDF HVAC systems. It is described in Section B2 6 2 1)

B2 5 9 1 Monitoring and Control System

Summary Description

The MCS is the interface between the operators and the CVDF process systems. Its function is to provide active indication, alarm, and control of MCO processing and support functions throughout the facility. The MCS provides automatic operation of each phase of MCO processing and accepts operator commands and overrides. The system provides process values and status to the operators and shift manager in a graphical format. The MCS also monitors the utility systems, including radiation monitoring, stack monitoring, VPS chilled water, tempered water cooling, helium supply, and instrument air. The MCS interfaces with the following process systems in each of the process bays:

- VPS
- Tempered water (annulus) system
- PWC system
- General-service helium system
- Deionized water system

In addition, the MCS receives signals from the SCIC system and, under normal circumstances, is allowed to control MCO isolation valves used by the SCIC system. However, the MCS cannot override SCIC system commands. The MCS does not support, nor is it required to operate for, the SCIC system to perform its required functions.

The MCS consists of interactive computers, logic circuits, panels, cabinets, input/output modules, and the wiring up to but not including process sensors (e.g., pressure, temperature, flow). There are four networked computers, including two operator workstations and an engineering workstation in the control room (room 107 in the administrative building), and one workstation (with view access only) in the shift manager's office (room 103 in the administrative building). The main PLC control panel also is located in the control room and includes a local alarm with silence button. All central processing units are connected on a local area network, which allows simultaneous access to the control system from multiple displays.
controlled networked input/output modules are conveniently located in each of the active processing bays, mechanical room, and the process water tank room. The field-mounted remote input/output modules can be individually controlled from the central control room.

**Safety Considerations**

The MCS is classified as general service.

**B2 5 9 2 Safety-Class Instrumentation and Control System**

**Summary Description**

The SCIC system provides actuation logic, actuation signals, and control interfaces. The SCIC system includes all of the equipment, actuation logic, electrical cabinets, conduits and wiring, local indication of the system status, and remote alarms and controls for system operation and testing.

The SCIC system provides active detection and response to process anomalies. Specifically, actuation of the SCIC system performs two safety-class functions: (1) signal closure of isolation valves leading to and from the MCO to the process systems and signal opening of SChE system isolation valves to provide MCO purging and pressurization, and (2) removal of power from the tempered water heater. The SCIC system also provides safety-class alarms in the CVDF control room for low annulus water level and notification of an MCO isolation and SChE purge trip. An additional PWC prepurge and postpurge failure alarm is also provided by the SCIC system as a defense-in-depth feature.

To perform these functions, the SCIC system monitors process and seismic parameters, detects off-normal conditions, and removes power from relays to de-energize:

- MCO isolation and SChE valves
- Tempered water heater
- PWC circulating pumps

To perform the annunciator functions, the SCIC system provides the following alarms:

- MCO isolation and purge
- Annulus low level
- PWC purge low (not safety-class but defense in depth)

The SCIC system requires no operator action to detect and respond to process upsets within the SCIC system controls. However, operator action is necessary to set the SCIC mode switch to the appropriate mode to facilitate operations.
The SCIC system has three distinct functions under defined upset conditions, or a manual trip.

**Multi-Canister Overpack Isolation and Purge** An MCO isolation and purge trip places the effected bay into the following conditions: VPS, general-service helium, PWC isolation valves closed (MCO is isolated) and SCHe valves open (MCO is purged). The following parameters can cause an MCO isolation and purge trip:

- MCO pressure (both positive pressure and vacuum)
- Helium flow rate
- Process bay high temperature switches
- Seismic trips
- Timer and vacuum trips

The MCO pressure and helium purge rates are used to prevent explosive accumulations of hydrogen and oxygen. MCO high pressure specifically provides for a safety-class vent path from the MCO. MCO pressure is also used for the 8-4-4 vacuum limit timer. The process bay high temperature is used to protect against the effects of high bay temperature on the accuracies of the safety-class instrumentations. Separate temperature switches are provided that, if exceeded, will initiate the safety-class isolation and SCHe system purge.

A vacuum limit timer monitors the time under vacuum to limit heatup of the fuel. This vacuum condition reduces thermal conduction from the MCO. After the vacuum cycle, a minimum time above atmospheric pressure is required to cool down the fuel. The SCIC system ensures that exceeding the time under vacuum, or returning to vacuum without first meeting the minimum time above atmospheric pressure, will result in MCO isolation and SCHe purge.

**Removal of Excessive Heat Input to a Multi-Canister Overpack** The tempered water high temperature trips remove power from the water heater through the heater contactors.

**Safety-Class Annunciation to Control Room** The SCIC system provides safety-class alarms to the control room (room 107) for low annulus water level and MCO isolation and purge trip. In addition, alarms for PWC prepurge and postpurge failure are provided as a defense-in-depth feature.

**System Configuration**

The SCIC system consists of two logic trains and redundant instruments and control functions. There is a set of SCIC panels located in each process bay. One of the two panels contains a PLC that provides one of the two logic trains for that process bay. The other PLC for that process bay is located in the adjacent process bay. Redundant instruments and control functions are provided to the two SCIC logic trains A and B. The PLC in process bay 2 serves as train A for process bays 2 and 3. The process bay 3 controller serves process bays 2 and 3 as
A similar arrangement is used for process bays 4 and 5. The PLC performs the various setpoint comparisons and provides safety-related timing functions.

Separation is achieved per Institute of Electrical and Electronics Engineering requirements identified in Table B4-3. Each process bay has instrument racks and SCIC instrument panels for monitoring and control of train A and train B for that process bay. The instrumentation consists of the following capabilities in each process bay:

- A local manual ISO & PURGE button that isolates the MCO and activates the SCHe system (activation of either train A or B ISO & PURGE pushbutton will initiate a trip that will close one set of safety-class MCO isolation valves to sufficiently isolate the MCO and will activate the SCHe system, both ISO & PURGE buttons must be activated to provide MCO isolation by both safety-class valves in each process system line)
- ISO & PURGE trip reset button
- Trip status and indicator lights for BAY ISO & PURGE trip, tempered water high temperature trip, seismic trip, process bay high temperature trip, and cask annulus low level alarm status
- Tempered water high temperature trip reset button
- Logic test switches

In a similar manner, the CVDF control room has SCIC system train A and B control room panels for each bay with the following capabilities:

- SCIC mode selection panel with duplicate key switches for the following operation sequence selection: (1) BYPASS, (2) HEATUP, (3) DRAIN, (4) PURGE/FLUSH, (5) DRYING, (6) PROOF, and (7) PRESSURE TEST; the two panels in the control room have key switches for all operations in process bays 2 through 5
- An annunciator and control panel with large lighted alarms for BAY ISO & PURGE, ANNULUS LOW LEVEL, and PWC LOW FLOW, alarm test capability, alarm acknowledgment, and annulus low level alarm bypass switches, and ISO & PURGE buttons for MCO isolation and activation of the SCHe system for each of the process bays.

During cold vacuum drying processing of an MCO, the SCIC system is placed into the mode appropriate for each processing stage as shown in Figures B2-10 and B2-11. When the MCO is first received, the SCIC system is positioned in the (1) BYPASS mode while the cask headspace is being vented, the cask lid is being removed, the process hood seal ring assembly is being bolted on, and the two sealing bladders are being inflated. The tempered water (annulus)
The SCIC system is connected. The SCIC system is switched to the (2) HEATUP mode when the port connectors are attached and the MCO headspace is being vented. When water is to be removed from the MCO, the SCIC system switch is placed on the (3) DRAIN mode. The SCIC system switch is then positioned in the (4) PURGE/FLUSH mode to flush particulate from the drain line. When the MCO is to be evacuated for vacuum drying, the SCIC system is placed in (5) DRYING mode, and when the drying is completed and proof testing is to be performed, the mode switch is placed in the (6) PROOF position. After proof checking, the SCIC system is placed in the (7) PRESSURE TEST mode for the one-hour pressure rebound test and preparing the MCO for shipment. As a final step, the MCO port valves are closed and the MCO is prepared for shipment and then the SCIC system is placed in the (1) BYPASS mode. Each of these modes enables the SCIC system to monitor different sensors with setpoints and logic appropriate for that processing step. Redundant sensors located in the process systems provide inputs to the SCIC system as indicated below:

- MCO pressure, from the VPS
- Helium purge flow rates, from the general-service helium system
- Tempered water high temperature switches, from the tempered water (annulus) system
- Cask-MCO annulus water low level switches, from the tempered water (annulus) system
- Process bay temperature switches
- Seismic recorder and trip status integral to the SCIC

The seismic monitors will activate the SCIC system trip independent of the logic. The seismic monitors directly trip the SCIC system output relay, which actuates the SCHe system and MCO isolation valves. A seismic event will also trip the tempered water high temperature protection circuit that shuts down the tempered water heater. Loss of electric power will de-energize the SCIC system output relay, which will isolate the MCO, actuate the SCHe system, and cut power to the tempered water (annulus) system heater. Once a seismic trip is activated all other logic is circumvented and no longer has a safety-class function.

SCIC PLC functional tests or calibrations require the use of an SCIC calibration and test computer unit that will test logic functions and allow for detailed calibration functions. The calibration and test computer is part of the SCIC system but is not normally connected to the SCIC system PLC. The safety-class cabinets are bolted to the process bay floor to meet performance category 3 seismic requirements.

To ensure sufficient reliability of the seismic system and to reduce spurious trips, three independent sensors are located in separate process bays. In addition, two-out-of-three trip logic
Annex B — Cold Vacuum Drying Facility

The SCIC system also provides safety-class alarms in the control room. The SCIC system monitors the tempered water (annulus) system low level switch and activates an alarm that notifies the operators when the water level in the cask-MCO annulus is low. In addition, the SCIC system also monitors the tempered water high temperature switch and initiates a tempered water (annulus) system heater shutdown if the temperature exceeds the setpoint.

A diagram of the SCIC system boundary (the various inputs and their associated responses) is provided in Figure B2-26. The general layout for the SCIC and seismic shutdown systems is provided in Figure B2-27.

Safety Considerations

The SCIC system is a safety-class system.

B2 6 CONFINEMENT SYSTEMS

This section identifies and describes the functional and physical and operational features of the confinement systems that provide protection against release of liquid and airborne radioactive or hazardous material. The primary confinement feature consists of the stainless steel MCOs. The MCOs are transported to the CVDF inside a transportation cask that protects the MCO. The mechanically closed cask-MCO combination forms a confinement barrier during transportation and receipt. The primary confinement of airborne and liquid effluents from the spent fuel during processing in the CVDF is provided by the MCO and isolation piping.

The process bays, the process water tank room, and surrounding rooms use HEPA-filtered exhaust systems to maintain appropriate building ventilation zone pressures such that air-flow is from less to more potentially contaminated areas. Secondary confinement is provided by the process bay local exhaust HVAC and process vent system and the building structures, in conjunction with the process general supply/exhaust HVAC system. The process general supply/exhaust HVAC system along with the process bay local exhaust HVAC and process vent system provide differential pressure for the CVDF process bay area, process support area, and process water tank room.

The administrative building has no confinement function and is ventilated for personnel comfort and air quality. The building is maintained at a positive pressure with respect to
atmosphere to preclude inadvertent air flow from process areas that are maintained at negative pressure

B2 6.1 Confinement Approach

The MCO and isolation piping of the cold vacuum drying processing systems form the primary confinement boundary during processing. The MCO is connected through three process lines to the VPS, general-service helium system, deionized water system, and PWC system process equipment. The pipes and valves that make up the isolation piping of the cold vacuum drying process systems form the physical boundary that isolates the MCO contents from the secondary confinement. All equipment exhausts and vents are directed through the process bay local exhaust HVAC and process vent system. Any leaks from the MCO or from the process equipment will be into the process bay or process water tank room.

The process bay local exhaust HVAC and process vent system provides secondary confinement at the top of the MCO with an open face process hood and filters all contaminated air flows from the process hoods, process vents from the VPS and tempered water (annulus) system, cask venting, and the SCHe system prior to discharge from the CVDF. During normal operation, secondary confinement is provided with a differential pressure established by the process general supply/exhaust HVAC system. Each process bay recirculating supply system is automatically controlled individually to adjust temperature and differential pressure of each bay by the ATC system.

The cask-MCO annulus is physically isolated from the MCO interior. The tempered water circulating in the cask-MCO annulus could be contaminated from the K Basins water. Therefore, the tempered water (annulus) system could also be contaminated. At the top of the MCO, a pressurized isolation barrier (MCO-cask seal ring assembly) between the cask and the MCO isolates the water in the cask annulus from the atmosphere in the process bay. The inflatable seals (barrier) are pressurized with a connection to the instrument air supply. There are two connections from the cask annulus to the tempered water (annulus) system. The cask-MCO forms a physical boundary for the cask annulus water. The tempered water (annulus) system pipes, valves, pumps, and heat exchangers form the physical boundary isolating the cask annulus water from the process bay. All equipment exhausts and vents are directed through the process bay local exhaust HVAC and process vent system. The system design isolates and controls releases of water from the cask annulus. Any releases from the cask annulus, or from the tempered water (annulus) system will be into the process bay confinement area (process bay local exhaust HVAC and process vent system, process bay recirculation HVAC system, process general supply/exhaust HVAC system, and/or floor sump and drain).

Contaminated process water removed from the MCO during processing is pumped to the process water receiver tank located in the process water tank room (room 132). Access to the room is via a change room (room 130). The process water tank room is maintained at a negative pressure via the process general supply/exhaust HVAC system. The piping from each process bay
to the receiver tank and the tank itself form a confinement boundary for the contaminated liquid. The piping is routed through each process bay to where it enters the process water tank room. All piping runs are within the confinement of the process bays or the process water tank room. The process water storage tank vent is HEPA filtered through a breather filter back to the process water tank room. The PWC system receiver tanks are vented to the process bay local exhaust HVAC and process vent system.

Liquid spills within each process bay will be confined in the sump in each process bay.

The process water tank room is designed as a liquid retention basin to contain all the water from the PWC system (e.g., tanks, piping, valves) in case of a leak or spill.

Liquid process confinement systems and the VPS were discussed in Section B2.5 HVAC confinement systems are discussed in the following subsections.

**B2.6.2 Heating, Ventilation, and Air Conditioning Systems**

Two HVAC systems (i.e., process bay local exhaust HVAC and process vent system and process general supply/exhaust HVAC system) provide airborne radioactive material confinement within the radiologically controlled areas of the CVDF and provide HEPA-filtered discharge via the CVDF stack. Each process bay also has an independent process bay recirculation HVAC system that provides outside air supply and HEPA-filtered recirculation for heating and air-conditioning. The humidity is monitored in all HEPA-filtered ventilation systems, and a humidity sensor alarms in the control room on high humidity. The CVDF administrative building has an independent supply and exhaust HVAC system that operates at a positive pressure to preclude inleakage from outside or adjacent areas. Figure B2-28 shows a composite flow diagram of the HVAC systems. A layout of the major components of the process bay recirculation HVAC system and process general supply/exhaust HVAC system is provided in Figure B2-29.

All exhaust systems are functioning during normal operation. Monitoring of the differential pressure facilitates maintaining confinement in the facility except when the telescoping door to a process bay is opened. If a telescoping door is open (e.g., when an MCO is being received or shipped out), the process bay recirculation HVAC system inlet damper is closed to increase flow through the doorway.

The HVAC systems utilize isolation dampers to stop the flow of air to maintain confinement within the facility and preclude cross-contamination between areas during upset conditions.
Process General Supply/Exhaust Heating, Ventilation, and Air Conditioning System

Isolation  The process general supply/exhaust HVAC system is isolated during any of the following events:

- Upon failure of the HVAC general supply fan, the general supply air isolation damper is hard-wired to close. The general exhaust fan continues to operate.

- If the HVAC general supply air temperature sensor detects a temperature of 4 °C (40 °F), then the general supply fan stops and the general supply air isolation damper closes. The general exhaust fan continues to operate.

- Upon detection of smoke at the supply air duct smoke detector, the general supply fan will turn off and the supply air isolation damper will close. The general exhaust fan continues to operate.

- The process general supply/exhaust HVAC system inlet isolation dampers will close on loss of power or instrument air. This is to preclude backflow out the inlet ducts which are not HEPA-filtered.

- The process general exhaust isolation dampers in each bay will close on a loss of power or instrument air. This is to maintain confinement in the process bays. These dampers also close upon a fire alarm in each bay.

Process Bay Recirculation Heating, Ventilation, and Air Conditioning System

Isolation  The process bay recirculation HVAC system is isolated during any of the following events:

- Upon sensing the personnel door or roll-up door position is open, the ATC closes the supply outside inlet air isolation damper for the affected process bay. Upon closure of either door, the outside inlet air isolation damper opens. The unaffected process bays continue to operate with no intervention.

- Upon detection of smoke at the supply duct smoke detector, the supply fan will turn off and the outside inlet air damper will close. The unaffected bays continue to operate. The general and local exhaust fans continue to operate with no intervention.

Process Bay Local Exhaust and Process Vent System Isolation  The process hood isolation dampers fail closed. The hood isolation dampers are provided with an instrument air reservoir for operation on standby power. Fire alarms in each bay will close the process hood isolation damper.
B2 6 2 1 Automatic Temperature Control System  The ATC system is capable of integrating multiple building functions including equipment supervision and control, alarm management, energy management, and historical data collection and archiving.

The ATC system is a control network composed of two levels of control (1) operator workstations and (2) application-specific PLCs. A local network utilizes a dual independent media network for critical data transfer and control between the redundant operator workstations and PLCs.

Two operator workstations are provided. One is in the control room (room 107) and one is in the mechanical room (room 207). The workstation in the mechanical room is the ATC system main control panel. The ATC system main control panel contains two PLCs (one primary and one secondary) that operate as redundant controllers. Only the primary PLC controls the I/O; however, if the primary PLC fails or is placed offline, the secondary PLC asserts control of the system without operator action to ensure continued system operation. The PLCs contain the system control program logic for all software interlocks, relationships, and actions. Control parameter manipulation for system operation is accessed via the operator workstations at either the control room (room 107) or the ATC system main control panel (room 207), or portable PC connections. Because all control is maintained at the PLC level, control is not dependent on either operator workstation for operation. The operator workstations enable control parameter manipulation, system monitoring, and data archiving.

A differential pressure alarm panel is located in the control room (room 107) where it provides continuous, independent monitoring of the differential pressure in each process bay (including process bay 1) and the process water tank room. A dedicated circuit from the facility uninterruptible power supply (UPS) panel (see Section B2 6 2 4 for discussion of the UPS system) supplies 120 VAC to the differential pressure alarm panel.

In the event of loss of normal power, the PLCs are powered by the UPS and undergo an orderly shutdown to prevent the loss of database or operating system software. Upon restoration of normal power, the PLCs automatically resume full operation without manual intervention.

Safety Considerations

The ATC system has been classified general service. The ATC system is relied upon for normal operation of the ventilation confinement systems. It is not required during operation of the process bay local exhaust HVAC and process vent system on standby power.

B2 6 2 2 Administrative Building Heating, Ventilation, and Air Conditioning System

Summary Description

The administrative building HVAC system maintains indoor space temperatures. The temperature is actively controlled by the administrative building ATC system. The system
maintains the space pressure of the administrative building positive with respect to change rooms, toilet rooms, the adjacent process areas of the facility, and the outside. The administrative building HVAC system uses two units: (1) a packaged heat pump unit located outdoors on a concrete mounting pad to the west of the building, and (2) an air conditioning and evaporation unit that supplies conditioned air to the electrical/communications room (room 108).

The heat pump air handling unit services all rooms within the administrative building excluding the electrical/communications room. Air is recirculated in this system with a minimum of makeup air to maintain air quality and provide air supply for the change room and shower area exhaust system (per ASHRAE-62). Air from the change room and shower areas is exhausted directly to the outside and is not recirculated. To prevent possible contamination, air in the corridor connecting the administrative building (corridor 115) to the transfer corridor of the process building (corridor 116) is not recirculated but is directed toward the transfer corridor (which is exhausted by the HEPA-filtered general exhaust system).

**Safety Considerations**

The administrative building HVAC system does not serve any safety functions and is classified as general service. Differential pressure monitoring and alarms for upset conditions are provided between the administrative building and the process area to ensure the correct direction of air flow. The control room is not required to be manned after DBAs, therefore, the supply ventilation is not provided with HEPA filtration.

**B2 6 2 3 Process Bay Recirculation Heating, Ventilation, and Air Conditioning System**

**Summary Description**

A majority of the process bay air is recirculated to conserve energy. The supply and return air passes through a prefilter and two HEPA filter stages to control airborne contamination. Makeup air is supplied, as required, to maintain air quality in the process bay and modulated to maintain differential pressure in the process bay. Each process bay air intake duct is provided with a pneumatic isolation damper, volume damper, and backdraft damper to prevent backflow of air to the outside. The outside air louver is provided with a mesh screen. The mix of outside air and interior air flow rates is controlled by dampers and can be adjusted to meet airflow and differential pressure requirements. Alarm and monitoring of all HVAC functions is provided by the ATC system in the control room and in the mechanical room.

The process bay recirculation HVAC system is sized to supply air to the process bays at a minimum rate of six air changes per hour. Outside air supply to maintain air quality is provided to each process bay. Normal process bay temperatures are maintained at a maximum of 25.5 °C (78 °F) in cooling mode and a minimum of 22.2 °C (72 °F) in heating mode. The temperature is actively controlled by the ATC system. Instrumentation is provided for detection of smoke in accordance with NFPA 90A, *Standard for the Installation of Air Conditioning and Ventilating Systems*, and for controlling space temperature. Equipment and ductwork that make up the...
process bay recirculation HVAC system is supported and anchored in accordance with the requirements necessary to meet the criteria of performance category 2 construction. All ductwork for the process bay recirculation HVAC system is fabricated of galvanized steel.

**Safety Considerations**

The process bay recirculation HVAC system is classified as general service. The pneumatic isolation damper at the air inlet is safety significant. The system continuously removes dust and airborne radioactive particulate, if present, from the air within the process bays, thereby limiting levels of airborne radioactive contamination within the process bays to acceptable levels during normal operations. The process bay recirculation HVAC system is designed and qualified for performance category 2, as defined in DOE-STD-1020-94. The process bay recirculation HVAC system does not discharge exhaust air to the environment. A backdraft damper is provided on the outside air inlet to prevent airflow reversal to the outside. The volume damper is modulated by the ATC system to maintain differential pressure in the process bays. The pneumatic isolation damper at the air inlet is safety significant and fails closed on loss of normal power. On standby power the process bay local exhaust maintains the differential pressure in the process bays.

**B2 6 2 4 Process Bay Local Exhaust Heating, Ventilation, and Air Conditioning and Process Vent System**

**Summary Description**

Each process bay contains a branch of the process bay local exhaust HVAC and process vent system. This system serves the MCO process hood and the process vent streams that may normally be contaminated (e.g., vacuum pump exhaust, VPS condenser tank vents, tempered water [annulus] system tank vents, SCHe discharges and the 30 lb/in² rupture disk).

The process bay local exhaust HVAC system is designed for the following functions:

- Maintain sufficient differential pressure in the process bays during normal operations to confine any airborne radionuclides within the CVDF ventilation systems and associated confinement structures. A differential pressure shall also be maintained following a loss of normal electrical power via support of the standby power system (see Section B2 8 5) when other ventilation systems are not operable. The system shall also prevent overpressurization of the exhaust ductwork following a loss of power, instrument air, or other offnormal conditions.

- Maintain a minimum dilution airflow rate to preclude potentially flammable concentrations of hydrogen within the process bay local exhaust HVAC system. A minimum flow rate of 1,000 ft³/min maintains a nonflammable concentration in the local exhaust duct.
Prevent accumulation and transportation of water that could migrate into other vent lines or damage equipment or components including HEPA filters.

Isolate the vent path from the cask vent or MCO vent at loss of electrical power. During cask or MCO venting, dilution of flammable mixtures transported to the exhaust duct is controlled by a flow switch located in the local exhaust duct. When the flow drops below the setpoint, the vent path is isolated via a solenoid valve from the duct. After reestablishing the flow rate, the vent path to the local exhaust can be opened.

Pneumatic isolation dampers are provided on the duct connecting to the process bay process hood. The process vents are open to the HEPA filters during operation and in the event the system shuts down. Two 100% capacity exhaust fans (located in the mechanical room) are provided for the process bay local exhaust HVAC and process vent system. The air in this system passes through an air handling unit (located in the mechanical equipment room) containing a prefilter and two HEPA filter stages before exhausting through the CVDF stack. Each stage of filtration is actively monitored for pressure drop through the use of pressure differential switches. The system has low flow switches on each process bay duct branch that provide alarm of system upset. Lead and standby local exhaust fans are monitored through individual pressure differential indicating switches. The exhaust fans' variable frequency motor drives provide constant volume with HEPA filter differential pressure increase and speed indication and general alarm inputs to the ATC system. If the lead local exhaust fan fails to start or fails during operation, an alarm is given at the control room and the stand-by local exhaust fan automatically starts. The ATC system is located in the CVDF control room and the mechanical room, where alarm and monitoring of all HVAC functions is provided.

A standby power system, conforming to the applicable general electric supply requirements of DOE Order 6430 1A and the NFPA 70, National Electrical Code, is available to support the CVDF hydrogen mitigation strategy. The standby power system supports the local exhaust system functions of maintaining adequate differential pressure for confinement in the process bays and reestablishing the minimum airflow rate as required for hydrogen dilution in the local exhaust system ductwork during a loss of normal electric power. The isolation dampers fail closed upon loss of electrical power, and each damper is provided an 8 3-gal compressed-air reservoir to operate the damper during standby power operation. Additional details on the standby power system is provided in Section B2 8.5.

The process bay local exhaust HVAC and process vent system process hoods effectively capture airborne contamination at its source by achieving a capture velocity of 125 ft/min at the top of the MCO in accordance with DOE Order 6430 1A and ACGIH Industrial Ventilation Manual hood design (ACGIH 1998).

Equipment and ductwork that make up the process bay local exhaust HVAC and process vent system are supported and anchored in accordance with the requirements necessary to meet...
the criteria of performance category 2 construction. All ductwork for this exhaust system is fabricated of stainless steel and is of welded flange construction.

Manual isolation dampers allow for isolation of individual exhaust fans. Exhaust fan discharge backdraft dampers are provided after the exhaust fans to prevent airflow reversal. Process hood isolation dampers fail closed.

The following process vent sources are routed as separate lines to the process bay local exhaust HVAC system ductwork because they are expected to be contaminated or contain potentially flammable concentrations of hydrogen, oxygen (air), or hydrogen and oxygen at various times:

- SCHe vent lines (expected to contain hydrogen)
- Tempered water tank vent line (expected to contain oxygen)
- Cask lid vent line (expected to contain both hydrogen and oxygen at different times)
- Vacuum pump discharge line (expected to contain both hydrogen and oxygen at different times)
- PWC receiver tank vent line (expected to contain both hydrogen and oxygen at different times)

**Safety Considerations**

The process bay local exhaust HVAC and process vent system process vent is classified as safety significant and is designed to provide sufficient airflow to dilute the potential hydrogen releases to nonflammable concentrations. This exhaust system provides this function for cold vacuum drying normal operation and designated accident conditions.

The process bay local exhaust HVAC and process vent system maintains a negative differential pressure in the process bays and captures and removes airborne contamination during normal operation and during certain mitigated accident scenarios described in Chapter B3. The system uses HEPA filters to remove the particulate contaminants from the exhaust stream prior to discharging the exhaust air to the environment via an exhaust stack.

**B2 6 2 5 Process General Supply/Exhaust Heating, Ventilation, and Air Conditioning System**

**Summary Description**

The process general supply/exhaust HVAC system is sized to supply air to the support confinement areas at a minimum rate of six air changes per hour. System capacity can maintain...
spaces at a maximum of 25.5 °C (78 °F) in cooling mode and a minimum of 22.2 °C (72 °F) in heating mode. Instrumentation is provided for detection of smoke in accordance with NFPA 90A and for controlling room temperatures. Room differential pressures are to be maintained at design values that will promote air flow within the CVDF from areas of lower potential contamination to areas of higher potential contamination. Pneumatic isolation dampers are provided on all duct branches connecting to the general process supply/exhaust HVAC system to prevent backflow in the event of exhaust system shutdown. Equipment and ductwork that make up the process general supply/exhaust HVAC system are supported and anchored in accordance with the requirements necessary to meet the criteria of performance category 2 construction. All ductwork for the process general supply/exhaust HVAC system is fabricated of galvanized steel.

The transfer corridor, associated support rooms, the process water tank room, and the mechanical room are supplied with conditioned air from the process general supply HVAC system. The air in this system is not recirculated. Pneumatic isolation dampers are provided on the outside air intake and tank room supply duct to prevent backflow of air in the event of system shutdown.

Air is also supplied to the process bays from the transfer corridor. Air enters into the process bays through transfer grills equipped with backdraft dampers from the process bay change rooms (rooms 118, 121, 124, 127, and 130). The backdraft dampers close on loss of air flow. Process general exhaust isolation dampers are provided at each process bay and fail closed upon facility loss of electrical power or loss of instrument air. Closure of the dampers enables the process bay local exhaust HVAC and process vent system operating on standby power to maintain differential pressure in the process bays and preclude backflow and communication among the process bays and the transfer corridor.

The process general supply/exhaust HVAC system provides exhaust air flow to maintain a negative pressure differential in the process bays and process water tank room with respect to all other areas external to the bays (the process water tank room has a lower differential pressure than the process bays). Air from the transfer corridor, associated support rooms, the process water tank room, the mechanical room, and the four process bays with process equipment skids is exhausted into the process general exhaust HVAC system. Fail closed pneumatic isolation dampers are provided on all duct branches connecting to the process general exhaust HVAC system to prevent backflow in the event of exhaust system shutdown. Two 100% capacity exhaust fans are provided for the process general exhaust HVAC system. The air in the system passes through an air handling unit in the mechanical room. The air handling unit contains a prefiltter and two HEPA filter stages that are used to filter the exhaust air before exhausting through the stack. Each stage of filtration is actively monitored for pressure drop through the use of differential pressure instruments. Lead and standby general exhaust fans are monitored through individual differential pressure indicating transmitters. The exhaust fans have variable frequency motor drives to provide constant air flow volume with HEPA filtration differential pressure increase speed indication and general alarm inputs to the control station. If the lead general exhaust fan fails to start or fails during operation, an alarm is given at the control station and the stand-by general exhaust fan automatically starts. The ATC system is located in the control room.
and the mechanical room where alarm and monitoring of all HVAC functions is provided. The airflow through the process general supply/exhaust HVAC system is normally uncontaminated. Only during upset conditions (i.e., accidents) would radioactive contamination be vented by the general exhaust system. Such conditions include releases into a process bay or the process water tank room. For these conditions, the process general supply/exhaust HVAC system mitigates releases from the CVDF.

Manual isolation dampers allow for isolation of individual exhaust fans. Exhaust fan discharge backdraft dampers are provided after the exhaust fans to prevent airflow reversal.

**Safety Considerations**

Portions of the process general supply/exhaust HVAC system are classified as safety significant for accident mitigation, as discussed in Chapter B3.0. Exhaust air is HEPA filtered to remove radioactive particulate contamination prior to being discharged to the environment via the exhaust stack.

**B2.6.2.6 Reference Air System**

**Summary Description**

The reference air system provides capability for continuous monitoring of the differential pressure, relative to atmospheric pressure, of various spaces throughout the CVDF. The reference air pipe header is fabricated of copper tubing. The ATC provides general service visual indication and alarms in the control room for out-of-tolerance differential pressure conditions throughout the facility. A differential pressure alarm in the control room provides safety-significant differential pressure indication and alarms for the process bays and process water tank room. Piping and instruments that make up the reference air system are supported in accordance with the requirements necessary to meet the criteria of performance category 2 construction.

The process bays and the PWC system tank room are maintained at a negative pressure with respect to atmosphere and to the remainder of the CVDF by the process bay local exhaust HVAC system and the process general supply/exhaust HVAC system with the differential pressure controlled by the ATC system. The reference air system consists of a series of static differential pressure indicating transmitters, located throughout the CVDF, that are interconnected by copper tubing. The reference pressure is measured by a static pressure sensor located above the administrative building roof. Pressure differential is indicated locally with magnehelic gauges in the process water tank room (room 132), in the transfer corridor and access rooms (corridor 116 and rooms 117, 118, 121, 123, 124, 126, 127, 129, and 130), in the process bays in the mechanical equipment room (room 207), and the administrative building access corridor (corridor 115). The ATC system monitors all differential air pressures.
Safety Considerations

The reference air system is classified as safety significant and provides differential pressure instrumentation relative to the atmosphere for various spaces throughout the facility. The differential pressure indicates whether the HVAC confinement systems are functioning properly.

B2.7 SAFETY SUPPORT SYSTEMS

This section identifies and describes the principal systems that perform safety support functions. The descriptions include the purpose, a summary description, principal components operations, control functions, and safety considerations.

B2.7.1 Monitoring Systems

There are two personnel monitoring systems: the radiation monitoring system, which consists of area radiation monitors (ARMs) and continuous air monitors (CAMs), and the room air quality monitoring system, which provides oxygen monitors. The stack monitoring system is also discussed below.

B2.7.1.1 Radiation Monitoring System

Summary Description

The radiation monitoring system provides radiological monitoring for radiation exposure levels and airborne radioactivity levels in order to identify personnel hazards, enhance worker safety, characterize workplace conditions, and verify effectiveness of physical design features and administrative controls. The radiation monitoring system conforms to the requirements of 10 CFR 835 and HSRCM-1, Hanford Site Radiological Control Manual. Additional CVDF radiological design requirements are provided by the following:

- The optimization principles as discussed in ICRP Publication 37, Cost-Benefit Analysis in the Optimization of Radiation Protection
- External exposure limitations identified by HSRCM-1
- ALARA principles (including the ALARA recommendations presented in NRC Regulatory Guide 8.8)

ARMs are provided to monitor medium- to high-energy gamma field levels within and outside the process bays and within the routinely occupied areas and restricted access areas in the CVDF. CAMs are provided to monitor alpha and beta-gamma radiation levels within and outside of the process bays and within routinely occupied or restricted access areas. Personnel
Contamination monitors are provided at strategic points to/from the process area for personnel monitoring and contamination control. ARMs (gamma) are located in each process bay (two per bay in bays 2 through 5, one in bay 1) and the process water tank room (one). The gamma monitor in the process water tank room is installed on or adjacent to the PWC receiver tanks to detect fissionable material buildup from the MCO.

Air sampling equipment is located in the vicinity of workers to provide an indication of the airborne radioactivity levels to which the workers are exposed. In addition to record samplers located near work stations, CAMs are provided to monitor airborne contamination levels within the CVDF to detect alpha, beta, and gamma radioactivity levels within routinely occupied and restricted access areas. Alpha CAMs are separate units from beta-gamma CAMs but are provided in pairs. Two pairs of CAMs (alpha and beta-gamma) are located in each process bay (one pair on the floor and one pair on the mezzanine), one pair in bay 1, one pair in the process water tank room, one pair in the transfer corridor, and one pair in the mechanical room (room 207).

Automated personnel contamination monitors are provided for personnel monitoring and contamination control in addition to portable instruments at commonly used egress points from the process areas. These devices include beta and gamma detection (with some capability for alpha). Six portal monitors are provided for personnel contamination monitoring. One walk-in monitor located at each process bay access vestibule including bay 1 (access to the process water tank room is controlled through the bay 1 process bay access vestibule), and one walk-through monitor located at the exit from the transfer corridor to the main change rooms (room 115).

Additional air monitoring for radioactivity is provided by fixed-head record samplers that are cart mounted and typically positioned adjacent to the CAMs. This equipment collects airborne particulate on a filter that is periodically removed for later analysis and replaced in accordance with radiological procedures.

All ARMs, CAMs, and personnel contamination monitors provide local indication of contamination levels. The ARMs and CAMs are also interfaced with the CVDF MCS. Remote indications and alarms will be displayed at the operations control room and a remote alarm in the radiological control technician room.

_Safety Considerations_

The radiation monitoring system is classified as a general-service system that is provided for protection of facility workers from exposure to radiation and radioactive contamination associated with operation of cold vacuum drying processes.
B2 7 1 2 Room Air Quality Monitoring System

Summary Description

The CVDF process bays and the PWC room (room 132) contain processing equipment. Because there is the possibility of introducing, through accident or equipment failure, inert gas (helium) into these rooms, it is possible that an oxygen deficient atmosphere might occur within these locations. Worker safety can be compromised if the oxygen content of the atmosphere within an enclosed room is deficient. The air quality monitoring system monitors the processing areas (bays 2 through 5) and the process water tank room for unsafe low-oxygen atmosphere content. Eight sensors are provided in each bay and four are located in the PWC room. There is one controller for each group of four sensors. Alarms are located in the transfer corridor adjacent to each process bay. Process water tank room alarms are located within the room and in the transfer corridor adjacent to room 130.

Safety Considerations

The room air quality monitoring system is classified as general service and provides for personnel protection against low oxygen atmospheres during cold vacuum drying processing.

B2 7 1 3 Stack Monitoring System

Summary Description

The stack monitoring system is a microprocessor-based particulate and iodine monitor and particulate and iodine collector mounted in a two-component, open-frame skid and cabinet assembly with a sample probe subassembly. The system consists of an active monitoring train and a record sampling train. The primary purpose of the record sampling train is to collect particulate and iodine effluent on fixed media for later laboratory analysis and documentation of emissions. The active monitoring train is designed to monitor real-time alpha and beta particulate and ¹²⁹I gamma radiation effluent in the CVDF HVAC ventilation exhaust stack. The iodine monitor is not required for safety purposes at the CVDF. It is part of a standard monitoring system purchased for use at the Hanford Site. The system provides warning of offnormal emissions. Visual digital and local alarm indications and contact output for remote alarms are provided for high radiation and common failure conditions. Analog and digital outputs are provided to the MCS. The following is provided by the stack monitoring system to the MCS:

- Stack flow rate
- Stack gas temperature
- Individual sampler and monitor flow rate and temperature
- Radiation indication for alpha, beta, and iodine
- High-radiation alarm (alpha, beta, or iodine)
- Common failure alarm
- Other monitor function indications and readouts as appropriate
A computer data logging system is provided to record monitored functions.

The stack monitor skid is located in the CVDF mechanical equipment room near the exhaust stack. Piping to and from the stack to the skid is routed in a structural steel support assembly. The system receives power from the facility UPS following loss of normal power (see Section B2.7.4 for a description of the UPS system).

A shrouded probe is used for stack sampling in accordance with the requirements of ANSI N13.1, Sampling and Monitoring Releases of Airborne Radioactive Substances from the Stacks and Ducts in Nuclear Facilities.

The stack monitoring system provides an online indication of alpha- and beta-emitting particles and gamma-emitting $^{129}$I, as well as continuous record sampling for radioactive particles. Standard, approved, record sampling techniques are provided to identify and determine the concentration of various isotopes (e.g., $^{238}$Pu, $^{239/240}$Pu, $^{241}$Pu, $^{241}$Am, $^{137}$Cs and $^{90}$Sr). The stack monitoring system meets the requirements of WAC 246-247, “Radiation Protection—Air Emissions,” DOE Order 6430 1A (Section 1589-99 01), and ANSI N13.1.

Safety Considerations

The stack monitoring system is considered general service and continuously monitors effluent releases to the environment through the CVDF stack. Alarms will initiate response actions, but these actions are not credited in Chapter B3 0 accident analyses.
Summary Description

The fire protection system provides fire detection, suppression, and loss limitation for the CVDF structure, personnel, and processing equipment.

The fire alarm system was designed and installed in accordance with NFPA 72, National Fire Alarm Code. Fire alarm signals are transmitted to the Hanford Fire Department via a radio fire alarm reporter. Annunciation of local building fire alarms and shutdown of appropriate HVAC supply fans are initiated upon receipt of a fire alarm. Manual pull stations are provided at emergency exits. Fire alarm annunciating devices (audible and visible) are provided for occupant notification.

The facility is automatically monitored for fire and smoke by ionization-type smoke detectors. Automatic sprinkler protection has been provided throughout the facility in accordance with NFPA 13, Installation of Sprinkler Systems. The operations support area is designed for ordinary hazard group 1 occupancy while the process bays and process bay support area are designed for ordinary hazard group 2 occupancy. Water is provided to the CVDF sprinkler system via a new 6-in line tapped off a new 8-in line looped around the facility. The loop is connected to the existing service water system at Building 165KW via an 8-in line. The water supply, as demonstrated by water flow testing, is adequate to meet the sprinkler system design flow and pressure demand plus a margin in excess of 10%. Fire hydrants are located just outside of the CVDF, one at the northwest corner and the other at the southeast corner. The facility design is such that no hose lay is greater than 275 ft.

All fire protection system valves, components, instrumentation, and controls required to perform fire detection and suppression functions are designated general service and are designed and qualified for seismic performance category 1 as defined in DOE-STD-1020-94. The pipe supports for those portions of the system that, upon failure, could impact the performance and function of safety-significant or safety-class equipment are designed and qualified for performance category 2, as defined in DOE-STD-1020-94. Portable fire extinguishers of the appropriate size and class are located in the CVDF in accordance with the criteria of NFPA 10, Standard for Portable Fire Extinguishers.

Safety Considerations

The CVDF is of noncombustible construction except for the built-up roof over the process bay area. The installed roof assembly is a membrane roof with 4 in. of rigid insulation that is adhered to the welded steel plate deck. The roof is considered by the fire hazard analysis, SNF-4268, Fire Hazard Analysis for the Cold Vacuum Drying Facility, to be a combustible roof that will support combustion. The wall between the administrative building and the process support area is a 2-hour fire-rated wall. The wall between the administrative building and process bay has fire resistance equivalent to a 2-hour fire-rated wall. The construction specification for
the interior finish meets the flame spread and smoke development criteria as required in NFPA 101 and the floors meet the critical radiation flux criterion required by NFPA 101.

The HVAC system is provided with fire screens and rate-compensated thermal detectors ahead of the filter housings. The HVAC system is designed to shut down upon detection of a fire. Upon receipt of an alarm from the detectors, the system closes the appropriate isolation dampers to that process bay and shuts down the respective process bay recirculation HVAC system fan.

Deviations from fire protection criteria are identified in Chapter B110 and in the fire hazard analysis (SNF-4268). Suggested actions for the deviations are documented in SNF-4942, *Spent Nuclear Fuel Cold Vacuum Drying Facility Implementation Plan for Fire Hazard Analysis Suggested Actions*.

### B2 7.3 Criticality Protection

The cask-MCO physical configuration has been analyzed to assure criticality control is accomplished by passive geometry control. Refer to Chapter B60 for additional discussion.

The process water removed from the MCO may contain fissionable materials from metallic uranium corrosion. The analysis in Chapter B60 shows that for all normal operations and for accident conditions that satisfy the double contingency criterion, the equipment in the CVDF handling the process water from the MCO meets the acceptance criteria when the limits and guidelines are met. The limits, controls, and engineering features are further described in Chapter B60.

The designed criticality prevention features in the CVDF are the receiver tanks and the IXMs in the process water tank room. This is the only equipment where fissionable materials could accumulate in the facility in significant quantities. The tanks and the IXMs are critically favorable by design, in that their physical geometries preclude a criticality event even though the amount of fissionable material that could accumulate in the equipment is too small to present a criticality hazard.

### B2 8 UTILITY DISTRIBUTION SYSTEMS

#### B2 8.1 Electrical Power Distribution System

*Summary Description*

The electrical power distribution system provides electrical power distribution for the CVDF, equipment, and instruments as required. Normal power is provided with a grounding system to ensure safety to personnel and equipment, to provide a connection to earth for
transformer neutrals, to provide a discharge path to ground through lightning and surge arresters, and to provide a reference point for electronic systems.

The electrical power distribution system design includes the extension of an overhead 13.8-kV primary circuit from existing poles at a point adjacent to the CVDF site. The existing circuit is extended and routed overhead to a point near the south edge of the construction site. Lightning arresters and fused cutouts are provided on the last pole to provide power to a 1,500 kVA, 13.9 kV/480Y-277 volt pad-mounted transformer via an underground feeder installed in the concrete encased duct-bank. The primary underground feeder cable is rated at 15 kV. Also, outdoor type potential transformers, current transformers, and the metering cabinet are provided at the last pole for the energy monitoring and providing input to the electrical utilities field data acquisition system. A simplified one-line diagram of the electrical power distribution system is provided in Figure B2-30.

All underground primary conduit is concrete encased and buried a minimum of 2 ft below finished grade. The backfill is done in 6-in layers with each layer compacted to 95% of maximum density. A conduit marking tape is provided above the underground conduit route at a depth of 1 ft below finished grade.

A less-flammable oil filled, 13,800-480Y/277 V, 1,500 kVA, pad-mounted, self-cooled, transformer is located on the southwest side of the CVDF. The transformer is in accordance with requirements from IEEE C57, IEEE Standards Collection Distribution Power and Regulating Transformers, and is provided with backup current limiting fuses, no-load tap changer, pressure control valve, and devices to indicate oil temperature, pressure, and liquid level. Secondary power of the transformer is routed to a 480-V switchboard located inside the CVDF electrical room (part of office area) through underground feeders installed in a duct-bank.

Power is distributed by a free-standing, metal-enclosed switchboard. Phase, neutral, and ground bussing are provided. Switchboard main and feeder circuit breakers have adjustable solid-state trip units responsive to long-time, short-time, instantaneous, and ground-fault current characteristics. Power from the switchboard is distributed to 480 V distribution panels located in each bay, a motor control center in the mechanical room, 75 kVA distribution transformer in the electrical room, 30 kVA UPS transformer, and selected HVAC loads.

Motor loads that are not part of prepackaged equipment are powered from a 480-V, 3-phase motor control center located in the mechanical room. The motor control center is freestanding and metal enclosed with modular plug-in combination motor controllers. Assembly and wiring complies with the National Electrical Manufacturer's Association ICS Standards Type II-C and Underwriters Laboratories standards. All wiring is extended to terminal compartments for ready access. Controllers are National Electrical Manufacturer's Association-rated.

Panel boards for power distribution, lighting, receptacles, and small loads are constructed in accordance with National Electrical Manufacturers Association and Underwriters Laboratories.
Main circuit breakers are provided in panel boards. Panel board circuit breakers are the molded case bolt-on type.

120-V duplex receptacles are provided around the inside perimeter of the process bays. Ground-fault circuit interrupting type receptacles are provided for the receptacles located within 5 ft, 0 in. of wet surfaces and sinks, as required by NFPA 70. Ground-fault circuit interrupting circuit breakers are provided for receptacles located in bays 1 through 5 and the tank room because of the decontamination activities in those areas. The administrative building is provided with 120-V duplex receptacles. Appropriate receptacles are provided for cord-connected equipment such as lunchroom equipment, computer equipment, and radiation monitoring equipment.

The design provides for installation of feeders (conduit and wire) adequately sized for equipment to be installed. Generally, all power and control conduits used within the facility are rigid galvanized steel. Where equipment packages (e.g., the process equipment skid) have several motors or electrical loads, not all of which will operate simultaneously, the feed has been sized for the loads expected to operate simultaneously. The electrical system components are designated performance category 2.

Safety Considerations

The CVDF electrical power distribution system is designated as general service. The electrical power distribution system interfaces with safety systems to provide normal power. Safety SSCs fail safe upon loss of normal power. The safety-significant standby power system is provided for the operation of essential loads in accordance with Section B2 8.5.

B2 8.2 Lighting (External/Internal/Exit/Emergency)

Summary Description

Exterior building lighting is provided. Metal-halide, wall-mounted fixtures with photocells are installed at all exterior doors.

Interior facility lighting consists of energy-efficient fixtures typically operated at 120 V. High-bay area lighting consists of metal-halide fixtures when ceiling height permits good lighting design. Lighting for storage areas and mechanical areas are high-output industrial fluorescent fixtures. Other interior lighting consists of surface- or flush-mounted commercial fluorescent fixtures.

Exit signs are provided at the interior of each building exit. Exit signs include integral chargers, batteries, and relays to provide illumination automatically upon failure of the normal power source.
System emergency lighting is provided inside the CVDF in accordance with NFPA 101. Emergency lighting in areas with fluorescent lighting is provided by use of fluorescent fixtures with integrally mounted backup battery packs with a 90-minute capacity.

**Safety Considerations**

The lighting is classified as general service.

**B2 8 3 Ground System (Power/Instrumentation and Control)**

**Summary Description**

Grounding characteristics at the Hanford Site are such that supplemental cable for ground grid or loops and attachment to well casings is required to satisfactorily reduce ground resistance. All underground metallic piping, all building structural steel and rebar, and all underground metallic conduit and ground cables at the building are tied into the building ground grid.

Equipment grounding conductors are provided in accordance with Article 250-57(b) of NFPA 70 (Table 250-95). A minimum of a No 12 American Wire Gauge copper ground conductor is used with low-voltage power circuits. Grounding conductors are sized as a minimum in accordance with NFPA 70 and IEEE-142, *Practice for Grounding of Industrial and Commercial Power Systems*.

All structural steel and mechanical equipment with integral electric motors or equipment is grounded. A grounding electrode system is constructed in accordance with NFPA 70, Article 250. Interconnected elements include building reinforcing steel, water piping, and a concrete-encased grounding electrode. A separate equipment ground conductor is routed with all power conductors and lighting circuits in accordance with NFPA 70, Article 250. A separate instrumentation and control ground system is provided in accordance with NFPA 70, Article 250.

**Safety Considerations**

The ground system is classified as general service.

**B2 8 4 Uninterruptible Power Supply**

**Summary Description**

A central facility UPS system is provided for the radiation monitoring instrumentation, process bay differential pressure instrumentation, oxygen monitoring system, special purpose receptacles, stack sampling, and for the MCS. This UPS system is supplied from a central
isolation transformer for clean power to these systems. A second UPS system is provided for the security system to provide continuous power during but not after a design basis accident.

The facility UPS system is a 30-kVA, 480 V to 120/208V UPS system. The facility UPS system is complete with transformer, battery charger, battery packs, battery disconnect switch and circuit breaker, manual bypass switch, and a maintenance bypass circuit. The facility UPS system UPS-1 (see Figure B2-30, Panel/UPS-1), located in room 129, mechanical equipment area, is provided to all MCS PLCs, process bay remote input/output panels, operator control stations A and B, Hanford Local Area Network receptacles, CAMs, ARMs, and oxygen monitors. The UPS system provides a minimum of one-hour run time at full load.

One 3.1 kVA, 208/120 V to 208/120 V, UPS system complete with battery packs, battery disconnect switch and circuit breaker, and maintenance bypass circuit, located in the process support area (room 126), is provided to the security system for continuous power supplied during but not after a design basis accident. All security sensors, cameras, and sensor and video transmission equipment is provided with a UPS system with a minimum of eight hours run time at full load.

There are no safety function requirements to provide UPS power to any of the SCIC panels or equipment (including the annunciator panel in the control room). To aid in the control room response to a loss of site power, the two SCIC annunciators do have UPSs to provide 30 minutes of power to aid in the transition from the normal state to a loss of power state. The seismic monitors have battery power which is normally being charged with normal site power. On loss of power, the seismic equipment will continue to operate to record valuable data for restart. This feature is not required for safety.

Other battery backup power is provided for specific systems only by use of direct-current battery systems and battery chargers. Battery backup systems are provided for the following:

- Fire alarm control panel (mounted adjacent to the panel)
- Emergency egress and exit illumination (integrally mounted)
- Communications system (integrally mounted)

Safety Considerations

The facility UPS is classified as general service.
B2 8.5 Standby Power System

Summary Description

The CVDF utilizes a standby power system that conforms to the applicable general electric supply requirements of DOE Order 6430 1A and NFPA 70. The standby power system supports the following process bay local exhaust HVAC system functions:

- Reestablishing the minimum airflow rate as required for hydrogen dilution in the local exhaust system ductwork during a loss of normal electric power.
- Maintaining adequate differential pressure in the process bays to confine airborne radionuclides within the CVDF ventilation systems and associated confinement structures following loss of normal electrical power.

The CVDF standby power system consists of the following major components:

- A 100-kW diesel generator with an air-start motor (with integral air-operated relay valve and electrically operated pilot valve) and battery to operate engine controls, a second 100-kW diesel engine is in the diesel generator building but is not connected to the facility.
- A generator including an automatic voltage regulator, main generator circuit breaker, and current transformers.
- A automatic transfer switch that performs the following functions:
  - Selects either normal power or standby power for supplied loads.
  - Provides an engine start signal if the normal source voltage drops below a set level for a duration in excess of a selected delay.
  - Disconnects the load bank from the generator upon transfer to the standby power source.
- A load bank to test the diesel generator.
- A 50-gal capacity day tank providing a local source of fuel for the diesel engine.
- A 500-gal diesel storage tank.
- An air receiver that provides a source of stored energy to start the diesel engine.
- An air compressor to maintain pressure in the air receiver.
A load bank circuit breaker that provides overcurrent protection between the generator output circuit breaker and the load bank

A battery charger to maintain the diesel engine battery

The standby power system components (e.g., diesel engine, generator) are located in a 36 ft by 18 ft by 13 ft high building. The building is located 37 ft north and 100 ft west of the CVDF.

The standby power system provides power to the following systems:

- Process bay local exhaust HVAC system and restart circuit (Section B2 6 2 4)
- Process bay heat trace (Section B2 5 3 1 2)
- Facility UPS system (Section B2 8 4)
- Instrument air compressor (Section B2 9 2)

A simplified electrical system one-line diagram of the standby power distribution is provided in Figure B2-31.

The diesel generator components of the standby power system are designed to performance category 2 criteria. No redundant generator or dual feed capabilities are required. The standby power system is designed to restart the process bay local exhaust HVAC system to reestablish the required minimum dilution airflow rate following loss of normal electrical power to the local exhaust fans. Startup of the standby power system occurs upon loss of normal power to the automatic transfer switch for a duration in excess of a selected time delay. The standby power system has sufficient fuel to provide power for 24 hours.

**Safety Considerations**

The standby power system is classified as safety significant. The standby power system supports the restart of the process bay local exhaust HVAC system following loss of normal electrical power. Restart of the process bay local exhaust HVAC system minimizes the accumulation of potential flammable hydrogen concentrations within the process bay local exhaust HVAC system ductwork and maintains a negative differential pressure in the process bays.

**B2 8 6 Lightning/Surge Protection System**

**Summary Description**

Lightning protection is provided for the CVDF using pole-line mounted lightning arresters. The lightning protection system complies with all requirements of NFPA 780 and NFPA 70. The lightning/surge protection system is passive. All system equipment installed on the upper 25 ft of the exhaust stack is lead-covered copper or stainless steel. Air terminals and down conductors.
are provided on opposite sides of the stack, and an encircling conductor provided at both the top and bottom of the stack

**Safety Considerations**

The lightning protection system is classified as general service.

The lightning/surge protection system includes surge arresters on the 138 kV power pole where the overhead is converted to underground cable to protect the service transformer from switching and lightning-induced surges.

The facility stack includes a lightning protection system consisting of stack-mounted air terminals (rods and copper downcomer wires) connected to the ground system.

### B2.9 AUXILIARY SYSTEMS AND SUPPORT FACILITIES

#### B2.9.1 Communications Systems

**Summary Description**

The communications system provides operations personnel the ability to communicate within the facility for the efficient operation of the facility systems. The communication system interfaces with the 100 K Area communications, the Hanford Local Area Network system, and the local telephone network. The CVDF communications system consists of a voice paging system, a standard telephone system, and a data communications system.

The communications system is designed to send and receive routine CVDF operations messages between the CVDF administrative locations and the respective process and utility areas of the CVDF. In addition, the system is capable of transmitting and receiving emergency warning signals and messages to and from the 100 K Area alarm station. The CVDF communication system is designed in accordance with HNF-S-0403 *Standard Specification for Hanford Site Telecommunications Systems and Facilities.*

The voice paging system is controlled from the operations control room and is capable of one-way voice paging to wall-mounted speakers in the process bays, process water tank room, transfer corridor, mechanical equipment room, administrative building, and external equipment pads. Wall-mounted speakers are located throughout the CVDF. The voice paging system is capable of sending public address messages and alarms to multiple remote locations. Codes for evacuation and take-cover signals are included in the system code list. The voice paging system also is capable of receiving and translating alarm initiation codes from the 100 K Area alarm station. The voice paging system is capable of recognizing the emergency signal codes and broadcasting the standard Hanford Site alarms over the system throughout the CVDF.
remote alarm station at the CVDF is located in the control room. The sound level produced by the speakers is at least 10 dB above the local background noise, and flashing lights are used in areas where needed.

The telephone system provides standard telephone service with outside lines to the CVDF administrative building, including the control room. A telefax machine is available. An intercom and voice paging capability is integrated with the standard telephone, and is controlled from the control room. Every station is capable of receiving voice paging. Each intercom station can be individually addressed from the control room. The intercom system consists of speaker phones located in each of the five process bays, the tank room, mechanical equipment room, transfer corridor, administrative building (e.g. men’s and women’s change rooms, radiological control technician and radiation monitor room, control room, and corridor), and various locations outside. In addition to the standard telephone service, a crash-alarm telephone is located in the control room to receive sitewide and other emergency messages. The process bay telephones can directly connect to the crash-alarm system for relaying emergency messages to operations personnel.

The data communications system consists of connections to the Hanford Local Area Network service in the administrative building (including the control room). The Hanford Local Area Network provides a variety of data services including e-mail, online controlled documents, reference materials, data processing applications, and Internet connections. This service is provided to standard computers with network cards and Hanford Local Area Network connections available in the standard telephone outlets that have outside line connections.

Safety Considerations

While the communications system provides information during emergency situations of significance to personnel safety, the system has no direct safety function at the CVDF. The communication system is classified as general service.

B2 9 2 Instrument Air Systems

Summary Description

The instrument air system is used to produce and distribute compressed instrument quality air throughout the CVDF. The instrument air system provides the instrument air used in the cold vacuum drying process, in the HVAC dampers, and for tools, and it provides the instrument air used to operate valves, process instruments and HVAC instruments.

The instrument air system provides dry, filtered, oil-free air at approximately 100 lb/in². The system has a specified rating of 251 ft³/min at 175 lb/in² gauge with a maximum dewpoint of -40 °C (-40 °F). The CVDF instrument air system runs continuously in an automatic mode and provides a 4-hour instrument air supply in the event of compressor downtime. The instrument air
system uses redundant duplex, two-stage, piston-type compressors capable of delivering a minimum of 25 standard ft³/min each at 175 lb/in² gauge. The system has a 250-gal receiver tank. Drying of the air is provided by an instrument air refrigerant dryer and a heatless air dryer with automatic regenerative desiccant beds capable of drying 35 standard ft³/min with housings capable of an operating pressure of 175 lb/in² gauge and 38 °C (100 °F) to -40 °C (-40 °F) pressure dew point. A coalescing filter and prefilters and after-filters (sized for a minimum of 35 standard ft³/min with housings capable of an operating pressure of 175 lb/in² gauge at 100 °F) remove particulate from the air and include differential pressure gages. The instrument air system also consists of a flex connector, pressure control valves, low-pressure alarm, check valves and associated piping. Condensate from the air compressor and refrigerant air compressor is directed to the floor drains. Figure B2-32 shows the layout of the instrument air system.

The instrument air system is used to operate the automatic spring return gas-operated valves in the process and safety systems, to inflate the MCO seal ring pneumatic seals, to purge the cask–MCO annulus following completion of the cold vacuum drying process, to operate pneumatic tools, and to operate the air ride suspension for cask trailer leveling. The instrument air system provides instrument air for the HVAC system solenoid-operated valves, damper position controls for isolation, volume, and backdraft. The system also provides approximately 25 lb/in² gauge air to the HVAC system for monitoring and control and to process instruments used for monitoring and control. The instrument air is routed to the work areas through a distribution system with valves and quick-connect fittings.

To ensure the process hood dampers on the process bay local exhaust HVAC and process vent system are reopened when standby power is activated and the local exhaust fan restarts, a safety-significant instrument air system is installed in each air line to each process bay hood isolation damper. The safety-significant portion of the instrument air system in each process bay consists of an air tank, double-check valves in the inlet air supply line to each instrument air tank, piping from the tank to the hood isolation damper actuator, and a pressure-indicating gauge on the tank. Each instrument air tank reservoir has a minimum capacity of 8.3 gal and is designed for a maximum pressure of 200 lb/in² gauge. The normal operating pressure of 100 lb/in² gauge provides sufficient air volume in the reservoir to complete four actuations of the isolation damper. Double-check valves prevent loss of air to possible line breaks in the general-service portions of the system and local air pressure indication is provided for the operator to monitor the tank pressure in each bay.

The instrument air system interfaces with several safety-class systems by providing pneumatic power to operate safety-class valves. These valves are designed to fail safe upon loss of air. The instrument air compressors are supplied with power from the standby diesel generator following loss of normal electrical power (see Section B2 8.5 for a description of the standby power system).
**Safety Considerations**

Even though several safety-class systems use instrument air to operate control or isolation valves, their fail-safe configuration upon loss of air eliminates any safety functions for the instrument air systems. The instrument air system is classified as general service.

Safety-class Instrument air filters are provided in conjunction with the safety-class gas operated valves.

The instrument air reservoirs in each bay are safety significant.

**B2 9 3 Cranes and Hoists**

**Summary Description**

Four overhead trolley cranes, one in each process bay, are used to remove and install the cask lid from the cask and to install and remove the process hood from the top of the cask-MCO. The cranes can be used to assist in maintenance activities within the process bay when required. The cranes are designed in accordance with natural phenomena and hazard performance category 1 criteria and are qualified for seismic 3-over-1 criteria. Seismic 3-over-1 criteria are described in Chapter B4.0. The CVDF cranes are designed to category 3 criteria to not fall into the process bays. All lifts involving cask-MCO equipment are classified as critical lifts.

The CVDF cranes have service ratings of 4,000 lb. The cranes are designed in accordance with the criteria included in CMAA 74, with class D heavy service rating. The cranes are top-running, single-girder with capping channel. The bridge, trolley, and hoist are driven by electric motors and are capable of operation from the mezzanine level by the use of a pushbutton station. The pushbutton station is a three-motion, eight-button unit with a National Electrical Manufacturers Association rating of 12. Controls allow for hoist up or down, carrier forward or reverse, trolley forward or reverse, and crane power on or off. The pushbutton unit is permanently mounted to the mezzanine handrail. The crane has brakes in accordance with CMAA 74 and limit switches to prevent overtravel of the hoist in the raise direction only. The crane has attached seismic stops that prevent the end trucks from lifting off the runway rail during seismic events.

**Safety Considerations**

The process bay cranes are considered general service, but are considered in the 3-over-1 assessment within the process bays. Safety considerations involve following approved procedures (e.g., required load testing) for performing critical lifts. Because the lifts performed by these cranes (i.e., removal of the cask lids) have the potential for damage to the MCO, the definition from 10 CFR 72.3, "Definitions," as implemented by HNF-SD-SNF-DB-003 classifies the cranes to be important to safety. However, because any damage resulting from a cask lid drop has been
analyzed to be very minor, the important-to-safety category C classification has been assigned. A technical safety requirement control is imposed to restrict crane movement during MCO processing except as part of an approved recovery procedure.

**B2 9.4 Service Water System**

*Summary Description*

Service water is supplied to the CVDF from the existing 100 K Area service water system on the west side of the 165-KW Building. Fire sprinkler service is supplied from the facility service water. Reduced pressure backflow preventers are installed at interface locations. All service water piping is designed and constructed in accordance with ASME B31.3 *Process Piping Code*, or ASME B31.9, *General Services Piping Code*.

*Safety Considerations*

The service water system is classified as general service.

**B2 9.5 Deionized Water System**

*Summary Description*

The deionized water system provides deionized water to the PWC system, to the MCO for flushing the connectors, and to the tempered water (annulus) system.

Deionized water is supplied to the process areas via a package deionized water unit. The deionization system is sized for a peak flow of 10 gal/min and an average load of 1,500 gal/day. The system consists of exchange units, one activated carbon filter to remove organics from the water feed, three mixed-bed deionizer tanks, piped in parallel with one online at any one time, a holding tank, a 20-gal pressure tank and a final 1-micron rated filter. The holding tank has a minimum capacity of 150 gal. Water received from deionized water tanks will be recirculated through the holding tank on a continuous basis.

*Safety Considerations*

The deionized water system is classified as general service.
B2 9.6 Potable Water System

Summary Description

Potable water is used to supply the sinks, rest rooms, custodial service sinks, drinking fountains, decontamination shower, the deionized water system, and makeup water for the chilled and cooling water systems. Hot water is supplied by tank-type electric water heaters. The safety eye washes are provided with portable water containers.

Potable water is supplied to the CVDF from the existing 100 K Area sanitary water loop on the west side of Building 165-KW. The potable water service main is a 2-in.-diameter copper pipe. Backflow preventers and pressure-reducing valves are inside the CVDF. Potable water feeds the administrative building plumbing fixtures in standard copper piping. The potable water also feeds two residential-type, 52-gal hot water heaters to provide adequate hot water for the four showers (hot potable water). The potable water supplies the process deionized water unit via a reduced pressure backflow preventer and the chilled water makeup connection. All potable water lines are insulated.

Safety Considerations

The potable water system is classified as general service. Backflow preventers required to prevent backflow of water from process areas are considered industrial safety and are general service.

B2 9.7 Sanitary Collection System

Summary Description

The CVDF is not served by a sitewide sanitary sewage system. Sanitary sewage generated in the CVDF is collected in a holding tank outside the CVDF. There are no connections to the sanitary sewage system in the process bays of the CVDF. The sanitary sewer plumbing is designed in accordance to the Uniform Plumbing Code (UPC 1988), and the tank is designed, installed, and will be operated in accordance with WAC 246-272, "On-site Sewage System."

Sanitary sewage from the CVDF is gravity drained to a 5,000-gal underground holding tank located west of the facility. The holding tank is equipped with a fluid level sensor. The pipe material is polyvinyl chloride or acrylonitrile-butadiene-styrene, except where exposed, where it is galvanized. The holding tank has the capacity to store three days of sanitary waste with maximum occupancy of the facility. The tank is expected to be pumped by site forces using a pumper truck designed for such purposes. A radiation monitor is provided as required by DOE Order 6430.1A
Safety Considerations

The sanitary sewer and the monitoring system are classified as general service.

B2 98 Security System

Summary Description

This system design description addresses the CVDF security system. The system’s primary purpose is to provide reasonable assurance that breaches of security boundaries are detected and that assessment information is provided to protective personnel. In addition, the system is utilized by Operations to support reduced personnel radiation goals and to provide reasonable assurance that only authorized personnel are allowed to enter and exit the designated security areas.

Radiation protection features have been incorporated into the design of the CVDF to reduce radiation exposures to security equipment and personnel consistent with ALARA objectives. The principal source of radiation hazards in the facility is from SNF when a loaded cask–MCO is present in any of the process bays. Security personnel do not enter the process bays as part of their normal job requirements. There are no specific hazards to security equipment located in the process bays from radiation exposure. No unique ALARA requirements or worker radiological exposure issues are identified for security personnel or the security system.

There are no unique or specific industrial safety hazards or criticality safety requirements associated with the operation of the security system.

Natural phenomena hazards include seismic events, high winds, tornadoes, flooding, lightning strikes, and loads from accumulation of snow or volcanic ash. Natural hazards were evaluated for the design of the CVDF. There are no design requirements for the CVDF security system traceable to the natural phenomena hazard evaluation.

There are no chemical or process design requirements for the CVDF security system.

There are no technical safety requirement required surveillance’s that apply to the CVDF security system. The security system fabrication quality assurance/control program is based on the application of a graded approach as described in HNF-MP-599, Project Hanford Quality Assurance Program Description.

Safety Considerations

All security system components are categorized as general service and are designed and qualified as performance category 1 per DOE Order 5480 28 and administered using the guidance of HNF-PRO-097.
The security system is a stand-alone dedicated system and does not interface with safety-related alarms (e.g., fire, radiation). Equipping all pedestrian doors with panic hardware for emergency egress accommodates personnel safety.

The security system components, installation, and testing meet the applicable requirements of NFPA 70.

**B2 9 9 Specialty Equipment**

**Summary Description**

Several items of specialty equipment are required to operate the CVDF. Summary descriptions are provided below:

- A truck and tanker will be used to transport conditioned process water from the CVDF to the K Basins integrated water treatment system.
- A shielded cask will be used to store and transport water samples from the PWC system for analysis.
- Swipe count pigs are supplied in each process bay for measuring contamination levels on the MCO and cask.
- A jumper in each process bay will be used to refill the MCO cask annulus with deionized water for emergency recovery purposes.
- Wheel chocks are supplied in each process bay for chocking the cask trailer wheels.
- A cask lid lift fixture is provided for each process bay to remove the cask lid before installation of the process hood and seal ring.
- A storage fixture is provided for each process bay to store the cask lid after removing it from the cask. Features for the fixture allow for the decontamination of the lid and for lid seal replacement.
- A special system (exhaust trunk) is installed in each process bay to collect the exhaust fumes from the tractor to prevent them from entering the process bay during delivery or removal of the cask trailer.
- A pneumatic hose with quick-connect on one end and glad hand and control valve compatible with the cask transport trailer is provided for each process bay. The hose connects to the facility's instrument air system.
A process hood lift fixture is supplied in each process bay to install and remove the process hood-seal ring to the cask.

A lifting fixture is supplied for the PWC tank room hatch.

A portable crane is supplied for the removal and installation of the IXMs.

A portable radiation monitor is supplied to monitor the process bay floor drains for radiation.

A portable calibration cart is supplied for the periodic calibration of the RGMs.

A storage locker is supplied to each process bay for the storage of various tools and equipment.

Various process flexible jumpers.

**Safety Considerations**

All of the specialty equipment has been classified as general service.

**B2 9 10 Special Tools**

**Summary Description**

Several special tools are required to operate the equipment in the CVDF. The following list is not intended to be all inclusive, nor does it identify all necessary components for maintenance of the process skids or facility. Summary descriptions of special tools required to operate the process are provided.

- A torque wrench with extension, torque multiplier, and sockets for the cask lid bolts is provided for each bay. Various socket sizes, wrenches, and pneumatic tools are available for use in each bay.

- Tools are provided for each bay to remove and install the cask drain port cover and to install the tempered water lower cask port connection.

- A tool is supplied for each bay to remove and replace the cask vent port plug.

- A tool is supplied for each bay to remove and install the MCO process port covers.

- A torque wrench and sockets are supplied for each bay to remove and install the MCO process port connector and to open and close the MCO port plugs.
Tools, other than standard, are provided for the maintenance of the PWC system, VPS, and tempered water (annulus) system

Tools, other than standard, are provided for the removal of the HEPA filters from the filter housings

Calibration tools are supplied to verify and recalibrate instrumentation

Leak check equipment for the MCO process port connectors and port covers

MCO vent port valve and pressure monitor

Cask annulus refill tools

Cask annulus refill water storage container, pump, and hand truck

Cask vent jumper tool

MCO vent jumper tool

Safety Considerations

Two items of specialty tools, the cask vent jumper tool and the MCO vent jumper tool, have been classified as safety significant and are discussed in Chapter B4.0. All other specialty equipment tools are classified as general service.

B3 0 HAZARD AND ACCIDENT ANALYSES

B3 1 INTRODUCTION

This chapter presents a summary of the methodology, assumptions, and results of the safety hazard analysis and design basis accident (DBA) analyses that have been performed for the Cold Vacuum Drying Facility (CVDF). These analyses form a Safety Basis for the final safety analysis report (FSAR) and present a comprehensive evaluation of the drying process and related activities at the CVDF, and the natural phenomena and external hazards that can affect the public workers, and environment. Single and multiple initiating events from equipment and human error failures in the facility have been considered, as well as human-generated and natural events (i.e., common mode failure) outside the facility. When the FSAR is approved by the U.S. Department of Energy (DOE), this Safety Basis will help to establish an Authorization Basis for the Spent Nuclear Fuel (SNF) Project CVDF. Changes to the facility during operations will be reviewed to ensure they do not affect the Authorization Basis. This review process is described in Chapter 17 of the SNF Project FSAR and is termed the unreviewed safety question process.

The contents of this chapter are as follows:

- The requirements for establishing the safety basis for the CVDF are listed in Section B3 2. The requirements listed consist of DOE orders and standards and applicable U.S. Nuclear Regulatory Commission (NRC) rules and guidance.

- The CVDF hazard analysis methodology and results are summarized in Section B3 3. The complete hazard analysis is contained in HNF-SD-SNF-HIE-004 Cold Vacuum Drying Facility Hazard Analysis Report. The hazard analysis identifies hazard sources, hazardous conditions, potential accident scenarios and their initiators, and preliminary assessments of event frequencies and consequences. Hazards are identified by form and location and represent a complete spectrum of events that could occur throughout the facility. An initial set of safety features that would serve to prevent or mitigate the postulated accident scenarios was identified during the hazard analysis. A final set of safety features is identified in the accident analyses in Section B3 4 2 and in Chapters B4 0 and B5 0. A safety feature that prevents an accident scenario is defined as one that reduces the expected annual frequency of occurrence for the accident beyond extremely unlikely (less than 10⁻⁶ per year). The hazard analysis has been revised to reflect the final set of safety features.

- The final facility hazard classification, determined in accordance with DOE-STD-1027-92, Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480 23 Nuclear Safety Analysis Reports is addressed in Section B3 3 2 2. The CVDF has been assigned a final designation of hazard category 2 nuclear facility.
Section B3.2.3 contains discussions of defense in depth, worker safety, and environmental protection, including a detailed tabulation of engineered and administrative features that have been identified as providing for worker safety.

The hazard evaluation ranking performed in the hazard analysis identifies hazards and associated events that pose a challenge to offsite and onsite radiological dose evaluation guidelines. This ranking is used to select unique and representative accidents, with sufficiently high risk estimates for further detailed quantitative evaluation as DBAs. SNF-2770, Cold Vacuum Drying Facility Design Basis Accident Analysis Documentation, documents the derivation of the DBA frequency range. The six major DBA categories are evaluated in the following sections:

- Section B3.4.2.1, “Gaseous Release”
- Section B3.4.2.2, “Liquid Release”
- Section B3.4.2.3, “Multi-Canister Overpack External Hydrogen Explosion”
- Section B3.4.2.4, “Multi-Canister Overpack Internal Hydrogen Explosion”
- Section B3.4.2.5, “Multi-Canister Overpack Thermal Runaway Reaction”
- Section B3.4.2.6, “Multi-Canister Overpack Overpressurization”

The analysis process resulted in identification of safety-class and safety-significant structures, systems, and components (SSCs), and the functional requirements needed to prevent or mitigate potential accident sequences and ensure that the facility can be operated in a safe, controlled manner. The analysis also identified a set of controls (i.e., technical safety requirements [TSRs]) that ensure all identified vulnerabilities associated with facility operation have been adequately addressed. When required by the SNF Project’s commitments to meet equivalent NRC requirements, candidate features have been identified as “important to safety” and designed, engineered, and procured consistent with safety-class or safety-significant classification requirements.

Each of the six analyzed DBAs represents a bounding case for a category of hazards and accidents. An in-depth review has been performed of all remaining accidents identified by the hazard analysis in each of the categories. The accidents reviewed typically represent the same accidents with different initiators, or different accidents bounded by the cases presented. This review resulted in the selection of additional safety-class and safety-significant SSCs and TSRS to ensure that all individual hazards and accidents within a category have been addressed. The table that accompanies each DBA in Section B3.4.2 includes the preventive and mitigative features and associated TSRS for the bounding case presented and for all other events within that accident category. Defense-in-depth features also are identified in these tables.
This chapter interfaces with several other SNF Project safety documents. This chapter identifies and evaluates all hazards associated with the CVDF and analyzes bounding accident scenarios associated with processes and activities that occur within the CVDF. The hazards associated with transport and the accident scenarios that are postulated to occur during shipment are analyzed in HNF-SD-TP-SARP-017, Safety Analysis Report for Packaging, Onsite Multi-Canister Overpack Cask. The planned scope and content of various other SNF Project safety reports, TSRs, and supporting safety documents are defined in HNF-SD-SNF-PLN-012, Spent Nuclear Fuel Project Integrated Safety Management Plan. In particular, MCO design basis information is provided in HNF-SD-SNF-SARR-005, Multi-Canister Overpack Topical Report.

The CVDF hazard and accident analysis relies on the SNF in a multi-canister overpack (MCO) to be clean (i.e., loose surface contaminants removed) and the fuel loading to be controlled (e.g., the mass of fuel in a scrap basket, the number of scrap baskets) at the K Basins. In addition, to protect the limiting values assumed in the hazard analysis and the DBA analyses, the interface between the CVDF and the Canister Storage Building (CSB) requires that an MCO delivered to the CSB contain less than 200 g of free water and provide confinement of the combustible hydrogen gases within the mechanically sealed MCO. Safety-related performance documentation from the K Basins and the CSB is relied on to ensure that the as-received and as-shipped content and condition of the MCO are “as required” for the safety basis properties of the MCO.

### B3 2 REQUIREMENTS

Chapter 3 of the SNF Project FSAR lists the design codes, standards, regulations, and DOE orders that contain requirements and guidance for establishing the safety basis for the SNF Project. Only the requirements that are specific for the CVDF and that pertain to the safety analysis are provided here:

- **DOE Order 5480 23, Nuclear Safety Analysis Reports**  
  DOE Order 5480 23, Section 8b (3)(e) and (k), in conjunction with its Attachment 1, "Interim Guidance for DOE Order 5480 23," sets the requirements for analysis. This chapter complies with these requirements by documenting performance of the hazard and accident analyses. The methodology and criteria used to identify facility hazards, hazard rankings, candidate accidents, DBAs, preventive and mitigative features and controls, and the classification of these features (along with the definition of safety functions, performance criteria, and applicability) are described in Chapter 3 of the SNF Project FSAR and are documented in this Chapter B3 0.

- **DOE Order 5480 22, Technical Safety Requirements**  
  This order sets the requirements for the development and preparation of a TSR document. This chapter complies with these requirements by documenting the performance of hazard and accident analyses using implementing guidance from HNF-PRO-704, Hazard and
Annex B — Cold Vacuum Drying Facility

**Accident Analysis Process**, and DOE Order 5480 23  The results of the analyses have been used to identify specific safety functions of SSCs, performance requirements for the SSCs, and the times for application of the safety functions

- **DOE Order 6430 1A, General Design Criteria**  This order provides requirements for the identification of safety-class items  The analyses documented in this chapter use the SSC classification requirements of DOE Order 6430 1A to identify safety-class SSCs and their safety functions

**DOE-STD-1027-92 and DOE-STD-3009-94, Preparation Guide for US Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports**, are standards which provided guidance to satisfy DOE requirements of DOE Order 5480 23 in the CVDF hazard and accident analysis process and the preparation of this report

In Letter 95-SFD-167, Implementation of K Basins Spent Nuclear Fuel Project (SNFP) Regulatory Policy (Sellers 1995), DOE established the requirement for new SNF Project facilities to achieve "nuclear safety equivalency" to comparable NRC-licensed facilities  The SNF Project identified the NRC requirements that were to be met, in addition to existing and applicable DOE requirements, in order to establish nuclear safety equivalency  These NRC requirements and the process used to identify them are documented in HNF-SD-SNF-DB-003, Spent Nuclear Fuel Project Path Forward Additional NRC Requirements, and in WHC-SD-SNF-DB-010, Cold Vacuum Drying System Natural Phenomena Hazards  These documents establish the design requirements to be met for the CVDF to achieve NRC equivalency and considered the following

- **Title 10, Code of Federal Regulations, Part 72, "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel and High-Level Radioactive Waste"** (10 CFR 72)  This rule is used for the licensing of independent spent fuel storage installations  Section 72 122, "Overall Requirements," requires that the design bases for SSCs important to safety reflect appropriate combinations of the effects of normal and accident conditions and the effects of natural phenomena  Section 72 24, "Content of Application Technical Information," provides requirements in Paragraph 72 24(m) for the analyses of accidents and natural phenomena events that could result in a dose at the controlled area boundary

- **NRC Regulatory Guide 3 26, Standard Format and Content of Safety Analysis Reports for Fuel Reprocessing Plants**  This guide establishes the format and content for license applications for fuel reprocessing facilities

While these documents have particular significance to this chapter, they do not, by themselves, establish requirements for the CVDF or the Chapter B3 0 accident analyses  Requirements identified in HNF-SD-SNF-DB-003 and WHC-SD-SNF-DB-010 address NRC equivalency  These requirements include safety documentation for (1) determining “important-to-safety” classifications for preventive and mitigative features, (2) identifying and resolving worker safety issues in DOE Order 6430 1A, DOE Order 5480 23, and

November 1999
DOE-STD-3009-94, and (3) evaluating nearby activities identified in Section B1 6, “External Human-Generated Threats,” that may represent a threat to the facility

Important-to-safety SSCs have been identified in accordance with 10 CFR 72 3 Once SSCs have been identified as having a function meeting the definition of important to safety, the requirements specified in 10 CFR 72 are imposed A graded approach is applied to an important-to-safety SSC by using the guidance provided in NUREG/CR-6407, Classification of Transportation Packaging and Dry Spent Fuel Storage System Components According to Importance to Safety, as follows

- **Category A — Critical to Safe Operation**

  SSCs in Category A include those whose failure or malfunction could directly result in a condition adverse to public health and safety Important-to-safety SSCs in this category are classified as “safety class,” as defined in DOE Order 6430 1A, with the additional requirements therein

- **Category B — Major Impact on Safety**

  SSCs in Category B include those whose failure or malfunction could result in a condition adversely affecting collocated worker health and safety Note that from the definition of Category C, Category B is understood to include events that could significantly damage the MCO without severe impact to public health and safety SSCs in this category are classified as “safety significant,” as defined in DOE-STD-3009-94

- **Category C — Minor Impact on Safety**

  SSCs whose failure or malfunction would not significantly reduce containment and would not be likely to create a situation adversely affecting public or collocated workers' health and safety SSCs in Category C are classified as “safety class 3” (nonsafety), as defined in DOE Order 6430 1A

The determination of important to safety is directly incorporated into the tables of identified preventive or mitigative safety function features at the end of each DBA scenario in Section B3 4 2, and external human-generated threats are discussed in Section B3 3 2 3 The requirements of WHC-SD-SNF-DB-010 are incorporated into the natural phenomena hazard design criteria and are considered in the hazard evaluation

Letter 97-SFD-172, Risk Evaluation Guidelines (REGs) to Ensure Inherently Safer Designs (Sellers 1997) provides another SNF Project requirement that is significant in the development of this chapter This letter provides the onsite risk evaluation guidelines and offsite release limits for comparison to DBA consequences
B3 3 HAZARD ANALYSIS

The hazard identification and evaluation process provides a thorough, predominantly qualitative evaluation of the spectrum of risk to the public, workers, and the environment caused by accidents that involve the hazards identified in the hazard analysis. The hazard analysis process is fully described in Section 3.3 of the SNF Project FSAR. A final hazard analysis has been performed to support the accident analyses and is documented in HNF-SD-SNF-HIE-004. The final hazard analysis systematically reviewed the final CVDF design, as described in Chapter B2.0, to identify any hazardous materials or energy sources that have the potential to initiate an accident that could require further review or analysis. This process resulted in the selection of six candidate accidents for more comprehensive analysis in Section B3.4.2.

B3 3.1 Methodology

The methodology used to identify and evaluate SNF Project facility hazards is described in detail in Section 3.3 of the SNF Project FSAR. This section discusses those areas of the methodology that are specific to the CVDF. The hazard evaluation process identified hazardous conditions, determined causes and preventive and mitigative features, and qualitatively estimated the consequences and frequencies of occurrence (HNF-SD-SNF-HIE-004). The results of the application of this methodology to the CVDF are presented in Section B3.3.2. The hazard analysis was performed in accordance with DOE-STD-3009-94 and implements the requirements of DOE Order 5480.23. Figure B3-1 shows the hazard and accident methodology used for the CVDF.

B3 3.1.1 Hazard Identification During normal operations, small amounts of airborne particulate from the MCO are expected to be lifted off the surface of the SNF as the process system sweeps the MCO with helium. This particulate is filtered at the MCO exit port before entering the process system. In addition, the process system flow is directed through a two-stage, high-efficiency particulate air (HEPA) filter before exiting the stack. No adverse consequences for the public or the work force or contamination of the environment are expected under these normal conditions (normal operating releases are discussed in more detail in Chapter B9.0).

The CVDF hazard analysis covers activities beginning with the approach of the cask-MCO transporter to the facility, anticipated normal facility operations, the MCO drying and proof processes, preparing the cask-MCO and the trailer for shipping, and ending with the transporter leaving the facility. Hazard identification for the CVDF was based on examination of the six major building areas in the facility:

1. Administrative area (AA)
2. Transfer corridor and mechanical equipment room (TC)
3. Process bays 2 through 5 (PB)
4. Process bay 1, an unused bay (SB)
The CVDF processes and activities that can take place within each area were identified, and the hazards were identified by form (e.g., electrical, thermal, friction), type (e.g., motors, power tools, winng), and building location. A standardized hazardous material/energy source checklist was used to group potentially hazardous materials and energy sources in each of the six major facility areas. The two letter abbreviations shown for the six areas are a portion of the unique identification designator used for tracking in the analysis process. If a hazard affected more than one area, it was evaluated in all facility areas where material at risk (MAR) was present. Figure B3-2 shows the standardized hazardous material/energy checklist for the CVDF hazards identification.

B3 3 1 2 Hazard Evaluation The identified hazards were evaluated to determine the causes of the hazard, potential accidents that could result from the presence of each hazard and consequences to the public offsite, collocated and facility workers onsite the environment, or the CVDF. Safety features, segregated into preventive and mitigative features, were identified for each hazard based on the ability of the feature to prevent or mitigate the consequences. Qualitative estimates of the frequency and consequence of the hazardous condition were assigned. See Section 3 3 1 2 of the SNF Project FSAR (HNF-3553) for the criteria used in assigning the consequence and frequency categories.

B3 3 2 Hazard Analysis Results

The hazard analysis process is documented in HNF-SD-SNF-HIE-004. The results of that process in their order of progression, are as follows:

- A series of checklist-style tables describing hazardous materials and energy sources organized by major facility area — These tables were used to develop the hazard analysis accident scenarios.

- A series of tables describing the standard industrial hazards considered, organized by major facility area — These events were judged to have no contribution to uncontrolled radiological and/or hazardous materials releases and were not considered in the selection of DBAs, safety-class or safety-significant features, or TSRs. They were among the hazards considered and, therefore, are included for completeness.

- A series of tables describing potential hazard scenarios, organized by major facility area — These tables included hazardous energy sources and materials, hazardous conditions, causes and initiators, potential accidents, qualitative determinations of event frequencies and consequences, safety features for prevention and/or mitigation of the consequences, and defense-in-depth or worker safety features.
A table, organized by major facility area, assigning risk bins to causes associated with significant consequences to offsite and onsite receptors — Consistent with DOE-STD-3009-94, the events located in risk bins representing "situations of concern," or "situations of major concern," were evaluated as candidate DBAs.

- A final list of candidate DBAs, sorted by risk ranking and energy change or release — This list formed the basis for selecting the DBAs presented in Section B3 4 2.

DBA selection is addressed in Section B3 3 2 3 5 and its accompanying Table B3-4. In terms of the risk binning process, the accidents chosen from the hazard analysis for further analysis as DBAs were all events identified in consequence categories S3, indicating significant effects to offsite receptors, and S2, indicating significant effects to onsite receptors.

The hazard analysis (HNF-SD-SNF-HIE-004) has been reconciled with the up-to-date CVDF facility design described in Chapters B2 0, B4 0, and B5 0 and the accident analyses in this chapter.

**B3 3 2 1 Hazard Identification**

The final CVDF hazard analysis tables are shown in HNF-SD-SNF-HIE-004. A checklist designator (from the hazard analysis tables) associated with each hazard contains a two-letter facility location designation, a letter corresponding to the general type of hazardous energy or material source, and a final number (sometimes with an associated letter) that identifies the specific source of the hazardous energy or material. The main inventory of hazardous material in the CVDF is the radionuclide content of the MCOs. The toxicological hazards of the radionuclide inventory were reviewed. As described in Section 3 4 1 1 of the SNF Project FSAR, the radiological guidelines were found to be more limiting than the toxicological guidelines for the release of the SNF particulate in the MCO. Other hazardous material identified by the hazard identification process includes pyrophoric metals and hydrides, oxidizers, hydrogen, diesel fuel, and other flammable or combustible materials. Table B3-1 provides a summary that identifies hazards by form, type, location, and total quantity.

A specific and comprehensive analysis of all fire hazards associated with the CVDF has been completed (SNF-4268 and SNF-4942) to augment the standard hazard analysis.

The CVDF does not have an operating history, so major hazards resulting from facility operation cannot be identified or summarized as suggested by DOE-STD-3009-94. However, as described in Section 3 3 2 1 of the SNF Project FSAR, the CVDF spent fuel drying process is similar to the vacuum drying process used by independent spent fuel storage installations issued licenses under 10 CFR 72. Major hazards from similar independent spent fuel storage installations were considered when performing the hazard analysis for the CVDF. These hazards include failure of drying processes, defects in cask integrity, and the spread of external contamination (see SNF Project FSAR, Section 3 3 2 1).

HVAC = heating, ventilation, and air conditioning (filter)
IMO = in-core exchange module
MAR = material at risk
MCO = multi-canister overpack
MTU = metric ton of uranium
NA = not applicable
SNF = spent nuclear fuel.
B3 3 2 2 Hazard Classification  A final hazards categorization of the CVDF has been performed based on the final hazard analysis (HNF-SD-SNF-HIE-004) and the accident analysis documentation (SNF-2770) for the facility  Consistent with DOE-STD-1027-92, the final categorization was based on MAR chosen to bound the MAR from the worst-case DBA in Section B3 4 2 These CVDF material quantities have been compared against the DOE-STD-1027-92 threshold quantities  The CVDF final hazard categorization found the CVDF to be a hazard category 2 nuclear facility

The established safety basis radiological nuclide inventory (fuel activity) per metric ton of uranium (HNF-SD-SNF-SARR-005) was used to estimate the material quantities available for release by multiplying the MAR and the specific nuclide inventories (fuel activity) per metric ton of uranium (see Table B3-2)  For any DBA described in this section, the maximum MAR is less than 200 kg UO₂ dispensible particulate (Section B3 4 2 5)  This quantity is compared against the category 2 threshold quantities from DOE-STD-1027-92, Table A 1 (see Table B3-2)  The ratios of the constituents of the MAR to the category 2 threshold quantities were calculated and summed to compare with the summation of the radionuclide ratios for category 2 threshold criteria  Since one radionuclide, ²⁴¹Am, is greater than the corresponding hazard category 2 threshold quantity, and since the sum of ratios is greater than one, the CVDF remains a category 2 nuclear facility as identified during the preliminary hazard classification

The hazard classification process does not rely on segmentation of the radionuclide inventory (HNF-SD-SNF-DRD-002)  The final hazard analysis does not identify any toxicological consequences or any intentional chemical process systems, except the ion-exchange resin system  Analysis shows that the radiological guidelines are more limiting than the toxicological guidelines, as discussed in Section 3 4 1 1 of the SNF Project FSAR  The categorization level would not change if the quantity of MAR were to increase because the CVDF cannot be a category 1 facility unless designated category 1 by order of the responsible DOE program senior official (DOE-STD-1027-92)

B3 3 2 3 Hazard Evaluation  The final CVDF hazard analysis identified hazards associated with actual processes used in the CVDF (HNF-SD-SNF-HIE-004)  Standard industrial hazards were identified (HNF-SD-SNF-HIE-004, Tables 9 through 14) and removed from the list of facility hazards used to identify DBAs  The results of the hazard analysis identified hazard scenarios for each major area in the CVDF  These scenarios were used to define the CVDF DBAs selected for further analysis in Section B3 4 2

Evaluation of nearby external human-generated activities that may represent a threat to the facility is required by DOE-STD-3009-94 and is an additional NRC equivalency requirement specified in HNF-SD-SNF-DB-003  The external hazards from the human-generated activity identified in Section B1 6 involve only those from aircraft activity  Section B1 6 identifies 10 active airports within a 24-mile radius of the CVDF (Beary 1997) and defines the overall frequency of aircraft impact from all sources to be 4.6 x 10⁻⁷ per year  The total impact frequency is less than 10⁻⁶ per year and therefore the safety risk is below the level of concern  As stated in Section B1 6, nearby truck, rail, and barge traffic does not exceed the guidelines for shipments of hazardous materials that could present a risk to the CVDF

*a The material at risk used to calculate the final Cold Vacuum Drying Facility hazard category bounds the material at risk in the worst-case unmitigated design basis accident

*b Category threshold values are from Table A.1 of DOE STD 1027.92 Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23 Nuclear Safety Analysis Reports

MTU = metric ton of uranium
Threats from natural phenomena and nearby facilities are evaluated in HNF-SD-SNF-HIE-004 and Chapter B3. As described in detail in Chapter B2, the design criteria for natural phenomena were defined based on applicable DOE orders and NRC equivalency requirements, as documented in WHC-SD-SNF-DB-010. These design criteria have been incorporated into the design and engineering of SSCs, as described in Chapter B4. Therefore, credible natural phenomena hazards are addressed in the design of the facility.

Threats from nearby facilities are identified and evaluated in Section B1.7 based on applicable DOE orders, regulations, and NRC equivalency requirements. Potential hazards to the CVDF from offsite hazardous operations or facilities are examined under three general classifications:

- Nonreactor nuclear and nonnuclear industrial facilities within 5 mi of the CVDF
- Nuclear reactors within an 50-mi radius of the CVDF
- Military activities

No significant risks are identified that could impact CVDF operation.

The CVDF fire hazard analysis (SNF-4268) and associated implementation plan (SNF-4942) identified the fire hazards, fire loading criteria, and appropriate requirements for addressing fire hazards during CVDF operation, based on applicable DOE orders, regulations, and NRC equivalency requirements. The fire hazard analysis evaluated several fires that involved either the tractor and trailer, the trailer only, the MCO, or various safety equipment. The fire included the combustible loading of the unit, including the tires, fuel, tractor cab, and special work permit clothing. Fire protection features (e.g., fire detection equipment and sprinklers) for the CVDF are described in Section B11.4. The DBA analyses do not develop separate fire scenarios but instead rely on the scenarios developed in the fire hazard analysis (SNF-4268) and implementation plan (SNF-4942). The controls on combustibles are identified in the pertinent DBA tables in Section B3.4.2, and in Chapter B5.

**B3.3.2.3.1 Planned Design and Operational Safety Improvements** This section is used to discuss commitments for planned major design or operational improvements for the facility that are not yet implemented. Because the facility design and accident analysis have been developed in parallel, the opportunity to provide feedback for design consideration has been available. As the hazard evaluation and specific accident analyses have progressed, cost-effective modifications that improve safety have been incorporated into the design. Therefore, no plans for major design or operational improvements are needed as a result of the hazard evaluation.

**B3.3.2.3.2 Defense in Depth** A summary of fundamental points relevant to the concept of defense in depth is described in Section 3.3.2.3.2 of the SNF Project FSAR.

**Features Chosen to Provide Defense in Depth for the Cold Vacuum Drying Facility** Defense-in-depth features for the CVDF were selected based on a relative ranking of the hazards from the hazard identification process, followed by a selection of safety-class and safety-significant features and TSRs for the DBAs, which are described in Section B3.4.2.
Preventive and mitigative features identified in the hazard analysis (HNF-SD-SNF-HIE-004), but not identified in the accident analyses as safety class, safety significant, or TSRs, are identified as additional defense-in-depth features. The defense-in-depth features are presented in the tables that accompany each DBA in Section B3.4.2. Administrative features identified in these tables are in addition to those already identified in the programmatic chapters (e.g., Chapters B7.0, B8.0, and B11.0).

The initial layer of defense in depth at the CVDF is facility design. All SSCs are designed in accordance with applicable codes and standards with a high degree of reliability, and the design encompasses human factors considerations to ensure that operations can be conducted safely. Other defense-in-depth features for preventing and mitigating hazards and accidents, and for preventing or mitigating radiological consequences to the facility or collocated workers, have also been identified. Recovery actions after a safe and stable state has been reached, if necessary, will be based on analysis and a recovery plan specific to the event developed by an appropriate qualified management team. Chapter B17.0 describes the unreviewed safety question process that must be used for recovery actions, if those actions are not within the bounds of the authorization basis provided by this FSAR.

The MCO internal HEPA filter connected to the filtered process exit port provides a measure of defense in depth in nearly all accidents involving the MCO. However, because the filter is not testable when in place, no credit is taken for it in the DBA analyses. In practical terms, the filter provides for contamination control of process lines and helps to keep worker exposures as low as reasonably achievable (ALARA). The internal HEPA filter is metallic and will continue to filter if wetted, and it will not plug under any identified condition (SNF-4636).

Operator training, approved operating and maintenance procedures (as indicated by vendor-supplied information), and routine maintenance provide a measure of protection against nearly all operational hazards. To avoid unnecessary repetition, these features are not stated in the DBAs as providing defense in depth.

Safety-Significant Structures, Systems, and Components Safety-significant SSCs are predominantly required to prevent or mitigate consequences of postulated accident events to the collocated onsite worker. DOE Letter 97-SFD-172 (Sellers 1997) provides a correlation of the evaluation guidelines to identification of the safety-significant SSCs. In addition, DOE-STD-3009-94 suggests that SSCs be designated as safety significant if they play a key role in defense in depth (or worker safety). The severity of the event being prevented or mitigated and the number of barriers present are provided in DOE-STD-3009-94 as guidance for the identification of defense-in-depth safety-significant SSCs. No safety-significant defense-in-depth SSCs have been identified for the CVDF outside of those features already identified as safety significant in the DBA.

Technical Safety Requirements TSRs were identified for postulated accident events that could challenge accident consequence release limits and evaluation guidelines for the offsite public and collocated onsite worker. TSRs are identified in the individual DBA sections and further explained in Chapter B5.0. In addition, criticality prevention features are controlled by TSRs, as
identified in Chapter 50 of the SNF Project FSAR and Chapters B50 and B60. Only one feature has been identified that requires TSR coverage based on defense in depth considerations; a TSR is required to perform pressure tests on the MCO to minimize hydrogen generation within the cask during transport to the CSB.

**B3.3.2.3 Worker Safety**  Worker safety for the CVDF is ensured by a combination of design features that reduce exposure to radioactive, toxic, and industrial hazards and by institutional practices that, in total, protect workers from these hazards. Protecting the facility worker from the standard industrial hazards identified for the CVDF is achieved through adherence to the institutional safety programs described in Chapters 70, 80, 90, 100, 150, and 170 of the SNF Project FSAR and documented in lower-tier documents such as health and safety plans and job hazards analyses. Such industrial hazards do not require specific safety-significant SSCs or TSR-level administrative controls. Therefore, in accordance with the guidance of DOE-STD-3009-94, the remainder of this section deals with protecting workers from those hazards of facility operation that are exclusive of standard industrial hazards.

The final CVDF hazard analysis provides an overview of the major features protecting facility workers at the CVDF (see HNF-SD-SNF-HIE-004). Worker safety features are an integral part of facility design and operation. The major features of worker protection are identified in Table B3-3 (based on the hazards analysis) and are categorized by hazard. The features presented in Table B3-3 are in addition to those identified as safety-class or safety-significant features in the DBA sections. The hazard energy source or material and the hazardous condition are identified along with the features protecting the worker, including passive, active, and administrative protective features. No safety-significant SSCs or TSRs have been identified for the CVDF based solely on worker safety considerations. The controls identified in the analysis of the DBAs, in conjunction with the safety features identified in the hazard analysis and the institutional programs, are adequate to ensure worker safety. In one case, a safety-class SSC provides a safety-significant function that is not identified in the DBA analysis. The cask and MCO shield plug are credited as safety-class SSCs for establishing initial conditions and allowing other safety-class SSCs to properly function. The shielding function, however, is not identified in the DBA analysis, but is safety significant based on the potential for high dose rates that would be associated with an unshielded MCO.

In general, items included in Table B3-3 exclude standard industrial hazards, hazards that are beyond extremely unlikely and hazards that have no safety consequences. In addition, the features listed in the table exclude features and controls listed in the controls tables for the DBAs and include only those features from the hazard analysis pertaining to worker safety.

**B3.3.2.4 Environmental Protection**  The hazard to the environment from CVDF operations involves the potential release of radioactive contaminants. The predominant release pathway for these contaminants is via the air to the boundaries and receptors discussed in Section B1.3.13. While accidents involving liquid releases have been identified, the quantities and concentrations of the liquids and contaminants are not large enough to result in a significant release to the environment as evaluated in HNF-SD-SNF-HIE-004. Where liquid releases are possible, they are contained by design of the facility (e.g., the sump on the process water conditioning [PWC] skid).

Note: For those hazards related to the cranes in the process bays there is a TSR restricting crane movement during MCO processing except as part of an approved recovery procedure.

---

*Hazard analysis checklist designators are from, HNF SD SNF HIE-004 1999 Cold Vacuum Drying Facility Hazard Analysis Report Rev 4 Fluor Daniel Hanford Incorporated Richland Washington Figure B3.2 shows the hazardous material/energy source checklist that was used to group potentially hazardous materials and energy sources for each of the six major building areas:

AC Administrative area
TC Transfer corridor and mechanical corridor
PB Process bays 2 through 5
SB Process bay 1 an unused bay
PW Process water tank room
OU Outside

DBA = design basis accident
DOE = U.S. Department of Energy
HEPA = high efficiency particulate air (filter)
HPT = health physics technician
HVAC = heating ventilation and air conditioning
MCO = multi canister overpack
PWC = process water conditioning
SCIC = safety-class instrumentation and control
TRU = transuranic
Based on the CVDF design and operating information, no use of toxic chemicals has been identified. The toxicological hazards of the radionuclide inventory have been reviewed. As described in Section 3.4.1.1 of the SNF Project FSAR, the radiological guidelines have been found to be more limiting than the toxicological guidelines (HNF-SD-SNF-TI-059). Potential consequences, including offsite releases, and required prevention and mitigation features are discussed in Section B3.4.2. Implementation of the prevention and mitigation features will prevent releases that could have significant environmental impact. The CVDF features that protect the onsite collocated worker and the offsite public against radiological exposure also serve to prevent and mitigate radiological release to the environment. In addition, sitewide programs for environmental monitoring provide for assessment of the impact of facility releases. Normal CVDF operational activities are expected to have a minor impact on the local and regional environment, as noted in DOE/EIS-0245F, Addendum (Final Environmental Impact Statement) Management of Spent Nuclear Fuel from the K Basins at the Hanford Site, Richland Washington.

B3.3.2.3.5 Accident Selection The methodology for the selection of DBAs is specified in DOE-STD-3009-94. DBAs have been selected to ensure that the range of accident scenarios analyzed represents a complete set of representative and bounding conditions. This selection criterion is a common requirement among the SNF Project facilities and is described in Section 3.3.2.3.5 of the SNF Project FSAR.

The list of six candidate accidents that resulted from the hazards binning process for the CVDF is presented in Table B3-4. The table also contains all accidents identified as category S3 and S2 bounded by each candidate accident. The candidate accidents, and the controls selected for their prevention and mitigation, are described in DBA Sections B3.4.2.1 through B3.4.2.6. The other events listed in Table B3-4, and the controls selected for their prevention and mitigation, are included in the safety feature summary table provided in each DBA section.

From each risk bin, the accident qualitatively determined to be of highest overall risk (a function of frequency and consequence) and highest consequence (regardless of frequency) was selected as a DBA for further evaluation. Currently, a single accident from each bin meets both criteria (being the highest risk as well as highest in consequence), requiring only one accident to be developed per bin. For bins containing multiple accidents of equal risk rank, the DBA was chosen based on both a qualitative evaluation of which accident presented the greatest consequence due to energy present for release and an evaluation of significant local effects (i.e., potentially great impact to facility personnel).

B3.3.3 Abnormal Events for the Cold Vacuum Drying Facility

The purpose of this section is to develop NRC safety equivalency by analyzing “off-normal or abnormal operations” at the CVDF. Abnormal events are expected to occur during the facility lifetime and include non-accident conditions resulting from situations outside of normal operations, where normal operations are defined by process flow diagrams, system design...

<sup>a</sup>O = operational  NP = natural phenomena  EI= externally intuated

<sup>b</sup>S2 = Sufficient material and release energy to affect an onsite receptor (collocated worker) 100 m from the source of the release
S3 = Sufficient material and release energy to affect a receptor at the nearest point of uncontrolled public access (site boundary)
F0 = Beyond extremely unlikely (not credible)
F2 = Foreseeable but unlikely
F3 = Likely to occur during the lifetime of the facility

Hazard analysis checklist designators are from, HNF SD SNF HIE-004 1999 Cold Vacuum Drying Facility Hazard Analysis Report Rev 4 Fluor
Danzel Hanford, Incorporated, Richland, Washington  Figure B3 2 shows the hazardous material/energy source checklist that was used to group potentially hazardous materials and energy sources for each of the six major building areas
AA Administrative area
TC Transfer corridor and mechanical corridor
PB Process bays 2 through 5
SB Process bay 1 an unused bay
PW Process water tank room
OU Outside
An alpha numeric designator from the standardized checklist is combined with the building identifier to provide a unique identifier for each hazard
(e g AA A-01 identifies an electrical source in the administrative area specifically battery banks)  If a hazard is evaluated in the hazard analysis tables (HNF SD SNF HIE-004) using multiple rows a lowercase letter following the designator is used to differentiate between rows (e g AA A-01a AA A-01b)

Chosen as a representative and bounding accident for further accident analysis development

Normally F0 events are excluded from the accident bins but the hydride reaction as an independent initiator is identified explicitly to demonstrate that it has been considered. Hydride reactions are included in the calculations for other DBAs

CVDF = Cold Vacuum Drying Facility
HVAC = heating, ventilation, and air conditioning
MCO = multi-canister overpack
descriptions, and operation and maintenance procedures. Abnormal events encompass malfunctions of systems, operating upset conditions, equipment failures, safety system trips, natural phenomena or operator error that may impact operational or programmatic schedules. While many postulated CVDF abnormal events have similar initiators as the DBAs and other accidents analyzed in Section B3.4, there are no radiological releases outside the facility. Facility worker exposure to radiological hazards associated with abnormal events are controlled by Hanford Site, SNF Project, and CVDF radiological protection and ALARA programs and practices.

The CVDF abnormal event analysis was developed from a review of HNF-SD-SNF-HIE-004 which identified hazardous conditions and their potential accidents or events meeting the abnormal event profile. Hazardous conditions having common failures or impacts on facility operations were then grouped into categories. The following five abnormal event categories, each having distinct initiators and operational consequences, were identified for the CVDF process:

1. MCO received in a suspect condition
2. Single or multiple, empty process bays out-of-service
3. Single, processing process bay loss of processing ability
4. Shipping delays from the CVDF
5. Safe and stable state following safety system actuation

The following sections provide a description of these five CVDF abnormal event categories. For each of the abnormal event categories, the descriptive information includes the event, the cause of the event, the consequence of the event, the means of detection for the event, and corrective actions. After the safe and stable condition is achieved for each type of event, any necessary recovery actions or plans must be developed based on the specific abnormal condition. All applicable requirements must be followed in the recovery actions or plans (e.g., reviewed safety question evaluations).

B3.3.1 Multi-Canister Overpack Received in a Suspect Condition

- **Event** An MCO shipped from the K Basins is received in a suspect or indeterminate condition at the CVDF. Events in this category have a potential impact on CVDF operations by causing delays due to the uncertain chemical or thermal status of the SNF in the MCO. MCO transportation requirements are established in the safety analysis report for packaging (HNF-SD-TP-SARP-017), which requires transport from the K Basin to the CVDF within a shipping window. Events occurring during transport are analyzed in the safety analysis report for packaging. Cask-MCOs experiencing unusual transportation conditions and received and accepted by the CVDF would require evaluation prior to processing.

- **Postulated Cause of Event** Events in this category involve (1) receiving an MCO with a transport time greater than the shipping window, (2) receiving an MCO that
experienced unusual transport conditions, (3) receiving an MCO with higher than expected pressure, or (4) receiving an MCO with an incomplete or irregular quality assurance package

- **Detection of Event**  Events in this category are detected by operator observations or direct readings from pressure test instrumentation. A higher than expected pressure reading requires a special venting procedure.

- **Analysis of Effects and Consequences**  Events in this category could impact the facility or project schedules and may result in an increase of facility occupational exposure totals. Receiving an out-of-specification MCO would likely require an investigation and could cause facility delays, if special venting or processing requirements were identified and imposed. While the facility exposure totals and ALARA goals may be impacted, individual workers would not exceed radiological protection limits while responding to events in this category.

- **Corrective Actions**  Immediate operator actions to stabilize events in this category are contained in standard operating procedures, alarm response procedures, and/or emergency response guides. Once the event has been stabilized, facility management will develop a recovery plan based on the existing facility conditions, the cause of the abnormal event, and safety requirements.

### B3 3 2  Single or Multiple, Empty Process Bays Out of Service

- **Event**  One or more process bays at the CVDF are out of service. Events in this category impact CVDF operations because conditions cause one or more empty operating bays to be out of service and unable to receive an MCO and cask from the K Basins. Until the equipment or structures are repaired or returned to operating status, the bay or bays are unable to receive an MCO.

- **Postulated Cause of Event**  Conditions causing a bay or bays to be declared out of service could result from electrical or mechanical failure, structural damage, fire, or operator errors.

- **Detection of Event**  Events in this category are detected by instrument readings, direct observation of equipment failure by operator or maintenance personnel, and visual or audible alarms.

- **Analysis of Effects and Consequences**  Events in this category primarily result in schedule delays for the CVDF and the potential for programmatic delays to the SNF Project. Equipment failures can lead to facility delays for repairs and tests and additionally, possible delays for investigations to resolve the reasons for the equipment failures and to determine future requirements.
HNF-3553 REV 0  
Annex B — Cold Vacuum Drying Facility

- **Corrective Actions**  Immediate operator actions to bring events in this category to operational safe and stable states are contained in alarm response procedures and/or emergency response guides. In most cases, equipment operations during recovery are expected to be the same as those contained in the standard operating and/or maintenance procedures.

**B3 3 3 3 Single, Processing Process Bay Loss of Processing Ability**

- **Event**  A process bay loses the ability to continue processing an MCO. Events in this category impact CVDF operations by delaying processing in the affected bay. Depending on the cause and duration of the event, an impact to programmatic schedules may occur. Until the equipment or structure is repaired or returned to operating status, the MCO is maintained in a safe and stable condition identified in alarm response procedures.

- **Postulated Cause of Event**  Conditions affecting the ability to process an MCO in a single bay could result from electrical or mechanical failure, structural damage, fire, or operator errors.

- **Detection of Event**  Events in this category are detected by instrumentation readings, direct observation of equipment failure by operator or maintenance personnel, visual or audible alarms, or notification from Hanford Site or offsite entities.

- **Analysis of Effects and Consequences**  Events in this category primarily result in schedule delays for the CVDF, the potential for programmatic delays to the SNF Project, and the potential need to perform unreviewed safety question evaluations to assess delay impacts to safety analysis assumptions before resumption of processing. Equipment failures can lead to facility delays for repairs and tests, and additionally, possible delays for investigations to resolve the reasons for the equipment failures and to determine future requirements. In the event of a fire, equipment and personnel could be impacted by smoke, heat, and chemical vapors.

- **Corrective Actions**  Immediate operator actions to bring events in this category to operational safe and stable states are contained in alarm response procedures and/or emergency response guides. Once the event has been stabilized, facility management will develop a recovery plan based on the existing facility conditions, the cause of the abnormal event, and safety requirements. In most cases, equipment operations during recovery are expected to be the same as those contained in the standard operating and/or maintenance procedures.
B3 3 3 4 Shipping Delays from the Cold Vacuum Drying Facility

- **Event**  An MCO cannot be shipped from the CVDF and remains in the process bay. Events in this category occur following the drying process and impact CVDF operations by reducing the availability of processing bays for receipt of cask-MCOs from K Basins. Since the drying process has been completed, the affected MCO is in a safe and stable condition.

- **Postulated Cause of Event** Conditions affecting the ability to ship the cask-MCO could result from electrical or mechanical failure, structural damage, fire problems at the CSB, weather delays, or operator errors.

- **Detection of Event** Events in this category are detected by instrumentation readings, direct observation by operating personnel, visual or audible alarms, or by notification from Hanford Site or offsite entities.

- **Analysis of Effects and Consequences** Events in this category primarily result in schedule delays for the CVDF and the potential for programmatic delays to the SNF Project, and exceeding the shipping window to the CSB. Equipment failures can lead to facility delays for repairs and tests, and additionally, possible delays for investigations to resolve the reasons for the equipment failures and to determine future requirements. In the event of a fire, equipment and personnel could be impacted by smoke, heat, and chemical vapors.

- **Corrective Actions** Immediate operator actions to bring events in this category to operationally safe and stable states are contained in standard operating procedures, alarm response procedures, and/or emergency response guides. Once the event has been stabilized, facility management will develop a recovery plan based on the existing conditions, the cause of the abnormal event, and safety requirements.

B3 3 3 5 Safe and Stable State following Safety System Actuation

- **Events** CVDF safety systems are actuated, which halts normal MCO processing. Events in this category are the safe and stable states established as a result of automatic or manual safety-class instrumentation and control (SCIC) system actuation. Facility and programmatic delays occur as a result of these events ranging from the time necessary to return the system to normal processing to the time necessary to investigate the event cause and institute corrective measures.

- **Postulated Cause of Event** Events in this category occur as a result of (1) SCIC system automatic protective action, if monitored process or facility parameters reach predetermined limits, or (2) operating personnel manually tripping the safety-class helium (SCHe) system in response to a process upset, alarm response procedure, or
emergency response procedure  Potential initial causes for the automatic or manual protective action are the analyzed accidents described in Section B3.4.2

- **Detection of Event**  SCIC system and SCHe system actuation are alarmed in the facility control room

- **Analysis of Effects and Consequences**  SCIC system and SCHe system actuation occur to prevent and mitigate events before unacceptable conditions are reached  These systems place a single bay, MCO, or all MCOs in the facility in safe and stable states depending on the event  Events in this category primarily result in schedule delays for the CVDF, with the potential for programmatic delays to the SNF Project  SCIC automatic actuation may require an investigation, reporting and possible corrective measures  Manual SCHe actuation would require similar activities

- **Corrective Actions**  Immediate operator actions to bring events in this category to operational safe and stable states are contained in alarm response procedures and/or emergency response guides  Operating personnel are routinely trained and qualified in the use of these procedures and guides  Once the event has been stabilized facility management will develop a recovery plan based on the existing facility conditions, the cause of the SCIC actuation, and safety requirements  In most cases equipment operations during recovery are expected to be the same as those contained in the standard operating and/or maintenance procedures

**B3.4 ACCIDENT ANALYSIS**

This section presents the methodology used to analyze the DBAs identified in Table B3-4, and the quantified results of those analyses  It also presents the safety-class and safety-significant SSCs and TSRs related to these accident events that are necessary for the protection of the offsite public and onsite workers  For each DBA, the following standard topics are discussed (DOE-STD-3009-94)

- **Scenario development**

  Accident analysis for each DBA starts with a formal description of the accident scenario  Each description is supported by a basic event tree (SNF-2770)  The major assumptions in each scenario are identified

- **Source term analysis**

  The source term for each accident is obtained through phenomenological and system response calculations
Consequence analysis

Atmospheric dispersion or other relevant pathways of concern are used in calculating the consequences of each DBA. Because the potential consequences of the CVDF DBAs are significant, computer modeling using site-specific meteorological data was used to model the dispersion.

Comparison with guidelines

The consequences determined for each DBA are compared with release limits and risk evaluation guidelines. From this, it is determined whether safety-class SSC designation is needed. The need for accident-specific TSRs to meet release limits and risk evaluation guidelines is determined.

Summary of safety SSCs and TSRs

The safety SSCs and TSRs are summarized. Detailed descriptions of safety-class SSCs are presented in Chapter B4.0, and detailed descriptions of the TSRs are presented in Chapter B5.0.

In addition to the DBAs analyzed in this section, common cause (facility-wide) events are discussed in Section B3.4.2.7, and beyond design basis accidents (BDBAs) are discussed in Section B3.4.3.

The DBAs are summarized below and are developed in greater detail in Section B3.4.2.

Gaseous release (Section B3.4.2.1)

The bounding scenario for this accident category describes a pressurized release of helium gas and entrained contaminated particulate through a process line leak. The unmitigated consequences of this event do not exceed the offsite release limits but do exceed the onsite risk evaluation guidelines. No safety-class features are required to mitigate this event. Safety-significant features selected for this event include portions of the process general supply/exhaust heating, ventilation, and air conditioning (HVAC) system, the process bay local exhaust HVAC and process vent system (including backup electrical power supplied by the standby power system) and the process bays and process water tank room differential pressure alarms. Mitigated consequences of this event are well below both offsite release limits and onsite risk evaluation guidelines. Refer to Section B3.4.2.1, Table B3-9, for a detailed list of safety features selected to prevent, mitigate, or provide defense in depth for the accident scenarios binned in the gaseous release accident category.
Liquid release (Section B3 4 2 2)

The bounding scenario for this accident category describes a pressurized leak of water and entrained contaminated particulate from the PWC piping. The unmitigated consequences of this event do not exceed the offsite release limits but do exceed the onsite risk evaluation guidelines. No safety-class features are required to mitigate this event. Safety-significant features selected for this event include portions of the process general supply/exhaust HVAC system (duct work and HEPA filters for process water tank room) and the process water tank room differential pressure alarm. Mitigated consequences of this event are well below both offsite release limits and onsite risk evaluation guidelines. Refer to Section B3 4 2 2, Table B3-12, for a detailed list of safety features selected to prevent, mitigate, or provide defense in depth for the accident scenarios binned in the liquid release accident category.

MCO external hydrogen explosion (Section B3 4 2 3)

The bounding scenario for this accident category describes accumulation of hydrogen outside an MCO when it is vented from the MCO into the local exhaust process ventilation system and mixed with air, followed by ignition and explosion of the hydrogen gas. The unmitigated consequences of this event do not exceed the offsite release limits but do exceed the onsite risk evaluation guidelines. No safety-class features are required to prevent or mitigate this event. Safety-significant features selected to prevent this event include portions of the process bay local exhaust HVAC and process vent system (ensuring minimum flow rate), a flow-restricting orifice to limit the cask vent flow rate, and the standby power system. Potential releases are mitigated by HEPA filter loading limits. Because the selected safety features prevent and mitigate this event both offsite release limits and onsite risk evaluation guidelines are satisfied. Refer to Section B3 4 2 3, Table B3-14, for a detailed list of safety features selected to prevent, mitigate, or provide defense in depth for the accident scenarios binned in the external hydrogen explosion accident category.

MCO internal hydrogen explosion (Section B3 4 2 4)

The bounding scenario for this accident category describes the ignition and explosion of a hydrogen-air mixture inside an MCO. The unmitigated consequences of this event do not exceed the offsite release limits but do exceed the onsite risk evaluation guidelines. No safety-class features are required to prevent or mitigate this event. However, some safety-class features preventing the MCO thermal runaway reaction and overpressurization events (i.e., multiple safety features to detect process upsets, the SCHe system, portions of the tempered water [annulus] system, and the water isolation components) also prevent this accident, but in a safety-significant role. The safety-significant portions of the process bay local exhaust HVAC (including backup...
power to the process bay local exhaust HVAC from the standby power system) and the process general exhaust HVAC systems also provide a mitigation function, which represents an added safety barrier if any of the prevention features fail. Because the designated safety features prevent and mitigate this event, both offsite release limits and onsite risk evaluation guidelines are satisfied. Refer to Section B3 4 2 4, Table B3-16, for a detailed list of safety features selected to prevent, mitigate, or provide defense in depth for the accident scenarios binned in the internal hydrogen explosion accident category.

- **MCO thermal runaway reaction (Section B3 4 2 5)**

The bounding scenario for this accident category describes an accident that is initiated by a reduction of heat removal from the MCO. This condition results in escalation of the chemical reaction within the MCO and high temperatures in the MCO. The high temperatures in the unmitigated scenario ultimately lead to a release of gas and radioactive particulate for an extended period of time. The release is caused by rapid uranium-water reactions inside the MCO. The unmitigated consequences of this event exceed the offsite release limits and exceed the onsite risk evaluation guidelines. Safety-class features selected to prevent this event include portions of the tempered water (annulus) system to provide adequate heat transfer from the MCO, a TSR, and associated equipment to refill the annulus if annulus water is lost. The SCHe system, and safety-class instrumentation to detect process upsets and actuate the SCHe system, act in a defense-in-depth role by providing more time before a thermal excursion occurs (purge and vent function). The estimated frequency for failure of the preventive features is in the beyond extremely unlikely category (less than $10^{-6}$ per year). Refer to Section B3 4 2 5, Table B3-18, for a detailed list of safety features selected to prevent, mitigate, or provide defense in depth for the accident scenarios binned in the MCO thermal runaway accident category.

- **MCO overpressurization (Section B3 4 2 6)**

The bounding scenario for this accident category describes an overpressurization of an isolated MCO with no pressure relief. The pressure in an isolated MCO increases with the formation of hydrogen gas as a product of the uranium-water reaction. The MCO internal pressure would continue to increase until the MCO pressure boundary is breached or until the fuel or water are completely consumed. The overpressurization leads to a pressurized release of gas and radioactive particulate followed by an extended period of a slow continuous release driven by the continued oxidation of the uranium inside the MCO. The unmitigated consequences of this event exceed both the offsite release limits and the onsite evaluation risk guidelines. Safety-class features selected to prevent this event include multiple safety features to detect process upsets, the SCHe system, the 30 lb/in² gauge rupture disk and vent line, the 150 lb/in² gauge rupture disk, and portions of the tempered water (annulus).
system These safety-class features reduce the frequency and mitigate the occurrence of this event to well within the offsite release limits. Additional safety significant features for confinement and filtration are identified to mitigate the onsite consequences to well below the onsite risk evaluation guidelines. Refer to Section B3 4 2 6, Table B3-22, for a detailed list of safety features selected to prevent, mitigate, or provide defense in depth for the accident scenarios binned in the MCO overpressurization accident category.

In a small number of cases, operator actions are credited as TSR items for response to upset conditions. In all of these cases, the credited actions are simple and can easily be accomplished in the time available. In addition, credit for such actions is minimized and only taken in cases where the risk is already low (frequencies or consequences are small).

Letter 97-SFD-172, Risk Evaluation Guidelines (REGs) to Ensure Inherently Safer Designs (Sellers 1997), provides guidance for determining the need for safety-class and safety-significant SSCs. Table B3-5 is extracted from the SNF Project FSAR and summarizes that guidance for radiological consequences. If a credible event can cause an offsite radiation exposure exceeding 0.5 rem, then safety-class SSCs must be provided in the design to prevent or mitigate the consequences of the event. Similarly, if a credible event can cause an onsite radiation exposure, then safety-significant SSCs must be provided to prevent or mitigate the consequence. If failure of a credited safety-class system is credible, the offsite consequences must be limited to the value in Table B3-5 for the appropriate likelihood category.

**B3 4 1 Methodology**

This section identifies CVDF-specific methods and assumptions used to quantify the consequences of the DBAs. Methods and assumptions that are common or generic to all the SNF Project facilities at the K Basins, CVDF, or CSB are described in Chapter 30 of the SNF Project FSAR.

**B3 4 1 1 Source Term** The bounding source term used for the accident analysis is based on data for the SNF in the K East and K West Basins that is provided in HNF-SD-SNF-TI-009, 105-K Basin Material Design Basis Feed Description for Spent Nuclear Fuel Project Facilities. This document defines an inventory for safety analysis based on the inventories of Mark IV and Mark IA fuel in the K Basins. High-burnup Mark IV fuel, the fuel type that results in the highest estimated dose per gram, was selected as the bounding inventory from the radiological dose perspective. Nuclear accountability records provide the basis for the quantity, exposure variation, and decay time variation of the stored fuel. The radionuclide inventory has been estimated from these data (HNF-SD-SNF-TI-009).
The MCO contains finely divided particulate material associated with the oxidation of the SNF. This material includes an oxide layer on the fuel and particulate remaining on fuel surfaces and in crevices after fuel washing and racking into the MCO as well as oxidation products that are created during queuing at the K Basins and processing at the CVDF. The particulate inventory of the MCO dominates the airborne release.

For both the onsite and offsite receptors at all accident frequency categories, the radiological guidelines are more limiting than the toxicological guidelines for the release of SNF particulate. Therefore, the toxicological consequences of the postulated airborne releases do not require mitigating features beyond those required by the radiological consequences (see Section 3.4.1 of the SNF Project FSAR).

No routine chemical processes will be conducted within the CVDF. Purging and backfilling the MCOs will involve the use of an inert gas. Some chemicals, such as those used for equipment decontamination, may be used occasionally (HNF-SD-SNF-CM-001). However, there are no chemical inventories of concern for safety analysis considerations.

**B3 4.1.2 Consequence Analysis** Radiological inhalation dose consequences are calculated for four receptor locations:

- **Hanford Site boundary (10,090 m [33,100 ft])** — release limits defined, used for calculation of offsite doses and selection of safety-class features.

- **Collocated worker at 100 m (328 ft)** — risk evaluation guidelines defined, used for calculation of onsite doses and selection of safety-significant features.

- **Near bank of the Columbia River (onsite, at a distance of approximately 650 m [2,130 ft])** — no evaluation guideline defined, doses calculated for the purpose of identifying any additional measures considered necessary to reduce the dose to individuals at this receptor location.

- **100 Area Fire Station (onsite, at a distance of approximately 3,750 m [12,300 ft])** — no evaluation guideline defined, doses calculated for the purpose of identifying any additional measures considered necessary to reduce the dose to individuals at this receptor location.

Radiological inhalation dose consequences for each accident analyzed are based on the following factors:

- **Mass of material at risk (MAR) available for release, g**

- **Airborne release fraction (ARF) (or the product of the airborne release rate [ARR] and release time [T]) and respirable fraction (RF)**
• Leak path factor (LPF)

• Mass of respirable material released (M)

• Atmospheric transport factor (\(x/Q'\)), s/m³

• Breathing rate (BR), m³/s

• Dose per unit intake (UD) of SNF, rem/g (Sv/g)

• Duration of exposure

• Committed effective dose equivalent (D), rem (Sv)

The quantity of respirable material released (M) is determined by the specific accident scenario. The quantity M is a function of the MAR, total ARF (or ARR times T), the RF, and the leak path factor of any passive structural enclosure that may cause deposition of an airborne release before the release enters the atmosphere. The leak path factor is based on a time-integrated calculation of aerosol deposition within and release from an enclosure of given dimensions with specified leakage area, pressure, and temperature differentials. The specific value of each parameter is determined in the individual DBA analysis and based on the physical phenomena of the accident, thus the values are specific to the CVDF.

The atmospheric transport factor (\(x/Q'\)) is based on specific release conditions (e.g., ground level or elevated, long or short duration) and the receptor's distance from the release. While the methodology is common to the SNF Project, the atmospheric transport factor is the time-integrated normalized air concentration at the receptor's location, which is a measured distance from the CVDF. The transport factor includes the dilution of an airborne contaminant caused by atmospheric mixing and turbulence. The air transport values used in this report have been generated using the GXQ computer program (WHC-SD-GN-SWD-30002 WHC-SD-GN-SWD-30003). Table B3-7 contains the air transport values used to determine onsite and offsite consequences.

Air transport factors were calculated using methods found in NRC Regulatory Guide 1 145, Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants.

Exposures to the collocated worker onsite are bounded by exposures of the individual at the 100-m location. The risk evaluation guidelines apply to this individual (Sellers 1997). For assessment purposes, DOE has directed (Sellers 1996) that the Hanford Site boundary be considered the location of the offsite receptor. Consequences at the near bank of the Columbia River are provided for information related to evaluation of possible additional controls applied to protect receptors at this location.

*Units for these values are seconds per cubic meter. In all cases the releases are assumed to be point sources at ground level to maximize the dose consequences.

*Air transport factors are computed by logarithmic interpolation between the 1 to 2 hours value and the annual average value.

*No adjustment for plume meander.

*Plume meander adjustment used is found in NRC Regulatory Guide 1 145 1982 *Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants* U.S. Nuclear Regulatory Commission Washington D.C.

*The 12 hour durations are used for onsite exposures and the 24 hour durations are used for offsite exposures.

(HNF SD SNF T1 059 1999 *A Discussion on the Methodology for Calculating Radiological and Toxicological Consequences for the Spent Nuclear Fuel Project at the Hanford Site* Rev 2 Fluor Daniel Hanford Incorporated Richland Washington) These are bounding exposure times.

NA = not applicable

If the offsite receptor were assumed to be coincident with the receptor at the Columbia River location, it is expected that no additional controls would be imposed and impacts to existing controls would be minimal. For the gaseous release, liquid release, and external explosion DBAs, dose consequences would still be below release limits, so no impacts to controls would be realized. The internal explosion DBA consequences would increase from safety significant to safety class, but many of the credited systems for internal explosion are already safety class because of the thermal runaway and overpressurization DBAs. The thermal runaway and overpressurization DBAs are already safety class and would not be affected.

None of the accidents analyzed in this document adjusts the air transport factors for building wake effects or for the elevation of the release above ground level (the stack height is not sufficient to be used for atmospheric dispersion). It is conservative to ignore building wake and stack effects because both of these effects serve to disperse the release such that the collocated worker and the offsite receptor receive a lower estimated dose, if the effect is included. Section 1 4 1 2 8 of the SNF Project FSAR provides additional information on the calculation of.
the air transport factors. The basis for defining the location of the onsite and offsite receptors is provided in Section 13.13.

The breathing rate (BR) depends on individual exertion factors and exposure duration. This methodology is common to the SNF Project facilities and is described in Chapter 3.0 of the SNF Project FSAR.

The dose per unit intake (UD) is the 50-year dose commitment for all relevant exposure pathways per gram of radioactive material inhaled (HNF-SD-SNF-TI-059). The major radiation exposure pathway for the identified accidents is inhalation of radioactive material. This methodology is common to the SNF Project facilities and is described in Chapter 3.0 of the SNF Project FSAR.

B3.4.1.3 Frequency Estimates. The determination of frequency estimates is based on methodology common to the SNF Project facilities and is described in Chapter 3.0 of the SNF Project FSAR. The CVDF accident frequencies are documented with the DBA development descriptions in Section B3.4.2.

Calculated accident frequencies for each of the six DBAs are presented in Appendix A of SNF-2770. The frequencies for both the unmitigated and the mitigated consequences for a given DBA are presented. An unmitigated event sequence that has a calculated frequency of $10^{-6}$ per year or less does not need further consideration. Unmitigated event sequences with calculated frequencies greater than $10^{-6}$ per year must be evaluated against the offsite release limits and appropriate onsite risk evaluation guidelines in Table B3-5.

B3.4.1.4 Risk Guidelines. The DOE-recommended radiological risk evaluation guidelines (Sellers 1997) are applied across the SNF Project and are described in Chapter 3.0 of the SNF Project FSAR. Satisfaction of the SNF Project radiological evaluation guidelines will meet the goals of SEN-35-91, Nuclear Safety Policy, as discussed in Chapter 3.0.

B3.4.1.5 Safety Structures, Systems, and Components. "Safety class" and "safety significant," as related to the SSCs are defined consistently for the SNF Project in Chapter 3.0 of the SNF Project FSAR.

For each accident scenario, the violation of criticality controls and the airborne radiological dose calculated using the methods described here and in Chapter 3.0 of the SNF Project FSAR, are compared with the appropriate onsite and offsite evaluation guidelines and release limits from Letter 97-SFD-172 (Sellers 1997). If the radiological dose for the unmitigated case exceeds the guideline, mitigative or preventive safety features with appropriate safety-class and/or safety-significant functional classifications, are identified. The dose consequences are recalculated taking appropriate credit for the mitigating safety features to verify that the mitigated doses satisfy the guidelines.
The controls tables at the end of each DBA (e.g., Table B3-9) provide the safety SSCs and administrative features for the evaluated accidents. In addition, other defense-in-depth features are listed. The tables may be used to evaluate with cost-benefit analyses any future improvements in any of these features or safety systems in order to improve operations, maintenance, or design by using the tables' general arrangement of most important systems and features to least important.

The controls tables do not list operability TSRs related to supporting the credited SSCs because their designation is already dictated by specification of the SSCs. For example, by crediting an SSC for a specific function, it is given that the SSC must be available and operable. Such TSRs were not listed to avoid increasing the length of the tables and removing focus from unique TSRs and other controls.

In the selection of controls, general-services SSCs are considered as candidates for providing a safety function if the performance of the general-service SSC is monitored by a safety-related SSC. In these cases, if the general-service SSC fails to provide the necessary function, the safety-related monitoring allows compensatory measures to be taken. For example, the general-service helium system provides a supply of helium, and safety-class flow instrumentation monitors its performance. If the general-service helium system does not function properly, compensatory measures are taken. The CVDF provides a similar approach for confinement function general-service fans with safety-significant HEPA filters provide the confinement function, and the differential pressure from the process bay to the environment has safety-significant monitors to demonstrate the availability of the filtered ventilation. If the differential pressure is lost, confinement cannot be assured and compensatory measures are taken.

B3 4 2 Design Basis Accidents

The results of the DBA analyses that have been performed for the CVDF are summarized in this section along with the key assumptions used in those analyses. The DBAs summaries are based on the guidelines provided in DOE-STD-3009-94, and include the following DBA categories:

- Gaseous release (Section B3 4 2 1)
- Liquid release (Section B3 4 2 2)
- MCO external hydrogen explosion (Section B3 4 2 3)
- MCO internal hydrogen explosion (Section B3 4 2 4)
- MCO thermal runaway reaction (Section B3 4 2 5)
- MCO overpressurization (Section B3 4 2 6)

The DBAs have been analyzed to quantify consequences, and those consequences have been compared with the release limits for offsite consequences and evaluation guidelines for onsite consequences. The process is iterative, starting by taking no credit for mitigative features and comparing the results to the limits or guidelines. Credit is then taken for safety SSCs that
prevent or mitigate the consequences to show that the results are below the release limits and evaluation guidelines. The process continues after the evaluation guidelines are met by identifying other SSCs that, while not designated as safety class or safety significant, provide additional mitigative features as defense in depth. In addition, each individual DBA section references a supporting calculational note (SNF-2770) that provides more detail.

The following assumptions have some relevance to all the DBAs:

- The bounding MCO is loaded at the K Basins with two scrap baskets and three Mark IV fuel baskets. The scrap baskets are at the top and bottom of the MCO. The scrap has an exposed surface area (uranium fuel area without cladding, including indentations, cracks, and crevices exposed to MCO gases or liquids) of 45,000 cm² per scrap basket. Each of the three fuel baskets contains 54 assemblies, and the fuel has an exposed surface area of 7,900 cm² per fuel basket. The total exposed surface area in the bounding MCO is 120,000 cm² (HNF-SD-SNF-TI-015).

- After the fuel is washed, the baskets are queued and loaded into the MCO, transported to the CVDF, and prepared for draining. At this point in the process, the bounding value for the mass of particulate in the bounding MCO is 15 kg in the form of UO₂. Normal values for the mass of particulate in an MCO are expected to be less than 0.1 kg. The complete processing of the MCO at the CVDF produces an additional 10 kg of particulate (SNF-2770, Chapter 10) for a total of 25 kg of UO₂.

- Hydrogen gettering by uranium, and hydrogen production from radiolysis during the processing time interval, is negligible (HNF-SD-SNF-CN-006) and is ignored in this analysis.

**B3 4 2 1 Gaseous Release** This section addresses the consequences of a pressurized release of helium gas and entrained contaminated particulate through a process leak. The quantity of radioactive material released is calculated, and this value is used to calculate the dose consequences to both offsite and onsite receptors.

The unmitigated dose consequences of the bounding gaseous release do not exceed the offsite release limit, so no safety-class features are required to mitigate or prevent this accident. However, the dose consequences exceed the onsite risk evaluation guideline so safety-significant features have been identified to mitigate the consequences of a gaseous release. The process bay local exhaust HVAC system (for the process bays) and the process general exhaust HVAC system (for the PWC tank room) are credited with HEPA filtration of the gaseous release scenarios. In addition, the reference air system is credited with monitoring the differential pressure in the process bays to ensure that any releases are drawn through the HEPA filters. The HEPA filters remove entrained contaminated particulate material from the released gas, mitigating the DBA. With safety-significant features credited, the mitigated onsite dose is well below onsite risk evaluation guidelines. Details of the calculations for this DBA are provided in SNF-2770, Chapter 20.
B3 4 2 1 1 Scenario Development  The CVDF hazard analysis (HNF-SD-SNF-HIE-004) identified and categorized (i.e., binned) a series of potential accidents in the gaseous release accident category. This accident category includes releases from the MCO and CVDF processing equipment during various phases of the cask venting, draining, and vacuum drying process. Gaseous release accidents include leaks in a process line and subsequent removal of entrained particulate in the helium purge flow. This set of accidents involves a slightly pressurized MCO exhausting, ultimately, to the environment. This condition could exist any time there is a purge flow through the MCO.

A purge flow through the MCO could be present at any time following draining of bulk water. Initially, the purge flow will be from the filtered process exit port side to the long axially process tube side immediately following the drain and during purge and flush of the process lines. At this time a leak could occur in the PWC room. Following purge and flush, the normal purge flow will be established from the long axially process tube side to the filtered process exit port side. Following establishment of the normal purge flow through the MCO, a purge could exist, as needed, at any time prior to the end of the process. During any of these times a leak could exist in the bay.

A leak in the MCO purge line (VPS-*02-SS-1", VPS-*02-SS-2") or the connections to the MCO during helium purge will result in a gaseous release accident. The leak allows a continuous release of pressurized helium carrying particulate that could be released to the process bay. Pressure is maintained in the system because the helium lost through the leak is made up by the helium supply system. During this phase of the cold vacuum drying process, an additional 10 kg of particulate could be generated, which means that the MCO could now contain a maximum of 25 kg of particulate matter. A leak at this time is selected as the bounding and representative accident. The scenario is based on the following assumptions:

- The operating parameters are within the normal range, and the instrument and control systems do not indicate that a problem exists.
- The time period associated with helium purge following draining is nominally 0.5 hours, and the time associated with the purge following the vacuum process is nominally 4 hours. However, for the purposes of this analysis, the purge gas will be assumed to flow throughout the entire exposure period for both onsite and offsite receptors (12 and 24 hours, respectively).
- The SCIC system includes a high-pressure alarm and a low-pressure alarm for the VPS. As long as the alarm setpoints are not violated, the helium system will attempt to maintain the helium pressure by increasing purge flow to the MCO.

B3 4 2 1 2 Source Term Analysis  Section 5.2.4 of DOE-HDBK-3010-94, *Airborne Release Fractions/Rates and Respirable Fractions/Rates for Nonreactor Nuclear Facilities*, states that the value for the aerodynamic entrainment of uranium “powders lying on a heterogeneous surface under debris or for static conditions within facilities” is $4.0 \times 10^{-6}$ per hour.
with an RF of 1.0. Before the fuel is loaded into an MCO, it is washed to remove debris and oxide. The material produced since washing and available for transport from the MCO by purge gas flow is assumed to be comparable to that of powder lying on a heterogeneous surface under debris. Thus, an ARR of $4.0 \times 10^{-6}$ per hour with an RF of 1.0 is used in this analysis. This scenario was not modeled as a pressurized release even though the pressure in the MCO at the time of the accident is above atmospheric. This is because the releasable material is partially located on the bottom of the MCO and is exposed to relatively low air velocities. The loaded internal containers in the MCO will provide substantial protection from air velocity effects produced by the purge gas flow. Thus, the conditions the releasable powder material is exposed to are more closely approximated by ambient atmospheric wind conditions than by a pressurized powder release.

Because the representative accident could happen at the end of processing the MCO at the CVDF, the total 25 kg of particulate is used in this analysis. The 25 kg of uranium dioxide particulate contains approximately 22 kg of uranium, which is the amount of the MAR for this accident. The amount of respirable material released from the MCO is calculated using the following formula

$$M = \text{MAR} \times \text{ARR} \times \text{RF} \times T$$

where

- **MAR** = material at risk (22 kg)
- **ARR** = airborne release rate ($4.0 \times 10^{-6}$ per hour)
- **RF** = respirable fraction (1.0)
- **T** = time (hours)

For a 12-hour release, the amount of respirable radionuclide material released is

$$M = (22 \text{ kg})(1,000 \text{ g/kg})(4.0 \times 10^{-6}/\text{h})(1.0)(12 \text{ h})$$

$$= 1.1 \text{ g}$$

For a 24-hour release, the amount of respirable radionuclide material released is two times the 12-hour release or $2.2 \text{ g}$

**B3 4 2 1 3 Consequence Analysis** The effective dose equivalent to a receptor is calculated by using the following equation

$$DE = M \times \frac{X}{Q'} \times BR \times UD$$

B3-47

November 1999
where

\[ \text{DE} = \text{effective dose equivalent based on inhalation exposure only (rem)} \]
\[ M = \text{respirable quantity released into the air (grams)} \]
\[ \chi/Q' = \text{air transport factor (s/m³)} \]
\[ \text{BR} = \text{average inhalation rate during the release (m³/s)} \]
\[ \text{UD} = \text{committed effective dose equivalent per unit gram inhaled} \]

For the onsite receptor, the duration of worker exposure can be assumed to be 12 hours on the basis of anticipated 12-hour work shifts. For the offsite receptor, the duration of exposure is taken to be 24 hours (HNF-SD-SNF-TI-059). The air transport factor \( \chi/Q' \) for a 12-hour or a 24-hour release is the logarithmic interpolation between the 2-hour \( \chi/Q' \) with plume meander and the chronic \( \chi/Q' \) (HNF-SD-SNF-TI-059).

The light activity breathing rate of \( 3.33 \times 10^4 \text{ m}^3/\text{s} \), as defined in HNF-SD-SNF-TI-059, *A Discussion on the Methodology for Calculating Radiological and Toxicological Consequences for the Spent Nuclear Fuel Project at the Hanford Site*, is used for the onsite receptor. For the offsite receptor, an average 24-hour breathing rate of \( 2.64 \times 10^4 \text{ m}^3/\text{s} \) is used.

The dose per unit of respirable material inhaled is \( 4.38 \times 10^5 \text{ rem/g} \) of fuel, as specified in Section 3 4 1 2 of the SNF Project FSAR. All the material released from the building is treated as respirable (i.e., less than 10-μm aerodynamic diameter).

Using the respirable radionuclide release quantities calculated in Section B3 4 2 1 2, doses to various receptors are calculated as a function of leak duration.

**Unmitigated Consequences** The following dose calculation equation is used to calculate the dose to the onsite receptor:

\[
\text{DE}_{\text{onsite}} = M \times \frac{\chi}{Q'} \times \text{BR} \times \text{UD}
\]

\[
= (1 \text{ g})(6.28 \times 10^{-3} \text{ s/m}^3)(3.33 \times 10^{-4} \text{ m}^3/\text{s})(4.38 \times 10^5 \text{ rem/g})
\]

\[
= 1.0 \text{ rem} (1.0 \times 10^{-2} \text{ Sv})
\]

The unmitigated dose consequences at the remaining receptor sites are calculated in the same manner and are shown in Table B3-8.

$^\ast$Fifty year committed effective dose equivalent.

$^b$Evaluation guideline (for onsite receptor) and release limit (for offsite receptor) for unmitigated accidents in the anticipated frequency category (i.e., frequency $>10^{-5}$ per year)

$^c$Evaluation guideline/release limit based on a mitigated accident frequency of extremely unlikely
Mitigated Consequences  Since the unmitigated accident does not exceed offsite release limits, no mitigated offsite doses were calculated. For the mitigated onsite dose, the release is assumed to continue for the same period of time, but the process bay local exhaust HVAC system (including standby power to this system) for the process bays is credited with confinement of the release by filtering the release via the HEPA filters in the system. The general exhaust HVAC system is credited with filtration of releases into the process bays or process water tank room, and the differential pressure instrumentation and alarms provide indication if the general exhaust is not providing its filtering function. The mitigated onsite dose calculation includes the effects of the leak path factor for radioactive material released from the building via the HEPA filters. For a HEPA filter efficiency of 99.9%, this leak path factor is 0.001 and is applied as indicated in the following equation:

\[
DE_{\text{on-site}} = M \times \frac{X}{Q'} \times BR \times UD \times LPF
\]

\[
= (1.1 \text{ g})(6.28 \times 10^3 \text{ s/m}^3)(3.33 \times 10^4 \text{ m}^3/\text{s})(4.38 \times 10^5 \text{ rem/g})(0.001)
\]

\[
= 0.001 \text{ rem (1.0 } \times 10^5 \text{ Sv)}
\]

With safety-significant functions credited, mitigated onsite consequences for the event are 0.001 rem (1.0 \times 10^5 Sv). The mitigated gaseous release consequences also are summarized in Table B3-8.

B3.4.2.1.4 Comparison with Guidelines

Comparison of Unmitigated Doses  The unmitigated frequency for gaseous release is in the anticipated category (i.e., an unmitigated frequency greater than 1\times10^{-2} \text{ per year}) (see SNF-2770, Appendix A). The unmitigated sequence considered the processing of 200 MCOs per year and a leak from either the flexible hose connections themselves or from installation error, the piping, or the valves. The unmitigated radiological offsite dose for this event is below offsite release limits, while the unmitigated onsite dose for an anticipated event is above onsite risk evaluation guidelines.

Comparison of Mitigated Doses  The mitigated frequency of the event tree sequences that represent this DBA as an unfiltered release is 1 \times 10^{-5} \text{ per year}, thus this mitigated DBA is extremely unlikely (see SNF-2770, Appendix A). The mitigated sequence credited leak verification, local exhaust fan operation, loss of differential pressure in the process bays, response to loss of differential pressure, and HEPA filter functionality. With safety-significant features credited, the mitigated onsite dose for an extremely unlikely event is well below onsite risk evaluation guidelines.

B3.4.2.1.5 Summary of Safety-Class Structures, Systems, and Components and Technical Safety Requirement Controls  Under normal operating conditions, no unfiltered gaseous releases to the process bay or PWC tank room are expected. Under upset or accident
conditions, safety-significant equipment is required in order to ensure dose consequences do not exceed onsite risk evaluation guidelines.

The checklist designators included in the accident bins, other than the accident selected as the DBA, represent additional accident sequences slightly different than the DBA. All of these binned accidents are bounded by the DBA because they have lesser or equivalent worst-case consequences and frequencies.

In addition to the DBA, accident scenarios in the G1 bin were identified in the hazard analysis, including random process line failure, line failure due to crane load drop, local or general exhaust HEPA filter failure, random ventilation system failure (differential pressure and filtration), and PWC drain line failure (process bay, spare bay, or PWC room) (HNF-SD-SNF-HIE-004). Because of the length of piping and numerous locations where a leak could occur (e.g., fittings, valves), the general approach taken for G1 bin gaseous releases is to mitigate a release. Confinement of the release is ensured by active ventilation and HEPA filtration. To support the confinement function, the differential pressure in each bay is monitored, and the standby power system (and selected isolation dampers) ensures maintenance of confinement under a loss of facility power. However, a leak in the PWC drain line is prevented rather than mitigated because that line travels through all bays and the spare bay before entering the PWC room. Confinement provided by the ventilation systems is not maintained in the spare bay and cannot be ensured in all process bays because one of the bays could have a rollup door open.

The safety-significant equipment designated to mitigate the dose consequences of the gaseous release accident analyzed in this section is described below.

Safety-class equipment (performing a safety-significant function) for confinement

- Cask-MCO

The cask-MCO is a major part of the pressure boundary for confinement of radioactive materials during processing, its integrity prevents a gaseous release.

Safety-significant equipment for confinement and filtration

- Process bay local exhaust HVAC and process vent system (exhaust fans and plenums duct work, HEPA filters)

The process bay local exhaust HVAC and process vent system mitigates a gaseous release into the process bay by sweeping it through HEPA filters before it is discharged outside the facility.

- Process bay local exhaust HVAC and process vent system process hood isolation damper and instrument air supply.
Isolation dampers in the process bay local exhaust HVAC and process vent system process hood fail closed to ensure confinement by isolation of the unfiltered process hood. If power is lost, dampers will open with electrical power from the standby power system and instrument air supplied by the local dedicated tank. The hood isolation damper and instrument air supply operate in conjunction with the standby power system to facilitate HVAC operating while on standby power.

- Process general supply/exhaust HVAC system (exhaust HEPA filter, exhaust duct work, isolation damper)

The process general supply/exhaust HVAC system mitigates a release into the process bay or process water tank room by filtering it before discharging it outside the facility. This ensures that leaks during processing or following bulk water drain (including PWC room) are captured. The process general supply/exhaust HVAC system also provides confinement in conjunction with the facility's structure by maintaining a negative building pressure. Fail-closed exhaust dampers from the process bays and process water tank room isolate other flow paths and ensure that differential pressure is maintained.

- Process bay recirculation HVAC system isolation dampers (outside air inlets)

The process bay recirculation HVAC system provides fail-closed outside air inlet dampers so the local exhaust on standby power can maintain process bay differential pressure.

- Reference air system (reference air header, differential pressure alarms for both process bays and process water tank room)

The reference air system monitors the negative pressure in the process bays and process water tank room by providing differential pressure indication and alarms to the control room for operator response.

- PWC line between the MCO and the process water tank room

The design and installation of the PWC transfer line provide confinement of contaminated process water and gases during transfer from the MCO to the PWC room.

- Standby electrical power (diesel generator and process bay local exhaust HVAC and process vent system restart circuit)
The standby power system provides connections to restart the local exhaust fans and
supporting equipment. Operation of the local exhaust on standby power will maintain
building differential pressure sufficient for confinement during facility power outages.
Assumptions made that require protection by TSRs are listed below:

- Perform process connector leak test before processing

Before processing, a leak test must be performed to ensure that the process
connectors do not leak. This test protects safety analysis assumptions relative to air
inleakage into the MCO.

The bounding accident (G 1) and the other accidents identified in the CVDF hazard analysis
report (HNF-SD-SNF-HIE-004) that may potentially lead to a gaseous release are listed in
Table B3-9 along with corresponding checklist designators from the hazard analysis report.

The accidents in the remaining bins require the following safety SSCs and TSRs, in addition
to those identified for the DBA (G 1):

G 2 Gaseous release due to delays in shipping from the CVDF

The accident scenario identified in the hazard analysis for the G 2 bin represents a slow
release from an MCO awaiting shipment from the CVDF (HNF-SD-SNF-HIE-004). The MCO is
slightly pressurized by the fuel corrosion reaction and the MCO is leaking or a port valve was not
properly closed. The control in the G2 bin prevents the gaseous release by preventing
pressurization of the MCO that results from excessive free water remaining in the MCO.

Assumptions made that require protection by TSRs are listed below:

- Proof-of-dryness demonstration at the CVDF to minimize hydrogen generation within
  the MCO during transport to and storage at the CSB

A proof-of-dryness demonstration must be successfully completed before the final
pressure rebound test steps can begin.

G 3 Gaseous release due to line break caused by a seismic event

The accident scenario identified in the hazard analysis for the G 3 bin represents releases into
the transfer corridor or process bay following a seismic event (HNF-SD-SNF-HIE-004). The
seismic event is an unlikely event for which the onsite risk evaluation guideline is 10 rem.
Because the worst-case gaseous release dose is less than 10 rem, the guideline is satisfied without
controls.

No additional requirements result from analysis of this accident.

G 4  Gaseous release caused by facility fire

The accident scenario identified in the hazard analysis for the G 4 bin represents releases into the process bay caused by a facility fire (HNF-SD-SNF-HIE-004). The unmitigated frequency for the events in bin G 4 is unlikely (HNF-SD-SNF-HIE-004) for which the onsite risk evaluation guideline is 10 rem. Since the worst-case gaseous release dose is less than 10 rem, the guideline is satisfied without controls.

No additional requirements result from analysis of this accident.

B3 4 2 2 Liquid Release  This section addresses the consequences of a pressurized release of water and entrained contaminated particulate through a leak in the PWC system. The quantity of radioactive material released is calculated and that value is used to calculate the dose consequences to both offsite and onsite receptors.

The unmitigated dose consequences of the bounding liquid release do not exceed the offsite release limit, so no safety-class features are required to mitigate or prevent this accident. However, the dose consequences exceed the onsite risk evaluation guideline, so safety-significant features have been identified to mitigate the consequences of a liquid release. The building process general supply/exhaust HVAC system is credited with filtering the release through the HEPA filters in the system. A safety-significant differential pressure alarm is provided to detect low differential pressure to provide an indication if the general exhaust system is not providing its filtering function. With safety-significant features credited, the mitigated onsite dose is well below onsite risk evaluation guidelines. Details of the calculations for this DBA are provided in SNF-2770, Chapter 3.

B3 4 2 2 1 Scenario Development  The cask-MCO arrives at the CVDF from the K Basins with the MCO containing enough K Basin water to cover the fuel. At the CVDF, the MCO is connected to process equipment and the water is drained from the MCO. A leak in the pressurized portion of this process equipment in the process water tank room during draining could result in the release of MCO water, along with entrained particulate matter from the MCO to the process water tank room and eventually to the environment.

The CVDF hazard analysis (HNF-SD-SNF-HIE-004) identified and categorized a series of potential accidents as liquid release accidents. This accident category consists of releases from leaks developing in the PWC system. The PWC system includes the piping and other hardware involved in removing MCO water from the MCO, filtering the water, and ultimately sending the water to a holding tank until it is processed by the K Basins integrated water treatment system. The bounding event is a leak in the pressurized PWC system piping. Other locations for this accident were considered in the hazard analysis. However, the consequences were determined to be bounded by a leak that occurs at the pump outlet where the PWC system pressure is the greatest. The leak sprays water containing particulate into the process water tank room, fills the room with respirable aerosols, and creates a pool of contaminated water on the floor of the room. Additional particulate is released to the room through aerodynamic resuspension and evaporation.
from the pool’s surface. During the MCO water draining operation, the water entrains radioactive particulate in the MCO. The particulate released during the spray is ultimately released into the environment.

**B3 4 2 2 2 Source Term Analysis** The following assumptions are used in the analysis:

- The total quantity of water available for release into the process water tank room is 650 L. At the start of processing, there is 500 L in the MCO and 150 L in the receiver tanks (PWC-TK-4032, PWC-TK-4033). The water in the receiver tanks is used to prime the pump (PWC-P4035, PWC-P-4036, only one operating) in the PWC system and provide recirculation through the ejector (PWC-EJR-4031) to establish a vacuum on the drain header (PWC-001-SS-1")

- The density of the dry aerosol particulate is assumed to be 5.0 kg/L (HNF-SP-1201). The maximum density of this particulate is assumed to be 10.0 kg/L (HNF-1523).

- The spray release develops during pumping of the process water in the line from (PWC-005-SS-1") the PWC circulation water pumps. This is the point in the system with the highest pressure 60 lb/in² gauge. The liquid temperature is assumed to be 46 °C. The viscosity of water at this temperature is 0.588 centipoise.

- The inventory at risk includes the contents of the process water receiver tanks (650 L of water) and 10% of the particulate from a single MCO (15 kg) (SNF-2770). The estimate of 10% is supported by prototype tests using cerium oxide powder (HNF-4057, Section 3.4). The density of cerium oxide is 6.9 kg/L, which is high enough to represent uranium oxide. In addition, the cerium oxide particle diameters were distributed in the range from 0 μm to 10 μm, consistent with SNF particulate. Residual particulate in the PWC tanks is not included in the release calculation because the system purifies the water from previous MCO drain operations and any residual would add a negligible amount to the postulated suspended solids concentration.

- During the MCO draining operation, the drained liquid circulates around a loop that includes a pump, two tanks, and an ejector. Following the draining, the PWC system is reconfigured to circulate the contaminated MCO drain water through ion exchange modules (PWC-IXM-4037, PWC-IXM-4038, one is standby). Eventually the de-ionized liquid is transferred through a filter (PWC-F-4042) to a holding tank (PWC-TK-4001). There is no limit on the established length of time that the water can be recirculated. Therefore this accident is evaluated for a spray leak continuing for both 12 and 24 hours. These are bounding exposure times for onsite and offsite receptors downwind (HNF-SD-SNF-TI-059).
During the course of a spray release accident, a large fraction of the sprayed water falls to the floor and collects in a pool. This pool contributes a relatively small amount to the released source term. The spray release accident source term has three components included in the dose calculations:

- Particulate released with the spray of water
- Particulate resuspended from the surface of the pool of water
- Particulate released by evaporation from the pool of water

**Spray of Water** Some fraction of the solution issuing from a leak will atomize, carrying suspended SNF particulate with it. The droplets quickly evaporate leaving behind SNF particles with some water still trapped in the pores. Large leaks in piping lead to less atomization while small holes lead to lower leak rates. The SPRAY computer program (WHC-SD-GN-SWD-20007) has been used to find the bounding case hole diameter with the largest respirable release rate. User input to the program includes the water pressure, PWC liquid density and viscosity, and the largest droplet diameter that evaporates to a respirable-sized particle.

The SPRAY computer program describes the atomization of a liquid jet due to the kinetic energy of the jet itself. Because atomization of a liquid jet is a random process, the resultant spray consists of a wide range of drop sizes and must be represented by a distribution rather than a single parameter. The SPRAY computer program computes the fraction of droplets that are below a limiting diameter input by the user. It also varies the leak size to find the leak with the greatest respirable leak rate. Documentation for the SPRAY computer program (WHC-SD-GN-SWD-20007) includes user guide, verification tests, and configuration control. The code uses empirical relationships and has been validated by hand calculations.

The water pressure is assumed to be 60 lb/in², the maximum pressure expected from the PWC pump. The PWC liquid viscosity is that of water at 46 °C, namely, 0.588 centipoise. The density of the water in the PWC system is not appreciably increased by the 1.5 kg of suspended particulate.

The largest droplet diameter that will evaporate down to respirable-sized particulate is calculated to be 55 μm (SNF-2770). Airborne particles are respirable if their "aerodynamic diameter" is less than 10 μm. (The term "aerodynamic diameter" is defined to be the diameter of a unit-density sphere with the same settling velocity.) The largest SNF particle diameter that could be considered respirable is shown to be 4.3 μm. With 1.5 kg of particulate suspended in 650 L of water, the bounding liquid droplet that evaporates down to this diameter is shown to be 55 μm.

The values were input to the SPRAY code to obtain the following bounding release fractions (SNF-2770):

- The optimum hole diameter is 642 μm.
The bounding leak rate from this hole is $4.54 \times 10^{-6}$ m$^3$/s, of which $9.23 \times 10^{-8}$ m$^3$/s is respirable.

Note that these leak rates correspond to 16.3 L/h (total) and 0.332 L/h (respirable). The total leak rate determines the growth of the pool of water on the floor of the PWC tank room. The respirable leak rate determines the amount that becomes airborne from the spray of liquid from the leak.

The total volume of liquid released from the PWC system, as well as the respirable mass that becomes airborne from the spray leak, depends on the duration of the leak. Equations to represent these quantities are shown below:

$$M_{\text{spray}} = (L_{\text{spray}})(T_{\text{leak}})(M_{\text{SNF}})/(V_{\text{tot}})$$

$$V_{\text{leak}} = (L_{\text{leak}})(T_{\text{leak}})$$

where

- $M_{\text{spray}}$ = mass of SNF airborne as respirable particles by atomization during the leak (g)
- $L_{\text{spray}}$ = leak rate for respirable particles computed by the SPRAY code (0.332 L/h)
- $T_{\text{leak}}$ = duration of the leak (hours)
- $M_{\text{SNF}}$ = total mass of SNF in the PWC system (1,320 g fuel)
- $V_{\text{tot}}$ = total volume of liquid in the PWC system (650 L)
- $V_{\text{leak}}$ = volume of PWC solution that has leaked from the PWC system (L)
- $L_{\text{leak}}$ = total leak rate computed by the SPRAY code (16.3 L/h)

Note that the mass of SNF (1,320 g) is used rather than the mass of particulate (1,500 g) to calculate the mass airborne. Note also that the leak must continue for at least 40 hours for the PWC system to lose its entire inventory of liquid (650 L). The bounding exposure times at downwind receptor locations (i.e., 12 hours onsite and 24 hours offsite) apply to this release. The environmental release may be terminated after 24 hours through actions such as pump shutdown and spill cleanup.

The mass of SNF released by atomization as respirable particles after 12 hours is calculated as follows:

$$M_{\text{spray}} = (0.332 \text{ L/h})(12 \text{ h})(1,320 \text{ g})/(650 \text{ L}) = 8.09 \text{ g SNF}$$

The mass of SNF released by atomization as respirable particles after 24 hours is calculated as follows:

$$M_{\text{spray}} = (0.332 \text{ L/h})(24 \text{ h})(1,320 \text{ g})/(650 \text{ L}) = 16.18 \text{ g SNF}$$

The summary of masses released is given in Table B3-10.

The mass released is grams of spent nuclear fuel (metal) rather than grams of particulate (uranium oxide).

**Release by Resuspension from the Pool** With respect to resuspension, DOE-HDBK-3010-94, Section 3.1, suggests that for aerodynamic entrainment and resuspension indoors, on a heterogeneous surface (stainless steel, concrete), and with low air speeds from normal facility ventilation flows, a bounding ARR is $4.0 \times 10^7$/h. Since the pool from which resuspension takes place is growing linearly with time, the total resuspended increases with the square of the time, as shown below. The factor of $\frac{1}{2}$ comes from the time integration. Since the spray leak pool volume increases linearly with time, the surface area is assumed to increase linearly with time also. This is a bounding assumption because the pool might encounter boundaries that prevent increases in surface area. With a bulk leak rate of 16.3 L/h, the volume of the pool will be 39.1 L after 24 hours. Assuming an average depth of 1 cm, the wet surface area is 39.1 m$^2$ (420 ft$^2$) at the end of 24 hours.

$$M_{RESUS} = \left(\frac{1}{2}\right)R_{RESUS}(LR_{LEAK})(T_{LEAK})\frac{(M_{SNF})}{(V_{TOT})}$$

where

- $M_{RESUS}$ = mass of SNF airborne as respirable particles by resuspension from the pool (g)
- $R_{RESUS}$ = respirable release rate from the surface of a pool by resuspension ($4 \times 10^7$/h)
- $LR_{LEAK}$ = total leak rate computed by the SPRAY code (16.3 L/h)
- $T_{LEAK}$ = duration of the leak (hours)
- $M_{SNF}$ = total mass of SNF in the PWC system (1,320 g fuel)
- $V_{TOT}$ = total volume of liquid in the PWC system (650 L)

The mass of SNF released by resuspension as respirable particles after 12 hours is calculated as follows

$$M_{RESUS} = \left(\frac{1}{2}\right)(4 \times 10^7/h)(16.3 \text{ L/h})(12 \text{ h})\frac{(1,320 \text{ g})}{(650 \text{ L})} = 0.0010 \text{ g SNF}$$
The mass of SNF released by resuspension as respirable particles after 24 hours is calculated as follows:

\[ M_{\text{RESUS}} = \left( \frac{1}{2} \right) \left( \frac{4 \times 10^7}{h} \right) (16.3 \, \text{L/h})(24 \, h)^2 \left( \frac{1320}{650} \, \text{g} \right) = 0.0038 \, \text{g SNF} \]

The summary of masses released is given in Table B3-10.

**Release by Evaporation from the Pool**  
With respect to evaporation, an upper bound of \( 5.3 \times 10^7 \) for the ARF of suspended particulate resulting from evaporation stresses is found in DOE-HDBK-3010-94, Section 3.2. This ARF is based on a 2-hour sampling time for air flowing at 0.5 m/s over small quantities of concentrated plutonium nitrate solution heated to 90 °C. These experimental conditions lead to greater emissions than those expected from conditions in the PWC room during the liquid release event. Since the spray leak pool volume increases linearly with time, the surface area is assumed to increase linearly with time as described earlier. This is a bounding assumption because the pool might encounter boundaries that prevent increases in surface area. The release of suspended particulate due to evaporation from this growing pool increases linearly with time. The total amount of suspended particulate released from the pool increases with the square of the time, as shown below. The factor of \( \left( \frac{1}{2} \right) \) comes from the time integration.

\[ M_{\text{EVAP}} = \left( \frac{1}{2} \right) \left( R_{\text{EVAP}} \right) \left( L_{\text{LEAK}} \right) \left( T_{\text{LEAK}} \right)^2 \left( M_{\text{SNF}} \right) / \left( V_{\text{TOT}} \right) \]

where:

- \( M_{\text{EVAP}} \) = mass of SNF airborne as respirable particles by evaporation from the pool (g)
- \( R_{\text{EVAP}} \) = average respirable release rate from the surface of a pool by evaporation \( (5.3 \times 10^7/2 \, h = 2.6 \times 10^7/\text{h}) \)
- \( L_{\text{LEAK}} \) = total leak rate computed by the SPRAY code (16.3 L/h)
- \( T_{\text{LEAK}} \) = duration of the leak (hours)
- \( M_{\text{SNF}} \) = total mass of SNF in the PWC system (1,320 g fuel)
- \( V_{\text{TOT}} \) = total volume of liquid in the PWC system (650 L)

The mass of SNF released by evaporation as respirable particles after 12 hours is calculated as follows:

\[ M_{\text{EVAP}} = \left( \frac{1}{2} \right) \left( 2.6 \times 10^7/\text{h} \right) (16.3 \, \text{L/h})(12 \, h)^2 \left( \frac{1320}{650} \, \text{g} \right) = 0.0006 \, \text{g} \]
The mass of SNF released by evaporation as respirable particles after 24 hours is calculated as follows:

\[ M_{\text{EVAP}} = \left(\frac{1}{2}\right) \left(2.6 \times 10^7 \text{h}\right) \left(16.3 \text{ L/h}\right) \left(24 \text{ h}\right)^2 \left(1.320 \text{ g}/(650 \text{ L})\right) = 0.0025 \text{ g} \]

The summary of masses released is given in Table B3-10.

From the release quantities presented in Table B3-10, it can be seen that the combined resuspension and evaporation from the pool is less than three orders of magnitude lower than the spray release. Thus, a spill of contaminated water might result in a localized spread of contamination but would not result in a significant release. If the water were filtered (e.g., a spill sometime after passing through the ion-exchange modules), the release would be even less.

**B3.4.2.2.3 Consequence Analysis** The radiological dose (effective dose equivalent) to a receptor is calculated by using the following equation:

\[ D_E = M \times \frac{x}{Q'} \times BR \times UD \]

where:
- \( D_E \) = effective dose equivalent based on inhalation exposure only (rem)
- \( M \) = respirable particulate quantity released into the air (grams)
- \( \frac{x}{Q'} \) = air transport factor (s/m³)
- \( BR \) = average inhalation rate during the release (m³/s)
- \( UD \) = committed effective dose equivalent per unit gram inhaled

For the onsite receptor, the duration of worker exposure can be assumed to be 12 hours on the basis of an anticipated 12-hour work shift. For the offsite receptor, the duration of exposure is taken to be 24 hours. For releases occurring over a 12-hour or a 24-hour time period, the air transport factor \( \frac{x}{Q'} \) is the logarithmic interpolation between the 1-hour to 2-hour \( \frac{x}{Q'} \) with plume meander and the annual average \( \frac{x}{Q'} \) (HNF-SD-SNF-TI-059). The logarithmic interpolation is a method recommended in NRC Regulatory Guide 1.145 for release durations between 2 hours and 1 year.

The light activity breathing rate of \( 3.33 \times 10^4 \text{ m}^3/\text{s} \), as defined in HNF-SD-SNF-TI-059, is used for the onsite receptor. For the offsite receptor, an average 24-hour breathing rate of \( 2.64 \times 10^4 \text{ m}^3/\text{s} \) is used.

The dose per unit of respirable material inhaled is \( 4.38 \times 10^5 \text{ rem/g} \) of fuel, as specified in Section 3.4.1.2 of the SNF Project FSAR. All the material released from the building is treated as respirable (i.e., less than 10 μm aerodynamic diameter).
Unmitigated Consequences  For the collocated worker (100 m east of the CVDF) during a 12-hour leak event, the dose from the spray atomization portion of the leak is calculated as follows

\[ D_{\text{onsite}} = M \times \frac{X}{Q'} \times BR \times UD \]

\[ = (8.09 \text{ g})(6.28 \times 10^3 \text{ s/m}^3)(3.33 \times 10^{-4} \text{ m}^3/\text{s})(4.38 \times 10^5 \text{ rem/g}) \]

\[ = 74 \text{ rem (0.074 Sv)} \]

Using the respirable radionuclide releases from Table B3-10 and the air transport factors from Table B3-11, doses at the various receptor locations as a function of the spray leak duration are calculated as demonstrated below. The results are summarized in Table B3-11.

Mitigated Consequences  The release in the mitigated case is assumed to continue for the same period of time, but the building process general supply/exhaust HVAC system is credited with confinement of the release by maintaining a negative differential pressure and filtering the release via the HEPA filters in the system. The mitigated dose calculation includes the effects of the leak path factor involved with the radioactive material released exiting the building via the HVAC system HEPA filters. If a HEPA filter efficiency of 99.9% is assumed, this leak path factor is 0.001 and is applied as indicated in the following equation:

\[ D_{\text{onsite}} = M \times \frac{X}{Q'} \times BR \times UD \times LPF \]

\[ = (8.09 \text{ g})(6.28 \times 10^3 \text{ s/m}^3)(3.33 \times 10^{-4} \text{ m}^3/\text{s})(4.38 \times 10^5 \text{ rem/g})(0.001) \]

\[ = 7.4 \times 10^3 \text{ rem (7.4 \times 10^{-1} Sv)} \]

With safety-significant functions credited, mitigated onsite consequences for the event are 7.4 \times 10^3 rem.

B3 4 2 2 4 Comparison with Guidelines

Comparison of Unmitigated Doses  Event tree sequences indicate an unmitigated frequency for the liquid release DBA is in the anticipated category (i.e., an unmitigated frequency greater than 10^{-2} per year) (see SNF-2770, Appendix A). The unmitigated sequence considered the processing of 200 MCOs per year and a leak from either the PWC pump, the piping, PWC valves, or the flexible hose connections. The unmitigated radiological offsite dose for this event is below offsite release limits, while the unmitigated onsite dose for an anticipated event is above onsite risk evaluation guidelines.

</table>

*Fifty year committed effective dose equivalent

*Evaluation guideline (for onsite receptor) and release limit (for offsite receptor) for unmitigated accidents in the anticipated frequency category (i.e., frequency >10⁻² per year)

*Because the unmitigated accident does not exceed offsite release limits, mitigated consequences were only calculated for onsite receptor locations.
**Comparison of Mitigated Doses** The mitigated frequency of the event tree sequences that represent this DBA as an unfiltered release is $3 \times 10^{-6}$ per year, thus this mitigated DBA is extremely unlikely (see SNF-2770, Appendix A). The mitigated sequence credited differential pressure monitoring in the PWC room, operator response to shut off the pump, and general exhaust HVAC system HEPA filter functionality. With safety-significant features credited, the mitigated onsite dose for an extremely unlikely event is well below onsite risk evaluation guidelines.

**B3 4 2 2 5 Summary of Safety-Class Structures, Systems, and Components and Technical Safety Requirement Controls** Under normal operating conditions, no liquid releases to the process bay or process water tank room are expected. Under upset or accident conditions, safety-significant equipment is required in order to ensure dose consequences do not exceed onsite risk evaluation guidelines.

The checklist designators included in the accident bins, other than the accident selected as the DBA, represent additional accident sequences slightly different than the DBA. All of these binned accidents are bounded by the DBA because they have lesser or equivalent worst-case consequences and frequencies.

In addition to the DBA, an accident was identified in the L1 bin representing a spray leak from a random line failure in the PWC room (HNF-SD-SNF-HIE-004). The controls in the L1 bin provide mitigation of the liquid release (spray) by HEPA filtration. The filtration function is monitored, and if it is lost, compensatory measures are taken to make sure that a release cannot occur.

The safety-significant equipment designated to prevent or mitigate the dose consequences of the liquid release accident analyzed in this section is described below.

Safety-significant equipment for confinement and filtration:

- **Process general supply/exhaust HVAC system (exhaust HEPA filter exhaust duct work)**

  The process general supply/exhaust HVAC system mitigates a spray leak in the process water tank room by filtering it before discharging it outside the facility. The process general supply/exhaust HVAC system also provides confinement in conjunction with the facility's structure by maintaining a negative building pressure.

- **Reference air system (reference air header, differential pressure alarms for process water tank room)**

  The reference air system monitors the negative pressure in the process water tank room by providing differential pressure indication and alarms to the control room for operator response. Such monitoring ensures that the air in the PWC room is being
HNF-3553 REV 0
Annex B — Cold Vacuum Drying Facility

drawn into the process general supply/exhaust HVAC system so that the credited filtration function is being performed. The alarms allow operators to take action to stop PWC pump operation (see TSR below) if differential pressure is lost in the PWC room (e.g., a component failure halts ventilation flows)

Assumptions made that require TSR controls are listed below

- Stop PWC pump operation on loss of differential pressure in the PWC room

If differential pressure is lost in the PWC room, PWC pump operation must be terminated. This control ensures that a spray leak does not occur at a time when filtration by the general exhaust system is not available.

The bounding liquid release accident (L1) and the other accidents identified in the CVDF hazard analysis report (HNF-SD-SNF-HIE-004) that may potentially lead to a liquid release are listed in Table B3-12 along with corresponding checklist designators from the hazard analysis.

The accidents in the remaining bins require the following safety SSCs and TSRs, in addition to the ones identified for the DBA (L1)

L2 Spray release due to facility fire

The accident scenarios identified in the hazard analysis for the L2 bin represent a spray leak in the PWC room caused by a fire (HNF-SD-SNF-HIE-004). The control in the L2 bin precludes a liquid release (spray) by precluding the possibility of a significant fire. Although the worst-case liquid release consequences are less than the onsite risk evaluation guideline of 10 rem for the unmitigated fire (an unlikely event according to HNF-SD-SNF-HIE-004), the control is credited to preclude the possibility of multiple sprays.

Assumptions made that require protection by TSRs are listed below

- Combustible loadings limited

While an MCO is present in the facility, combustible loadings are limited as determined by the fire hazard analysis implementation plan (SNF-4942). These limits ensure that any fire in the CVDF does not result in uncontrolled releases (e.g., fire-caused loss of process control).

L3 Spray release due to line break caused by a seismic event

The accident scenario identified in the hazard analysis for the L3 bin represents a spray leak in the PWC room following a seismic event (HNF-SD-SNF-HIE-004). For this event, which is unlikely in the unmitigated case, no controls are necessary because the event meets all onsite risk evaluation guidelines and offsite release limits. The unmitigated frequency for the seismic

event is unlikely (HNF-SD-SNF-HIE-004), for which the onsite risk evaluation guideline is 10 rem. Because the worst-case liquid release is less than 10 rem, the guideline is satisfied without controls. In addition, a single optimized spray leak bounds multiple non-optimized leaks because the dose consequences of a spray release drop rapidly as the leak departs from optimal conditions.

Defense in depth

- Process water conditioning system (seismic detector and pump interlock)

The PWC system’s seismic detector provides a signal to the PWC pump shutdown interlock to stop the process water pumps during a seismic event.

B3 4 2 3 Multi-Canister Overpack External Hydrogen Explosion This section addresses the consequences of an MCO external hydrogen explosion. The quantity of radioactive material released is calculated and that value is used to calculate the dose consequences to both offsite and onsite receptors.

The unmitigated dose consequences of the bounding MCO external hydrogen explosion do not exceed the offsite release limit, so no safety-class features are required to mitigate or prevent this accident. However, the dose consequences exceed the onsite risk evaluation guidelines, so safety-significant features have been identified to mitigate the consequences of an external hydrogen explosion. Safety-significant features selected to prevent buildup of flammable concentrations of hydrogen for the bounding external hydrogen explosion DBA include a cask vent jumper tool, MCO vent jumper, a fixed orifice in the cask vent line to restrict hydrogen flow rate during cask venting, a minimum flow rate in the process bay local exhaust HVAC system, and an interlock that interrupts cask venting if a low process bay local exhaust HVAC flow rate is detected. In addition, the particulate buildup on the HVAC HEPA filters is limited by measuring the radiation level near the filter banks and changing out the HEPA filters that register above a predetermined limit. Limiting particulate buildup on the HEPA filters provides an additional barrier that mitigates the potential dose consequences from external hydrogen explosion events. With safety-significant features credited, the mitigated onsite dose is below onsite risk evaluation guidelines. Details of the calculations for this DBA are provided in SNF-2770, Chapter 4.

B3 4 2 3 1 Scenario Development When the cask-MCO first arrives at the CVDF, it contains helium and hydrogen in the void space over the water-covered fuel. The helium is introduced at K Basins to displace air from the cask-MCO headspace. Hydrogen is produced during transfer of the cask-MCO to the CVDF primarily by the corrosion of uranium and also by the radiolytic decomposition of water. One of the first actions at the CVDF is to vent the excess pressure created by hydrogen generation to the process bay local exhaust HVAC and process vent system. The cask lid can then be safely removed and replaced with the process hood. If significant hydrogen has accumulated in the cask-MCO before venting, an explosive mixture of hydrogen and air could be formed in the process bay local exhaust HVAC and process vent system when the cask-MCO is vented.
B3 4 2 3 2 Source Term Analysis  The following assumptions are used in the analysis

- The process bay local exhaust HVAC and process vent system is operating at its normal flow rate, and the pressure in the cask is relieved quickly, or the exhaust system is operating at reduced flow rates, and the pressure in the cask is relieved slowly. Either of these cases could produce flammable mixtures of hydrogen and air in the process bay local exhaust HVAC and process vent system.

- An ignition source is present near the process bay local exhaust HVAC and process vent system HEPA filter array. This source could be from rapid oxidation of uranium hydride or static electrical discharge. The resulting hydrogen deflagration causes release of the radioactive material on the filters to the environment.

- The MCO is transported on a hot day within the bounding transportation and preparation times. The bounding hydrogen generation rate can be estimated from the bounding corrosion rate estimated to occur while the fuel is wet. The hydrogen generation rate depends on the assumed fuel temperature. During shipment from the K Basins to the CVDF, the average fuel temperature is assumed to increase from 16 °C (61 °F) to 43 °C (109 °F) according to the time and temperature projections for a hot, sunny day (HNF-SD-W441-CN-001). The bounding shipping window duration is 24 hours. This is the time from cask closure at the K Basins to cask venting at the CVDF. The total hydrogen generated during the shipping window is 8.29 moles of H₂ (SNF-2770).

- The void space in the cask–MCO during shipment is estimated to be 41.2 L. This is based on a gas layer 4.25 in thick and 20 in diameter at the top of the MCO. In addition, there is a layer 0.6 in thick between the outside of the MCO and the inside of the cask. This region is treated as a cylindrical shell 16 in tall with a diameter of 24 in. The space between the bottom of the cask lid and the top of the MCO is a cylinder 1 in tall with a diameter of 24 in. All volumes are taken from the MCO Topical Report (HNF-SD-SNF-SARR-005).

- It is estimated that a HEPA filter housing that reads 100 mR/h on contact contains about 131 g of fuel (SNF-2770). This includes a factor of 10 to account for possible loss of 137Cs due to radioactive decay and greater solubility.

The mathematical analysis of the cask venting accident focuses on the hydrogen concentration in the process bay local exhaust HVAC and process vent system duct work.

The void space in the cask–MCO is filled initially with helium at a pressure of 3 lb/in² gauge (HNF-SD-SNF-OCD-001). From the ideal gas law, the cask initially contains 2.06 g moles of helium. The gas temperature is assumed to be 20 °C (68 °F) because the helium is added before the cask–MCO heats up during transport. With the addition of 8.29 moles of hydrogen...
and 0.09 gmoles water vapor, the absolute pressure in the cask at the time it is vented is 6.41 atm or 79.6 lb/in² gauge.

The gas in the cask is vented to the process bay local exhaust HVAC and process vent system at atmospheric pressure and at a temperature of 30 °C (86 °F). This temperature is several degrees below the temperatures assumed in the shipping analysis (HNF-SD-TP-SARP-017) for conditions after arrival at the CVDF. This temperature assumption has minimal effect on the calculated fraction of cask-MCO gas that leaves during venting. The amount of hydrogen vented is computed in two steps. The first step is to compute the quantity of the hydrogen-helium mixture that will leave the MCO during venting. The second step is to apply the mole ratio of hydrogen to helium to calculate just the hydrogen amount.

The volume of the hydrogen-helium gas mixture that will leave the MCO cask during venting is the total amount of gas minus the amount left in the cask at atmospheric pressure:

\[10.44 \text{ gmoles} - 1.63 \text{ gmoles} = 8.81 \text{ gmoles}\]

The second step is to calculate the amount of hydrogen that leaves the cask and enters the process bay local exhaust HVAC and process vent system. Of the 10.44 moles of gas in the MCO, 8.29 moles (79.4%) are hydrogen. Thus, the amount of hydrogen vented is calculated to be 7.00 gmoles.

To evaluate hydrogen concentrations in the process bay local exhaust HVAC and process vent system duct work, it is necessary to have values for the flow rates of both hydrogen and air into the duct. To estimate the rate at which the hydrogen in the cask would enter the local exhaust process vent system, it is assumed that the vent connection on the lid of the cask has a diameter of 0.5 in (HNF-SD-TP-SARP-017). Gases cannot exit a hole faster than the speed of sound. The minimum cask pressure needed to cause sonic flow has been calculated to be 49.2 lb/in² absolute (SNF-2770). The expected pressure of 79.6 lb/in² gauge is enough to cause sonic flow. The sonic flow rate has been computed to be 22.3 gmoles/s (0.125 lbm/s). Flow through a flexible line would reduce this value. Nevertheless, the majority of the cask hydrogen will enter the process bay local exhaust HVAC and process vent system in less than 1 second. It is therefore assumed that all 7.00 gmoles of H₂ enter the duct in 1 second. If the flow were less than sonic velocity, the hydrogen would take longer to vent, resulting in lower concentrations in the exhaust duct.

If the hydrogen in the duct were ignited near the process bay local exhaust HVAC and process vent system HEPA filter, the blast wave could damage the HEPA filters and their housing, allowing radioactive contamination on the filter to be released. The amount of radioactivity released to the environment by this hydrogen can be estimated using bounding assumptions. HEPA filters normally are changed when the differential pressure becomes too large, indicating that the filter is becoming plugged. In addition, the dose rate on the housing to the side of the filters is limited administratively. Since the filters must be changed by hand, the exposure to personnel during changeout of filters would be excessive if the dose rate limit were
not in place. For HEPA filter blasts, DOE-HDBK-3010-94, Section 5.2.2.2, has a bounding release fraction of 0.01 with an RF of 1.0. For a filter loaded with the amount of fuel (131 g) needed to give a reading of 100 mR/h, the airborne release is 1.31 g fuel.

B3 4.2.3.3 consequence analysis. The radiological dose (effective dose equivalent) to a receptor is calculated by using the following equation:

\[ DE = M \times \frac{X}{Q'} \times BR \times UD \]

where

- **DE** = effective dose equivalent based on inhalation exposure only (rem)
- **M** = respirable particulate quantity released into the air (grams)
- **\( \frac{X}{Q'} \)** = air transport factor (s/m³)
- **BR** = average inhalation rate during the release (m³/s)
- **UD** = committed effective dose equivalent per unit gram inhaled

The respirable particulate quantity is the 1.31 g fuel calculated in Section B3 4.2.3.2. The value for \( \frac{X}{Q'} \) is that shown in Table B3-13. The light activity breathing rate is \( 3.33 \times 10^{-4} \) m³/s, as defined in HNF-SD-SNF-TI-059. The dose per unit of respirable material inhaled is \( 4.38 \times 10^5 \) rem/g, as specified in Section 3.4.1.2 of the SNF Project FSAR.

**Unmitigated Consequences**. The unmitigated dose to the onsite receptor is calculated as follows:

\[ D_{\text{on site}} = M \times \frac{X}{Q'} \times BR \times UD \]

\[ = (1.31 \text{ g})(7.32 \times 10^{-2} \text{ s/m}^3)(3.33 \times 10^{-4} \text{ m}^3/\text{s})(4.38 \times 10^5 \text{ rem/g}) \]

\[ = 14 \text{ rem (0.14 Sv)} \]

The dose consequences at the remaining receptor sites are calculated in the same manner and are shown in Table B3-13.

**Mitigated Consequences**. Mitigation of the cask venting accident involves (1) preventing flammable concentrations in the process bay local exhaust duct work, and (2) ensuring the HEPA filter loading is low enough that a flammable gas explosion in the filters would not release enough activity to the environment to exceed the onsite risk evaluation guideline.

\(a\) Fifty year committed effective dose equivalent

\(b\) Evaluation guideline (for onsite receptor) and release limit (for offsite receptor) for unmitigated accidents in the anticipated frequency category (i.e. frequency >10\(^{-2}\) per year)

\(e\) Evaluation guideline/release limit based on a mitigated accident frequency of extremely unlikely
A flammable mixture in the duct work may result from two situations (1) rapid venting of the cask into normal process bay local exhaust air flow, or (2) venting of the cask into a duct with no air flow. The first situation is prevented by the presence of a flow-reducing orifice in the vent line. The second situation is prevented by a valve that is interlocked to local exhaust flow in each bay. If local exhaust flow is lost during the venting operation, the flow of gas from the cask is halted. Both the design of the vent line and the reliability of the process bay local exhaust system ensure that there is only a low probability of a flammable mixture forming.

The activity on the process bay local exhaust filters can be limited by limiting the dose rate near the filters. Routine surveys are performed by health physics technicians to measure dose rates near the filters. The routine measurements ensure that the filter dose rates do not exceed administrative criteria chosen to limit exposure to workers who must change the filters. Normally, filters are changed if the differential pressure indicates reduced flow rates. Excessive dose rates can also trigger a filter change. Filter changes involve contact handling of the filters and may result in large personnel doses if the filter dose rates are high.

To ensure that onsite risk evaluation guidelines would not be exceeded from a hydrogen explosion involving the local exhaust HEPA filters, a limitation on the dose rate near the filter housing has been developed. A dose rate of 82 mR/h on contact at the filter housing corresponds to 94 g of SNF on the filters, assuming that the relative amounts of $^{137}$Cs and $^{241}$Am are 10 times lower on the filters than in the SNF (SNF-2770). The explosion would release 1% of the activity (bounding) on the filters, so that 0.94 g of SNF would be released as respirable particles. This release would result in an onsite dose of 10 rem, which is equal to the onsite risk evaluation guideline (unlikely frequency category). The conservative nature of the dose calculation combined with the reduced frequency of the mitigated event ensures that this dose rate limit (82 mR/h) is adequate to protect onsite workers.

**B3 4 2 3 4 Comparison to Guidelines**

**Comparison of Unmitigated Doses** Event tree sequences indicate that the unmitigated frequency for the external hydrogen explosion DBA is in the anticipated category (i.e., an unmitigated frequency greater than $10^{-2}$ per year) (see SNF-2770, Appendix A). The unmitigated sequence considered the processing of 200 MCOs per year and sufficient hydrogen accumulation in cask prior to venting. The unmitigated radiological offsite dose for this event is below offsite release limits, while the unmitigated onsite dose for an anticipated event is above onsite risk evaluation guidelines.

**Comparison of Mitigated Doses** The mitigated frequency of the event tree sequences that represent this DBA as an external hydrogen explosion and unfiltered release is $2 \times 10^{-6}$ per year thus this mitigated DBA is extremely unlikely (see SNF-2770 Appendix A). The mitigated sequence credited installation of flow restriction in the cask vent line, local exhaust running, and HEPA filter loading. With safety-significant features credited, the mitigated onsite dose for an extremely unlikely event is below onsite risk evaluation guidelines.
B3 4 2 3 5 Summary of Safety-Class Structures, Systems, and Components and Technical Safety Requirement Controls

Under normal operating conditions, there is no external accumulation of flammable concentrations of hydrogen. Under upset or accident conditions, safety-significant equipment is required in order to ensure flammable concentrations of hydrogen external to the MCO and CVDF systems are precluded.

The checklist designators included in the accident bins, other than the accident selected as the DBA, represent additional accident sequences slightly different than the DBA. All of these binned accidents are bounded by the DBA because they have lesser or equivalent worst-case consequences and frequencies.

In addition to the DBA, an accident was identified in the E1 bin representing an external hydrogen explosion caused by elevated hydrogen generations from misloaded fuel in an MCO or a shipping delay to CVDF (HNF-SD-SNF-HIE-004). The controls in the E1 bin provide both prevention and mitigation of an external explosion event, as well as protection of initial condition assumptions made in the analysis. The accident is prevented by directing the hydrogen from the cask to the local exhaust where it is diluted to less than flammable concentrations, and by terminating the vent operation if the dilution airflow is lost in the local exhaust duct. These preventative controls make the accident unlikely (SNF-2770, Appendix A) for which the onsite risk evaluation guideline is 10 rem. The dose consequence of the worst-case external hydrogen explosion is greater than 10 rem, so credit is taken for a limit on the material at risk (on the HEPA filters) to provide mitigation of the consequences. With this additional control, the frequency of the accident is reduced to extremely unlikely, and the dose consequence falls within risk evaluation guidelines. One additional control is applied to protect initial cask-MCO conditions that were assumed in the analysis.

The safety-significant equipment is described below.

Safety-significant equipment for dilution:

- Cask venting orifice and jumper

The process bay local exhaust HVAC and process vent system provides a cask venting connection with a flow restricting orifice to keep concentrations of hydrogen below the flammable limit with at least 1,000 ft³/min of flow in the duct work. The cask vent jumper tool also directs hydrogen from the cask to the local exhaust to provide for worker safety.

- MCO vent jumper tool

The MCO venting tool provides a means to vent an MCO prior to process connections being made (after the cask lid has been removed). This vent tool controls MCO pressures in case of process delays by venting to the local exhaust through the same vent line (including orifice restriction). The vent tool also provides for worker safety by directing the hydrogen from the cask to the local exhaust.
Cask venting interlock with process bay local exhaust HVAC and process vent system

A shutoff valve interlocked to the local exhaust low-flow alarm is provided because flammable concentrations would be generated almost instantaneously if the cask were vented into a stagnant local exhaust duct.

Process bay local exhaust HVAC and process vent system (exhaust fans and plenums, duct work, HEPA filters, and flow switch)

The process bay local exhaust HVAC and process vent system mitigates a gaseous release into the process bay by sweeping it through HEPA filters before it is discharged outside the facility. Low flow alarms are set at 1,150 ft³/min to provide an actual flow of greater than 1,000 ft³/min. The flow switch is interlocked with the shutoff valve.

Safety-class equipment (performing a safety-significant function) for confinement

Cask-MCO

The cask-MCO is a major part of the pressure boundary for confinement of radioactive materials during processing.

Assumptions made that require protection by TSRs are listed below

Receipt transportation window

The transportation cask must be vented to the process bay local exhaust HVAC and process vent system HEPA filters within 24 hours from being sealed at the K Basins.

Limitation on the radionuclide inventory on the process bay local exhaust HVAC and process vent system HEPA filters

The HEPA filter and prefilter housing contact dose radiation levels must be maintained equal to or less than 70 mR/h consistent with the source term used in the accident analysis.

The bounding MCO external hydrogen explosion accident (E 1) and the other accidents identified in the CVDF hazard analysis report (HNF-SD-SNF-HIE-004) that may potentially lead to a flammable hydrogen mixture outside the MCO are listed in Table B3-14, along with corresponding checklist designators from the hazard analysis report, safety functions, and SSCs.

The accidents in the remaining bins require the following safety SSCs and TSRs, in addition to the ones identified for the DBA (E 1).

E 2 Hydrogen explosion outside an MCO due to instrumentation failure

The accident scenarios identified in the hazard analysis for the E2 bin represent external hydrogen explosions caused by elevated bay temperatures (and subsequent potential for elevated fuel temperatures and reaction rates) and actuation of the SCHe system concurrent with a no-flow condition in the local exhaust (HNF-SD-SNF-HIE-004). The controls in the E2 bin prevent the external hydrogen explosion by providing dilution in the local exhaust system and mitigation by limiting the material at risk on the local exhaust HEPA filters. In addition, the general exhaust system and SSCs that support process bay confinement are credited because the local exhaust cannot be guaranteed to provide confinement in all cases following the external explosion.

- Process bay local exhaust HVAC and process vent system process hood isolation damper and instrument air supply

  Isolation dampers in the process bay local exhaust HVAC and process vent system process hood fail closed. If power is lost, dampers will open with electrical power from the standby power system and instrument air supplied by the local dedicated tank. The hood isolation damper and instrument air supply operate in conjunction with the standby power system to facilitate HVAC operating while on standby power.

- Process general supply/exhaust HVAC system (exhaust HEPA filter, exhaust duct work, isolation damper)

  The process general supply/exhaust HVAC system mitigates a release into the process bay by sweeping it through HEPA filters before discharging it outside the facility. The process general supply/exhaust HVAC system also provides confinement in conjunction with the facility's structure by maintaining a negative building pressure. Fail-closed exhaust dampers from the process bays isolate other flow paths and ensure that differential pressure is maintained.

- Reference air system (reference air header, differential pressure alarms)

  The reference air system monitors the negative pressure in the process bays and process water tank room by providing differential pressure indication and alarms to the control room for operator response.

- Standby electrical power (diesel generator and process bay local exhaust HVAC and process vent system restart circuit)

  The standby power system provides connections to restart the local exhaust fans and supporting equipment. Operation of the local exhaust on standby power will maintain building differential pressure sufficient for confinement during facility power outages.
Process bay recirculation HVAC system isolation dampers (outside inlets)

The process bay recirculation HVAC system provides fail-closed outside air inlet dampers so the local exhaust on standby power can maintain process bay differential pressure.

E 3 Hydrogen explosion outside an MCO due to excessive water in MCO

The accident scenarios identified in the hazard analysis for the E 3 bin represent external hydrogen explosions caused by excessive water remaining in an MCO (instrumentation failure or operator error) (HNF-SD-SNF-HIE-004). The controls in the E3 bin prevent the external hydrogen explosion by providing dilution in the local exhaust system and by preventing excessive free water in an MCO at an unexpected time. Mitigation is provided by a limitation on the material at risk on the local exhaust HEPA filters. In addition, the general exhaust system and SSCs that support process bay confinement are credited because the local exhaust cannot be guaranteed to provide confinement in all cases following the external explosion.

- All HVAC system equipment identified for accident E 2

Assumptions made that require protection by TSRs are listed below

- Procedure to verify the results of the pressure rebound tests before continuing process steps

An initial pressure rebound test surveillance (pressure rise test) must be met before entry into the proof-of-dryness demonstration is allowed. Similarly, a proof-of-dryness demonstration surveillance must be met before the final pressure rebound test steps can begin. Finally, a final pressure rebound test must be met before shipment preparation steps can begin.

E 4 Hydrogen explosion outside an MCO due to process upset of key parameters

The accident scenarios identified in the hazard analysis for the E 4 bin represent external hydrogen explosions caused by elevated hydrogen generation rates (high temperature tempered water, water ingress into MCO, air ingress into MCO, loss of annulus water), venting of MCO before breakthrough during draining, and venting cask-MCO while preparing for shipping (HNF-SD-SNF-HIE-004). The controls in the E4 bin prevent the external hydrogen explosion by providing dilution in the local exhaust system and mitigation by limiting the material at risk on the local exhaust HEPA filters. In addition, the general exhaust system and SSCs that support process bay confinement are credited because the local exhaust cannot be guaranteed to provide confinement in all cases following the external explosion.

- All HVAC system equipment identified for accident E 2
E 5 Hydrogen explosion outside an MCO due to loss of support utilities

The accident scenarios identified in the hazard analysis for the E 5 bin represent external hydrogen explosions caused by a loss of a support system (e.g., instrument air) because of accidents in adjacent bays, crane load drops, and accidents in the spare bay. This bin also includes loss of power events caused by external forces (e.g., vehicle accident), flooding, and lightning strike (HNF-SD-SNF-HIE-004). The controls in the E 5 bin prevent an external hydrogen explosion by providing dilution in the local exhaust system and by controlling specific initiators that result in a loss of support utilities (e.g., crane load drop and facility loss of power). In addition, the general exhaust system and SSCs that support process bay confinement are credited because the local exhaust cannot be guaranteed to provide confinement in all cases following the external explosion.

- All HVAC system equipment identified for accident E 2
- SCHe system (vent delay)
  The pressure-regulated discharge flow path from the MCO to the local exhaust system ensures a minimum 1 0-minute delay from SCHe initiation until discharge flow initiation to the local exhaust to allow standby power restart of the local exhaust
- Lines and valves to isolate and purge the MCO
  Lines and valves for isolating the MCO include the isolation valves (and filters on air supply to valve actuators) in the VPS, general-service helium system, PWC system, and SCHe system. Upon demand, all the valves close to isolate the MCO, except the SCHe system valves, which open to allow helium to the MCO. These SSCs ensure the proper functioning of the SCHe system.
- VPS components (pressure management)
  The 30 lb/in² gauge check valve on the 30 lb/in² gauge pressure relief line (backup pressure management to the SCHe system) opens, vents a small amount of hydrogen, and then re-seats to limit hydrogen flows into the local exhaust duct. The valve prevents a blowdown of the MCO from 30 lb/in² gauge to atmospheric pressure and the corresponding release of a large volume of hydrogen.

Assumptions made that require protection by TSRs are listed below:

- Administrative procedure for restricting crane movement during MCO processing except as part of an approved recovery plan
  Bridge crane movement is not allowed from the time that draining operations begin until the proof-of-dryness demonstration is complete and the MCO isolation valves...
are closed unless as part of an approved recovery plan. This restriction ensures that key process lines cannot be sheared by crane movement, which could cause failure of features that provide hydrogen control.

E 6 Hydrogen explosion outside an MCO due to facility fire

The accident scenarios identified in the hazard analysis for the E 6 bin represent external hydrogen explosions caused by an internal or external facility fire, including a fire in the transfer corridor caused by maintenance activities (HNF-SD-SNF-HIE-004). The controls in the E 6 bin prevent an external hydrogen explosion by ensuring that control of the MCO and process is not lost in the event of a fire in the process bay. The control on combustibles precludes damage to safety-related SSCs whose malfunction could result in the loss of control of the MCO or process. The control on combustibles necessitates protection of the initial bay temperature, which is an assumption made in the fire hazards analysis.

Safety-class equipment (performing a safety-significant function) to prevent an external hydrogen explosion:

- SCIC process bay high temperature trip

  The SCIC process bay high temperature trip acts to protect an initial condition assumption in the fire hazards analysis.

Assumptions made that require protection by TSRs are listed below:

- Combustible loadings limited

  While an MCO is present in the facility, combustible loadings are limited as determined by the fire hazard analysis implementation plan (SNF-4942). These limits ensure that any fire in the CVDF does not result in uncontrolled releases (e.g., fire-caused loss of process control).

- Restore bay temperature following a process bay high temperature trip

  On high bay temperature trip alarm, operations must return the process bay temperature to within acceptable limits.

E 7 Hydrogen explosion outside an MCO due to contamination of helium supply

The accident scenarios identified in the hazard analysis for the E 7 bin represent external hydrogen explosions caused by contaminants in the helium supply (unexpected fuel reactions) (HNF-SD-SNF-HIE-004). The controls in the E 7 bin prevent an external hydrogen explosion by controlling the helium supply.
Assumptions made that require protection by TSRs are listed below:

- Shipment paperwork for gas bottle content during receipt

  The manufacturer's paperwork and shipping papers will be checked upon helium cylinder receipt at the CVDF, both the normal and safety-class supply, to verify that the cylinder's contents were sampled by the supplier and that the sample met the required purity specification of >99% helium.

E 8  Hydrogen explosion outside the MCO due to line break caused by a seismic event

  The accident scenarios identified in the hazard analysis for the E 8 bin represent external hydrogen explosions in the transfer corridor or process bay caused by a seismic event (HNF-SD-SNF-HIE-004). A seismic event is an unlikely initiating event, therefore no credit is taken for preventative features in the E8 bin. Credit is taken for limiting the material at risk on the local exhaust HEPA filters.

No additional requirements result from analysis of this accident.

B3 4 2 4  Multi-Canister Overpack Internal Hydrogen Explosion  This section addresses the consequences of an MCO internal hydrogen explosion. The quantity of radioactive material released is calculated and that value is used to calculate the dose consequences to both offsite and onsite receptors.

  The unmitigated dose consequences of the bounding MCO internal hydrogen explosion do not exceed the offsite release limit, so no safety-class features are required to mitigate or prevent this accident. However, the dose consequences exceed the onsite risk evaluation guideline, so safety-significant features have been identified to mitigate the consequences of an internal hydrogen explosion. Components of the SCIC, VPS, general-service helium, tempered water (annulus), and SCHe systems function to prevent MCO internal hydrogen explosion accidents. For this accident category, these safety-class systems are functioning in a safety-significant prevention role. The safety-significant portions of the process bay local exhaust HVAC system (including standby power), the process general exhaust HVAC system, and the differential pressure alarms provide an additional barrier to mitigate a release into the process bays during the postulated accident scenario. Details of the calculations for this DBA are provided in SNF-2770, Chapter 5.

B3 4 2 4 1  Scenario Development  Because hydrogen is expected to be generated in the MCO during processing at the CVDF, the cold vacuum drying process incorporates many features to remove hydrogen and prevent the ingress of oxygen (air) into the MCO. The primary method of maintaining an oxygen-free atmosphere and a low hydrogen concentration in the MCO is to inert the MCO with helium before shipping and to pressurize and purge the MCO with helium at appropriate stages of the CVDF process. Process monitoring during drying is used to ensure that hydrogen is not building up in the system. Therefore, conditions that could result in significant quantities of oxygen and hydrogen accumulating inside the MCO during the draining,
drying, and proof-testing portions of the process require multiple failures of equipment and process monitoring.

With no helium fed into and no helium or hydrogen bled from the system to prevent hydrogen buildup, hydrogen gas concentration in the MCO and piping system increases with time. The bounding accident scenario postulates a line break that occurs when the MCO is under partial vacuum. Either process line, the one connected to the long axial process tube or the one connected to the filtered process exit port, could fail and provide the source of the air ingress. Since a motive force is needed to draw the air into the MCO, the event is postulated to occur under worst-case vacuum conditions (e.g., early in the drying process).

**B3 4 2.4.2 Source Term Analysis** The following assumptions are used in the analysis:

- A vacuum pressure of 0.3 atm (228 torr) exists in the MCO when the line break occurs. This pressure allows enough air to be drawn into the MCO to form a relatively large quantity of gas having a two-to-one mixture of hydrogen to oxygen (a stoichiometric ratio). This mixture yields a maximum energy release when it is ignited.

- An ignition source in the MCO exists. This source could be from rapid oxidation of uranium hydride or a static electrical discharge.

- Complete combustion takes place, that is, all the hydrogen reacts with all the oxygen to produce water.

- The average fuel temperature is assumed to be 75 °C (167 °F) so that the hydrogen generation rate is adequate to produce nearly pure hydrogen gas in the MCO at a pressure of 0.3 atm within 8 hours (SNF-2770).

- The MAR includes 15 kg of particulate generated between the time fuel washing is completed at the K Basins and draining operations are completed at the CVDF and 10 kg of particulate generated from the start of drying up to the time of the explosion (see Section B3 4 2). The total MAR, 25 kg of particulate treated as UO₂, represents approximately 22 kg of uranium (unit doses are calculated on a per-gram-of-uranium basis).

- It is assumed that particulate not removed by washing at K Basins (21 kg) will not be released by the hydrogen explosion. The conservatism associated with the MAR calculation and ARF selection is adequate to bound the potential for additional particulate removal by detonation shockwaves in localized areas in the MCO. The particulate is not uniformly distributed over the surface of the fuel but is located in cracks and crevices that would not be exposed to the detonation shockwaves.

Reaction of water with uranium metal is the main source of hydrogen. Other sources are from radiolysis and the degradation of uranium hydride. The hydrogen generation rate for fuel
and water at a temperature of 75 °C (167 °F) is calculated to be several moles per hour (SNF-2770). This hydrogen generation rate is adequate to flush most of the helium from the MCO. It also is assumed that a vacuum pressure of 0.3 atm (228 torr) has been achieved in the MCO when the line break occurs. This pressure produces a stoichiometric mixture of hydrogen and oxygen after the air enters the MCO. These conditions give maximum values for combustion energy release.

In the unmitigated scenario, when the mixture ignites, the resulting deflagration or detonation pressurizes the MCO and particulate matter is blown out through the line break or a rupture disk. The first concern is to determine whether the pressure impulse from the hydrogen combustion event can catastrophically fail the MCO vessel boundary. For the purposes of this analysis, the event is conservatively treated as a detonation with a shock wave at twice the adiabatic combustion pressure. This will occur for hydrogen concentrations of approximately 30% by volume. The worst-case peak pressure in the MCO following a hydrogen burn could exceed the 150 lb/in² gauge or 30 lb/in² gauge rupture disk pressure (SNF-2770) but will not catastrophically fail the MCO. The MCO can withstand static pressures in excess of 340 lb/in² gauge (HNF-SD-SNF-SARR-005) with the limiting components being the threads on the shield plug and MCO collar. The MCO shell can withstand a pressure of 1,790 lb/in² gauge. The peak reflected pressure from a detonation shockwave could reach 530 lb/in² gauge (SNF-2770), but such a pressure pulse would not exist long enough to allow for complete relaxation of the MCO collar or shield plug threads, therefore, catastrophic failure would not occur. The peak equilibrium pressure due to thermodynamic effects following the burn is approximately 110 lb/in² gauge, which does not challenge the MCO boundary. Because of the possible multiple release pathways (rupture disks and the line leak that allowed the air ingress), no holdup of the source term in the MCO is assumed (i.e., the entire source term is released).

The MCO is pressurized by heating the gas. The MCO will vent for as long as it takes for the pressure in the MCO to return to atmospheric pressure. With complete combustion of hydrogen, the gas will consist of steam, nitrogen, helium, and radioactive particulate matter that is aerodynamically entrained by the explosion. DOE-HDBK-3010-94, Section 4 4 2 3 2 gives an overall respirable release factor of $2 \times 10^3$ for venting of pressurized gas through UO₂ powders (see Section B3 4 2 6). DOE-HDBK-3010-94 presents two choices for release fractions under these conditions, one for low pressure (less than 25 lb/in² gauge) and one for relatively high pressures (greater than 25 lb/in² gauge). The release fraction for low pressure conditions was selected even though failure occurs at higher pressures. This is because the experiments investigating the release fraction were performed under high air flow conditions, whereas the powder in the MCO will be exposed to very low air velocities. Thus the smaller release fraction, $2 \times 10^3$, was assumed in this analysis. This value bounds the effects of shock, blast, and venting. The source term is the product of the expelled volume fraction, the MAR, and the release factor.

$$
(22 \text{ kg}) \left( \frac{1,000 \text{ g}}{1 \text{ kg}} \right) (2 \times 10^3) = 44 \text{ g U}
$$
B3 4 2 4 3 Consequence Analysis  The radiological dose (effective dose equivalent) to a receptor is calculated by using the following equation

\[ DE = M \times \frac{\chi}{Q'} \times BR \times UD \]

where

- \( DE \) = effective dose equivalent based on inhalation exposure only (rem)
- \( M \) = respirable particulate quantity released into the air (grams)
- \( \chi/Q' \) = air transport factor (s/m³)
- \( BR \) = average inhalation rate during the release (m³/s)
- \( UD \) = committed effective dose equivalent per unit gram inhaled

The respirable particulate quantity is the 44 g of fuel calculated in Section B3 4 2 4 2. The value for \( \chi/Q' \) is that shown in Table B3-15. The low activity breathing rate is \( 3.33 \times 10^{-4} \) m³/s as defined in HNF-SD-SNF-TI-059. The dose per unit of respirable material inhaled is \( 4.38 \times 10^5 \) rem/g of fuel as specified in Section 3 4 1 2 of the SNF Project FSAR.

Unmitigated Consequences  The unmitigated dose to the onsite receptor is calculated as follows

\[ D_{on-site} = M \times \frac{\chi}{Q'} \times BR \times UD \]

\[ = (44 \text{ g})(7.32 \times 10^{-2} \text{ s/m}^3)(3.33 \times 10^{-4} \text{ m}^3/\text{s})(4.38 \times 10^5 \text{ rem/g}) \]

\[ = 470 \text{ rem (4.7 Sv)} \]

The dose consequences at the remaining receptor sites are calculated in the same manner and are shown in Table B3-15.

Mitigated Consequences  Mitigation of the internal hydrogen explosion accident takes credit for the integrity of selected isolation valves and lines to isolate the MCO, the SCIC system and related instrumentation in other systems, the \( \text{SCH}_e \) system, the tempered water (annulus) system, and the cask–MCO. The isolation valves and lines inside the safety-class portion of the VPS and PWC systems ensure that there is no air ingress into the MCO. The SCIC system provides control functions to initiate isolation and purge of the MCO (isolation and purge trip) if the process upsets exceed trip setpoints. The \( \text{SCH}_e \) system provides a positive means of providing a minimum dedicated helium purge to the MCO to sweep hydrogen or air (if an air ingress were to occur) from the MCO, in the event that general-service helium were not available. The tempered water (annulus) system ensures that MCO temperatures, and subsequent hydrogen generation rates, remain within analyzed bounds.

$^a$Fifty year committed effective dose equivalent.

$^b$Evaluation guideline (for onsite receptor) and release limit (for offsite receptor) for unmitigated accidents in the anticipated frequency category (i.e., frequency $>10^{-2}$ per year)

$^c$The features designed to prevent this accident result in an estimated accident frequency in the beyond extremely unlikely range (i.e., $<10^{-4}$ per year)
Since the unmitigated accident does not exceed the offsite dose limits, no mitigated consequences were calculated for the offsite receptor. The unmitigated accident leads to onsite doses that are greater than the risk evaluation guideline for anticipated events. With the credited controls, the accident is prevented to beyond extremely unlikely. In addition, the presence of HEPA filters reduces the onsite dose for the confinement boundary failure postulated in the scenario.

**B3 4.2.4.4 Comparison to Guidelines**

**Comparison of Unmitigated Doses** Event tree sequences indicate that the unmitigated frequency for the internal hydrogen explosion DBA is in the anticipated category (i.e., an unmitigated frequency greater than $10^{-2}$ per year) (see SNF-2770, Appendix A). The unmitigated sequence considered the processing of 200 MCOs per year. The unmitigated radiological offsite dose for this event is below offsite release limits, while the unmitigated onsite dose for an anticipated event is above onsite risk evaluation guidelines.

**Comparison of Mitigated Doses** The mitigated frequency of the event tree sequence that represents this DBA as an internal hydrogen explosion is $3 \times 10^{-7}$ per year, thus this mitigated DBA is beyond extremely unlikely (see SNF-2770, Appendix A). With safety-class and safety-significant features credited (performing a safety-significant function), the mitigated internal hydrogen explosion is both prevented and mitigated.

**B3 4.2.4.5 Summary of Safety-Class Structures, Systems, and Components and Technical Safety Requirement Controls** Under normal operating conditions, helium flow through the MCO precludes the accumulation of flammable concentrations of hydrogen in the MCO. Under upset or accident conditions, safety-significant equipment is required in order to ensure this capability is not lost. The function of precluding flammable concentrations could be compromised by a loss of helium flow or an air ingress.

The checklist designators included in the accident bins, other than the accident selected as the DBA, represent additional accident sequences slightly different than the DBA. All of these binned accidents are bounded by the DBA because they have lesser or equivalent worst-case consequences and frequencies.

The accident scenarios identified in the hazard analysis for the I 1 bin represent internal hydrogen explosions caused by elevated fuel corrosion rates (high temperature tempered water), water ingress into MCO, and air ingress into MCO (HNF-SD-SNF-HIE-004). The controls in the I 1 bin prevent an internal hydrogen explosion by controlling the hydrogen concentration in the MCO and by preventing air ingress into the MCO. The normal hydrogen concentrations inside the MCO are controlled to ensure that if the MCO gas contents were to be mixed with air, the resulting gas mixture would not be flammable. The likelihood of an internal explosion is further reduced by crediting features that prevent air ingress so that onsite risk evaluation guidelines and offsite release limits are satisfied. The SSCs that limit fuel temperature also are credited to protect the analysis assumption pertaining to hydrogen generation rates. In addition, because the scenario postulates a process line break that is tantamount to a gaseous release, confinement.
systems are credited with controlling that release. Note that the confinement systems are not credited with mitigation of the internal explosion release but only with mitigation of the gaseous release associated with the line break.

The safety-significant equipment and controls designated to prevent the dose consequences of the MCO internal hydrogen combustion accident are described below.

Safety-class equipment (performing a safety-significant function) for detection of process upset:

- **SCIC system including vacuum cycle timer (8-4-4 logic)**
  
The SCIC system uses programmable logic controllers, wiring to process instrumentation, vacuum limit timer, signals from seismic detectors and temperature monitors, system controls, and output relays to perform an isolation and purge trip and a tempered water trip.

- **General-service helium system safety-class flow instrumentation**
  
The general-service helium system provides helium flow information to the SCIC system to initiate MCO isolation and SCHe actuation during process upset conditions.

- **Vacuum purge system pressure instrumentation**
  
Pressure indicators on the vacuum purge system provide MCO internal pressure information to the SCIC system, which initiates MCO isolation and SCHe actuation during process upset conditions.

- **Tempered water (annulus) system temperature trip**
  
The tempered water (annulus) system includes antisiphon valves, low water level indication and alarm, and manual refill capability to ensure a minimum water level is maintained above the elevation of the fuel within the MCO. The system detects high water temperature and signals the SCIC system to actuate the tempered water trip.

- **Tempered water (annulus) system low level alarm**
  
Redundant liquid level indicators are used by the tempered water (annulus) system to detect a low water level in the cask–MCO annulus and to provide a signal to the SCIC system to actuate the low-level alarm.

- **Tempered water (annulus) system level check petcocks**
The level check petcocks provide a manual means of verifying the presence of water in the annulus. The petcocks are located in and above the double-walled portion of the tempered water (annulus) piping and are connected to the outer and inner pipes above the height of the fuel in the MCO. If a low-level alarm is received, the petcocks can be used to verify the presence of water in the inner or outer pipe, thus indicating the presence of water in the annulus.

Safety-class equipment (performing a safety-significant function) for confinement, purge, and pressurization

- **Cask-MCO**

The cask-MCO is a major part of the pressure boundary for confinement of radioactive materials during processing and provides connections for the process piping to the SCHe system. The MCO also acts as the vessel for helium dilution of hydrogen.

- **SCHe system**

The SCHe system provides two redundant and independent paths for purging and pressurizing the MCO and venting to the process vent. The SCHe purging and pressurizing functions prevent flammable concentrations of hydrogen and oxygen from forming within the MCO.

- **Tempered water (annulus) system piping and antisiphon valves**

The tempered water system provides for sufficient heat transfer from the MCO so that excessive corrosion rates and related hydrogen generation rates are not experienced.

- **Lines and valves to isolate and purge the MCO**

Lines and valves to isolate the MCO include the isolation valves (and filters on air supply to valve actuators) in the VPS general-service helium system, PWC system, and SCHe system. Upon demand, all the valves close to isolate the MCO, except the SCHe system valves, which open to allow helium to the MCO. These SSCs ensure the proper functioning of the SCHe system.

Safety-significant equipment for confinement

- **Process bay local exhaust HVAC and process vent system (exhaust fans and plenums, duct work, HEPA filters)**

The process bay local exhaust HVAC and process vent system mitigates a gaseous release (that would occur subsequent to the line break postulated in this event) into
the process bay by sweeping it through HEPA filters before it is discharged outside the facility

- Process bay local exhaust HVAC and process vent system process hood isolation damper and instrument air supply

Isolation dampers in the process bay local exhaust HVAC and process vent system process hood fail closed. If power is lost, dampers will open with electrical power from the standby power system and instrument air supplied by the local dedicated tank. The hood isolation damper and instrument air supply operate in conjunction with the standby power system to facilitate HVAC operating while on standby power.

- Process general supply/exhaust HVAC system (exhaust HEPA filter, exhaust duct work, isolation damper)

The process general supply/exhaust HVAC system mitigates a release into the process bay or process water tank room by filtering it before discharging it outside the facility. The process general supply/exhaust HVAC system also provides confinement in conjunction with the facility’s structure by maintaining a negative building pressure. Fail-closed exhaust dampers from the process bays and process water tank room isolate other flow paths and ensure that differential pressure is maintained.

- Reference air system (reference air header, differential pressure alarms)

The reference air system monitors the negative pressure in the process bays and process water tank room by providing differential pressure indication and alarms to the control room for operator response.

- Standby electrical power (diesel generator and process bay local exhaust HVAC and process vent system restart circuit)

The standby power system provides connections to restart the local exhaust fans and supporting equipment. Operation of the local exhaust on standby power will maintain building differential pressure sufficient for confinement during facility power outages.

- Process bay recirculation HVAC system isolation dampers (outside air inlets)

The process bay recirculation HVAC system provides fail-closed outside air inlet dampers so the local exhaust on standby power can maintain process bay differential pressure.

Assumptions made that require protection by TSRs are listed below.

- Perform process connector leak test before processing
The VPS process connectors must be verified to be leak tight to protect analysis assumptions in relation to air inleakage into the MCO and process systems. In the frequency analysis, credit is taken for a reduced likelihood of an air inleakage upon a leak test of the process connectors.

- Close long axial process tube port before closing filtered process exit port at the end of processing.

When isolating the MCO at the end of processing, the long axial process tube port must be closed at least 5 minutes before closing the filtered process exit port. This ensures that an SCIC trip will occur if the procedure to isolate the MCO is inadvertently conducted on an MCO still to be processed. Under some conditions, if the filtered process exit port is closed first on an MCO still being processed, it is possible to bypass SCIC trips.

The bounding MCO internal hydrogen explosion accident (I1) and the other accidents identified in the CVDF hazard analysis report (HNF-SD-SNF-HIE-004) that can potentially involve hydrogen combustion in an MCO are itemized in Table B3-16, along with corresponding checklist designators from the hazard analysis report, safety functions, and SSCs.

The other accidents within the remaining bins require the following safety SSCs and TSRs in addition to the ones identified for the DBA (I1):

- I2 Hydrogen explosion within an MCO due to instrumentation failure (significant air ingress into the MCO)

The accident scenario identified in the hazard analysis for the I2 bin represents an internal hydrogen explosion caused by elevated fuel corrosion rates (high bay temperature) (HNF-SD-SNF-HIE-004). The controls in the I2 bin prevent an internal hydrogen explosion by protecting against the malfunction of SSCs. Upon detection of elevated temperatures in the process bay, the MCO is placed into a safe and stable configuration to remove reliance on non-safety related SSCs. For an internal explosion to be possible, a line leak must have occurred to allow an air ingress. To mitigate the gaseous release associated with a line leak, credit is taken for confinement systems to control that release. Note that the confinement systems are not credited with mitigation of the internal explosion release but only with mitigation of the gaseous release associated with the line leak.

Safety-class equipment (performing a safety-significant function) for detection:

- SCIC process bay high temperature detection

The SCIC high bay temperature trip isolates the MCO and actuates the SCHe system so excessive temperatures in the bay cannot cause instrument inaccuracies or malfunctions that might result in MCO overpressurization.

I 3 Hydrogen explosion within an MCO due to loss of MCO control caused by facility fire (significant air ingress into the MCO)

The accident scenarios identified in the hazard analysis for the I 3 bin represent internal hydrogen explosions caused by process upsets during fire in the bay (HNF-SD-SNF-HIE-004). The controls in the I 3 bin prevent an internal hydrogen explosion by protecting safety-related SSCs from damage during a fire in the process bay. Controlling the combustibles in the bay prevents such damage. In addition, credit is taken for controls to protect a bay temperature assumption made in the fire hazards analysis.

Safety-class equipment (performing a safety-significant function) to prevent an internal hydrogen explosion:

- SCIC process bay high temperature trip

The SCIC process bay high temperature trip acts to protect an initial condition assumption in the fire hazards analysis.

Assumptions made that require protection by TSRs are listed below:

- Combustible loadings limited

While an MCO is present in the facility, combustible loadings are limited as determined by the fire hazard analysis implementation plan (SNF-4942). These limits ensure that any fire in the CVDF does not result in uncontrolled releases (e.g., fire-caused loss of process control).

- Restore bay temperature following a process bay high temperature trip

On high bay temperature trip alarm, operations must return the process bay temperature to within acceptable limits.

I 4 Hydrogen explosion within an MCO due to hydride reaction

The accident scenarios identified in the hazard analysis for the I 4 bin represent internal hydrogen explosions caused by hydride reactions (HNF-SD-SNF-HIE-004). The uranium hydride reaction, in and of itself, has been shown to produce insufficient quantities of hydrogen to cause an internal hydrogen explosion. Thus, no controls are necessary for this bin. Hydrides have been accounted for as a contributor to other internal hydrogen explosion bins and other DBAs by an increase in the effective corrosion reaction rate.

No additional requirements result from analysis of this accident.
15 Hydrogen explosion within an MCO due to loss of support utilities (significant air ingress)

The accident scenarios identified in the hazard analysis for the 15 bin represent internal hydrogen explosions caused by loss of support systems resulting from accidents in adjacent bays, crane load drops, and accidents in the spare bay. This bin also includes loss-of-power events caused by external forces (e.g., vehicle accident), flooding, and lightning strike. The controls in the 15 bin prevent an internal hydrogen explosion by protecting against the malfunction of SSCs and by controlling specific initiators that would result in a loss of support utilities. For an internal explosion to be possible, a line leak must have occurred to allow air ingress. To mitigate the gaseous release associated with a line leak, credit is taken for confinement systems to control that release. Note that the confinement systems are not credited with mitigation of the internal explosion release but only with mitigation of the gaseous release associated with the line leak.

Assumptions made that require protection by TSRs are listed below:

- Crane movement restricted during MCO processing except as part of an approved recovery procedure

  Bridge crane movement is not allowed from the time that draining operations begin until the proof-of-dryness demonstration is complete and the MCO isolation valves are closed, except as part of an approved recovery procedure. This restriction ensures that key process lines cannot be sheared by crane movement, which could result in damage to systems relied upon to preclude an internal hydrogen explosion.

16 Hydrogen explosion within an MCO due to line break caused by a seismic event

The accident scenarios identified in the hazard analysis for the 16 bin represent internal hydrogen explosions caused by process upsets following a seismic event (HNF-SD-SNF-HIE-004). The controls in the 16 bin prevent an internal hydrogen explosion by removing reliance on nonqualified SSCs (piping and valves) whose failure could allow air ingress into the MCO. The MCO will be vented and confinement SSCs are credited with controlling the potential gaseous release. Note that the confinement systems are not credited with mitigation of the internal explosion release but only with mitigation of the gaseous release.

Safety-class (performing a safety-significant function) equipment for detection

- SCIC seismic trip

  On detecting a seismic event, the SCIC system seismic trip isolates the MCO and actuates the SCHe system and de-energizes the tempered water (annulus) system heater to ensure the seismic event will not initiate thermal runaway.
Assumptions made that require protection by TSRs are listed below

- Trailer placement controlled such that movement from seismic events will not impact key shutdown systems

Before connecting CVDF systems to the MCO, the cask, which is located upon the transporter, must be positioned such that the central axis of the cask is no greater than an established safe distance from the ideal horizontal placement, as identified in Chapter B4. This control protects the MCO during seismic events

17 Hydrogen explosion within an MCO due to contamination of helium supply

The accident scenarios identified in the hazard analysis for the I7 bin represent internal hydrogen explosions caused by fuel reactions with contaminants in the helium supply (HNF-SD-SNF-HIE-004) The controls in the I7 bin prevent an internal hydrogen explosion by controlling the helium supply sent to the MCO

Assumptions made that require protection by TSRs are listed below

- Shipment paperwork verified for helium supply gas content during receipt

The manufacturer's paperwork and shipping papers should be checked upon helium cylinder receipt at the CVDF, both the normal and safety-class supply, to verify that the cylinder's contents were sampled by the supplier and that the sample met the required purity specification of > 99% helium

B3 4.2.5 Multi-Canister Overpack Thermal Runaway Reaction Thermal runaway reaction accidents would occur if heat removal from the MCO is not sufficient to prevent fuel elements and scrap fuel from heating up as a result of decay heat and chemical reaction heat. As the temperature increases, the chemical reaction rate increases, producing more gas and heat. If the thermal runaway reaction is allowed to continue, the temperature would continue to increase until all fuel or water is consumed by the fuel–water chemical reaction. Detailed calculations of the consequences of an MCO thermal runaway reaction are provided in SNF-2770, Chapter 6. The SSCs designated to prevent the MCO runaway reaction are designated safety class because unmitigated consequences exceed the offsite release limit of 0.5 rem (0.005 Sv).

Version 1.3.2 of the HANSF computer code (SNF-3650) was used to simulate the thermal runaway cases. HANSF calculates the fuel, gas, and MCO structure temperatures and MCO pressure based on uranium-water and hydride-water reactions, decay heat, and heat transfer. The code also calculates the particulate or MAR for the thermal cases over time. Validation and verification assurance for the HANSF code at the Hanford Site is described in SNF-5226.

*Comparison Cases Simulated with HANSF 1.3.2 to Supplement Thermal Analyses Documented in HNF-SD-SNF-CN-023*
Safety-class features that prevent a thermal runaway accident include portions of the tempered water system to provide adequate heat removal, a tempered water high temperature trip, the SCIC and associated safety-class instruments to detect process upsets and activate the SCHe system, and the SCHe system to provide an MCO purge and vent function. These safety-class preventive features reduce the estimated thermal runaway accident frequency into the beyond extremely unlikely frequency range (less than $10^{-6}$ per year). No additional mitigation features are required.

**B3 4 2 5 1 Scenario Development** The CVDF hazard analysis report (HNF-SD-SNF-H1E-004) identified several potential accidents leading to a thermal reaction runaway. These included events such as loss of annulus water, degraded vacuum pump capability, and high tempered water temperature. From the identified potential thermal runaway reaction accidents, a bounding accident of a loss of water in the annulus between the MCO and transportation cask was selected and developed as the DBA. This accident was selected as the DBA based on a qualitative estimate of the likelihood of the binned thermal runaway events.

All of the thermal runaway scenarios require an insufficient rate of heat removal from the inside of the MCO, which is considered to be a process parameter upset. The amount of heat removal capability needed depends on the amount of decay heat and the fuel–water reaction rate in the MCO. Under normal conditions, the main heat sink for the MCO is the flowing annulus water. Because of the high thermal conductivity of water, heat removal from the MCO is still adequate under conditions of stationary annulus water and off-center MCO in cask. Any metal-to-metal contact would improve thermal conductivity. Higher temperature annulus water has less heat removal capability than cooler temperature annulus water. The temperature capability of the tempered water system is from 10 °C to 100 °C (50 °F to 212 °F) with a nominal operating value of from 40 °C to 50 °C (122 °F). If the annulus water is not flowing or is lost, the air surrounding the cask becomes the heat sink. The temperature of the annulus water is limited to 50 °C to ensure that the process remains within analyzed bounds while maintaining a temperature high enough to dry the fuel. The 50 °C limit also ensures that the fuel and MCO do not experience elevated temperatures such as postulated in the unmitigated scenario. Because of conservatisms built into the analysis, a short duration temperature above 50 °C could be tolerated provided that the tempered water heater is deactivated at ≤ 50 °C.

For an MCO with insufficient heat removal, the temperatures in the MCO essentially continue to increase until the water is consumed. With sufficient initial water available, temperatures in excess of the eutectic temperature for uranium and iron (725 °C) (HNF-SD-SNF-SARR-005) could be reached, with the potential for localized damage to MCO internal components (e.g., scrap and fuel baskets).

With the postulated loss of cask–MCO annulus water (e.g., leak or failure of lower port connection on cask), heat generation inside the MCO exceeds the heat removal capability. In the DBA scenario, there is no helium flow through the MCO, but there is pressure relief through the normal processing vent path. The loss of annulus water causes the temperatures inside the MCO to slowly increase at first, but after 10 hours, the rate of temperature rise increases significantly.
About 11.5 hours after loss of annulus water, some MCO fuel temperatures exceed 725 °C but no fuel temperatures exceed 1,010 °C, which is below the uranium melting temperature of 1,125 °C.

The high fuel temperature results in the continuous release of particulate from within the MCO, driven by the gases generated from the uranium fuel reaction within the hot MCO. This release would continue as long as unreacted uranium is in contact with water vapor. The loss of annulus water has been shown to be credible for the unmitigated accident scenario (see SNF-2770, Appendix A).

The fuel temperatures reached in localized regions inside the MCO could exceed the uranium-steel eutectic temperature and allow the formation of some eutectic. This could cause spalling and limited structural damage to MCO components such as the scrap and fuel baskets. The thermal calculations (SNF-2770) with the HANSF code (SNF-3650) predict that about 700 kg of fuel in a Mark IV MCO (all in the bottom scrap basket) will reach a temperature in excess of 700 °C, with a maximum center post temperature less than 1,000 °C. The maximum wall temperature for the Mark IV MCO during the loss of annulus water is 500 °C. For the Mark IA MCO, no fuel reaches temperatures in excess of 710 °C, with a maximum center post temperature of 640 °C. The maximum Mark IA MCO wall temperature is less than 520 °C. These calculations show that no temperatures are reached during the thermal runaway sufficient to cause structural damage to the MCO walls for either fuel type or to the Mark IA baskets and center post. Only limited damage to the bottom Mark IV scrap basket and center post is predicted. Thus, the safety-class confinement and criticality contingency function of the MCO and the criticality contingency function of the Mark IA basket center post is not challenged during the thermal runaway. Because the Mark IV baskets are not safety class, limited structural damage would be tolerable.

The water in the MCO reacts with exposed fuel, causing a continuous stream of gases and entrained particulate to flow out of the MCO. Both the scrap fuel and exposed fuel elements react with the water vapor that is flowing through the MCO. The water vapor continues to react with uranium and uranium hydride until the water is completely consumed, which for the scrap baskets, is about 14 hours after the loss of annulus water (SNF-2770).

The bounding unmitigated thermal runaway scenario, therefore, requires the following conditions:

- MCO processing without helium flow (the flow of helium does not prevent the thermal runaway but lengthens the time required to reach high temperatures).

- Loss of cask-MCO annulus water.

- Continuous release through a failed process line (the release continues as long as unreacted uranium is in contact with water vapor or oxygen).
The following assumptions are used in the analyses

- The MCO thermal runaway reaction scenario is assumed to begin when the water draining process is finished but some undrained (residual) water is still present in the MCO to react with the fuel. It is assumed that 26.5 kg of free undrained (residual) water (15 kg in the top scrap basket, 6 kg in the bottom scrap basket, 18 kg in three fuel baskets, and 1 kg in the gap between the bottom fuel basket and the MCO bottom plate) is present when the thermal runaway accident is initiated (SNF-2770).

- Uranium hydrate contains 119 kg of water (HNF-SD-SNF-TI-015).

- The MCO is at bounding configuration with two scrap baskets:
  - Enhancement factor or rate multiplier fuel–water reaction equals 10 (HNF-SD-SNF-TI-015).
  - Surface area equals 12 m² (HNF-SD-SNF-TI-015).
  - Decay heat rate equals 705 W for three fuel baskets and two scrap baskets (HNF-SD-SNF-TI-015).

- Uranium hydride is included using an enhancement factor or rate multiplier of 12 to account for the mass fraction of hydride and its surface area (HNF-SD-SNF-TI-015). This factor is multiplied by the reaction rate from literature in order to conservatively enhance the oxidation rate. The rate multipliers of 12 for hydride–water reactions and 10 for uranium–water reactions are kept separate in the model because each reaction produces different amounts of heat and hydrogen. Hence, the rate multiplier of 22 is just a convenient way to say that both reactions are modeled.

- The effects of fuel crumbling at high temperatures were not explicitly included in the analysis but were included in the rate multiplier of 22. Increased reaction rates were not observed experimentally in fuel samples that crumbled over time (HNF-4206), although other samples that did not crumble had lower rates by a factor of 2 to 4. The analysis assumes that the reaction rate multiplier of 10 for uranium and 12 for uranium hydride for a combined rate multiplier of 22 bounds any effects of increased surface area caused by fuel crumbling. For comparison, the crumbled samples had rate multipliers less than 4 (HNF-4206).

- No hydrogen gettering takes place because of the presence of water at the beginning of the scenario and air at the end of the scenario. Hydrogen gettering or uranium–hydrogen reaction (\( \text{U} + 1.5 \text{H}_2 \rightarrow \text{UH}_3 \)) has been shown not to occur to any significant degree in the presence of water or oxygen (SNF-3650).
About 15 kg of particulate are generated between the time the MCO leaves the K Basins and the time it is drained at the CVDF. This newly generated particulate is available to be entrained by exiting gases during a release.

With the high temperatures produced by the thermal runaway conditions, the uranium hydrates will decompose and produce more water (up to 1.19 kg) for the fuel-water reactions.

The water contained in aluminum hydroxide, a maximum of about 3.3 kg (HNF-SD-SNF-TI-015), is used in this analysis to account for aluminum hydroxide decomposition at elevated temperatures. Only three baskets have temperatures in excess of 150 °C where some aluminum hydroxide could decompose (ALCOA 1987, Figure 4-4). A total of about 0.74 kg of hydroxide water is released for this scenario.

**B3 4 2 5 2 Source Term Analysis** The respirable source term is based on the MAR (material at risk), the ARF (airborne release fraction), and the RF (respirable fraction). The MAR is the sum of the amount of particulate created before the release and the amount of particulate created during the release.

- **MAR₁** = 15 kg UO₂ generated between the time the fuel is cleaned at the K Basins and completion of the draining process. This equates to 13.2 kg of uranium (HNF-SD-SNF-TI-015). This value was not calculated by the HANSF code and is only used as part of the following MARs.

- **MAR₂** = 52 kg UO₂ for the 12-hour continuous release. This equates to about 46 kg of uranium (includes MAR₁). The amount of particulate in MAR₂ that exceeds that in MAR₁ is generated by the continuing corrosion reaction under the DBA conditions (SNF-5226). This newly formed particulate is assumed to be susceptible to release in addition to MAR₁.

- **MAR₃** = 178 kg UO₂ for the 24-hour continuous release. This equates to about 157 kg of uranium (includes MAR₁). The amount of particulate in MAR₃ that exceeds the amount in MAR₁ is generated as a result of the continuing corrosion reaction (SNF-5226).
Airborne Release Fraction and Respirable Fraction  The ARF of all the radionuclides in the fuel, such as the fission products (e.g., cesium), may not be the same as the uranium particulate release under very high temperature conditions. For example, the cesium in the fuel could vaporize at temperatures in excess of 600 °C, increasing the rate at which it becomes airborne (DOE-STD-1027-92). However, cesium and the other nontransuranic radionuclides contribute less than 0.5% of the total rem per gram of SNF fuel dose factor of the SNF (HNF-SD-SNF-TI-059).

The bounding value for the respirable release fraction for uranium at temperatures greater than 500 °C is $1 \times 10^3$ (DOE-HDBK-3010-94, page 4-3). The bounding respirable release fraction for falling molten droplets at temperatures greater than 1,100 °C is $1 \times 10^2$ (DOE-HDBK-3010-94, page 4-3). Since falling molten droplets with high surrounding gas velocities are not the physical situation in the high-temperature MCO, $1 \times 10^2$ is considered overly conservative. However, since some fuel temperatures exceed 1,000 °C, and may approach the melting temperature of uranium (1,125 °C), the $1 \times 10^3$ release fraction for fuel temperature greater than 500 °C may not be conservative enough. Hence, an intermediate respirable release fraction of $5 \times 10^3$ was selected for the analysis.

Additional analyses using the HANSF version 1.3.2 code (SNF-3650) may adequately demonstrate that fuel melting does not occur. The implications of a revised thermal runaway DBA with reduced consequences (as a result of not incorporating a molten fuel ARF) are being evaluated further to assess impact on selected controls. The ARF used in this analysis is conservative.

The source term $M_2$, for the 12-hour continuous release is calculated by multiplying $\text{MAR}_2$, the particulate MAR for the 12-hour continuous release, by the product of ARF and RF and converting to uranium metal as follows:

$$M_2 = (\text{MAR}_2)(\text{ARF} \times \text{RF})$$

$$= (46 \text{ kg U})(1,000 \text{ g/kg})(5 \times 10^3)$$

$$< 230 \text{ g U}$$

The source term $M_3$, for the 24-hour continuous release (offsite) is calculated by multiplying $\text{MAR}_3$, the particulate MAR for the 24-hour continuous release, by the product of ARF and RF and converting to uranium metal as follows:

$$M_3 = (\text{MAR}_3)(\text{ARF} \times \text{RF})$$

$$= (157 \text{ kg U})(1,000 \text{ g/kg})(5 \times 10^3)$$

$$< 785 \text{ g U}$$
B3 4 2 5 3 Consequence Analysis  The radiological dose is calculated using the following equation

\[ DE = M \times \frac{\chi}{Q'} \times BR \times UD \]

where

- \( DE \) = effective dose equivalent based on inhalation exposure only (rem)
- \( M \) = respirable quantity released into the air (grams)
  - \( M_2 \) for 12-hour (onsite) continuous release (225 g U)
  - \( M_3 \) for 24-hour (offsite) continuous release (785 g U)
- \( \frac{\chi}{Q'} \) = air transport factor (s/m³)
- \( BR \) = average inhalation rate during the blowdown and 12-hour release (m³/s)
- \( UD \) = committed effective dose equivalent per unit gram inhaled

Unmitigated Consequences  The dose calculation equation is used to calculate the dose to the offsite receptor

\[ D_{\text{offsite}} = M_3 \times \frac{\chi}{Q'} \times BR \times UD \]

\[ = (785 \text{ g U})(6.50 \times 10^{-6} \text{ s/m}^3)(2.64 \times 10^{-4} \text{ m}^3/\text{s})(4.38 \times 10^5 \text{ rem/g U}) \]

\[ = 0.590 \text{ rem (0.0059 Sv)} \text{ for 24-hour continuous release} \]

The dose consequences at the remaining receptor sites are calculated in the same manner and are shown in Table B3-17 for the continuous release.

Mitigated Consequences  With safety-class features credited for this event the accident is prevented. The key safety-class features that combine to prevent the thermal runaway reaction are (1) the tempered water (annulus) system which removes heat from the MCO and fuel, and (2) the manual capability to provide annulus water and (3) the SCHe system, which provides pressure vent and cools the fuel, reducing the fuel-water reaction rate. Credit also is taken for restriction of crane movement during processing to protect the tempered water (annulus) system and the other process lines. With the credited preventive features the frequency of the thermal runaway DBA is beyond extremely unlikely so release limits are met. In addition credit is taken for local exhaust operation to filter and dilute SCHe flows (local exhaust is not credited except as it filters and dilutes the SCHe flows).

---

a Fifty year committed effective dose equivalent.

b Evaluation guideline (for onsite receptor) and offsite release limit for unmitigated accidents in the unlikely frequency category (i.e. frequency between $10^4$ and $10^7$ per year).

c Mitigated accident frequency of beyond extremely unlikely

Failure of preventive features is beyond extremely unlikely ($< 10^6$ per year).
Prevention is achieved through a tempered water (annulus) system design that provides a high level of assurance that annulus water will not be lost, thus sufficient MCO heat removal is maintained. In addition, detection and alarm of the loss of annulus water levels ensures operator actions for restoration. The safe and stable state following process upsets is for the MCO to have pressure relief, a helium cover inside, annulus water at or below 50 °C available (not necessarily flowing) for heat transfer purposes, and process bay temperatures less than 115 °F.

The safety-class function of the tempered water (annulus) system is to remove heat from the MCO, thus preventing excessive fuel reactions. The key requirement of the annulus water is that it should be at a high level in the cask-MCO annulus so that good thermal conductivity exists between the MCO and cask, which will help cool the MCO and prevent a thermal runaway reaction accident. Thermal analyses performed in HNF-SD-SNF-CN-023, *Thermal Analysis of Cold Vacuum Drying of Spent Nuclear Fuel* (1998), demonstrate the capability of the tempered water (annulus) system to provide the necessary thermal conductivity when annulus water levels are high. The design provides the capability for operator actions to restore low annulus water levels. The temperature of the annulus water also is important. The thermal analysis assumes that annulus water does not exceed 50 °C (122 °F). A safety-class tempered water high temperature trip is provided to prevent annulus water overheating. The thermal analysis also assumes that the temperature in the process bay (the final heat sink if the tempered water is not flowing) is less than 115 °F. A high-bay-temperature trip initiates a safety-class alarm (the isolation and purge alarm) in the control room to alert operators so they can restore bay temperatures to normal.

**B3 4 2 5 4 Comparison to Guidelines**

**Comparison of Unmitigated Doses.** The unmitigated frequency of the event tree sequences that represent this DBA, including an unfiltered release, is $5 \times 10^{-4}$ per year, thus this unmitigated DBA is unlikely (see SNF-2770, Appendix A). The unmitigated sequence considered the processing of 200 MCOs per year and failure of single-walled tempered water system inlet piping. The unmitigated radiological offsite dose for this event is above the safety-class dose limit of 0.5 rem, but below the offsite release limit for an unlikely event of 5.0 rem.

**Comparison of Mitigated Doses.** The mitigated frequency of the event tree sequences that represent this DBA as a thermal runaway excursion is $1 \times 10^{-5}$ per year without release. Thus this mitigated DBA is beyond extremely unlikely (see SNF-2770, Appendix A). The accident is prevented with safety-class features (i.e., tempered water double-walled pipe and the ability to detect low annulus water and refill the system). Failure of prevention features is beyond extremely unlikely. Thus, the offsite release limits and onsite risk evaluation guidelines are met.
B3 4 2 5 5 Summary of Safety-Class Structures, Systems, and Components and Technical Safety Requirement Controls

Under normal operating conditions, annulus water levels and helium in the MCO provide adequate heat transfer to prevent thermal runaway reactions. Under upset or accident conditions, safety-class equipment is required in order to ensure this capability is not lost. The heat transfer from the MCO could be compromised by a loss of water level or high tempered water temperatures. The heat transfer within the MCO could be compromised by a loss of helium.

The checklist designators included in the accident bins, other than the accident selected as the DBA, represent additional accident sequences slightly different than the DBA. All of these binned accidents are bounded by the DBA because they have lesser or equivalent worst-case consequences and frequencies.

The accident scenarios identified in the hazard analysis for the T1 bin represent thermal runaway accidents caused by failure of the proof-of-dryness demonstration (instrumentation failure or operator error) and degraded vacuum pump and subsequent possible elevated fuel temperatures. This bin also includes thermal runaways in a loss-of-power event caused by external forces (e.g., vehicle accident), flooding, and lightning strikes (HNF-SD-SNF-HIE-004). The controls in the T1 bin prevent a thermal runaway by ensuring that an adequate heat sink is available. In addition, credit is taken for controls that prevent bypass of safety features by incorrectly proceeding with the cold vacuum drying process or by operator error.

The safety-class equipment designated to prevent the dose consequences of thermal runaway reaction accidents are described below.

Safety-class equipment for detection of process upset

- Tempered water (annulus) system level alarm

  Redundant liquid level indicators are used by the tempered water (annulus) system to detect a low water level in the cask-MCO annulus and to provide a signal to the SCIC system to actuate the low-level alarm.

- Tempered water (annulus) system level check petcocks

  The level check petcocks provide a manual means of verifying the presence of water in the annulus. The petcocks are located in and above the double-walled portion of the tempered water (annulus) piping and are connected to the outer and inner pipes above the height of the fuel in the MCO. If a low-level alarm is received, the petcocks can be used to verify the presence of water in the inner or outer pipe, thus indicating the presence of water in the annulus.
Safety-class equipment for heat removal

- Tempered water (annulus) system piping and antisiphon valves

  A portion of the tempered water (annulus) system contains double-walled safety-class piping and antisiphon valves to ensure retention of a minimum water level above the elevation of the SNF inside the MCO

- Manual refill piping and vent port

  The tempered water (annulus system) provides manual refill capability, which could be required if a low annulus water level were detected

- Cask-MCO

  The cask-MCO is a major part of the pressure boundary for tempered water (annulus) and a confinement of radioactive materials during processing and provides connections for the process piping to the SCHe system

Assumptions made that require protection by TSRs are listed below

- Administrative procedure for restricting crane movement during MCO processing except as part of an approved recovery procedure

  Bridge crane movement is not allowed from the time that draining operations begin until the proof-of-dryness demonstration is complete and the MCO isolation valves are closed except as part of an approved recovery procedure. This restriction ensures that key process lines cannot be sheared by crane movement which could result in loss of annulus water if the lower tempered water (annulus) line were damaged

- Procedure to verify the results of the pressure rebound tests before continuing process steps

  An initial pressure rebound test surveillance (pressure rise test) must be met before entry into the proof-of-dryness demonstration is allowed. Similarly, a proof-of-dryness demonstration surveillance must be met before the final pressure rebound test steps can begin. Finally, a final pressure rebound test must be met before shipment preparation steps can begin
Close long axial process tube port before closing filtered process exit port at the end of processing.

When isolating the MCO at the end of processing, the long axial process tube port must be closed at least 5 minutes before closing the filtered process exit port. This ensures that an SCIC trip will occur if the procedure to isolate the MCO is inadvertently conducted on an MCO still to be processed.

The bounding thermal runaway accident (T1) and the other accidents identified in the CVDF hazard analysis report (HNF-SD-SNF-HIE-004) that can potentially involve a thermal runaway reaction in an MCO are itemized in Table B3-18, along with corresponding checklist designators from the hazard analysis report, safety functions, and SSCs.

The accidents within the remaining bins require the following safety SSCs and TSRs, in addition to those identified for the DBA (T1).

T2 Thermal runaway reaction in MCO due to instrumentation failure.

The accident scenarios identified in the hazard analysis for the T2 bin represent thermal runaway accidents caused by elevated fuel temperatures resulting from a high bay temperature and high annulus water temperature (HNF-SD-SNF-HIE-004). The controls in the T2 bin prevent a thermal runaway by monitoring key process parameters and by protecting safety-related SSCs from damage. SCHe actuation is credited, therefore confinement and dilution provided by the local exhaust system also are credited.

Safety-class equipment for detection of process upset or instrumentation failure:

- VPS instrumentation (pressure)
  
  Pressure indicators on the VPS provide MCO internal pressure information to the SCIC system, which initiates MCO isolation and SCHe actuation during process upset conditions.

- SCIC vacuum cycle timer (8-4-4 logic)
  
  The SCIC system uses programmable logic controllers, wiring to process instrumentation, vacuum limit timer, signals from seismic detectors and temperature monitors, system controls, and output relays to perform an MCO isolation and purge trip and a tempered water trip.

*Checklist designators are from HNF SD SNF HIE 004 1999 Cold Vacuum Drying Facility Hazard Analysis Rev 4 Fluor Daniel Hanford, Incorporated, Richland Washington

²U.S. Nuclear Regulatory Commission important to safety classifications Category = critical to safe operation, Category B = major impact on safety Category C = minor impact to safety

Lines and valves to isolate the MCO include the isolation valves (and filters on air supply to valve actuators) in the VPS general service helium system, PWC system, and SCHe system.

HEPA = high efficiency particulate air (filter)
HVAC = heating, ventilation, and air conditioning
HVACC/PV = process bay local exhaust HVAC and process vent system
ITS = important to safety
MCO = multi-canister overpack.
NRC = U.S. Nuclear Regulatory Commission
PWC = process water conditioning
SCHe = safety class helium
SCIC = safety-class instrumentation and control
TSR = technical safety requirement.
VPS = vacuum purge system
8 4 4 = 8 hour initial vacuum cycle 4 hour subsequent vacuum cycles 4 hour return to pressure between vacuum cycles
Tempered water (annulus) system temperature trip

The system has temperature indicators and transmitters to detect high tempered water (annulus) water temperature and signals the SCIC system to actuate the tempered water trip.

SCIC process bay high temperature trip

The SCIC high bay temperature trip isolates the MCO and actuates the SCHe system. A safety-class alarm alerts operations to the bay condition.

Safety-class equipment for confinement, purge, and pressurization

Cask–MCO

The cask–MCO is a major part of the pressure boundary for confinement of radioactive materials during processing and provides connections for the process piping to the SCHe system.

SCHe system

The SCHe system provides two redundant and independent paths for purging and pressurizing the MCO and venting to the process vent. The SCHe purging and pressurizing functions help to prevent elevated temperatures inside the MCO.

Lines and valves to isolate and purge the MCO

Lines and valves to isolate the MCO include the isolation valves (and filters on air supply to valve actuators) in the VPS, general-service helium system, PWC system, and SCHe system. Upon demand, all the valves close to isolate the MCO, except the SCHe system valves, which open to allow helium to the MCO.

Safety-significant equipment for dilution and filtration to support SCHe operation

Process bay local exhaust HVAC and process vent system (exhaust fans and plenums, duct work, HEPA filters)

The process bay local exhaust HVAC and process vent system mitigates a gaseous release into the process bay by sweeping it through HEPA filters before it is discharged outside the facility. This ensures that SCHe flows are filtered and diluted.
Process bay local exhaust HVAC and process vent system process hood isolation damper and instrument air supply

Isolation dampers in the process bay local exhaust HVAC and process vent system process hood fail closed. If power is lost, dampers will open with electrical power from the standby power system and instrument air supplied by the local dedicated tank. The hood isolation damper and instrument air supply operate in conjunction with the standby power system to facilitate HVAC operating while on standby power. This supports operation of the local exhaust to filter and dilute SCHe flows.

Standby electrical power (diesel generator and process bay local exhaust HVAC and process vent system restart circuit)

The standby power system provides connections to restart the local exhaust fans and supporting equipment. Operation of the local exhaust on standby power will maintain building differential pressure sufficient for confinement during facility power outages. This supports operation of the local exhaust to filter and dilute SCHe flows.

Assumptions made that require protection by TSRs are listed below:

- Restore bay temperatures following process bay high temperature trip

  On high bay temperature trip alarm, operations must return the process bay temperatures to within acceptable limits.

T 3 Thermal runaway reaction in MCO due to loss of MCO control caused by facility fire

The accident scenarios identified in the hazard analysis for the T 3 bin represent thermal runaway accidents caused by process upsets from internal and external facility fires (HNF-SD-SNF-HIE-004). The controls in the T 3 bin prevent a thermal runaway by protecting safety-related SSCs from damage during a fire event in the bay. Credit also is taken for controls on the bay temperature to protect an assumption made in the fire hazards analysis.

Safety-class equipment for detection

- SCIC process bay high temperature trip

The SCIC process bay high temperature trip acts to protect an initial condition assumption in the fire hazards analysis.
Assumptions made that require protection by TSRs are listed below

- Combustible loadings limited

  While an MCO is present in the facility, combustible loadings are limited as determined by the fire hazard analysis implementation plan (SNF-4942)

- Restore bay temperature following a process bay high temperature trip

  On high bay temperature trip alarm, operations must return the process bay temperature to within acceptable limits

T4  Thermal runaway reaction in MCO due to loss of support utilities

  The accident scenarios identified in the hazard analysis for the T4 bin represent thermal runaway accidents caused by a loss of a support system because of accidents in adjacent bays, crane load drops, and accidents in the spare bay (HNF-SD-SNF-HIE-004) The controls in the T4 bin prevent a thermal runaway by monitoring key process parameters, precluding water addition to the MCO, and placing the MCO into a safe and stable configuration SCHe actuation is credited, therefore confinement and dilution provided by the local exhaust system also are credited

  Safety-class equipment to prevent process upsets

  - Deionized water and PWC drain line isolation valves interlocked closed after being used in the process

    The VPS isolation valves (on the deionized water supply line) and the PWC drain line isolation valves prevent water from entering the MCO After these lines are used in the process, they are closed and interlocked to the SCIC system so they cannot be inadvertently opened later in the process

T5  Thermal runaway reaction in MCO due to contamination of helium supply

  The accident scenario identified in the hazard analysis for the T5 bin represents a thermal runaway accident caused by fuel reactions with contaminants in the helium supply (HNF-SD-SNF-HIE-004) The controls in the T5 bin prevent a thermal runaway by controlling the helium supply to the MCO
Assumptions made that require protection by TSRs are listed below

- Shipment paperwork verified for gas bottle content during receipt

  The manufacturer's paperwork and shipping papers shall be checked upon helium cylinder receipt at the CVDF, both the normal and safety-class supply, to verify that the cylinder's contents were sampled by the supplier and that the sample met the required purity specification of >99% helium

T 6 Thermal runaway reaction in MCO due to line break caused by a seismic event

The accident scenarios identified in the hazard analysis for the T 6 bin represent thermal runaway accidents caused by process upsets following a seismic event (HNF-SD-SNF-HIE-004). The controls in the T6 bin prevent a thermal runaway by removing reliance on nonqualified SSCs and placing the MCO into a safe and stable configuration.

Safety equipment for detection of seismic event

- SCIC seismic trip

  On detecting a seismic event, the SCIC system seismic trip isolates the MCO and actuates the SCHe system and de-energizes the tempered water (annulus) system to ensure the seismic event will not initiate thermal runaway.

Assumptions made that require protection by TSRs are listed below

- Trailer placement controlled such that movement from seismic events will not impact key shutdown systems

  Before connecting CVDF systems to the MCO, the cask, which is located upon the trailer, must be positioned such that the cask is no greater than an established safe distance from the ideal horizontal placement. This control protects the MCO and safety-class components during seismic events.

B3 4 2 6 Multi-Canister Overpack Overpressurization Overpressurization accidents occur if there is no pressure vent or relief on a sealed MCO. The internal pressure in the MCO would increase until the MCO confinement failed or until all the fuel or water was consumed by the fuel-water chemical reaction. Detailed calculations of the consequences of an MCO overpressurization reaction are provided in SNF-2770, Chapter 7.0. The SSCs designated to prevent or mitigate MCO overpressurization are designated safety class because unmitigated consequences exceed offsite release limits.

Version 1 3 2 of the HANSF computer code (SNF-3650) was used to simulate the overpressurization cases. HANSF calculates the fuel, gas, and MCO structure temperatures and
MCO pressure based on uranium-water and hydride-water reactions, decay heat, and heat transfer. The code also calculates the particulate or MAR for the thermal cases over time. Quality assurance for the HANSF code at the Hanford Site is described in SNF-5226.

Safety-class features that prevent an MCO overpressurization accident include the SCIC system and instrumentation to detect process upsets and activate the SCHe system; the SCHe system to provide the MCO purge and vent function, the 30 lb/in² gauge pressure vent path, the 150 lb/in² gauge rupture disk, and the safety-class portions of the tempered water system. These preventive features reduce the estimated overpressurization accident frequency into the extremely unlikely range. Since the unmitigated offsite dose is well below the release limit of 5 rem for an extremely unlikely event, no additional safety-class mitigation features are required. However, success of some of the credited prevention features (e.g., the 30 lb/in² gauge rupture disk) might result in dose consequences that exceed onsite guidelines. Thus, safety-significant mitigation features provided for the MCO overpressurization accident include components of the process bay local exhaust HVAC system, process general exhaust HVAC system, associated HEPA filtration, process bay differential pressure alarms, and electrical standby power. The safety-significant mitigated dose for this accident is well below the applicable guideline.

**B3 4 2 6 1 Scenario Development** Based on the CVDF hazard analysis report (HNF-SD-SNF-HIE-004), several potential accidents have been identified that would lead to MCO overpressurization. From all of the potential overpressurization reaction accidents, a bounding accident was chosen for the unmitigated consequence analysis. The most credible high-pressure scenario consists of an isolated MCO with stationary annulus water. Without the safety features identified in this section, a loss of power would close the isolation valves and shut off the tempered water pump leaving the MCO isolated and without flowing annulus water.

The overpressurization DBA is assumed to begin after the water draining process is finished with some undrained, residual water still present in the MCO to react with the fuel. As little as 5 kg of residual water can pressurize the MCO vessel to 300 lb/in² gauge. This is caused by the residual water reacting with uranium and hydride, which produces hydrogen gas that pressurizes the isolated MCO. The greatest consequences are expected for the overpressurization accident with the highest pressure conditions. High internal gas pressure is required to cause a breach of MCO confinement and a blowdown release.

With uranium-water reaction rates producing hydrogen gas at all MCO temperatures, the overpressurization accident scenario will eventually lead to an increase in pressure sufficient to breach the MCO. An isolated MCO will reach unacceptable pressures given enough time (more than a week for cool tempered water annulus cases). The key aspect of high-pressure overpressurization accidents is the amount of time required to breach the MCO.

The MCO overpressurization scenario consists of the following events and processes:

- MCO pressurization until the isolated MCO is breached.
Blowdown release of particulate through an opening assumed to be equivalent to 1-in-diameter circle

Continuous release of gases and particulate from uranium–water reactions (the release continues as long as unreacted uranium is in contact with water vapor or oxygen)

The following assumptions are used in the analyses:

- The MCO overpressurization reaction scenario is assumed to begin when the water draining process is finished but some undrained (residual) water is still present in the MCO to react with the fuel. It is assumed that 26.5 kg of free undrained (residual) water (1.5 kg in the top scrap basket, 6 kg in the bottom scrap basket, 18 kg in three fuel baskets, and 1 kg in the gap between the bottom fuel basket and the MCO bottom plate) is present when the high-pressure overpressurization accident is initiated (HNF-SD-SNF-CN-023 [1998]). As little as 5 kg of residual water can pressurize the MCO vessel to 300 lb/in² gauge.

- Uranium hydrate contains 119 kg of water (HNF-SD-SNF-TI-015)

- The MCO is at bounding configuration with two scrap baskets:
  - Enhancement factor or rate multiplier fuel-water reaction equals 10 (HNF-SD-SNF-TI-015)
  - Surface area equals 12 m² (HNF-SD-SNF-TI-015)
  - Decay heat rate equals 776 W for five fuel baskets and 705 W for three fuel baskets and two scrap baskets (HNF-SD-SNF-TI-015)

- Uranium hydrides are included using an enhancement factor or rate multiplier of 12 to account for the mass fraction of hydride and its surface area (HNF-SD-SNF-TI-015).

- No hydrogen gettering takes place because of the presence of water during the entire scenario. Hydrogen gettering or uranium-hydrogen reaction ($U + 1.5\ H_2 \rightarrow UH_3$) has been shown not to occur to any significant degree in the presence of water or oxygen (SNF-5226).

- About 15 kg of particulate is generated between the time the MCO leaves the K Basins area and the time it is drained at the CVDF (HNF-SD-SNF-TI-015). This newly generated particulate is available to be entrained by exiting gases during a blowdown release and the subsequent long continuous release.
Annex B — Cold Vacuum Drying Facility

- Unmitigated blowdown release pressure is assumed to be 345 lb/in² gauge, which is greater than the MCO design pressure of 150 lb/in² gauge

- The bay temperature is assumed to be 90 °F

For the unmitigated MCO overpressurization accident sequence, the MCO vents or port valves are postulated to be closed or blocked. Thus, the uranium—water chemical reaction generates hydrogen gas, which pressurizes the MCO. The steam or water vapor from the heated liquid water also increases the MCO pressure (for an isolated MCO) and, more importantly, provides an oxidant for the exposed fuel in the scrap and fuel baskets. The increasing gas temperature in the MCO also helps pressurize the MCO. The blowdown at a pressure of 345 lb/in² gauge is assumed to occur about 96 hours after MCO isolation. This pressure would cause the rupture disk (rated at 150 lb/in² gauge) to burst and could also fail the MCO. However, to be conservative, the MCO is assumed to retain confinement until the 345 lb/in² gauge pressure is reached.

The MCO Topical Report (HNF-SD-SNF-SARR-005) states that based on the codes used in the MCO design, the mechanically closed MCO (before welding at the CSB) would not suffer any damage at internal pressures up to 340 lb/in² gauge. At some pressure in excess of 340 lb/in² gauge, the thread root of the collar would begin to yield, and at some pressure very much larger than 340 lb/in² gauge, leakage around the HelicoFlex seal would result. An MCO was built and tested to an internal pressure of 562.5 lb/in² gauge to match the test requirement to be placed on MCO procurements. In that test, no leakage and no permanent damage were observed. Credit is not taken for the pressure test, however, because the data is in draft form and the ramifications on selected controls have not been fully evaluated. Therefore, the MCO is assumed to be susceptible to failure at any pressure greater than 340 lb/in² gauge.

If the MCO were to be breached from high pressure, most of the gas and some suspended particulate would be carried out of the MCO in a very short time (<10 seconds). In addition to the particulate, hydrogen also would be released during the blowdown. The consequences of hydrogen releases are discussed in Section B3 4 2 3. The features and controls that prevent or mitigate the particulate release also prevent or mitigate the hydrogen consequence.

After the MCO is breached, the fuel-water reactions continue without the high pressure. Even with no air ingress into the MCO, the remaining water in the MCO keeps reacting with the exposed fuel, causing a continuous stream of gases and entrained particulate to flow out of the MCO. Both the scrap fuel and exposed fuel elements will react with the water vapor that is flowing upwards through the MCO and exiting out the orifice. The water vapor continues to react with uranium and uranium hydride until the water is completely consumed, which is more than 24 hours after the blowdown.

**B3 4 2 6 2 Source Term Analysis** The respirable source term is based on the MAR, the ARF and the RF. These terms are summarized in the following sections.
Material at Risk  In summary, the total particulate MAR consists of two distinct groups of particulate (UO₂) based on the two different types of releases (blowdown and continuous)

- MAR₁ = 60 kg UO₂ for the blowdown release, which is all of the particulate generated between the time the fuel is cleaned at the K Basins and the time of the blowdown. This equates to 52.9 kg of uranium.

- MAR₂ = 64 kg UO₂ for the 12-hour continuous release, which is all of the particulate newly generated after blowdown plus the new particulate created before blowdown and not released during blowdown (this latter amount is approximately equal to MAR₁, as only a small percentage is released during initial blowdown). This equates to less than 57 kg of uranium.

- MAR₃ = 69 kg UO₂ for the 24-hour continuous release, which is all of the particulate newly generated after blowdown plus the new particulate created before blowdown and not released during blowdown (this latter amount is approximately equal to MAR₁). This equates to about 61 kg of uranium.

Airborne Release Fraction and Respirable Fraction  The ARFs are different for each type of release. For the "venting of pressurized powders" with pressures less than 25 lb/in² gauge, the bounding respirable release fraction is 2 x 10⁻³, as reported by DOE-HDBK-3010-94 (Section 4.4.2.3.2, page 4-73). The respirable release fraction is multiplied by the MAR for the blowdown MAR₁ in order to obtain a particulate source term for the quantity of material released to the environment by the blowdown. The lower pressure values are used rather than the values listed for pressures greater than 25 lb/in² gauge, in order to avoid being overly conservative as discussed below.

The very large release fractions associated with high-pressure venting (pressures greater than 25 lb/in² gauge) are overly conservative for the MCO blowdown release and are not used. They are overly conservative because the high-velocity (initially sonic) gases in the MCO blowdown occur in the rupture disk orifice and shield plug and not underneath the particulate in the MCO as is the case in the high-pressure vented gas experiments described in DOE-HDBK-3010-94. Furthermore, the gas velocities inside the MCO baskets are low. At the time of blowdown, the gas velocities (averaged velocities inside the baskets, not at the basket base plate) range from 0.01 m/s near the MCO bottom, to 0.3 m/s at the lower part of bottom fuel basket (or upper part of bottom scrap basket), to 1 m/s at lower part of top scrap basket. The mass flow rates were derived using the HANSF code (SNF-3650). Flow velocities were calculated using the upstream flow rates calculated by the code. The velocities are higher in the holes of the basket base plates, ranging from 1.5 m/s to 15 m/s, but the particulate is not located in these holes. The particulate is located above these holes where the gas velocities are lower because of the larger flow area in the basket. All of these MCO blowdown velocities in the baskets are very low compared with the actual velocity (1.024 m/s) of the mixed gas in the orifice during the blowdown and compared with the velocities encountered under the powder in the high-pressure gas experiments in DOE-HDBK-3010-94 (Section 4.4.2.3.2, page 4-73).
DOE-HDBK-3010-94 presents two choices for release fractions under these conditions, one for low pressure (<25 lb/in² gauge) and one for relatively high pressures (>25 lb/in² gauge). The release fraction for low pressure conditions was selected even though failure occurs at higher pressures. This is because the experiments that investigated the release fractions were performed under high air flow conditions, whereas the MCO particulate will be exposed to low gas velocities during a blowdown. Thus, the smaller respirable release fraction, $2 \times 10^{-3}$, was assumed in this analysis.

In addition, the leak flow path is very tortuous in the MCO, especially in the scrap basket, and some particulate is located out of the gas flow path. Both of these characteristics reduce the ARF for the blowdown release out of the MCO but are not included in the source term analysis because of their calculational difficulty, and they were not included in the release experiments (DOE-HDBK-3010-94, Section 4.4.2.3.2).

The source term, $M_1$, from the blowdown release is calculated by multiplying $MAR_1$ by the product of ARF and RF and converting the particulate to uranium metal as follows:

$$M_1 = (MAR_1) (respirable \ release \ fraction)$$

$$= (52.9 \ kg \ U) (1,000 \ g/kg) (2 \times 10^{-3})$$

$$< 106 \ g \ U$$

The source term, $M_2$, for the 12-hour continuous release is calculated by multiplying $MAR_2$, the particulate MAR for the 12-hour continuous release, by the respirable release fraction ($4.8 \times 10^{-5}$) for gaseous release under debris for 12 hours (DOE-HDBK-3010-94, Section 4.4.1.2) as follows:

$$M_2 = (MAR_2) (respirable \ release \ fraction)$$

$$= (57 \ kg \ U) (1,000 \ g/kg) (4.8 \times 10^{-5})$$

$$< 3 \ g \ U$$

The source term, $M_3$, for the 24-hour continuous release (offsite) is calculated by multiplying $MAR_3$, the particulate MAR for the 24-hour continuous release, by the respirable release fraction for 24 hours ($9.6 \times 10^{-5}$) as follows:

$$M_3 = (MAR_3) (respirable \ release \ fraction)$$

$$= (61 \ kg \ UO_2) (1,000 \ g/kg) (9.6 \times 10^{-5})$$

$$< 6 \ g \ U$$
In summary, the total bounding source term (unmitigated) for environmental doses consists of three distinct groups based on the duration of the release:

- \( M_1 = 106 \text{ g U} \) for the blowdown release
- \( M_2 = 3 \text{ g U} \) for the 12-hour continuous release
- \( M_3 = 6 \text{ g U} \) for the 24-hour continuous release

### B3 4 2 6 3 Consequence Analysis

The radiological dose is calculated using the following equation:

\[
D_E = M \times \frac{\chi}{Q'} \times BR \times UD
\]

where

- \( D_E \) = effective dose equivalent based on inhalation exposure only (rem)
- \( M \) = respirable quantity released into the air (grams)
  - \( M_1 \) for blowdown release (106 g U)
  - \( M_2 \) for 12-hour (onsite) continuous release (3 g U)
  - \( M_3 \) for 24-hour (offsite) continuous release (6 g U)
- \( \chi/Q' \) = air transport factor (s/m³)
- \( BR \) = average inhalation rate during the blowdown and 12-hour release (m³/s)
- \( UD \) = committed effective dose equivalent per unit gram inhaled

#### Unmitigated Consequences

The dose calculation equation is used to calculate the dose to the offsite receptor:

\[
D_{\text{offsite1}} = M_1 \times \frac{\chi}{Q'} \times BR \times UD
\]

\[
= (106 \text{ g U}) (4.48 \times 10^5 \text{ s/m}^3) (3.33 \times 10^{-4} \text{ m}^3/\text{s}) (4.38 \times 10^5 \text{ rem/g U})
\]

\[
= 0.69 \text{ rem (0.0069 Sv) for blowdown release}
\]

\[
D_{\text{offsite3}} = M_3 \times \frac{\chi}{Q'} \times BR \times UD
\]

\[
= (6 \text{ g U}) (6.50 \times 10^6 \text{ s/m}^3) (2.64 \times 10^{-4} \text{ m}^3/\text{s}) (4.38 \times 10^3 \text{ rem/g U})
\]

\[
= 0.0045 \text{ rem (4.5 \times 10^{-3} Sv) for 24-hour continuous release}
\]

Adding the doses for the blowdown and continuous releases yields a total offsite dose of about 0.7 rem (0.007 Sv) with almost all of the dose coming from the blowdown release.

The dose consequences at the remaining receptor sites are calculated in the same manner and are shown in Table B3-19 for the blowdown and continuous release. The frequency of the unmitigated event is greater than \( 10^{-2} \) per year (see SNF-2770, Appendix A)

**Notes:**
- The dose limits are for the High-Pressure Overpressurization Release scenario.
- The values are in rem (rems).
- The table is for the Columbia River and Hanford Site boundary.

**Additional Information:**
- Accident frequencies are provided for each receptor location.
- The table is from the HNF-3533 document, REV 0, Annex B — Cold Vacuum Drying Facility.

**References:**
- The methodology for calculating radiological and safety class decisions for unmitigated and mitigated doses is detailed in the referenced documents.

**Table B3.19:** Dose Consequence Summary for High-Pressure Overpressurization Release.
Mitigated Consequences  With safety-class features credited for this event (not including the 150 lb/in² gauge rupture disk), the estimated frequency for MCO overpressurization (without relief) is reduced to $4 \times 10^{-7}$ per year (beyond extremely unlikely category). The key safety-class features that reduce the likelihood of the overpressurization event are (1) the SCHe system, which provides pressure vent and helps cool the fuel, reducing the uranium–water reaction rate, (2) the 30 lb/in² vent path, which vents the MCO pressure, and (3) the 150 lb/in² MCO rupture disk, which relieves the MCO pressure. Additional safety-significant mitigation is provided by the HVAC systems and associated HEPA filters that reduce the onsite dose consequences from pressure venting. The safety-significant features reduce the mitigated onsite doses to well within applicable guidelines. All of the safety-class features are described in Section B3.4.2.6.5 along with the safety-significant features that provide additional mitigation for doses to the onsite receptor.

The safe and stable state following process upsets is an isolated MCO with pressure relief, a helium cover gas inside, and annulus water temperature at or below 50 °C (not necessarily flowing). If the annulus water is not flowing, the process bay temperature must be kept below 115 °F to keep fuel temperatures stable (SNF-2770).

If the SCHe system were assumed to not be available or not functional, the 30 lb/in² gauge vent path would vent the isolated MCO. The doses from the 30 lb/in² gauge vent path release meet offsite release limits guidelines when the local exhaust system with filters is functional. If both the SCHe system and 30 lb/in² gauge vent path were not available or not functional, the 150 lb/in² gauge rupture disk would relieve the isolated MCO. If, as expected, the local exhaust system filters remain at least 99% efficient under a hydrogen deflagration as expected (SNF-2770), the resulting doses from the 150 lb/in² gauge rupture disk release meet onsite risk evaluation guidelines and offsite release limits.

The scenarios for the releases at the following three pressures are summarized as follows:

1. The SCHe system is functional with 50 °C (or stationary) annulus water, functional local exhaust system with filters, and the MCO is isolated except for the 10 lb/in² gauge SCHe system. This is the normal configuration upon detection of a process upset. The frequency is in the anticipated category ($> 10^{-2}$ per year).

2. The SCHe system fails in a mode that isolates the MCO. The 30 lb/in² gauge vent path is functional with stationary annulus water, a bay temperature of 90 °F, functional local exhaust system with filters, and the MCO is isolated except for the 30 lb/in² gauge vent path. The frequency of this release sequence is estimated at $1.31 \times 10^{-4}$ per year, which is in the unlikely category.

3. Both the SCHe system and the 30 lb/in² gauge vent fail. Relief is provided through the 150 lb/in² gauge rupture disk. There is stationary annulus water, the bay temperature is 90 °F, the local and general exhaust systems with filters are functional, and the MCO is isolated except for 150 lb/in² gauge rupture disk.
The estimated frequency of this release sequence is $3.95 \times 10^{-7}$ per year (SNF-2770), which is beyond extremely unlikely.

The source terms for these scenarios are given in Table B3-20. The radiological doses are calculated in SNF-2770, and the total doses for several receptor locations with guidelines are shown in Table B3-21.

The SCHe system and normal operations are expected to prevent the MCO gas pressure from reaching 30 lb/in² gauge, thus, the 30 lb/in² vent path will not likely be used and is provided as backup to the SCHe system. The following section describes a scenario with two safety devices, the 30 lb/in² vent path, which includes the 30 lb/in² rupture disk and 30 lb/in² check valve, and stationary water in the cask-MCO annulus. Even if the water in the cask-MCO annulus is stationary, the thermal conductivity and heat capacity of the water are enough to keep the MCO at stable temperatures for process bay temperatures below 46 °C (115 °F) (SNF-2770). This is because (1) the stationary water conducts heat from the MCO to the cask better than air does (as in the loss of annulus water cases), and (2) the stationary water becomes cooler than the normal 50 °C annulus water at early times because of the cooling effects of the process bay temperature if the process bay temperature is less than 46 °C (115 °F).

The 30 lb/in² vent path with annulus water mitigated scenario assumes the process bay temperature is at 90 °F (32.2 °C). This scenario is the same as the unmitigated scenario except that the 30 lb/in² vent path is functional. The 30 lb/in² check valve is modeled to open at 35 lb/in² gauge pressure and close again at 20 lb/in² gauge pressure. The orifice size of the check valve was taken to be 0.2 in in the model, which is smaller than the actual real size of 0.25 in.

\textsuperscript{a} Evaluation guideline for onsite (100 m) receptor only
\textsuperscript{b} Unlikely event frequency is \( >10^4 \) to \( \leq 10^{-2} \)
\textsuperscript{c} Includes a decontamination factor of 1 E-03 for the SCHe system and 30 lb/in\textsuperscript{2} gauge consequences and 1 E-02 for the 150 lb/in\textsuperscript{2} gauge consequences to account for safety significant HEPA filters. Without credit for the HEPA filtration, the offsite consequences are below offsite release limits but the onsite doses for the 30 lb/in\textsuperscript{2} gauge release are above onsite risk evaluation guidelines.
\textsuperscript{d} Fifty year committed effective dose equivalent
\textsuperscript{e} The likelihood of a 150 lb/in\textsuperscript{2} gauge release is beyond extremely unlikely so comparison with guidelines and limits is not applicable. Consequences are provided for information only.

HEPA = high-efficiency particulate air (filter)
SCHe = safety-class helium

The blowdown from 150 lb/in\textsuperscript{2} gauge expels about 360 g of hydrogen gas in the first 10 seconds. The 12-hour continuous release will expel only an additional 27 g of hydrogen gas after the 10-second blowdown release, for a total of 387 g of hydrogen gas. At a pressure of 1 atm and a temperature of 267 °C, 360 g of hydrogen gas will occupy about 4 m\textsuperscript{3}. Diluting this volume to 20% hydrogen (a concentration that is high enough to produce destructive shock waves when it burns) requires a volume of air that is four times greater. Thus, the 360-g release needs to mix with about 16 m\textsuperscript{3} of air. For comparison, the CVDF process bays each have a volume of about 1,600 m\textsuperscript{3}, with enough fresh air added (>1 m\textsuperscript{3}/s from the local and general exhaust systems) to give more than two complete air changes per hour. Hence, flammable mixtures are possible, depending on the circumstances.

Actual events following the discharge of a large volume of hydrogen are difficult to predict. For the mitigated case, the local exhaust system is functioning and the likely events following the blowdown release are summarized below.

Most of the expelled hydrogen is drawn into the process bay local exhaust system. For the first 10 seconds, the hydrogen flow rate is about 0.4 m\textsuperscript{3}/s. This is about 80% of the nominal process bay local exhaust system flow rate (0.5 m\textsuperscript{3}/s [1,000 ft\textsuperscript{3}/min]). The hydrogen...
concentration will be very high in the duct. However, for the first 2 seconds of release, the hydrogen flow rate is much higher, so the nominal local exhaust rate will not capture all of the hydrogen. Some quantity of hydrogen will remain in the process bay after the blowdown starts. The sudden discharge of hydrogen into the local exhaust system will fill the process bay local exhaust system duct. When the hydrogen flow joins the air flow from the other bays, the hydrogen will be diluted to form an explosive mixture. An explosion of the hydrogen-air mixture near the HEPA filters would dislodge radioactive material and cause a fraction of it to be discharged to the environment. This accident is similar to the one of the external hydrogen explosions analyzed in the external hydrogen DBA (Section B3 4 2 3). Even if one bank of HEPA filters is completely destroyed, the second bank of HEPA filters is expected to be at least 99% efficient (SNF-2770).

With very good mixing, the hydrogen that did not get drawn in by the local exhaust system during the first 2 seconds becomes a flammable volume of 10 m³. If 50% of the hydrogen burns, the average pressure increase in the process bay is less than 0.35 lb/in² or 50 lb/ft². No significant structural damage is expected with this pressure. Using the method of estimating injury probabilities described in SNF-2770, death by lung hemorrhage has greater than a 1% chance, at a distance of 1.8 m (6 ft) from the center of the free-air explosion. A worker would need to be standing within this distance from the MCO head for this explosion to be fatal.

The continuous release of hydrogen for 12 hours after the blowdown release is slow enough (0.007 L/s on the average) that the hydrogen concentrations are easily diluted below the lower flammability limit by the process bay local exhaust system.

B3 4 2 6 4 Comparison to Guidelines

Comparison of Unmitigated Doses. Event tree sequences indicate that the unmitigated frequency for the MCO overpressurization accident is in the anticipated category (i.e., an unmitigated frequency greater than 10⁻⁴ per year) (see SNF-2770, Appendix A). The unmitigated sequence considered the processing of 200 MCOs per year, common cause loss of tempered water (annulus) system flow and an isolated MCO (loss of power). The unmitigated radiological offsite dose for this event is above offsite release limits and onsite risk evaluation guidelines.

Comparison of Mitigated Doses. The mitigated frequency of the event tree sequence that represents this DBA as an MCO overpressurization and as an unfiltered release is 4 × 10⁻⁵ per year, thus this mitigated DBA is extremely unlikely (see SNF-2770, Appendix A). The mitigated sequence credited SCHe injection, venting through the SCHe system vent path, relieving through the 30 lb/in² vent path, venting through the 150 lb/in² vent path, local exhaust operation and standby power, and HEPA filter functionality. With safety-significant features credited, the mitigated MCO overpressurization and unfiltered release meets both offsite release limits and onsite risk evaluation guidelines.
B3 4 2 6 5 Summary of Safety-Class Structures, Systems, and Components and Technical Safety Requirement Controls

Under normal operating conditions, annulus water levels and helium flow provide adequate heat transfer to prevent MCO overpressurization. Under upset or accident conditions, safety-class equipment is required in order to ensure this capability is not lost. The heat transfer characteristics of the annulus water could be compromised by a loss of water level or high tempered water temperatures. The heat transfer characteristics of the normal helium supply could be compromised by a loss of helium flow, high MCO pressures (e.g., isolated MCO), or low process system pressures (e.g., leaks).

The checklist designators included in the accident bins, other than the accident selected as the DBA, represent additional accident sequences slightly different than the DBA. All of these binned accidents are bounded by the DBA because they have lesser or equivalent worst-case consequences and frequencies.

The accident scenarios identified in the hazard analysis for the P1 bin represent overpressurization accidents caused by elevated fuel corrosion rates (high-temperature tempered water, excessive water remaining in an MCO because of proof-of-dryness demonstration failure [instrumentation failure or operator error]), inadvertent water addition to the MCO following final pressure rebound test, and loss of power because of flooding (HNF-SD-SNF-HIE-004). The controls in the P1 bin prevent an MCO overpressurization by monitoring the MCO pressure and by providing multiple vent paths from the MCO. Credit also is taken for controls that prevent bypass of safety systems by incorrectly proceeding with the cold vacuum drying process or by operator error. To protect the analysis assumption pertaining to the maximum rate of hydrogen generation, credit is taken for SSCs to control fuel temperatures. Credit also is taken for controls that prevent malfunction of safety-related SSCs (high bay temperature). In addition, SCHе actuation is credited, therefore confinement and dilution provided by the local exhaust system also are credited. The filtration function is also credited with mitigating a blowdown of the 30 lb/in² gauge vent path. Note that the 150 lb/in² gauge MCO rupture disk is identified in the analysis and shown in Table B3-22, but that the accident would be adequately controlled (prevented to beyond extremely unlikely) without crediting this rupture disk.

The safety-class equipment designated to prevent or mitigate the dose consequences of overpressurization accidents are described below.

Safety-class equipment for detection of process upset

- VPS instrumentation (high pressure trip)

Pressure indicators on the VPS provide MCO internal pressure information to the SCIC system, which initiates MCO isolation and SCHе actuation during process upset conditions.

Checklist designators are from HNF SD SNF HIE-004 1999 *Cold Vacuum Drying Facility Hazard Analysis* Rev 4 Fluor Daniel Hanford, Incorporated, Richland Washington

<sup>a</sup>U.S. Nuclear Regulatory Commission important to safety classifications Category A = critical to safe operation, Category B = major impact on safety Category C = minor impact to safety

<sup>b</sup>Lines and valves to isolate the MCO include the isolation valves (and filters on air supply to valve actuators) and the air filters on the isolations valves in the VPS general service helium system, PWC system and SCHe system

- HEPA = high efficiency particulate air (filter)
- HVAC = heating, ventilation, and air conditioning
- HVACC/PV = process bay local exhaust HVAC and process vent system
- HVACB = process bay recirculation HVAC system
- HVACD = process general supply/exhaust HVAC system
- ITS = important to safety
- MCO = multi canister overpack
- NRC = U.S. Nuclear Regulatory Commission
- SCHe = safety-class helium
- SCIC = safety class instrumentation and control
- TSR = technical safety requirement
- VPS = vacuum purge system
Annex B — Cold Vacuum Drying Facility

- SCIC system (monitoring process parameters)

  The SCIC system uses programmable logic controllers, wiring to process instrumentation, signals from seismic detectors and temperature monitors, system controls, and output relays to isolate the MCO and actuate the SCHe system or cut power to the tempered water heater, if abnormal process or environmental conditions are detected.

- Tempered water (annulus) system temperature trip

  The tempered water (annulus) system includes antisiphon valves, low-water-level indication and alarm, and manual refill capability to ensure a minimum water level is maintained above the elevation of the fuel within the MCO. The system detects high water temperature and signals the SCIC system to actuate the tempered water trip.

- Tempered water (annulus) system low level alarm

  Redundant liquid level indicators are used by the tempered water (annulus) system to detect a low water level in the cask-MCO annulus and to provide a signal to the SCIC system to actuate the low-level alarm.

- Tempered water (annulus) system level check petcocks

  The level check petcocks provide a manual means of verifying the presence of water in the annulus. The petcocks are located in and above the double-walled portion of the tempered water (annulus) piping and are connected to the outer and inner pipes above the height of the fuel in the MCO. If a low-level alarm is received, the petcocks can be used to verify the presence of water in the inner or outer pipe, thus indicating the presence of water in the annulus.

- High bay temperature trip

  The SCIC high bay temperature trip isolates the MCO and actuates the SCHe system so excessive temperatures in the bay cannot cause instrument inaccuracies or malfunctions that might result in MCO overpressurization.

Safety-class equipment for heat removal

- Tempered water (annulus) system piping and antisiphon valves

  A portion of the tempered water (annulus) system contains safety-class piping and antisiphon valves to ensure retention of a minimum water level above the elevation of the SNF inside the MCO.
Safety-class equipment for pressure management

- **SCHe system (vent path)**
  
  SCHe system piping and valves provide a pressure vent path to the local exhaust system precluding high pressures in the MCO

- **VPS 30 lb/in² gauge rupture disk and vent path lines and valves**
  
  The VPS 30 lb/in² gauge rupture disk and valves in the vent path to the local exhaust duct preclude high pressures

- **MCO 150 lb/in² gauge rupture disk**
  
  The MCO 150 lb/in² gauge rupture disk on the MCO provides backup capability for the 30 lb/in² gauge rupture disk on the VPS vent path line. The two rupture disks are connected or installed in different MCO process ports. Releases through the 150 lb/in² gauge rupture disk would be discharged to the process bay and swept through HEPA filters before being released to the environment.

Safety-class equipment for confinement and purge

- **Cask–MCO**
  
  The cask–MCO is a major part of the pressure boundary for confinement of radioactive materials during processing and provides connections for the process piping to the SCHe system

- **SCHe system**
  
  The SCHe system provides two redundant and independent paths for purging and pressurizing the MCO and venting to the process vent

- **Lines and valves to isolate and purge the MCO**
  
  Lines and valves for isolating the MCO include the isolation valves (and air filters on air supply to valve actuators) in the VPS, general-service helium system, PWC system, and SCHe system. Upon demand, all the valves close to isolate the MCO, except the SCHe system valves, which open to allow helium to the MCO

Safety-significant equipment for confinement and dilution

- **Process bay local exhaust HVAC and process vent system (exhaust fans and plenums, ductwork, HEPA filters, and flow switch)**
The process bay local exhaust HVAC and process vent system mitigates a release by sweeping it through HEPA filters before it is discharged outside the facility. Low flow alarms are set at 1,150 ft³/min.

- Process bay local exhaust HVAC and process vent system process hood isolation damper and instrument air supply

Isolation dampers in the process bay local exhaust HVAC and process vent system process hood fail closed. If power is lost, dampers will open with electrical power from the standby power system and instrument air supplied by the local dedicated tank. The hood isolation damper and instrument air supply operate in conjunction with the standby power system to facilitate HVAC operating while on standby power.

- Reference air system (reference air header, differential pressure alarms)

The reference air system monitors the negative pressure in the process bays and process water tank room by providing differential pressure indication and alarms to the control room for operator response.

- Standby electrical power (diesel generator and process bay local exhaust HVAC and process vent system restart circuit)

The standby power system provides connections to restart the local exhaust fans and supporting equipment. Operation of the local exhaust on standby power will maintain building differential pressure sufficient for confinement during facility power outages.

- Process general supply/exhaust HVAC system (exhaust HEPA filter, exhaust ductwork isolation damper)

The process general supply/exhaust HVAC system mitigates a release into the process bay or process water tank room by sweeping it through HEPA filters before discharging it outside the facility. The process general supply/exhaust HVAC system also provides confinement in conjunction with the facility structure by maintaining a negative building pressure. The system's isolation dampers fail closed to maintain negative differential pressure in the processing bays and process water tank room.

- Process bay recirculation HVAC system isolation dampers (outside air inlets)

The process bay recirculation HVAC system provides fail-closed outside air inlet dampers so the local exhaust on standby power can maintain process bay differential pressure.
Assumptions made that require protection by TSRs are listed below

- **Procedure to verify the results of the pressure rebound tests before continuing process steps**

  An initial pressure rebound test surveillance (pressure rise test) must be met before entry into the proof-of-dryness demonstration is allowed. Similarly, a proof-of-dryness demonstration surveillance must be met before the final pressure rebound test steps can begin. Finally, a final pressure rebound test must be met before shipment preparation steps can begin.

- **Close long axial process tube port before closing filtered process exit port at the end of processing**

  When isolating the MCO at the end of processing, the long axial process tube port must be closed at least 5 minutes before closing the filtered process exit port. This ensures that an SCIC trip will occur if the procedure to isolate the MCO is inadvertently conducted on an MCO still to be processed.

**Defense in depth features**

- **General-service helium system safety-class flow instrumentation**

  The general-service helium system provides SCHe flow information to the SCIC system to initiate MCO isolation and SCHe actuation during process upset conditions.

- **10 lb/in² gauge safety relief valve for process relief**

  A general-service safety relief valve set at 10 lb/in² gauge and located on the process equipment skid provides pressure relief to the local exhaust duct.

  The bounding MCO overpressurization accident (P 1) and the other accidents identified in the CVDF hazard analysis report (HNF-SD-SNF-HIE-004) that can potentially involve MCO overpressurization are itemized in Table B3-22, along with corresponding checklist designators, safety functions, and SSCs.

  The accidents within the remaining bins require the following safety SSCs and TSRs in addition to the ones identified for the DBA (P 1).

**P 2 Overpressurization due to loss of support utilities**

The accident scenarios identified in the hazard analysis for the P 2 bin represent overpressurization accidents caused by loss of a support system because of accidents in adjacent
bays and accidents in the spare bay. This bin also includes loss-of-power events caused by external forces (e.g., vehicle accident) and lightning strike (HNF-SD-SNF-HIE-004). The controls in the P2 bin prevent an MCO overpressurization by providing multiple vent paths from the MCO. Monitoring of process parameters is not needed for the events in this bin because the SSCs that provide venting of the MCO fail safe on loss of support utilities. Confinement and dilution are credited because of SCHe actuation.

No additional requirements result from analysis of this accident.

P 3 Overpressurization due to excessive helium supply pressure

The accident scenario identified in the hazard analysis for the P 3 bin represents an overpressurization accident caused by failure of the pressure regulators on the helium supply (general service helium or SCHe) (HNF-SD-SNF-HIE-004). The controls in the P3 bin prevent an MCO overpressurization by controlling the helium supply pressure from the general service helium system and the SCHe system.

Safety-class equipment for pressure control

- General-service helium supply system safety-class relief valves

  Redundant pressure relief valves are provided on the general-service helium supply line to protect the MCO from overpressurization. General-service helium is supplied from the tube transporters at between 2,600 and 3,200 lb/in² gauge. The two pressure relief valves, which are arranged in series and set at 25 lb/in² gauge, prevent the MCO and related piping from experiencing the full supply pressure in the event of regulator failure.

- SCHe supply pressure control valves and rupture disks

  The SCHe system provides two redundant and independent paths for purging and pressurizing the MCO. Pressure control valves and rupture disks in each train protect the MCO from overpressurization by the helium bottles.

P 4 Overpressurization due to a line break caused by a seismic event

The accident scenarios identified in the hazard analysis for the P 4 bin represent overpressurization accidents caused by process upsets following a seismic event (HNF-SD-SNF-HIE-004). The controls in the P4 bin prevent an MCO overpressurization by removing reliance on nonqualified SSCs and by placing the MCO into a safe and stable configuration.
Safety-class equipment to prevent process upsets

- Deionized water and PWC drain line isolation valves interlocked closed after being used in the process

The VPS isolation valves (on the deionized water supply line) and the PWC drain line isolation valves prevent water from entering the MCO. After these lines are used in the process, they are closed and interlocked to the SCIC system so they cannot be inadvertently opened later in the process.

Safety-class equipment for detection of seismic events

- SCIC seismic trip

On detecting a seismic event, the SCIC system seismic trip isolates the MCO and actuates the SCHe system and de-energizes the tempered water (annulus) system to ensure the seismic event will not initiate thermal runaway.

Assumptions made that require protection by TSRs are listed below

- Trailer placement controlled such that movement from seismic events will not impact key shutdown systems

Before connecting CVDF systems to the MCO, the cask, which is located upon the trailer, must be positioned such that the central axis of the cask is no greater than an established safe distance from the ideal horizontal placement, as identified in Chapter B4. This control protects the MCO during seismic events.

P 5 Overpressurization due to facility fire

The accident scenarios identified in the hazard analysis for the P 5 bin represent overpressurization accidents caused by facility fire (HNF-SD-SNF-HIE-004). The controls in the P5 bin prevent an MCO overpressurization by protecting safety-related SSCs from damage in a process bay fire. Credit also is taken for controls on the bay temperature to protect an assumption made in the fire hazards analysis.

Safety-class equipment for detection

- SCIC process bay high temperature trip

The SCIC process bay high temperature trip acts to protect an initial condition assumption in the fire hazards analysis.
Assumptions made that require protection by TSRs are listed below

- **Combustible loadings limited**

  While an MCO is present in the facility, combustible loadings are limited as determined by the fire hazard analysis implementation plan (SNF-4942). These limits ensure that any fire in the CVDF does not result in uncontrolled releases (e.g., fire-caused loss of process control).

- **Restore bay temperature following a process bay high temperature trip**

  On high bay temperature trip alarm, operations must return the process bay temperature to within acceptable limits.

**B3 4 2 7 Common Cause Initiators** As part of the hazard analysis process, several common cause initiators were identified that have the potential to impact the CVDF (HNF-SD-SNF-HIE-004). These initiators have been addressed as discrete accidents within the respective accident bins but are discussed collectively below to address the issue of common cause failure risks at the CVDF.

**B3 4 2 7 1 Seismic Forces** Earthquake forces could affect systems across the entire facility. Without controls and safety SSCs, a seismic event could cause process upsets ranging from a liquid release in the PWC tank room to thermal runaway reactions within MCOs in the processing bays. It is unlikely that at any one point in time all MCOs in the facility will be susceptible to a thermal runaway reaction DBA or the overpressurization DBA, but to be conservative, the consequences of four MCOs experiencing such an event can be postulated in the unmitigated (i.e., no controls) case. In addition, other effects may be possible (e.g., gaseous release, external hydrogen explosion, PWC spray leak).

The bounding integrated facility doses for the unmitigated seismic event are approximately equal to the total doses from four design basis overpressurization accidents (the overpressurization DBA has the greatest unmitigated consequences). In the unmitigated case, the dose consequences of an external explosion and spray release from the PWC room are negligible compared to the overpressurization events. From the dose consequence summary table, Table B3-6, the unmitigated onsite consequences of four overpressurization events would be approximately 4,400 rem, and the offsite consequences would be approximately 28 rem. These doses clearly exceed both onsite and offsite criteria. The overpressurization accident analysis identified safety-class, performance category 3 equipment as a preventative feature. This equipment is presented in the seismic bins for the overpressurization DBA. In addition, safety-class, performance category 3 (performance category is used in the design of SSCs for resistance to natural phenomena) equipment is identified for the thermal runaway DBA, and safety-class, performance category 3 and safety-significant, performance category 2 equipment is identified for the internal hydrogen explosion (this event has safety-significant consequences but some equipment is safety-class, performance category 3 because it is credited in another DBA).
For the external hydrogen explosion DBA, a TSR limitation on HEPA filter loading is credited in the seismic event bin. From Table B3-6, with the credited controls applied, the mitigated dose consequences of a seismic event are reduced to approximately 10 rem onsite and $6 \times 10^4$ rem offsite. These doses correspond to the sum of the mitigated doses associated with four gaseous releases, an external hydrogen explosion, and a spray leak in the PWC room. All of the other DBAs are prevented to beyond extremely unlikely and have no associated dose consequences for the mitigated case. The mitigated dose consequences for the seismic event fall within offsite release limits and onsite risk evaluation guidelines. Therefore, the credited controls specified in the DBA analyses (seismic bins) are sufficient to prevent a release following a seismic event.

**B3 4 2 7 2 Loss of Facility Power** Natural phenomena events, such as rain, lightning, and freezing weather, can result in the temporary loss of facility power. In addition, certain external events such as vehicle impacts with components outside the facility could also result in a loss of facility power. Without controls, a loss of power can result in a loss of process control from the control room and subsequent upset conditions. Such upsets could potentially lead to several DBAs, including the thermal runaway reaction. However, loss of power does not result in any type of liquid spray or spill within the facility. For example, a loss of power could result in isolation of an MCO and subsequent overpressurization or failure to repressurize an MCO that is under vacuum.

The integrated facility doses for this event are bounded by those presented in the seismic forces discussion in Section B3 4 2 7 1. The instrumentation credited with detecting process upsets is designed to fail safe upon a loss of power, activating the necessary systems to bring the MCO to a safe and stable state (SChE, isolation valves and lines, SCIC power cutoff to the tempered water [annulus] heater). In addition, the facility has a standby power system designed to provide electrical power to key facility SSCs. As demonstrated, the bounding mitigated consequences are below all dose consequence criteria, so the controls specified in the DBA analyses for each bay are adequate to protect against a loss of facility power.

**B3 4 2 7 3 High Process Bay Temperatures** High process bay temperatures could affect certain systems within the process bays. The safety-related instrumentation associated with the tempered water (annulus) system is designed to survive high temperatures, but some of the instrumentation related to MCO process upset detection and activation of the SChE system could under abnormal or accident conditions, potentially experience temperatures above rated design limits. Without controls, this could result in instrumentation inaccuracies and lead to internal or external MCO explosions or place the MCO into unanalyzed conditions. For example, a high bay temperature could lead to elevated annulus water temperature and subsequent loss of heat sink for the MCO. High temperatures do not pose a hazard for the PWC tank room.

The integrated facility doses for the unmitigated event are bounded by those presented in Section B3 4 2 7 1. Safety-class equipment (process bay temperature detection instrumentation SChE system, and the lines and valves necessary to isolate the MCO) is identified in the DBA analysis to prevent process upsets caused by high bay temperatures. If high bay temperatures are...
reached, this equipment will place the MCOs in a safe and stable condition. A safety-class high-bay-temperature trip alerts facility personnel to the bay condition so bay temperatures can be restored. No release occurs in this mitigated case. Therefore, the controls identified in the DBA analyses for each bay are sufficient to prevent a release caused by high bay temperatures.

**B3 4 2 7 4 Loss of Facility Support Systems** A loss of facility support systems such as the normal helium supply, instrument air, and HVAC flow could impact multiple bays and systems within the CVDF. Support system loss can result in process upsets that can lead to unfavorable conditions in the MCO (e.g., a low helium flow, contaminated helium supply, and inaccurate instrumentation readings). A loss of ventilation flow does not result in any dose consequences, however, it does reduce the margin of safety should other events occur while the system is inoperable. A loss of facility support systems also is not expected to cause any type of spill or spray release in the PWC tank room. In the process bays, if multiple MCOs were being processed, the common cause effect would be multiple upset conditions.

The integrated facility doses for this event are bounded by those presented in Section B3 4 2 7 1. The equipment and controls for protection against process upsets will place the facility in a safe and stable state when process upsets occur. As demonstrated, the bounding mitigated consequences are below all dose consequence criteria, so that the controls specified in the DBA analyses for each bay are adequate to protect against a loss of support systems.

**B3 4 2 7 5 Multiple Bay Facility Fire** A facility fire has the potential to have impacts in multiple bays and to serve as an initiator for more than one of the DBAs in Section B3 4 2. Individual fire scenarios were developed and analyzed in the CVDF fire hazard analysis (SNF-4268) and associated implementation plan (SNF-4942), and these fires are considered as accident initiators in the applicable DBAs. Fires, as accident initiators, are controlled through the fire protection features designed into the facility and operating equipment, and through the combustible loading limitations (supported by the SCIC high temperature trip) as presented in the fire hazard analysis. In the DBA analysis, credit is taken only for the combustible loading limits presented in the fire hazard analysis and the SCIC high temperature trip. These controls preclude the potential consequences from a single fire involving multiple bays. The integrated facility doses for a worst-case multiple bay facility fire are bounded by those presented in the seismic forces discussion in Section B3 4 2 7 1.

**B3 4 2 7 6 Emergency Evacuation Due to External Events** Should the CVDF need to be evacuated because of external events at other facilities, a loss of operator control over the process could occur. Although the facility can be brought to a safe and stable condition prior to evacuation through emergency response procedures in such an event, the inherent risk is assessed without such procedures. Lack of operator control represents another initiator for a loss of process control. Without controls, this event could result in process upsets leading to DBAs in one or more of the process bays.

The integrated facility doses for the unmitigated event are bounded by those presented in Section B3 4 2 7 1. The safety-class equipment for protection against process upsets.
automatically place the facility in a safe and stable state when process upsets occur by placing each bay into a safe and stable state. There is no operating mode that requires operator action to place the process in a safe and stable state. Operator actions are credited in the DBA analysis, but such actions afford time delays that accommodate evacuation actions. However, no events were identified in which operator actions were credited in conditions that would also require evacuation. Therefore, a facility evacuation is adequately protected against with the existing controls identified within the DBAs.

**B3 4 3 Beyond Design Basis Accidents**

DOE-STD-3009-94 requires consideration of BDBAs for nuclear facilities but presents no clear guidelines as to how or to what criteria they should be evaluated and judged. The Standard indicates that the purpose of BDBA presentation is to gain insight into the magnitude of these events, particularly if they should be close in frequency to pertinent DBAs but beyond the credible range and if they should have consequences that exceed evaluation guidelines. While these events would be beyond the requirements for further safety-class or safety-significant functions, they might provide guidance for prioritizing long-term safety improvements for a facility. The Standard specifically excludes evaluation of human-generated external events as BDBAs.

The BDBA analysis for the CVDF included the following:

- **Extreme cold** — Breach of an MCO caused by excessively cold weather and resulting ice formation
- **Natural phenomena** — Collapse of the CVDF building superstructure as a result of natural phenomena forces of a severity larger than those comprising the design basis of the facility
- **Unmitigated DBAs** — Potential accident conditions exceeding the capabilities of the identified safety systems
- **Shipment to the CSB of excess free water in an MCO**

Each of these BDBA types is described below.

The evaluation of the BDBAs identified for the CVDF indicates that there is no sharp increase in dose consequences from the design basis to the beyond design basis, and thus no sharp increase in residual risk. No additional controls to mitigate the residual BDBA risk were identified.

**B3 4 3 1 Extreme Cold** During extremely cold weather conditions, the water inside the MCO or in the cask–MCO annulus could freeze. This event could rupture the MCO shell resulting in loss of the pressure boundary. This could prevent processing of the MCO because of the inability...
to maintain annulus water (i.e., draining the MCO also drains the annulus) and the inability to draw a vacuum on the MCO. If the cask also were to rupture, a continuous release of contamination could occur following a loss of annulus and MCO water (i.e., they both drain once the ice melts). In the worst case, this would be equivalent to the thermal runaway event (Section 3.4.2.5), so no significant increase in potential dose consequences would be realized from the beyond design basis event.

**B3 4 3 2 Natural Phenomena** A natural phenomenon BDBA involves a natural phenomenon force greater than the design basis of the facility. The two dominant natural phenomena forces for the CVDF, seismic and high wind forces, would result in similar structural impacts to the facility. However, a high wind would also result in very large dispersion factors for atmospheric transport and significantly lower dose consequences. Therefore, the natural phenomenon BDBA postulated for the CVDF is a beyond design basis seismic event.

In accordance with the codes and standards used for the CVDF, the facility SSCs are designed with significant safety margins. Thus, complete failure of all SSCs is not expected during or following a seismic event of a magnitude slightly larger than the design basis. However, there is a possibility that a severe beyond design basis seismic event with a very low return frequency could impact the facility and cause numerous SSC failures, including building structural failure. In such an event, any cask-MCO packages present in the facility would be impacted by failed facility structural components, and systems connected to the MCO would be damaged. In the worst-case scenario, the MCO could be overturned, and all process equipment, including the process hood and process connections, could be dislodged from the MCO.

Even under severe impacts from facility structural components, the cask-MCO package would not fail catastrophically because of its very strong physical design. However, some damage to the MCO could be realized and both process ports could be open or closed, depending on the process step at the time of the event. The bounding consequences from such an event would be for all four bays to have MCOs that had been drained but still had sufficient free water remaining in them to present thermal runaway and overpressurization hazards. This case is addressed in the common mode accident evaluation for seismic events in Section B3 4.2.7.1. This potential beyond design basis consequence does not constitute a large increase over the design basis consequences.

**B3 4 3 3 Unmitigated Design Basis Accidents** The unmitigated scenario analyzed for each DBA in Section B3 4.2 represents a beyond design basis event. Each unmitigated scenario represents failure of the credited controls through an internal mechanistic failure (e.g., isolation valve fails to open on demand) or through an external condition (e.g., a physical impact). By representing events and conditions that exceed the design basis (i.e., conditions in which SSCs do not function properly), the analyses of unmitigated events represent beyond design basis events. As demonstrated in the DBA analyses, the unmitigated events are adequately controlled.

**B3 4 3 4 Excess Free Water Following Cold Vacuum Drying Facility Processing** One event of particular interest is the shipping of an MCO containing more than the allowed amount of free water.
water to the CSB. The consequences of such an event would occur as a result of a deficiency in
CVDF operations but logically would not be an accident occurring at the CVDF because the
accident (i.e., overpressurization of an MCO) would occur at the CSB, not at the CVDF. This
scenario is postulated to occur as a result from the failure of validation and acceptance testing of
an MCO after it has been subjected to the cold vacuum drying process or from a late, inadvertent
addition of water after completing the testing but prior to the MCO leaving the CVDF. The
unmitigated consequences of this event would be similar to the unmitigated consequences
presented in Section B3 4 2 6 for the MCO overpressurization DBA. The frequency of shipping
an MCO from the CVDF to the CSB with greater than 200 g due to a process failure or
inadvertent water addition has been analyzed (SNF-2770). The conclusion of the analysis is that
the frequency of this event is beyond extremely unlike (or less than $1 \times 10^{-6}$ per year) is based on
the (1) CVDF operational procedures that include disconnecting deionized water lines, drying,
and recognizing excessive drying time, (2) redundant isolation valves on potential water sources,
and (3) redundant temperature measurement of the tempered water temperature. The cold
vacuum drying process and validation test are designed so that retention of free water (in excess
of the allowable quantity) following processing is not a credible occurrence.

SPENT NUCLEAR FUEL PROJECT
FINAL SAFETY ANALYSIS REPORT

HNF-3553
Revision 0

November 1999
This page intentionally left blank
EXECUTIVE SUMMARY

E 1 FACILITY BACKGROUND AND MISSION

The U.S. Department of Energy (DOE) established the Spent Nuclear Fuel (SNF) Project to address safety and environmental concerns associated with deteriorating SNF presently stored under water in the Hanford Site K Basins, which are located in the 100 K Area near the Columbia River. Recommendations for a series of projects to construct and operate systems and facilities to manage the safe removal and storage of K Basins fuel were made in WHC-EP-0830, *Hanford Spent Nuclear Fuel Recommended Path Forward* and its subsequent update WHC-SD-SNF-SP-005, *Hanford Spent Nuclear Fuel Project Integrated Process Strategy for K Basins Fuel*. The integrated process strategy recommendations include the following steps:

- Fuel preparation activities at the K Basins, including removing the fuel elements from their K Basins canisters, separating fuel particulate from fuel elements and fuel fragments greater than 0.25 in. in any dimension, removing excess sludge from the fuel fragments by means of flushing, as necessary, and packaging the fuel into multi-canister overpacks (MCOs).

- Transportation of MCOs loaded with SNF from K Basins to the Cold Vacuum Drying Facility (CVDF).

- Removal of free water by draining and vacuum drying at the CVDF in the 100 K Area.

- Dry shipment of fuel from the CVDF to the Canister Storage Building (CSB), a new facility in the 200 East Area.

- Interim storage of the MCOs in the CSB until a suitable long-term repository is established.
E 2 SPENT NUCLEAR FUEL PROJECT OVERVIEW

WHC-SD-SNF-SP-005 was developed to establish the technical framework for constructing facilities and implementing processes that are compatible with DOE goals. This process strategy subsequently evolved into the current SNF Project technical baseline. The current technical baseline is based on implementation of Baseline Change Request SNF-98-006, which describes the process and design approaches for removing, drying, and storing the K Basins SNF (Sieracki 1998).

SNF Project process steps include removing K Basins SNF assemblies from existing containers, cleaning the fuel, placing the fuel into specially designed baskets, and inserting the baskets into approximately 400 MCOs. The MCOs are filled with water and transported to the CVDF, where the water is drained and the MCOs are vacuum dried. MCOs are then sealed by mechanical means, leak tested, and shipped to the CSB where they are received, sampled, and permanently sealed by a welding process. The MCOs will be held in interim storage in vertical tubes at CSB until final disposition. A small number of the first MCOs shipped to the CSB will be monitored over a period of up to two years to validate that the process meets long-term storage requirements.

For more detailed discussions of the SNF Project facilities and processes, see Chapters 20 of the facility annexes to the SNF Project Final Safety Analysis Report (FSAR).

E 3 FACILITY HAZARD CLASSIFICATION

The final facility hazard classification of each SNF Project facility was performed in accordance with DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23 Nuclear Safety Analysis Reports*. The final hazard categorizations are based on unmitigated releases of available radiological materials from each
HNF-3553 REV 0

facility These inventories were compared against threshold quantities contained in DOE-STD-1027-92 Each SNF Project facility was classified as Hazard Category 2

E 4 SAFETY ANALYSIS OVERVIEW

Hazard identification and evaluation provides a thorough assessment of the spectrum of risks posed by a nuclear facility to the public, workers and the environment. A hazard analysis determines materials and systems and handling, processing, storage, and facility characteristics that can produce undesirable consequences as a result of equipment malfunctions, operator errors, manmade hazards, and/or natural phenomena hazards. Predominantly qualitative techniques are used to pinpoint weaknesses in the design or operation of the facility that could lead to accidents. A selection process is used to identify design basis accidents with the potential to cause unacceptable consequences to the offsite and onsite receptor groups and to the environment. The design basis accidents are further analyzed using quantitative methods and a set of controls is selected to ensure that the facility can be operated safely. The accident analysis for each design basis accident starts with a description of the accident scenario and the identification of major analysis assumptions. The accident source term is then determined through phenomenological and system response calculations. Once the source term has been determined, onsite and offsite consequences are determined and the consequences are compared to offsite release limits and onsite evaluation guidelines. Finally, a set of safety-class and safety-significant equipment and technical safety requirements (TSRs) is selected to ensure safe facility operation and worker protection.

E 5 U S DEPARTMENT OF ENERGY REGULATORY POLICY

The regulatory policy for the SNF Project (Sellers 1995) delineates the DOE policy for achieving nuclear safety equivalence for the design and construction of new facilities comparable to facilities licensed by the U.S. Nuclear Regulatory Commission (NRC).
E 5 1 U S Department of Energy Policy for Safety of New Facilities

DOE facility nuclear safety equivalence to comparable NRC-licensed facilities is accomplished by applying comparable technical requirements and by adopting appropriate features of the NRC licensing process in addition to applicable DOE orders and requirements. DOE requirements are not set aside or superseded by this process, rather, along with applicable NRC regulations, the DOE requirements and NRC regulations comprise the basis for SNF Project facility design and construction.

The intended outcome of the Nuclear Safety Policy (Sellers 1995) is to ensure that SNF Project facility designs meet the nuclear safety objectives of applicable NRC requirements. From a nuclear safety standpoint, rugged conservative designs, with clear capability to accommodate postulated accidents, provide the best confidence that the SNF Project facility designs are equivalent to NRC-licensed facility designs.

The regulatory policy for the SNF Project is to be applied to matters of nuclear safety (including radiological control issues) for new SNF Project facilities. The primary focus is on design and construction issues and preparation for operations. The policy does not apply to environmental Occupational Safety and Health Administration chemical accident safety or other nonnuclear safety issues. (These issues are covered elsewhere by DOE orders and statutory requirements.) Similarly, the life-of-facility oversight (e.g., operator training, performance assessment) applied by the NRC to NRC-licensed facilities is not covered by the SNF Project regulatory policy.

The following definitions are used in applying the SNF Project regulatory policy to new SNF Project facilities.
Safety equivalence to NRC-licensed facilities

For the purpose of the SNF Project regulatory policy, safety equivalence to NRC-licensed facilities is established for SNF Project facilities by conformance to the following technical and administrative requirements:

- Technical requirements that meet the nuclear safety objectives of NRC regulations for fuel treatment and storage facilities, including requirements regarding radiation exposure limits, safety analysis, design, and construction.

- Administrative requirements that meet the objectives of the major elements of the NRC licensing process, including formally documented design and safety analyses, independent technical reviews, and opportunities for public involvement.

NRC requirements for comparable facilities

The term "requirements" means design and construction measures that are specifically mandated by NRC regulations. Regulatory guidance and precedents, which are illustrative of implementation of the regulations, are considered optional rather than mandatory. The term "comparable facilities" in this case means SNF treatment and storage facilities.

E 5.2 Requirement Development Process

The proposed SNF Project regulatory requirements were identified by the contractor with the help of the Regulatory Requirements Team. The requirements development process included high-level screening of NRC regulations (10 CFR Parts 0 through 199) to select those applicable to the SNF Project facilities, comparison with DOE requirements to identify significant areas of...
difference and compilation of the composite set of requirements to be applied to the SNF Project. NRC regulatory guidance was used as needed to clarify the intent of the NRC regulations and to provide insight into suitable methods of implementation. The results of the Regulatory Requirements Team’s review were presented in WHC-SD-SNF-DB-002, *Spent Nuclear Fuel Project Path Forward Nuclear Safety Equivalency To Comparable Nuclear Regulatory Commission Licensed Facilities*.

Because the fuel form (metal) used at the Hanford Site differs from the normal U.S. commercial reactor fuel (metal oxide), engineering analysis was used where necessary to develop new (or modified) requirements in areas where neither the NRC or DOE requirements explicitly addressed SNF Project technical issues.

Each NRC technical safety equivalence requirement proposed for adoption was reviewed against the criteria provided in the DOE Nuclear Safety Policy (Sellers 1995). This review was conducted to ascertain whether the addition of a requirement would result in a cost-effective increase in safety.

In some cases the requirements were presented in the form of white papers that provided the arguments and discussions that supported the position of nuclear safety equivalency. For example, the white paper for seismic design criteria is documented in WHC-SD-SNF-DB-004, *Spent Nuclear Fuel Project Seismic Design Criteria NRC Equivalency Evaluation Report*.

The additional requirements as developed were agreed upon by the Regulatory Requirements Team, which was operating as a consensus technical body. The DOE Richland Operations Office approved the requirements with the concurrence of the Independent Review Panel and the DOE Office of Environmental Management, Office of Environment and Safety and Health. These requirements are documented in HNF-SD-SNF-DB-003, *Spent Nuclear Fuel Project Path Forward Additional NRC Requirements*.
E 5 3 Final Safety Analysis Report Documentation of the Requirements

The SNF Project facility NRC equivalency process described above was initiated early in the life of the SNF Project before the facility designs had progressed beyond the conceptual stage. The additional NRC requirements identified as designs progressed were transmitted to the facility design engineering firms for implementation. Because some requirements were identified during the early state of the designs, some items were included that are not applicable to the final designs. As the designs evolved, the SNF Project subprojects developed and then updated matrices identifying how the various NRC requirements were applicable to the current designs. The various chapters of the subproject FSARs included as annexes to the SNF Project FSAR, contain references to the applicable matrices and summarize how each facility meets the applicable NRC requirements.

The CSB FSAR, Annex A, includes additional content that has been extracted from NRC Regulatory Guide 3 48, Standard Format and Content for the Safety Analysis Report for an Independent Spent Fuel Storage Installation or Monitored Retrievable Storage Installation (Dry Storage). The CVDF FSAR, Annex B includes additional content that has been extracted from Regulatory Guide 3 26 Standard Format and Content of Safety Analysis Reports for Fuel Reprocessing Plants. This additional content is required by item 24 of HNF-SD-SNF-DB-003. The additional content requirement is further documented in HNF-SD-SNF-SP-012. Additional Guidance for Including Nuclear Safety Equivalency in the Canister Storage Building and Cold Vacuum Drying Facility Final Safety Analysis Reports. HNF-SD-SNF-SP-012 contains tables that delineate the additional NRC content on a chapter-by-chapter basis using the guidance provided in DOE-STD-3009-94 Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports, for organizing the safety analysis reports. The applicable chapters of the CSB and CVDF FSARs (Annexes A and B) contain this additional information in the appropriate DOE-STD-3009-94 location.
E 6 ORGANIZATIONS

Fluor Daniel Hanford, Incorporated (FDH) is responsible to the DOE for planning, integrating, and managing SNF Project activities including programs, projects, and operations. FDH is supported by subcontractors, including Duke Engineering and Services Hanford Incorporated. As management contractor, FDH is ultimately responsible for contract performance, which includes protecting the public workers, and the environment from hazards associated with Hanford Site operations. FDH also acts as a focal point for interaction with DOE and stakeholders and provides an Environment, Safety, and Health (ES&H) oversight organization. The ES&H organization is responsible for developing and implementing sitewide programs and for providing support to the SNF Project in areas such as occupational safety and health, emergency preparedness, nuclear safety, environmental protection, and radiation protection. The FDH Vice President in charge of ES&H reports to the FDH President. An FDH Vice President and Project Director is responsible for leadership, oversight, and control of the SNF Project and also reports to the FDH President. Other FDH sitewide entities with significant supporting relationships to the SNF Project are the Quality Assurance and Training Organizations.

The SNF Project has an established organizational structure, defined responsibilities, assigned interfaces, policies, and programs that support safe design, construction, and operational activities of SNF Project facilities. The SNF Project supports the mission to clean up the Hanford Site by managing and reducing hazards associated with the Hanford Site SNF inventory.

The SNF Project has responsibility for the design, construction, and operation of the SNF Project facilities. The SNF Project organization includes the Design Authority (Engineering), Operations, and Maintenance functions and has primary responsibility for executing the project mission. This includes defining systems, managing subprojects and programs, providing technical direction to design agents and construction managers, reviewing and approving products and activities, and ensuring that requirements are met. As the modifications to K Basins and construction of the CVDF and CSB are completed, the SNF Project will transition from its...
present role as an organization involved primarily with design, construction, surveillance, and maintenance to a processing role that will involve the activities of removing the SNF from K Basins, transporting the SNF to CVDF, conditioning the SNF at CVDF, and transporting the SNF to the CSB.

The SNF Project Engineering Manager and Chief Engineer has overall responsibility for establishing, implementing and maintaining the engineering technical baseline, facility authorization basis (including the FSAR and TSRs) and nuclear safety regulatory compliance for SNF Project facilities. As Design Authority for the SNF Project, the Chief Engineer defines requirements for and ensures the technical adequacy of all facility structures, systems and components. The Chief Engineer is also responsible for ensuring that the initial releases of all design and safety basis documentation are technically sound and that changes to these documents are consistent with the approved authorization basis. Within the SNF Project Engineering organization, the Nuclear Safety group is tasked with providing overall coordination and integration of SNF Project regulatory matters, preparing all authorization basis documents for the SNF Project facilities, and managing the unreviewed safety question evaluation process for SNF Project facilities. Other significant functions within the Engineering organization include Process Engineering (responsible for development of technical baseline documents and validation and monitoring of fuel storage processes) and Facilities Engineering (responsible for system upgrades and modifications).

The SNF Project Operations organization is responsible for managing and directing SNF Project operational activities in a safe and environmentally sound manner. This organization is charged with conducting all of their activities in compliance with DOE contractual orders and applicable federal, state and local laws. These activities include facility operations such as handling and storage of SNF, maintenance, start-up and testing, and operational support functions such as management of the occupational radiation safety program, training of facility operators and performance of operational readiness reviews.
Several internal and external organizations provide independent performance-based and compliance-based reviews of the SNF Project. These organizations are as follows:

- **Quality Assurance** – Independent assessments will be performed by the cognizant SNF Project Quality Assurance function to ensure that the requirements of the SNF Project quality assurance program plan are being satisfied. The types and frequencies of assessments performed will be based on the status, complexity, importance, and past performance of the activity or process being assessed.

- **Safety Review Board** – The primary responsibilities of the Safety Review Board are to provide a formal review and approval process for safety basis documents and to ensure adherence to the requirements of DOE orders and standards. Safety Review Board members are appointed by the SNF Project Director for a minimum term of one year. Safety basis documents to be reviewed include safety analysis reports, TSR documents, operational readiness reviews, fire hazard analyses, and criticality safety evaluation reports.

- **Facility Evaluation Board** – Members for the Facility Evaluation are provided by the FDH sitewide Quality Assurance organization. The Facility Evaluation Board is comprised of individuals not otherwise associated with the activity or process being assessed. The scope of a Facility Evaluation Board independent assessment includes radiological controls, occupational safety and health quality assurance environmental programs, engineering training configuration management, maintenance, nuclear safety, fire protection, and operations. The purpose of Facility Evaluation Board assessments is to establish facility compliance with external and internal requirements and to identify areas for improvement in the areas assessed.

- **Regulatory Requirements Team** – A Regulatory Requirements Team to meet requirements of the DOE Regulatory Policy comprises members from contractor.
organizations, DOE organizations, and outside consultants, all of whom are selected for their knowledge in areas relevant to the SNF Project. The Regulatory Requirements Team reports to the DOE Richland Operations Office, Spent Fuels Division Project Director. The purpose of the Regulatory Requirements Team is to identify, develop, and propose for approval selected regulatory requirements applicable to the SNF Project Facilities and to the fuel products removed from the K Basins.

- Independent Review Panel – An Independent Review Panel reporting to the Office of the Manager of DOE, Richland Operations Office, established to meet the requirements of the DOE Regulatory Policy, provides advice and high-level oversight of the implementation of regulatory policy with relation to the SNF Project. The Independent Review Panel comprises three members selected from outside the DOE complex based on their technical capabilities and experience applicable to the SNF Project. The Independent Review Panel is charged with review of SNF Project regulatory strategy, evaluation and concurrence with SNF Project regulatory requirements, and evaluation and concurrence with SNF Project safety analysis and safety evaluation reports, including those submitted for final approval to operate the SNF Project facilities.

E 7 SAFETY ANALYSIS CONCLUSIONS

For safety analyses conclusions for SNF Project facilities, consult Chapters 3 0 of the facility FSAR Annexes.
E 8 FINAL SAFETY ANALYSIS REPORT ORGANIZATION

The SNF Project FSAR is a multi-volume document. This Volume 1 contains SNF Project information applicable to all new project facilities. Volumes 2, 3, and 4 are facility FSAR Annexes A, B, and D, which contain the CSB CVDF, and 200 Area Interim Storage Area FSARs, respectively. The chapters in all four volumes of the FSAR follow the seventeen-chapter DOE-STD-3009-94 format. Chapters and sections in the SNF Project FSAR are numbered as 10111220, 30, and so forth. Chapter numbers in the facility FSAR Annexes contain the prefix of the respective annex. For example, the chapter and section numbers in Annex A, the CSB FSAR, are identified as A10, A11, A12, A20, A30, and so forth.

This report is based on the format and content guidance of DOE-STD-3009-94 and the requirements of DOE Order 5480 23 Nuclear Safety Analysis Reports. This report is also based on implementation of NRC nuclear safety equivalency as presented and approved in HNF-SD-SNF-DB-003.

On a chapter-by-chapter basis, the information contained in this Volume 1 of the SNF Project FSAR, is summarized as follows:

Chapter 10 contains descriptions of the Site Characteristics of the region in which all three SNF Project facilities are located, including geography, land and water uses, demography, meteorology, and natural phenomena hazards.

Chapter 20 includes Facility Description information that is common to all three SNF Project facilities. Most of this type of information is however facility-specific in nature and is found in the facility FSAR Annexes.

Chapter 30 describes requirements and methodology used to perform Hazard and Accident Analyses for the SNF Project facilities. Actual analyses are described in the facility FSAR Annexes.
Chapter 4 0  Describes requirements and methodology used to select Safety Structures Systems and Components for the SNF Project facilities Actual selected controls are described in the facility FSAR Annexes

Chapter 5 0  Describes requirements and methodology relevant to the Derivation of Technical Safety Requirements Actual elaboration of TSRs and their relationships to hazard and accident analyses and to safety equipment are described in the facility FSAR Annexes

Chapter 6 0  Describes requirements and methodology relevant to Prevention of Inadvertent Criticality, and contains characterizations of SNF inventories at SNF Project facilities Individual conclusions regarding criticality and related controls are found in the facility FSAR Annexes

NOTE  In those cases where policies programs and practices important to safe operation are described in detail in other documents the information is summarized in the programmatic chapters below and the documents are referenced The detailed programs and procedures described in referenced documents may be changed without further DOE approval to the extent that the changes do not constitute an unreviewed safety question as defined by DOE Order 5480.21 Unreviewed Safety Question

Chapter 7 0  Contains a description of the Radiation Protection program that applies to the SNF Project facilities

Chapter 8 0  Contains a description of the Hazardous Material Protection program that applies to the SNF Project facilities

Chapter 9 0  Contains a description of the Radioactive and Hazardous Waste Management program that applies to the SNF Project facilities
Chapter 10 0 Contains a description of the *Initial Testing  In-Services Surveillance and Maintenance* program that applies to the SNF Project facilities.

Chapter 11 0 Contains a description of the *Operational Safety* program that applies to the SNF Project facilities.

Chapter 12 0 Contains a description of the *Procedures and Training* program that applies to the SNF Project facilities.

Chapter 13 0 Describes requirements and methodology relating to evaluation and incorporation of *Human Factors* into the SNF Project facility designs. Specific human factors evaluations and design features are found in the facility FSAR Annexes.

Chapter 14 0 Contains a description of the *Quality Assurance* program that applies to the SNF Project facilities.

Chapter 15 0 Contains a description of the *Emergency Preparedness* program that applies to the SNF Project facilities.

Chapter 16 0 Describes some of the general types of design features and overall approach taken by the SNF Project facilities for *Provisions for Decontamination and Decommissioning*. Specific design features and other measures to ensure effective decontamination and decommissioning are described in the facility FSAR Annexes.

Chapter 17 0 Describes the *Management Organization and Institutional Safety Provisions* that characterize the SNF Project. Some of these organizational features specifically those that relate to aspects of safety management are also addressed in Section E 5 of this Executive Summary.

LIST OF TABLES

1-1 Projected Residential Population in a Fifty-Mile Radius of the Hanford Meteorological Station for the Period 1990 through 2040 1-8

1-2 Monthly and Annual Daily Average and Extreme Temperatures at the Hanford Meteorological Station 1-12

1-3 Average Number of Days at the Hanford Meteorological Station that Maximum and Minimum Temperatures were above or below Specific Limits for the Period 1945 through 1997 1-13

1-4 Monthly and Annual Average and Extreme Precipitation in Inches at the Hanford Meteorological Station for the Period 1945 through 1997 1-14

1-5 Extreme Precipitation Estimates for the Hanford Site 1-16

1-6 Monthly and Seasonal Snowfall at the Hanford Meteorological Station in Inches, Average and Maximum for the Period 1945 through 1997 1-17

1-7 Average Number of Thunderstorm Days at the Hanford Meteorological Station for the Period 1945 through 1997 1-18

1-8 Maximum Peak Gusts 50 Feet off the Ground at the Hanford Meteorological Station for the Period 1945 through 1997 1-19

1-9 Average Number of Days of Dust or Blowing Dust at the Hanford Meteorological Station for the Period 1945 through 1997 1-23

1-10 Monthly and Annual Number of Days with Fog and Dense Fog at the Hanford Meteorological Station for the Period 1945 through 1997 1-24

1-11 Average Sky Cover (Sunrise to Sunset) for the Period 1946 through 1997 and Number of Clear, Partly Cloudy, and Cloudy Days for the Period 1954 through 1997 at the Hanford Meteorological Station 1-25

1-12 Percent Frequency of Occurrence of Mixing Layer Thickness by Season and Time of Day at the Hanford Site 1-26

1-13 Percent Probabilities for Extended Periods of Surface-Based Inversions at the Hanford Site 1-27

1-14 Percent Frequency of Occurrence of Pasquill-Gifford Atmospheric Stability Classes A through G for the 100 Area 1-28

10 SITE CHARACTERISTICS

11 INTRODUCTION

The K West and K East Basin Fuel Storage Facilities and the Cold Vacuum Drying Facility (CVDF) are located in the 100 K Area of the U.S. Department of Energy (DOE) Hanford Site. The CVDF is used to remove free water from spent nuclear fuel (SNF) taken from the K West and K East fuel storage basins and to vacuum dry the SNF before it is transferred to the Canister Storage Building (CSB) in the 200 East Area. The objective of this chapter is to describe the characteristics of the region, Hanford Site, and the 100 K and 200 East Areas. Annex A contains information specific to the CSB in the 200 East Area. See Chapters 10 of the facility annexes to the SNF Project Final Safety Analysis Report (FSAR) for specific descriptions of facility sites. This information supports the hazard analysis and accident analyses in Chapters 30 in the facility FSAR Annexes.

12 REQUIREMENTS

The requirements that form the basis for facility siting are found in HNF-SD-SNF-RD-001, Spent Nuclear Fuel Project Standards/Requirements Identification Document. Specific requirements applicable to this chapter include:

- DOE Order 6430 1A, General Design Criteria
- DOE Order 5480 28, Natural Phenomena Hazards Mitigation
- DOE-STD-1022-94, 1994, Natural Phenomena Hazards Site Characterization Criteria
- DOE-STD-1023-95, 1995 Natural Phenomena Hazards Assessment Criteria
- DOE-STD-3014-96, 1996, Accident Analysis for Aircraft Crash into Hazardous Facilities
- NFPA 780 1995, Lightning Protection Systems
In Memorandum EM-36-3 167, *Concurrence with K-Basins Spent Nuclear Fuel Project Policy on Nuclear Safety Requirements* (Grumly 1995), DOE established the requirement for new SNF Project facilities to achieve "nuclear safety equivalency" to comparable U.S. Nuclear Regulatory Commission (NRC)-licensed facilities. The SNF Project identified the NRC requirements that were needed in addition to existing and applicable DOE requirements to establish nuclear safety equivalency. These NRC requirements and the process used to identify them are documented in HNF-SD-SNF-DB-003, *Spent Nuclear Fuel Project Path Forward Additional NRC Requirements*, and in WHC-SD-SNF-DB-010, *Cold Vacuum Drying System Natural Phenomena Hazards*, for CVDF and WHC-SD-SNF-DB-009 *Canister Storage Building Natural Phenomena Hazards*, for CSB.

13 SITE DESCRIPTION

The following sections address the geography, demography, and regional land and water use of the area encompassed by and surrounding the Hanford Site. Much of the information contained in these sections was obtained from DOE/EIS-0245F, *Management of Spent Nuclear Fuel from the K Basins at the Hanford Site Richland Washington*.

13.1 Geography

The Hanford Site is a 560 mi² area located in the state of Washington as shown in Figure 1-1. Principal cities and towns and prominent natural features are shown in Figure 1-1. Use of the Site is institutionally controlled by DOE for national security and health and safety reasons.

The Columbia River enters the Hanford Site at the northwest corner and flows through the northern portion of the Site where it is approximately 1,500 ft from the K Basins and the CVDF (Figure 1-2) before turning southward to form part of the eastern boundary. The CSB, which is in the 200 East Area, is approximately 6.5 mi from the Columbia River on a relatively flat terrace known as the 200 Area Plateau (Figure 1-3). The Yakima River flows from west to east, forming part of the southern boundary of the Site and empties into the Columbia River at the Tri-Cities (Richland, Kennewick, and Pasco) (Figure 1-4). The Hanford Site is bordered on the north by the Saddle Mountains and on the west by the Umtanum and Yakima Ridges and Rattlesnake Mountain (Figure 1-5). Dominant natural features include the Columbia River anticlinal ridges of basalt in and along the Hanford Site boundary, and sand dunes located near the Columbia River. The surrounding basaltic ridges rise to elevations as high as 3,600 ft.

The location of the Hanford Site with respect to local counties and regional highways is shown in Figure 1-4. The Hanford onsite road network consists primarily of rural arterial routes (Figure 1-3). Only 65 of the 288 mi of paved roads are accessible to the public. Most onsite employee travel occurs along Route 4 South and Route 11A, with controlled access at the Yakima and Wye Barricades. An additional access point to the 200 Areas from State Highway 240 (Rattlesnake Barricade) with limited hours of operation is located near the.
southeastern corner of the 200 West Area (see Figure 1-3). Route 11A, the closest to the 100 K Area of the two routes, passes within 4.5 mi of the CVDF and K Basins. Route 4 North, which has less usage, passes within 2.4 mi of the CVDF and K Basins. State Route 240 is the main public route through the Site. State Routes 24 and 243 also traverse the Site. State Route 240 passes through the Hanford Site and within 6 mi of the 100 K Area. Public access through the Hanford Site on Highways 24, 240, and 243 is not strictly controlled by DOE under normal circumstances. Large shipments, in particular components from dismantled nuclear submarines, are offloaded at the Port of Benton dock facilities discussed below. Overland wheeled trailers are then used to transport the shipments to the east side of the 200 East Area. Using this route, the shipments do not pass near the K Basins or CVDF in the 100 K Area or the CSB in the west side of the 200 East Area.

An on-site railroad system is owned by DOE, however, it is not currently in use. This line connects just south of the Yakima River with the Union Pacific line which in turn interchanges with the Washington Central and Burlington Northern–Santa Fe railroads at Kennewick.

There is no barge traffic on the Columbia River upstream (north) of the Port of Benton barge slip which is just north of Richland. The barge slip is located near the upper end of the McNary Dam impoundment and above this location the river is too swift and shallow to allow for safe operation of barges. In addition, there are no lock facilities at Priest Rapids Dam, the next upstream dam and there are no industrial facilities between the Port of Benton barge slip and the dam that would benefit from barge service.

There are two commercial airports within 35 mi of the 100 K Area that serve commercial or military aircraft. These are the Tri-Cities and Richland airports. Besides these, there are a number of small commercial and privately owned airports exclusively serving general aviation aircraft within a 24 mi radius of the 100 K Area and 200 East Area. They are discussed in detail in Section 1.6.1.

Traffic on the Columbia River in the airspace over the Hanford Site and on access routes into the areas used by U.S. Ecology Incorporated and Energy Northwest (formerly the Washington Public Power System) are not subject to strict controls under normal circumstances (see Figure 1-3). Under emergency plan conditions, DOE will control all road and railroad access to the Hanford Site and may close these Site routes to normal traffic. Notification of offsite agencies in the event of an emergency is provided so that they may take measures within their jurisdictions to ensure public protection (see Chapter 15). The U.S. Coast Guard and the Federal Aviation Administration in cooperation with DOE and other agencies, would assess the nature of the emergency and restrict river and airspace traffic if such action were deemed prudent for public safety.

**1311 Hanford Site Vegetation** The most broadly distributed vegetation on the Hanford Site is sagebrush, wheatgrass, blue bunch wheatgrass, cheatgrass, and other shrub plant species common to central Washington. The flora is prone to destruction by fire and can burn rapidly. The most recent severe grass fire at the Hanford Site occurred in August 1984 as a result of a range fire that started northeast of Sunnyside, Washington (see Figure 1-1). Extremely dry
vegetation, inaccessible mountain terrain, and winds up to 40 m/h limited attempts to extinguish
the fire. The fire front entered the Hanford Site adjacent to Rattlesnake Mountain, crossed
Highway 240, and traveled northeast along Army Loop Road south of the 200 East Area
(Figure 1-3) The fire was not controlled until it reached the Columbia River, by which time it
had burned approximately 312 mi² of range land. Hanford Site facilities near the fire were
protected by fire breaks cut by bulldozers and blades, and by fire-fighting tanker trucks. Vehicle
access is available for the areas around all major Hanford Site facilities. For this fire, air drops of
fire retardant material by U.S. Forest Service planes from the Wenatchee National Forest were
used to help protect major facilities. Losses related to this severe grass fire were limited to
burned railroad ties, wooden power poles, and several trailers. Several fire-fighting vehicles also
were damaged.

To protect the SNF Project facilities, a clear space is provided on all sides of the facility.
Unpaved areas are overlaid with a crushed rock surface. The potential impact of range fires on
SNF Project operation is addressed in the facility-specific hazard analyses.

13.1.2 Hanford Site Facilities In 1943 the U.S. Army Corps of Engineers selected the
Hanford Site for construction of nuclear reactors and chemical processing facilities in support of
the war effort. The current mission is environmental management of radioactive and hazardous
wastes, restoration of Site land, and conversion of useable facilities for other uses. DOE nuclear
facilities currently occupy approximately 6% of the total available Hanford Site land area. Site
operating areas are identified by area numbers and are briefly described below. Figure 1-3 shows
these numbered areas.

Six 100 Areas border directly on the Columbia River in the northernmost portion of the
Site. These areas were the locations for nine graphite-moderated plutonium production reactors.
Eight of these reactors, all of which started operation before 1960, were shut down in the
early 1970s. The ninth reactor, N Reactor, became operational in 1963 and continued operating
until 1986. The K Basins and the CVDF are located in the 100 K Area. The 100 Areas occupy
about 4 mi².

The 200 East and 200 West Areas are located near the center of the Hanford Site on a
relatively flat terrace known as the 200 Area Plateau. In the past, the 200 East and 200 West
Areas have received waste from the 100, 300, and 400 Areas in addition to the waste produced by
200 Area separation processes. The CSB is located in the 200 East Area. The 200 Areas occupy
approximately 8 mi².

The DOE has awarded a contract to a private company to design facilities on the east side
of the 200 East Area for the vitrification of the Hanford Site tank farms waste. At the conclusion
of the design phase, DOE will decide whether to proceed into a construction and operation phase.
These facilities will be located near the 241-AP Tank Farm. The effect of these and other new
facilities on CSB operations will be evaluated in scheduled updates of the SNF Project FSAR as
planning, construction, and operation proceed.
The 300 Area, located just north of Richland, is the site of various nuclear research and development facilities. This area covers 0.6 mi².

The 400 Area is the site of the Fast Flux Test Facility, a liquid-metal-cooled fast reactor used for testing breeder reactor fuels, materials, and components. The Fast Flux Test Facility is currently defueled and in standby mode, awaiting decision by the DOE to restart for future missions or proceed with preparations for eventual decontamination and decommissioning activities. The 400 Area covers 0.25 mi².

The 600 Area includes all of the Hanford Site not occupied by the 100, 200, 300, or 400 Areas. Land uses within the 600 Area include the following (Figure 1-3):

- An area measuring 120 mi² known as the Fitzner-Eberhardt Arid Lands Ecology Reserve, is located along the southwest boundary of the Hanford Site (Figure 1-5). This area is a limited-access area and has been set aside for ecological studies. The DOE may in the future enter into an agreement with the U.S. Fish and Wildlife Service to manage the area.

- An area measuring 15 mi², located between the 200 West and 200 East Areas, is leased by Washington State. A part of this area is managed by U.S. Ecology, Incorporated for the disposal of solid, low-level radioactive waste from commercial— not Hanford Site — sources.

- An area measuring 16 mi² is used by Energy Northwest for commercial nuclear power plants. This area is located approximately 10.5 mi southeast of the 200 East Area and approximately 3 mi west of the Columbia River. Three commercial nuclear power plants were originally planned for this site. Washington Nuclear Plant (WNP)-2, a boiling-water reactor, is currently in operation at this location. Construction has been terminated at the other two reactors, WNP-1 and WNP-4. Both were to be pressurized water reactors. Also located on the Energy Northwest leased property are the Plant Engineering Center and Plant Support Facility and the Bonneville Power Administration's H.J. Ashe substation.

- An area measuring 1 mi² has been transferred to Washington State as a potential site for the disposal of nonradioactive hazardous wastes. See Figure 1-3.

- About 50 mi² of land north of the Columbia River, the Saddle Mountains National Wildlife Refuge, is managed under a revocable use permit by the U.S. Fish and Wildlife Service. The U.S. Fish and Wildlife Service also manages seven islands in the Hanford Reach section of the Columbia River as part of the McNary National Wildlife Refuge.

- Another 87 mi² of land north of the Columbia River, the Wahluke Wildlife Recreation Area, is under a revocable use permit managed by the Washington State Department of Wildlife for recreational game management. Public outdoor recreational use is permitted in this area.
An area of less than 1 m² is occupied by the 616 Nonradioactive Dangerous Waste Disposal Facility. It is located approximately 200 ft north of Route 3 between the 200 East and 200 West areas. In the past, the facility received, stored, and shipped nonradioactive waste designated as extremely hazardous and dangerous that was generated at all DOE, Richland Operations Office facilities.

Support facilities for the controlled access areas and an electrical transmission substation at Midway near the northwest corner of the Hanford Site are maintained by the Bonneville Power Administration. The Hanford Site electrical distribution system (i.e., transmission lines and substations) are discussed in Section 2.8.

1313 Boundaries for Evaluation of Accident and Effluent Release Limits Activities in the 100 K Area and 200 East Area are within the DOE-controlled zone. A security fence limits general access by land. The fence stops at the high-water mark of the Columbia River. Access from the river is controlled by "No Trespassing" signs. The Hanford Patrol is responsible for enforcing the restriction on access to the area, including access from the river. No special security clearance other than a Site badge is required to pass through the gates that control access to the 100 K Area and 200 East Area. However, the DOE has the authority to determine all activities in this area including exclusion or removal of personnel and property. There are no permanent residences in this area. Specific boundaries used in the accident analyses are described in the facility FSAR Annexes.

1314 Regional Land and Water Use This section characterizes regional land and water use both inside and outside the Hanford Site boundaries based on information contained in DOE/EIS-0113, Final Environmental Impact Statement Disposal of Hanford Defense High-Level Transuranic and Tank Wastes Hanford Site, Richland Washington, PNL-6415, Hanford Site National Environmental Policy Act (NEPA) Characterization, and DOE/EIS-0245F.

13141 Land Use Within the Hanford Site Boundaries The majority of the land within the Hanford Site boundary is a limited-access area under control of the DOE for use in environmental restoration and remediation efforts. A number of areas at the Hanford Site are managed under a multipurpose concept and serve as buffer zones around areas of nuclear activity. These multipurpose areas are shown in Figure 1-3.

DOE is in the process of preparing a Hanford Site land use plan to comply with state and county land use planning laws and regulations. This plan establishes a blueprint for use of Hanford Site lands consistent with the Site mission of environmental cleanup and radioactive waste management. The strategy is documented in the revised DOE/EIS-0222D Draft Hanford Remedial Action Environmental Impact Statement and Comprehensive Land Use Plan (DOE 1998) currently being reviewed by DOE.

13142 Agricultural Land Use Outside Hanford Site Boundaries Land use in the six-county region surrounding the Hanford Site (i.e., Franklin, Walla Walla, Benton, Yakima, Adams, and Grant Counties [Figure 1-4]) is predominantly agricultural. Over 75% of the land...
area in this region is in agriculture-related use compared with less than 40% statewide. The percentage of agricultural land that is irrigated in this region varies from a high of 73% in Grant County to a low of 33% in Yakima County. However, areas of Yakima County near the Hanford Site have intensive irrigation.

Regional land used for agricultural purposes lies primarily north and east of the Columbia River and south of the Yakima River. The U.S. Bureau of Reclamation's Columbia Basin Irrigation Project is northeast of Othello. Part of the farmland northeast of Priest Rapids Dam is irrigated by the Columbia Basin Project; the rest is used for dryland farming. The area from Othello south to the Columbia River is irrigated farmland. The principal agricultural crops associated with the irrigated and dryland farming include hay, wheat, potatoes, corn, apples, soft fruit, and vegetables. Land in the area just outside the Hanford Site to the south and west is available for farming but is used mainly for grazing cattle and sheep. The agricultural land along the Yakima River is used for fruit orchards, grapes, hops, alfalfa, and annual row crops. Higher land away from the Yakima Valley floor is used principally for livestock grazing, dairies, and fruit orchards; with some grain crops. South and west of Kennewick, the land is used principally for dryland wheat farming, with some orchards.

13143 Nonagricultural Land Use Outside Hanford Site Boundaries The main industries in the Tri-Cities are, or are related to, agriculture and energy production. The DOE's nuclear and nonnuclear industrial activities within a 5-mile radius of the SNF Project facilities are described in Sections 17 of the facility FSAR Annexes. All industrial activities on Hanford Site leased land must be compatible with DOE activities and must be approved by the DOE. These land uses are discussed in Section 1312. The DOE retains the right to remove from lease any land not currently used or not under development by the state. The Big Bend Alberta Company owns mineral rights to several parcels of land in the Arid Lands Ecology Reserve (Figure 1-3) and holds the right to perform exploratory drilling.

The U.S. Army's Yakima Training Center covers 326,000 acres just northwest of the western Hanford Site boundary (Figure 1-4). The Center is used for firing all types of ordnance both in a direct mode and by indirect artillery and mortars. Weapons to 8-in are fired. Firing occurs frequently. Live ordnance used at the Center includes bombs up to 500 lb delivered by high-performance aircraft, helicopter weapons, which include automatic weapons and 2.75-in folding fin rockets and anti-aircraft missiles. The majority of the ordnance impacts a 20,000-acre area that is located in the central portion of the Center. All activities are confined to the geographical limits of the Center and/or its restricted air space unless special arrangements are made with affected agencies. Mechanized units (i.e., tanks and armored personnel carriers) from Fort Lewis and Reserve components conduct extensive maneuvers on all accessible areas of the Yakima Training Center and use specially designed ranges to practice firing their weapons. Training activity is greatest from March to November. War games sometimes involve troop and equipment deployment at the Richland airport and along Highway 243 west of the Vernita Bridge. Helicopters may fly near the Hanford Site, or military vehicles may travel over Highway 240.

13144 Water Use The major water uses, in decreasing order, are agricultural, industrial, and municipal. CVDF and CSB operation will involve no water withdrawals from or
direct discharges to the Columbia River Water removed from the multi-canister overpacks at the CVDF will be returned to K West Basin See WHC-SD-WM-SAR-062 K Basins Safety Analysis Report, for a description of the K Basins interface with the Columbia River

132 Demography

1321 Offsite Population The 1990 U.S. Bureau of the Census population distribution statistics for cities within a 50-mi radius of the Hanford Meteorological Station (HMS) are shown in Figure 1-6.

Population estimates for 1993 by the Forecasting Division of the Office of Financial Management of the State of Washington place the totals for Benton, Franklin, and Grant counties at 122,800, 41,100, and 60,300, respectively. The 1993 estimates for the Tri-Cities populations are Richland 34,080, Kennewick, 45,220, and Pasco 21,370. The estimated populations of Benton City, Prosser, and West Richland totaled 10,900 in 1993 (PNL-9823).

Major metropolitan areas within the broad vicinity of the SNF Project facilities include Spokane, Washington, about 120 mi to the northeast, Seattle, Washington, about 130 mi to the northwest and Portland, Oregon, about 150 mi to the southwest. Two other areas of significant population density include Moses Lake, Washington, about 30 mi north of the 100 K Area and the Yakima Valley, in Washington, extending from Yakima, about 45 mi west of the 100 K Area, to the Tri-Cities, in Washington, about 35 mi southeast of the plant.

The population distribution in the area surrounding the Hanford Site is not uniform. Most of the adjacent area to the east, north, and west is farm or range land with scattered farming communities. Table 1-1 shows the actual 1990 residential population and the projected residential population within a 50-mi radius of the HMS for decennial census years through 2040 (PNL-7803).

</table>
The Tri-Cities are located to the south-southeast of the 100 K Area and comprise the major population center of the area. The three cities (Kennewick, Pasco, and Richland) are estimated to have a combined population of approximately 104,000 based on 1994 estimates. The estimated unincorporated population of Benton County is 33,000 and of Franklin County is 18,000 (DOE/EIS-0245F). More recent data on the Tri-Cities population are not available although Hanford Site and total nonfarm employment are on a downward trend. The projected increase in the total population of Franklin County from 1995 to 2005 is from 41,336 to 48,213 (8.03%) and for Benton County from 121,328 to 136,892 (6.32%) (DOE 1995). The nearest residence to the 200 East Area is approximately 11 mi east across the Columbia River. The Richland city limits are approximately 16 mi to the southeast.

Other population centers of note within a 50-mi radius include the cities of Othello 22 mi east-northeast Mattawa 17 mi west-northwest and Yakima 43 mi west. The Yakima River Valley, stretching in an arc from the city of Yakima to the Tri-Cities, is a relatively densely populated agricultural area with a number of small towns.

There are currently no schools, hospitals, nursing homes, or penal institutions within 12 mi of the SNF Project facilities. The closest schools are located at Mattawa 17 mi west-northwest. These Mattawa schools, and their 1995 enrollments are:

- Mattawa Elementary School 482 students
- Morris Scott Middle School 301 students
- Wahluke High School 232 students

Also located in Mattawa is a medical clinic. There are currently no hospitals, nursing homes, or penal institutions in Energy Northwest's 10-mi emergency planning zone. The closest school to the CSB site is the Edwin Markham Elementary School with a 1995-1996 enrollment of 283 students. Evacuation of the Edwin Markham School and of the nearby Country Haven and Country Christen School is provided for in the Benton and Franklin Counties Fixed Nuclear Facility Emergency Response Plan.

1322 Onsite Population In 1996 approximately 11,000 persons were employed on the Hanford Site. Estimated employee populations located near the SNF Project facilities are:

- 305 at the 100 K Area
- 10 at the 100 D Area
- 379 at the 100 N Area
- 2,750 at the 200 East Area

Some Hanford Site work assignments include shift and weekend coverage. The total number of persons on the Site at any one time varies with the time of day, staffing requirements for current projects, and daily fluctuations in employee work attendance.

1323 Transient Population Figure 1-7 shows the estimated populations of migrant agricultural workers and recreationists. Both are defined as transient. These estimates were
developed by the then Washington Public Power Supply System in 1988 and are documented in *WNP-I, 2 Ten Mile EPZ Evacuation Time Assessment Study* (Mogle 1987). The center of the 10-m emergency planning zone, which is located midway between WNP-1, WNP-2, and WNP-4 is the geographic point from which estimates are made. The CSB is located approximately 12 m west-northwest from the center point. 100 K Area is located approximately 20 m northwest of the centerpoint (see Figure 1-7). This distance from the center point is not significant to the accident analyses in the facility FSAR Annexes as the location of the offsite receptor is determined by consideration of the Site boundary and the ability to control activities within the boundary as discussed in Section 13.1.3.

### 13.2.4 Emergency Response Considerations

Figure 1-3 shows the major roads that would be used for onsite and offsite evacuation routes. The roads shown will provide adequate evacuation of collocated workers and the general public, assuming worst-case evacuation conditions and maximum evacuation rates. Access to designated shelter or shielding areas is provided by the road system for worst-case evacuation rates considering anticipated delays. Sheltering and shielding parameters are included in the facility building emergency plans described in Section 15.4. Facility-specific onsite and offsite emergency response plans will address specific actions (i.e., notifications, take-cover, facility shutdown, evacuation) that are dependent upon the emergency condition. See Section 15.4 for a discussion of how the emergency response plans are developed.

### 14 Environmental Description

The following sections address the meteorology, hydrology, and geology of the Hanford Site.

#### 14.1 Meteorology

This section describes the regional climatology and the meteorological conditions of the Hanford Site. Climatological data are available for the HMS, which is located between the 200 East and 200 West Areas, approximately 6 mi south of the 100 K Area (Figure 1-8). Data have been collected at this location since 1945. Data from the HMS are representative of the general climatic conditions for the region and describe the specific climate of the 200 Area Plateau. Information contained in this section is taken primarily from PNL-11794 *Climatological Data Summary 1997 with Historical Data*, and PNL-4622 *Climatological Summary for the Hanford Area*. These data are used in the preparation of safety documentation and in the development of emergency response planning.

#### 14.1.1 Regional Meteorology

A wide range of meteorological variables is measured at the HMS and at the 125-m tower, which is located 1,614 ft east of the HMS. Temperature, relative humidity, precipitation, atmospheric pressure, solar radiation, cloud cover, visibility, and subsurface temperature are parameters measured or observed at the HMS. Wind data are measured at various levels on the 125-m tower. Three 200-ft towers with wind and temperature
measuring instruments at various levels, are located at the 300, 400, and 100 N Areas. Wind and temperature measurements also are taken on 23 30-ft towers distributed on and around the Hanford Site (see Figure 1-8). Data from all towers are telemetered to the HMS. The Hanford Meteorological Monitoring Network is described in detail in PNL-6684, *The Data Collection Component of the Hanford Meteorological Monitoring Program*.

Meteorological parameters have been measured in the vicinity of the Hanford Site since 1912. The HMS became operational in December of 1944. Since 1944, additional large-scale meteorological monitoring towers have also been constructed, including one in the 100 N Area.

**1412 Regional Climatology** The climate of the Pasco Basin, in which the 100 N Area is located, can be classified as midlatitude semiarid or midlatitude desert, depending on the climatological classification scheme used. Summers are warm and dry with abundant sunshine. Large diurnal temperature variation results from intense solar heating during the day and radiational cooling at night. Daytime high temperatures in June, July, and August periodically exceed 100 °F. Winters are cool with occasional precipitation. Outbreaks of cold air associated with modified arctic air masses can reach the area and cause temperatures to drop below 0 °F. Overcast skies and fog occur periodically during the winter season (PNL-4622).

Topographic features have a significant impact on the climate of the Hanford Site. All air masses that reach the Pasco Basin undergo some modification as a result of their passage over the complex terrain of the Pacific Northwest. The climate of the Pasco Basin is strongly influenced by the Pacific Ocean and the Cascade Range to the west. The relatively low annual average rainfall of 6.8 in. at the HMS is caused largely by the rain shadow created by the Cascade Range. This mountain range limits much of the maritime influence of the Pacific Ocean, resulting in a more continental-type climate than would exist if the range were not present. Maritime influences are experienced in the region during the passage of frontal systems and as a result of movement through the gaps in the Cascade Range (e.g., Columbia River Gorge).

The Rocky Mountains to the east and north of the Pasco Basin also influence the climate of the region. These mountains play a key role in protecting the region from the more severe winter storms and the extremely low temperatures associated with modified arctic air masses that move southward through Canada. The Yakima Ridge, Rattlesnake Hills, and Horse Heaven Hills to the west and south of the Hanford Site, the Saddle Mountains to the north, and the Columbia River also influence the local climate (see Figure 1-9).

The position of the jet stream directs storm systems into Washington State during the cooler months. These systems cause the majority of the precipitation at the Hanford Site. The cold, or occluded, fronts associated with these storm systems originate in maritime polar, continental polar, or arctic air masses. Warm fronts occur as warmer maritime air flows over colder continental air. An average of 10 identifiable warm fronts and 52 cold fronts pass through the Pasco Basin each year (PNL-4622). A majority of these passages occur during the colder months leading to increased frequency and intensity of precipitation. Periodic persistent high-pressure ridges in the upper troposphere in the cool season, which can trap cold air near the surface, lead to extended periods of wintertime stagnation.
The jet stream directs most storms north of the state of Washington during the warmer months, therefore frontal passages are fewer and weaker than in the cooler months. High pressure with stable, subsiding air is the dominant meteorological condition during this period. Warm weather precipitation tends to be associated with convective activity and the advection of moist, maritime air into the region (PNL-4622)

14121 Temperature Monthly and annual daily average temperatures for the Hanford Site from 1961 through 1990 and extreme temperatures from 1945 through 1997 are given in Table 1-2. At the Hanford Site, the annual average temperature is 53 °F (PNL-11794). July is typically the warmest month with an average maximum temperature of 91 °F, an average minimum temperature of 61 °F, and an average temperature of 76 °F. January tends to be the coolest month with an average maximum temperature of 38 °F, an average minimum temperature of 24 °F, and an average temperature of 32 °F. Observed temperature extremes for the Hanford Site range from 113 °F to -23 °F. The highest temperature ever recorded on the Hanford Site was 115 °F on July 27, 1939. The lowest temperature ever recorded on the Hanford Site was -27 °F on December 12, 1919. These temperatures were recorded before the HMS was operational and are not included in Table 1-2.

Note  Information in this table is from PNL 11794  1998 Climatological Data Summary 1997 with Historical Data  Pacific Northwest National Laboratory Richland Washington

*Denotes less than half a day
The Hanford Site and vicinity are known for severe and abrupt temperature changes. During winter the Site frequently experiences rapid rises in temperature accompanied by moderate west winds. This phenomenon, known as a chinook wind, has produced temperature variations of up to 22 °F in 0.5 hours and is responsible for rapid melting of snow (DOE/EIS-0113).

**14122 Precipitation** The annual average precipitation value at the HMS is 6.8 in with the annual precipitation value for the wettest documented year (1995) being 12.3 in and for the driest year (1976) being 2.99 in (PNL-11794). Monthly average and extreme precipitation amounts for the Hanford Site from 1945 through 1997 are given in Table 1-4. On average, 54% of normal annual precipitation falls during November through February. December is the wettest month receiving 1.03 in, and July is the driest month receiving only 0.18 in. The wettest month on record is December 1996 with 3.7 in, September 1991, August 1988, and August 1955 recorded no precipitation. An average of 125 days per year have a trace (less than 0.005 in) or more of precipitation. The average number of days per month with a trace or more ranges from 16 days in January to 5 days in July. Only 23 days a year receive totals of 0.1 in or more. During the 51-year period of record (1945 through 1997) only 4 days have had 1 in or more of precipitation.

*Most recent of multiple occurrences.

T = trace (0.005 in or less)
Hydrometeorological Report No 57, Probable Maximum Precipitation — Pacific Northwest States (Hansen et al 1994), a recent cooperative study by the National Oceanic and Atmospheric Administration, the Bureau of Reclamation and the U.S. Army Corps of Engineers, has updated the probable maximum precipitation (PMP) estimates for the Pacific Northwest. This document supersedes earlier work done by these organizations and is the source used for the PMP shown in Table 1-5. The PMP values are estimates of the maximum precipitation physically possible for both general storms (large air mass interactions) and local storms (unstable air thunderstorms). At the Hanford Site, the 6-hour local storm produces more precipitation than the 24-hour general storm. The 6-hour local storm PMP is related to the area of the storm, the smaller area yielding the most intense storm and highest precipitation. Data are presented for the 1-m$^2$ and the 10-m$^2$ storm. The SNF Project facilities are designed to accommodate the full range of PMP identified in Table 1-5. The effects of local PMP are determined according to ANSI/ANS-2 8-1992. Local protection for run-off is provided by earthwork and grading design and by the storm drain system consisting of culverts, ditches, channels, and catch basins as required.

No annual probability of exceedance is given in Hydrometeorological Report No 57 (Hansen et al 1994) for the PMP for either general or local storms. The PMP is conservatively assumed to have an annual probability of exceedance of less than $1 \times 10^{-6}$ (ASCE 1988).

The 6-hour PMP for more frequent storms shown in Table 1-5 is from PNL-4622 and is based on the analysis of extreme values from 22 years of meteorological data from the Hanford Site. The precipitation estimates for the 100- and 1,000-year return periods are based on data from the HMS. Although these values cannot be compared directly with either the 1-m$^2$ storm or the 10-m$^2$ storm, they provide a data-based estimate for extreme precipitation on the 200 Area Plateau. A 6-hour precipitation hazard curve is estimated using the 100-year and 1,000-year average return period values ($10^2$ and $10^3$ annual probability of exceedance respectively) of PNL-4622 and the 6-hour PMP at an assumed frequency of $10^{-6}$ (Figure 1-10).

Total annual snowfall, which includes all frozen precipitation, varied for the period 1945 through 1997 from a low of 0.3 in to a high of 56.1 in (PNL-11794). The average snowfall is 15.3 in a year. Table 1-6 presents the monthly and annual average and extreme snowfalls. The record snow depth at the HMS is 15.6 in in December 1995, but the record snow depth on the Hanford Site is 24 in in February 1916. The record number of days with snow depth greater than or equal to 6 in is 43 days in the winter of 1992-1993. The probability the depth of snow on the ground will exceed 6 in is 30% during the winter season (Figure 1-11).

The design ground snow load for the CVDF and CSB is 20 lb/ft$^2$ which is the ground snow load for the NRC-licensed WNP-2. This value is 5 lb/ft$^2$ greater than the ASCE requirement (ASCE 7-95).

*No value given for maximum 24 hour snowfall

Glaze ice is a coating of ice formed when rain or drizzle freezes on contact with any surface having a temperature that is below freezing. The average number of days with freezing rain or freezing drizzle is six and they generally occur between November and March. The highest number of days with glaze in any winter season was 18. The least number of days with glaze in any winter season was one. The greatest number of days with glaze in any given month was nine in January 1970. Rime ice (i.e., supercooled droplets that freeze on contact with solid objects) is generally associated with supercooled fog in the nearby hills or along the banks of the Columbia River.

14123 Thunderstorms A thunderstorm day is one in which thunder is heard at the observing station one or more times during a calendar day. Table 1-7 shows the number of thunderstorm days per month and per year for the period 1945 through 1997. The average number of thunderstorm days per year is 10. The total varies from a low of 3 to a high of 23 days (PNL-11794). The largest number of thunderstorm days in a single month was eight.

Thunderstorms can theoretically occur during any month of the year, but none have been observed in November or January. Thunderstorm season is essentially from April through September.

Thunderstorms are classified by the National Weather Service as severe when wind gusts exceed 58 mi/h and/or hail size equals or exceeds 1 in in diameter. Only 1.9% of all thunderstorm events observed at the HMS have been severe storms (PNL-6415). All severe storms met the wind gust criteria, but hail was seldom observed at the HMS. The maximum recorded number of days with hail in a year is two.

Large differences in electrical potential between cloud and earth can occur during thunderstorms and can lead to lightning strikes. There is an average of 0.06 lightning strikes per year per square kilometer at the Hanford Site (WHC-SD-WM-ES-387).

14124 Extreme Winds and Tornadoes  Table 1-8 shows the maximum recorded peak gusts at the HMS for the period 1945 through 1994. The highest peak gust measured at the 15-m (50-ft) height was 80 mi/h in January 1972 (PNL-11794). Estimates of extreme winds, based on peak gusts observed from 1945 through 1980, are given in PNL-4622. The extreme peak gust at
50 ft for a return period of 100 years is estimated to be 86 mi/h. The return period on gusts of 114 km/h (70 mi/h) at 50 ft is 10 years.

Two probabilistic wind hazard assessments have been completed for the Hanford Site. The first assessment was completed by Lawrence Livermore National Laboratory and reported in UCRL-53526, *Natural Phenomena Hazards Modeling Project: Extreme Wind/Tornado Hazard Models for Department of Energy Sites*. This assessment was based on more than 30 years of pre-1979 Hanford Site wind data. The results are shown in Figure 1-12. The wind speeds are fastest mile and therefore, for an equivalent probability considerably lower than the peak gusts illustrated in Table 1-8. Further, the hazard curves are based on winds 30 ft above ground surface and the peak gusts in Table 1-8 were measured at 50 ft above ground surface. Wind speed increases with distance above the ground surface. A second study, NUREG/CR-4492, *Methodology for Estimating Extreme Winds for Probabilistic Risk Assessments*, describes a procedure for estimating extreme wind probabilities. The application of this methodology to Hanford Site data including post-1979 data resulted in hazard curves also shown in Figure 1-12.

Note: Information in this table is from PNL 11794 1998 *Climatological Data Summary 1997 with Historical Data*. Pacific Northwest National Laboratory, Richland, Washington.
The wind hazard annual probability of exceedance for performance categories 1 and 2 is $2 \times 10^{-2}$ (DOE-STD-1020-94). On Figure 1-12, this is about 55 mi/h on the UCRL-53526 curve and about 58 mi/h on the NUREG/CR-4492 curve. However, a minimum design 3-second gust wind speed of 85 mi/h, which is equivalent to 70 mi/h, is required by the American Society of Civil Engineers in ASCE-7-95, *Minimum Design Loads for Building and Other Structures*, and recommended by DOE-STD-1020-94. Therefore, the Hanford Site design basis wind speed for performance categories 1 and 2 is 85 mi/h, 3-second wind gust or 70 mi/h fastest mile. Wind speeds are at 30 ft off the ground. Note that maximum (approximately 3-second) gusts in Table 1-8 are at 50 ft above the ground surface. Windspeed increases as the distance from the ground increases.

The straight wind hazard exceedance probability for performance category 3 is $1 \times 10^{-3}$. On Figure 1-12, this is approximately 67 mi/h on the UCRL-53526 curve and 72 mi/h on the NUREG/CR-4492 curve. In DOE-STD-1020-94, the minimum straight wind speed for a performance category 3 design is 80 mi/h (equivalent to a 95 mi/h, 3-second gust) which is higher than either of the wind hazard studies and is, therefore, the design basis for the Hanford Site.

Hanford Standard Architectural-Civil Design Criteria (DOE-RL-HPS-SDC-41) establishes the wind load requirements for the existing K Basins structures. Nonreactor safety class 1 structures, systems, components, and equipment shall be designed for wind loads using the following criteria:

- **Fastest-mile speed**: 90 mi/h at a height of 33 ft
- **Importance factor**: 1
- **Exposure class**: C
- **Missile (horizontal)**: 2 x 4 in timber plank, 15 lb, at 50 mi/h maximum trajectory height of 50 ft

The intersection of the straight-wind and tornado hazard curves determines whether tornadoes should be included in the design and evaluation criteria for DOE facilities. (UCRL-53526) If the exceedance probability at the intersection is less than $2 \times 10^{-4}$, straight winds control the design criteria. In Figure 1-12, this intersection is less than $2 \times 10^{-5}$ for both curves. Therefore, following DOE guidance, the Hanford Site does not have a DOE design basis tornado and no tornado is required for the K Basins analyses.

The NRC tornado criteria were followed at the CVDF and CSB. This was achieved by following the same requirements as the Washington Public Power Supply System. The NRC staff have proposed dividing the United States into two regions and making the total rotational and translational wind speeds for sites west of the Rocky Mountains 200 mi/h (SECY-93-087). The basis for this consideration is a tornado hazard study, NUREG/CR-4461 *Tornado Climatology of the Contiguous United States*. The Washington Public Power Supply System requested a revision of the tornado criteria for WNP-2 (Parrish 1995) based upon the NRC staff's proposal for...
tornado wind speeds west of the Rocky Mountains and on the staff's acceptance of the design basis tornado characteristics in NUREG-1503, *Final Safety Evaluation Report Related to the Certification of the Advanced Boiling Water Reactor Design*. The impact velocities for the proposed tornado missile spectrum based on the reduced wind speed of 200 m/h were calculated by the Washington Public Power Supply System. The NRC accepted the proposed revision (Clifford 1996). These same criteria have been applied to the CVDF and CSB.

- **Wind speed**
  - 200 m/h total
  - 160 m/h rotational
  - 40 m/h translational

- **Pressure drop**
  - 0.90 lb/in² at 0.30 lb/in²/s

For the CVDF and CSB, the need for protection of specific targets is addressed on a risk assessment basis. By this process, an estimate is made of the probability that a tornado-generated missile will strike a particular target and fail the target in such a way that unacceptable consequences result. For facilities with relative small targets areas such as the CVDF, the risk assessment can simply investigate the probability that a missile strikes a target. If the probability obtained of a missile striking and failing a target, or simply striking the target, satisfies established acceptance criteria, then no physical barriers against missiles need be provided.

The use of probabilistic risk assessment techniques to establish the need to provide tornado-generated missile protection for specific targets has been accepted by the NRC for several years and is well documented in their review and design guidance. For example, the NRC Standard Review Plan (NUREG-0800) Section 3.5.15 "Site Proximity Missiles (Except Aircraft)" includes the following statement relative to low risk of exposure to the public:

This requirement is met if the probability of site proximity missiles impacting the plant and causing radiological consequences greater than 10 CFR Part 100 exposure guidelines is less than about 10⁻⁷ per year (see SRP Section 2.2.3).

The NRC Standard Review Plan (NUREG-0800) Section 2.2.3 "Evaluation of Potential Accidents" accepts 10⁶ events/yr for offsite hazards exceeding the guidelines in Title 10 *Code of Federal Regulations* Part 100 "Reactor Site Criteria" (10 CFR 100), if when accompanied by reasonable qualitative arguments, the realistic value can be shown to be lower. These provisions have remained in the 1996 draft revision to Standard Review Plan 2.2.3. For the CSB, an acceptance criterion to not exceed the 5 rem (50 mSv) limit of Title 10 *Code of Federal Regulations* Part 72 "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel and High-Level Radioactive Waste" Section 72.106 (10 CFR 72), at the controlled area boundary should be used.
The probability of a tornado occurring near the site and generating a missile that results in acceptable consequences can be expressed as follows

$$P_{TM} = P_s \times P_{ms} \times P_f \times P_D$$

where

- $P_{TM}$ = The annual probability of a tornado missile striking such that an unacceptable radiological or chemical release occurs
- $P_s$ = The tornado annual point strike frequency (events/yr)
- $P_{ms}$ = The probability of a tornado-generated missile impacting a specific target (this includes the probabilities of the missile existing on the site being lifted and striking the target of a given area)
- $P_f$ = The probability of target failure as a result of being struck by a missile (this considers that not all missiles that strike the target will be of sufficient energy to fail the target)
- $P_D$ = The probability, given the failure of the target by a missile, that unacceptable radiological or chemical release occurs (this considers that not all target failures will be of sufficient severity to result in unacceptable consequences)

The above expression is simplified in that the analyses are usually performed for a range of tornado intensities and potential missiles. The tornado intensities considered are based upon available local severe weather data. The missiles considered vary in terms of their density on the site, ability to be lifted by a tornado of a given intensity, and ability to damage the target. The missiles appropriate for consideration are often established by a site survey with a radius of about 2000 ft.

It should be noted in the above equation that the missile selection is based upon realistic selection of potential missiles based upon a site survey. The results of the tornado missile risk assessment for the CVDF are provided in *Probabilistic Risk Analysis Tornado Missile Hazard to Cold Vacuum Drying System and Hot Conditioning System* (Beary et al 1996). The analysis concluded that the tornado missile strike frequency to exposed CVDF critical area and equipment is well below the NRC frequency criterion of $10^{-7}$ per year for a realistic analysis.

The results of the tornado missile risk assessment for the CSB are provided in Letter FRF-2855 *Tornado Loading Design Criteria - Revised* (Jacobs 1996). This assessment has been accepted by DOE (Sellers 1996). The estimated frequency for a missile strike on the CSB is $4 \times 10^9$ events/yr, which is well below the NRC criterion of $1 \times 10^6$ events/yr. The ability of the CSB to withstand the tornado loadings is addressed in Section A4.3 in Annex A.
Dust and Blowing Dust  Dust and blowing dust are weather phenomena that occur with some frequency at the Hanford Site. Dust and blowing dust are recorded at the HMS when horizontal visibility is reduced to 6 mi or less. Dust is carried into the area from distant sources and may or may not occur during strong winds. Dust has been observed with wind speeds ranging from 4 mi/h to 30 mi/h. Blowing dust occurs with strong winds when dust is being picked up locally. While both dust and blowing dust occur at the HMS, blowing dust is the most commonly observed.

Table 1-9 shows the average number of days of recorded dust or blowing dust for the period 1945 through 1997. The average number of days per year with dust or blowing dust is five. The greatest number of such days in any year is 20, while the fewest is 0. The greatest number of days with dust or blowing dust in any month was nine in May 1980. Dust and blowing dust occur most frequently between March and May and again in September and occur least frequently during November and December.

14126 Fog and Sky Cover Table 1-10 shows the average monthly and annual number of days with fog and dense fog for the period 1945 through 1997. Fog is reported any time horizontal visibility is reduced to 6 mi or less because of suspension of water droplets in the surface layer of the atmosphere. Dense fog is reported when horizontal visibility is reduced to 0.25 mi or less. Most of the fog at the HIMS is radiation fog, a common type of fog that forms on nights characterized by light wind, clear sky, and moist air in the lower levels of the atmosphere. Nearly 90% of both fog and dense fog occur during the late autumn and winter months. The longest duration for fog on the Hanford Site was 114 hours in December 1985 and the longest duration for dense fog was 47 hours in December 1957.

Horizontal visibility is reduced to 6 mi or less.

*Horizontal visibility is reduced to 0.25 mi or less.
The term sky cover is used to express the portion of the celestial dome that is (1) covered but not necessarily hidden by clouds or obscuring phenomena aloft, (2) hidden by an obscuring phenomenon on the ground (e.g., fog, smoke), or (3) a combination of (1) and (2). Sky cover is then determined hourly by scanning the sky and estimating the number of tenths that are covered (zero denotes clear sky and ten denotes overcast). Each day can be assigned a designation depending upon the average sky cover from sunrise to sunset. The designations are clear (zero to three tenths), partly cloudy (four to seven tenths), and cloudy (eight to ten tenths). Table 1-11 shows the average monthly sunrise to sunset sky values from 1946 through 1997 and the number of days of clear, partly cloudy, and cloudy days for the years 1954 to 1997. During the period of record (1954 through 1997), an average of 199 sunny days (sum of clear and partly cloudy days) were recorded per year at the HMS.

Note: Information in this table is from PNL 11794, 1998 Climatological Data Summary 1997 with Historical Data, Pacific Northwest National Laboratory, Richland, Washington.
14127 Relative Humidity  The annual mean relative humidity recorded at the HMS is 54%, with the highest average monthly relative humidity (80%) occurring in December and the lowest average monthly relative humidity (33%) occurring in July. Daily relative humidity can change 20% to 30% between early morning and late afternoon, except for the winter months when changes are less pronounced (PNL-4622). Higher relative humidity can be expected at locations near the Columbia River and at some locations on the Site periphery where there is increased airborne water vapor from the Columbia River, Yakima River, and irrigated land.

14128 Dispersion Climatology  Atmospheric dispersion is a function of wind speed, duration and direction of wind, atmospheric stability, and mixing depth. Dispersion conditions are generally favorable if winds are moderate to strong, if the atmosphere is of neutral or unstable stratification, and if there is a deep mixing layer. These conditions exist more than half the time at the Hanford Site in the summer. A less favorable dispersion condition may occur when the wind speed is light and the mixing layer is shallow. This condition is most common in the winter when moderately to extremely stable stratification exists about two-thirds of the time (PNL-6415). Less favorable dispersion conditions also occur periodically for surface and low-level releases in all seasons from about sunset to about an hour after sunrise as a result of ground-based temperature inversions and shallow mixing layers.

Mixing layers at the HMS are estimated remotely using a Doppler acoustic sounder. Variations in the mixing layer are summarized in Table 1-12. The shallowest mixing layers are usually found in the nighttime during the winter months. Mixing layers are usually larger in the daytime during the summer months.

Low-level inversions can also be associated with stagnant air in stationary high-pressure systems that occur primarily in the winter months. The probability of extended periods of low-level inversions is estimated in BNWL-1605, Climatology of the Hanford Area. The probability of an inversion period extending more than 12 hours varies from a low of about 10%.
in May and June to a high of about 64% in September and October. These probabilities decrease rapidly for durations of greater than 12 hours. Table 1-13 summarizes the probabilities associated with extended surface-based inversions.

Note: Information in this table is from PNL 6415 1995 *Hanford Site National Environmental Policy Act (NEPA) Characterization Rev 7 Pacific Northwest Laboratory Richland Washington*

The joint frequency distribution of hourly averaged wind data from the 100 Area meteorological towers for the 9-year period January 1983 to December 1991 are provided in PNL-3777, *Recommended Environmental Dose Calculation Methods and Hanford-Specific Parameters*. The data are given for various wind speed classes and stability classes. Stability class was determined using the method based on Pasquill (1961) which is a parameterization scheme based on time of year, time of day, wind speed, cloud cover, and visibility. Cloud cover and visibility were measured at the HMS but should be representative of the 100 Area.

The percent frequency of occurrence of each of the stability classes for the 9-year period for the 100 Area 10 m tower is given in Table 1-14. Stability Class D, relatively neutral dispersion conditions occurred 28% of the time. Conditions favorable for turbulent dispersion represented by the unstable classes A, B, and C occurred about 23% of the time. The stable classes E, F, and G indicative of conditions unfavorable for turbulent dispersion occurred about 49% of the time.

To support the accident analyses in the facility FSAR Annexes, air transport factors (X/Q and X/Q') were calculated (HNF-SD-SNF-TI-059). These air transport factors represent the dilution of a contaminant by atmospheric turbulence and diffusion as the contaminant travels downwind. The symbol X/Q is the ratio of the average air concentration at the receptor to the average release rate at the release point. It is used to assess potential radiological dose and noncorrosive chemical concentration at downwind locations. The symbol X/Q' is the normalized...
peak air concentration at the center of a puff divided by the quantity released and is used to assess the consequences to a receptor for corrosive chemicals.

The locations of maximum exposure to the public and to onsite workers were determined by calculating the air transport factors for the 16 directional sectors at the distances representing the nearest location of the potential receptors. Consequences to collocated workers are assessed at 100 m from the facility and for K Basins and CVDF at the 100 Area Fire Station. For ground-level releases, the direction of maximum exposure for the 100 m location was found to be east of the facility. For elevated releases, the maximum exposure to the onsite receptor occurs at distances greater than 100 m. The location of the maximum onsite dose for elevated releases was determined by calculating the transport factors for various distances from 100 m to the Site boundary in all sectors.

Exposure to public receptors is assessed both at the current Site boundary and the near bank of the Columbia River. The location of maximum exposure at the current Site boundary was found to be 12.0 km west of the 100 K Area facilities for both ground-level and elevated releases. The location of maximum exposure at the river is 700 m west of the facility for ground-level releases, and 580 m northwest for releases of 0.5-hour to 2-hour duration.

The joint frequency distribution of hourly averaged wind data from the 200 East Area meteorological tower for the 9-year period January 1983 to December 1991 are provided in PNL-3777. Stability class was determined using the method based on Pasquill (1961), which is a parameterization scheme based on time of year, time of day, wind speed, cloud cover, and visibility. Cloud cover and visibility were measured at the HMS but should be representative of the 200 East Area. The percent frequency of occurrence of each of the stability classes for the 9-year period for the CSB is given in Table 1-1. Stability Class D, relatively neutral dispersion conditions, occurred 28% of the time. Conditions favorable for turbulent dispersion, represented...
by the unstable classes A, B, and C occurred about 23% of the time. The stable classes E, F, and G, indicative of conditions unfavorable for turbulent dispersion, occurred about 49% of the time.

Additional facility-specific meteorological information is provided in the facility FSAR Annexes.

14.2 Hydrology

The Hanford Site is located within the Columbia River drainage basin with the 100 K Area situated along the river and the 200 East Area located in the 200 Area plateau. The Columbia River is the principal hydrologic surface feature in the area. Other surface hydrologic features in the region include the Yakima River, Snake River, and the Walla Walla River. However, none of these other rivers have impact on the 100 K Area or the 200 East Area.

The Hanford Site is underlain by unconsolidated to semiconsolidated sediments of the Hanford and Ringold Formations. The Columbia River Basalt Group (CRBG) and associated sedimentary interbeds lie beneath the sediments. The geology of the Hanford Site is described in Section 14.3.3.

The vadose zone at the Hanford Site is comprised mainly of unconsolidated gravels and sands. Its thickness ranges from 0 ft at the river bank and West Lake to over 328 ft in the 200 Areas. The vadose zone at the K Basins and CVDF site is approximately 70 ft thick.

The saturated sediments of the Hanford and Ringold Formations make up a series of aquifers and aquitards. In general, sand- and gravel-dominated stratigraphic units form aquifers, and fine-grained deposits form aquitards. The shallowest suprabasalt aquifer is unconfined.
beneath most of the Hanford Site. Confined aquifers are present in the sedimentary interbeds and/or interflow zones between dense basalt flows of the CRBG. The main water-bearing portions of the interflow zones are networks of interconnecting vesicles and fractures of the flow tops and flow bottoms.

The remainder of this section describes the surface water features, vadose zone, and aquifers as they relate to the 100 K and 200 East Areas of the Hanford Site.

14.2.1 Surface Water

This section describes the surface water bodies and the river flooding potential at the CVDF and K Basins sites from the Columbia River and for the potential at the CSB site from the Columbia River, Yakima River, and Cold Creek. An overview of artificial surface water bodies in and near the 200 Areas is also presented.

14.2.1.1 Water Bodies and Flooding Potential at the Cold Vacuum Drying Facility and K Basins

West Lake

West Lake is the only natural lake on the Hanford Site (Figure 1-13).

Columbia River

The Columbia River flows through the Hanford Site and forms part of its eastern boundary (Figure 1-13). The section of the river flowing through the Site, known as the Hanford Reach, is free-flowing and extends from Priest Rapids Dam, upstream of the Site, to the 300 Area. Flow through the Hanford Reach fluctuates significantly and is controlled by Priest Rapids Dam. Discharge ranges from about 36,000 ft³/s to nearly 400,000 ft³/s. The average flow of the Columbia River near the Priest Rapids Dam is about 120,000 ft³/s. Currently, the minimum discharge at points along the river is regulated by law. Minimum allowable discharges above the Hanford Site are calculated to be sufficient to not impact the functioning of raw water intake structures which supply much of Hanford's process and potable water.

The Columbia River originates in the mountains of eastern British Columbia, Canada, and drains an area of approximately 27,300 mi² en route to the Pacific Ocean (Figure 1-14). Flow on the Columbia River is regulated by seven upstream dams within the United States and several in Canada. The three dams with the largest reservoirs upstream from the Hanford Site are the Mica Dam and Hugh Keenleyside Dam in Canada and the Grand Coulee Dam in the United States. The dam-controlled flow of the Columbia River results in a lower flood hazard for high-probability floods (e.g., 100-year flood), but dam-failure scenarios are significant contributors for very-low-probability floods. A flood scenario involving a 50% breach of Grand Coulee Dam results in a flood level of about 480 ft above mean sea level at the 100 K Area (RLO-76-4).

The design basis flood level for the K Basins is identified by HPS-SDC-4.1 Standard Architectural-Civil Design Criteria Design Loads for Facilities, for safety class 1 structures and components (SSCs) (performance class 3) at 100-K Area as 432 ft, and there are no flood requirements for safety class 2, or 3 SSCs (performance class 1 and 2). The 181-KE River Pump Station is located at an elevation of 421 ft mean sea level, the 105-K fuel storage basins are located at an elevation of 465 ft mean sea level and the support equipment located in the 165-KE, 183-KE, and 190-KE are at an elevation of 459 ft mean sea level or higher.
A probabilistic flood hazard assessment of the Columbia River was performed as part of a safety evaluation of the Hanford Site N Reactor and documented in UCRL-21069, *Probabilistic Flood Hazard Assessment of the Department of Energy N-Reactor Hanford, Washington*. The most extreme potential flood scenarios result from dam failure on the Columbia River. Specifically, failures of Grand Coulee Dam and Mica Dam pose the greatest threat. The results of the flood hazard assessment show that the greatest contribution to the likelihood of flooding is dam failure initiated by seismic events. Conservative estimates of the seismic capacity of upstream dams were made primarily on engineering judgment. Further, the likelihood of random dam failure was based primarily on engineering judgment and the historic frequency of dam failures. See UCRL-21069 for a detailed discussion of the hazard assessment.

The performance category 3 flood level (10^-4 annual probability of exceedance [UCRL-21069]) at the 100 K Area is approximately 450 ft above mean sea level (WHC-SD-SNF-DB-010). The Columbia River flood design for the WNP-2 is 424 ft above median sea level (NUREG-0892) which corresponds to a 25% breach of the Grand Coulee Dam. The elevation of this flood is about 460 ft above mean sea level at the 100 K Area. This is the flood level to be applied to performance category 3 aspects at the CVDF. As discussed earlier in this section, the design flood level for the K Basins is 432 ft above mean sea level.

Extreme flooding on the Columbia River can also occur during extreme meteorologic and hydrologic events. Historically, the largest floods have occurred when rapid snow melt was accompanied by spring rain. Such floods are controlled by the dam system and are predicted to be less severe than comparable pre-dam record floods.

**Yakima River** The Yakima River forms part of the southern boundary of the Hanford Site (Figure 1-13). The Yakima River and its tributary, Cold Creek, are not a flood hazard for the 100 K Area.

14212 Water Bodies and Flooding Potential at the Canister Storage Building Site
A flood scenario involving a 50% breach of Grand Coulee Dam (RLO-76-4) results in a flood level of about 470 ft above mean sea level at Columbia River kilometer mile 365 (Figure A1-1 in Annex A), the closest flood route to the 200 Plateau. This flood level is about 230 ft below the ground surface at the CSB. The CSB is a flood-dry site with respect to the Columbia River (ANSI/ANS-2 8-1992).

The performance category 3 flood level (10^-4 annual probability of exceedance [UCRL-21069]) at river mile 365, the closest flood route to the 200 Area Plateau and the CSB (Figure A1-4 in Annex A), is approximately 435 ft above mean sea level, which is lower than the 50% breach scenario (WHC-SD-SNF-DB-009). The 200 Areas are dry sites with respect to Columbia River flooding and such flooding need not be considered in design or accident scenarios.

**Yakima River** The Yakima River forms part of the southern boundary of the Hanford Site (Figure 1-13). The Yakima River is approximately 12 mi south and more than 200 ft below the 200 Areas. The Yakima River is not a flood hazard for the CSB site.

fsar01 sur 1-31 November 1999
Cold Creek, a tributary of the Yakima River, and its tributary, Dry Creek are ephemeral streams within the Yakima River drainage basin (Figure 1-15). The Cold Creek watershed located in the southwestern portion of the Hanford Site, extends about 10 mi up the Cold Creek and Dry Creek valleys. A flood risk analysis of Cold Creek was conducted in 1980 (RHO-BWI-C-120) to determine the probable maximum flood for the Cold Creek system (Figure 1-15). The recurrence interval is not estimated for this flood, however each occurrence would be a flash flood of short duration. The probable maximum flood reaches an elevation of about 640 ft on the southwestern portion of 200 West Area and is not a hazard for the CSB.

14213 Artificial Surface Water Bodies In the past, numerous artificial surface water bodies were present in the 200 Areas. Effluent disposal sites (e.g., cribs, ponds, ditches) allowed waste water to infiltrate the ground and, in many cases, to affect groundwater flow and chemistry. Today only B Pond and the Treated Effluent Disposal Facility, both located east of 200 East Area receive significant volumes of effluent.

1422 Vadose Zone The term "vadose zone" is used here to refer to unsaturated sediments between the water table and the ground surface. Flow of water through the vadose zone is a function of the moisture content, matric potential, and unsaturated hydraulic conductivity for each hydrostratigraphic unit. In general, water flows and spreads laterally at a much greater rate in fine-grained units than in coarse-grained units. Fine-grained units in the vadose zone significantly influence the lateral distribution of water and the flux of water to the uppermost aquifer. Coarse-grained units may impede the flux of water through the vadose zone because of the formation of a capillary pressure barrier between the coarse-grained units and overlying fine-grained units.

The vadose zone beneath the 100 K Area includes backfill in areas near the buildings or facilities, Holocene surficial deposits, the Hanford formation, and the uppermost part of the Ringold Formation (unit E). The vadose zone varies from being absent along the shore of the Columbia River to over 150 ft in the southeastern portion of the 100 K Area. At the CVDF the vadose zone is approximately 75 ft thick. Most of the vadose zone lies within the gravel-dominated, relatively permeable facies of the Hanford formation and the upper part of Ringold Formation unit E (predominantly a fluvial gravel).

The vadose zone in the 200 East Area is comprised of interlayered gravel, sand, silt, and "mud" (i.e., silt and clay). In some locations the basalt has been uplifted and composes part of the vadose zone. Thickness of the vadose zone in the 200 East Area ranges from 121 ft near B Pond to 341 ft near the southern border of the area (DOE/RL-93-88). Fine-grained units in the Hanford formation and the Ringold Lower Mud unit significantly influence the lateral distribution and flux of water in the 200 East Area.

The fine-grained sedimentary units in the 200 East Area may produce perched water conditions near active waste disposal facilities. Perched water results when a discontinuous impermeable layer in the vadose zone traps discontinuous water above the saturated zone. Perched water has been observed to the east of the 241-BY tank farm and above the Lower Mud near B Pond (Figure 1-13) and the Treated Effluent Disposal Facility.
Routson and Johnson (1990) estimated the magnitude of recharge from natural precipitation on the 200 Areas plateau. Two sources of data were used in their evaluation: (1) moisture accumulated for 13 years in an 60-ft-deep 200 East Area lysimeter, and (2) distribution of $^{137}$Cs in a 200 West Area solid-waste burial ground in which contaminated soil had been buried for 10 years. There had been no detectable moisture accumulation in the bottom of the lysimeter from 1972 to 1985. Thus, the recharge rate was approximately zero over the 13-year period. Cesium-137 contaminated soil was placed in a burial ground in 1970. After 10 years the distribution of $^{137}$Cs was determined from core-drilled samples. No $^{137}$Cs above background was detected beneath the bottom of the trench, indicating there was no measurable downward movement, however, $^{137}$Cs was detected above the trench, most likely from evapotranspiration.

Routson and Johnson (1990) conclude that there appears to be very little potential for downward movement of contaminants in the upper vadose zone beneath much of the 200 Areas plateau under natural or minimally disturbed conditions. Highly disturbed sites with little vegetation (e.g., the CSB site) may allow more movement of water through the vadose zone.

PNL-10285, *Estimated Recharge Rates at the Hanford Site* compiled estimates of natural recharge on the Hanford Site. Recharge through the vadose zone was 3.4 in/yr in a gravel-covered, unvegetated lysimeter constructed to mimic the surface conditions at the tank farms.

Site-specific variables must be considered to estimate time for water to travel through the vadose zone. Variables include the amount of moisture infiltrating, the grain size and stratigraphy of the sediments, the amount of moisture already in each sedimentary layer, and the hydraulic conductivity. WHC-SD-EN-TI-014, *Hydrogeologic Model for 200 West Groundwater Aggregate Area* contains calculated travel times in four examples for the 200 West Area with steady recharge rates of 0.2 and 2.0 in/yr. Calculated travel times range from 150 years to over 2,000 years. The methods applied in WHC-SD-EN-TI-014 are not valid for transient conditions (e.g., spills, pipe leaks).

1423 Aquifers Two major aquifer systems lie beneath the 100 K Area and the 200 Areas: the suprabasalt aquifer system and the basalt and interbed aquifer system (see Figure 1-16). Stratigraphy of the 100 K Area is discussed in greater detail in Section 143. See Section A143 of Annex A for the stratigraphy of the 200 East Area.

14231 Suprabasalt Aquifer System

100 K Area The suprabasalt aquifer (Figure 1-16) in the vicinity of the 100 K Area is within the Ringold Formation and includes a series of confining and water-producing zones (WHC-SD-ER-TI-003). The upper part of the aquifer is an unconfined zone of generally higher hydraulic conductivity within a predominantly gravel unit of the Ringold Formation. Below the gravel unit there are zones of lower hydraulic conductivity (fine-grained sediments) that alternate with layers of higher conductivity sand and gravel forming locally confined aquifers.
Water level data from wells in the unconfined zone of the upper aquifer system indicate that the water table is about 70 to 75 ft below the ground surface in the vicinity of the 105-KW and 105-KE Buildings and slopes gently toward the Columbia River. Throughout most of the year, when the Columbia River is in its lower stages, the water table slopes almost directly toward the Columbia River in a northwesterly direction. The level of the water table where groundwater enters the 100 K Area (southeast boundary near wells K-35 and K-36) is relatively constant at about 394.8 to 396.0 ft elevation (Figure 1-17).

When the Columbia River is in a sustained higher water level stage, groundwater flow in the immediate vicinity of the 100 K area is affected in three ways:

- The level of the water table near the river is raised
- The overall gradient of the water table within the 100 K Area decreases from approximately 0.005 to approximately 0.003
- The slope (line perpendicular to water table contours) of the water table is slightly more northerly than during lower stages of the Columbia River with a corresponding shift in flow direction to a slightly more northerly direction.

Additional suprabasalt groundwater information is presented in WHC-SD-EN-TI-280, *Groundwater Monitoring Results for the 100 K Area Fuel Storage Basins March to December 1994*.

**200 East Area**

The suprabasalt aquifer system under the 200 Areas occurs primarily within the sediments of the Hanford and Ringold Formations. These sediments contain interlayered coarse- and fine-grained units forming a series of aquifers and aquitards. The depth to the water table under the 200 East Area ranges from less than 131 ft near B Pond to approximately 341 ft west of the 200 East Area. The CSB site is at about 708 ft above mean sea level and the elevation of the bottom of the basemat is 659 ft above mean sea level. The water table at 413 ft above mean sea level is 246 ft below the CSB basemat.

The suprabasalt aquifer system in the 200 East Area includes the Ringold Formation and parts of the Hanford formation. Sandy gravels dominate the saturated Hanford formation and gravels dominate the Ringold Formation. Significant silt- and clay-dominated intervals are absent except in the southwestern part of the 200 East Area and east of B Pond where the Lower Mud sequence is found. The suprabasalt aquifer system ranges in thickness from zero where basalt is present above the water table to 197 ft in the south and west portions of the 200 East Area. At the CSB site, the suprabasalt aquifer is about 300 ft below surface and about 100 ft thick.

Horizontal hydraulic conductivity of units within the suprabasalt aquifer system varies considerably (Table 1-16). WHC-SD-EN-TI-019, *Hydrogeologic Model for the 200 East Groundwater Aggregate Area*, documents the compiled and mapped hydraulic conductivity data for the upper portion of the uppermost aquifer in the 200 West and 200 East Areas. The highest conductivity occurs in a channel stretching from northwest to southeast across the 200 East Area.

Groundwater flow beneath the 200 East Area is complex because of the convergence of flow from the west (natural groundwater flow system) and from the east (artificial recharge from B Pond and the Treated Effluent Disposal Facility) (Figure 1-12). The high transmissivity beneath most of the 200 East Area causes hydraulic gradients to be very small. It is often difficult to define groundwater flow directions from water table maps of the 200 East Area, but contaminant plume maps of the 200 Areas indicate long-term trends in groundwater flow directions (PNL-10698). These plume maps indicate a north to northwest direction of flow in the extreme north central portion of the 200 East Area and a south to southeast direction of flow in the southeast portion of the 200 East Area.

Groundwater in the suprabasalt aquifer system is contaminated with various hazardous and radioactive constituents from waste previously discharged to the ground in the 200 Areas. The most significant contaminants include nitrate, carbon tetrachloride, tritium, and 99Tc. Contaminant plume maps for 1994 are presented in PNL-10698 *Hanford Site Ground-Water Monitoring for 1994*.

1 4 2 3 2 Basalt and Interbed Aquifer System The CRBG and associated sedimentary interbeds form a series of aquifers and aquitards. Generally, the dense basalt flows form aquitards and interflow zones (fractured basalt) and the sedimentary interbeds form aquifers (Figure 1-16).
The uppermost regionally extensive confined aquifer beneath the 200 Areas, K Basins and CVDF site is the Rattlesnake Ridge interbed and adjacent interflow zones

The interbed is 49 to 82 ft thick beneath the 200 Areas and generally thickens toward the west (RHO-ST-42 RHO-RE-ST-12P) Recharge to the Rattlesnake Ridge interbed aquifer occurs in the higher elevations to the west, north, and northeast. The flow of groundwater is generally toward the northeast beneath the 200 West Area and west to west-northwest beneath the 200 East Area (WHC-SD-ER-TI-003)

Beneath the 200 Areas the Rattlesnake Ridge interbed aquifer is generally separated from the unconfined aquifer system by the Elephant Mountain Member of the CRBG The Elephant Mountain Member is up to 115 ft thick. North of the 200 East Area the Elephant Mountain Member has been locally removed by erosion, allowing hydraulic communication between the Rattlesnake Ridge interbed aquifer and the suprabasalt aquifer system. RHO-RE-ST-12P, An Assessment of Aquifer Intercommunication with B Pond — Gable Mountain Pond Area of the Hanford Site determined that contamination found in the Rattlesnake Ridge interbed aquifer resulted from intercommunication through erosional windows between it and the overlyng unconfined aquifer. Transmissivity of the Rattlesnake Ridge interbed and the Elephant Mountain interflow zone are included in Table 1-16.

1 4 3 Geology

The Hanford Site lies within the Pasco Basin and the Pasco Basin lies within the Columbia Plateau a broad plain constructed from the Miocene CRBG and situated between the Cascade Range to the west and the Rocky Mountains to the east (Figure 1-18) In the central and western parts of the Columbia Plateau where the Hanford Site is located, the basalt is underlain predominantly by Tertiary continental sedimentary rocks and overlain by late Tertiary and Quaternary fluvial and glaciofluvial deposits. All these deposits were folded and faulted during the Cenozoic to form the present landscape of the region.

1 4 3 1 Physiographic Setting of the Hanford Site The physiography of the Columbia Basin, a subprovince of the Columbia Plateau is controlled by the late Cenozoic faulting and folding of the CRBG and the overlying sediments of the Ringold Formation (Figure 1-19) Surface topography has been modified within the past several million years by geomorphic processes related to Pliocene cataclysmic flooding. Holocene eolian activity, landsliding, and the Columbia River. The physiography of the Hanford Site is dominated by the low-relief plains northeast of the Site and by anticlinal ridges of the Yakima Folds physiographic region (Figure 1-19).

Cataclysmic flooding of the Hanford Site occurred when ice dams in western Montana and northern Idaho were breached allowing large volumes of water to spill across eastern and central Washington. The last major flood occurred about 13,000 years ago, during the late Pleistocene Epoch. Anastomosing flood channels, giant current ripples, bergmounds, and giant flood bars are among the landforms created by the floods and are readily seen on the Hanford Site. Most of the...
large landslides in the region occurred when these flood waters eroded the steep slopes of the ridges. The 200 Areas are located on a major Pleistocene flood bar, the Cold Creek bar.

Since the end of the Pleistocene, winds have locally reworked the flood sediments, depositing dune sands in the lower elevations and loess (windblown silt) around the margins of the Pasco Basin. Generally sand dunes have been stabilized by anchoring vegetation except where they have been reactivated where vegetation is disturbed.

1.4.3.2 Stratigraphy

The stratigraphy of the Pacific Northwest is a collection of accreted terrane rocks added onto the North American craton between the Precambrian and early Cenozoic. The accreted terrane rocks are now mostly covered by extensive Cenozoic volcanic rocks. Intercalated with the volcanic rocks in structural basins and along the evolving continental margin are sedimentary rocks derived from eroding uplands areas.

The generalized stratigraphy of the Columbia Basin and Hanford Site is shown in Figure 1-20. The principal bedrock of the Hanford Site is the CRBG and intercalated and overlying sedimentary rocks of the Ellensburg Formation. The overlying sedimentary rocks are principally of the Ringold Formation and the Pleistocene catastrophic flood deposits of the Hanford formation (informal designation). This is the general stratigraphy present at the SNF Project facilities.

Rocks older than the CRBG are exposed primarily along the margins of the Columbia Basin and vary widely in age, lithology, and structure. It is this complex stratigraphy and structure that underlies the CRBG of the Columbia Basin and Hanford Site and that is the probable source for seismic hazards under the basalt. Because of the thick basalt cover, the exact nature of the stratigraphy and the types of the structure under the Hanford Site is uncertain.

Along the northern and northwestern margins of the Columbia Basin in early Tertiary time, a series of sedimentary basins formed in the accreted terranes of the North Cascades (DOE/RW-0164, Campbell 1989). These basins are now separated by tectonic "blocks" or uplifts that have a northeast- to northwest-trending structural grain and trend toward the Hanford Site. Along the northeastern and eastern margins of the Columbia Basin, the CRBG laps onto Paleozoic rocks and Precambrian miogeosynclinal and cratonic rocks that are interspersed with granites of the Idaho Batholith and other Jurassic and Cretaceous intrusions (DOE/RW-0164). To the south and southwest, lower- to middle-Tertiary volcanic rocks and related volcanioclastic rocks primarily of the Clarno and John Day Formations directly underlie the CRBG and overlie accreted terranes of the Blue Mountains. To the west, younger volcanic rocks that erupted from the High Cascades cover the CRBG and obscure early Cenozoic volcanic and volcanioclastic rocks of predominantly Eocene and Oligocene age.

1.4.3.2.1 Columbia River Basalt Group

The CRBG, the principal bedrock unit in the Yakima Fold Belt (YFB) and under the Hanford Site, is a sequence of tholeitic flood basalt flows that were erupted between 17 and 6 million years ago (Ma) (Figure 1-20). The CRBG now covers approximately 63,325 mi² and consists of 41,700 mi³ of basalt (Tolan et al. 1989). The
flows were erupted from north-northwest-trending fissures or linear vent systems in north-central and northeastern Oregon, eastern Washington, and western Idaho (Swanson et al. 1975).

The CRBG has been divided into five formations (Swanson et al. 1979), only the Grande Ronde Basalt, the Wanapum Basalt, and the Saddle Mountains Basalt are exposed on the Hanford Site. The Imnaha Basalt occurs at the base of the CRBG under the Hanford Site (Tolan et al. 1989).

The basalt flows of the CRBG are recognized using a combination of lithology, chemistry, and paleomagnetic data (Swanson et al. 1979). Chemical composition and paleomagnetic data have proven to be the most reliable criteria for flow recognition and correlation. Lithology is reliable for many flows primarily within the Wanapum and Saddle Mountains Basalts, but chemical compositions are still used to confirm identifications.

Over 85% of the CRBG was erupted during the 2-million-year span of the Grande Ronde Basalt eruptions. In the field, the Grande Ronde Basalt is divided into four magnetostratigraphic units, which, from oldest to youngest are Reversed 1 (R1), Normal 1 (N1), Reversed 2 (R2), and Normal 2 (N2) (Swanson et al. 1979). The Grande Ronde Basalt is further subdivided into seventeen groups of flows based on chemical compositions (Reidel et al. 1989a).

The younger basalt flows of the Wanapum and Saddle Mountains Basalts on the Hanford Site have been locally eroded to varying degrees. Uplift along anticlinal ridges has resulted in erosion to different depths along the margins of the Pasco Basin. Within the synclines where the basalt surface is covered by sediment fill, the upper basalt flows have been locally eroded by fluvial activity and proglacial flooding. North of the 200 Areas between Gable Mountain and Gable Butte, the Saddle Mountains Basalt has been eroded down to the oldest member, the Umatilla Member. The Elephant Mountain Member is suspected of being eroded near the northeast corner of 200 East Area.

14322 Intercalated and Post-Columbia River Basalt Group Sediments The Hanford Site and the SNF Project facilities are situated on a sequence of sedimentary units that overlie the CRBG. These sediments are confined largely to the synclinal valleys and basins of the western Columbia Basin. The sedimentary record is incomplete, but it is a direct reflection of the structural development of the area (Fecht et al. 1987). The upper-Miocene to middle-Pliocene (late Neogene) record of the Columbia River system in the Columbia Basin is represented by the upper Ellensburg Formation, Ringold Formation, and Snipes Mountain conglomerate. Except for local deposits (e.g., the Pliocene-Pleistocene unit and the early Palouse soil [DOE/RW-0164]), there is a hiatus (i.e., lack of sedimentation or erosion) in the stratigraphic record between the end of the Ringold (3.4 Ma) and the Pleistocene (1.6 Ma).

Pleistocene to Recent (Quaternary) sediments overlying the CVDF at the Hanford Site include cataclysmic flood gravels and slackwater sediments of the Hanford formation.
Late Neogene Sediments Two main late Neogene sedimentary units occur in the
Columbia Basin and at the Hanford Site, the Ellensburg Formation and the Ringold Formation
(Figure 1-20)

Ellensburg Formation The Ellensburg Formation includes epiclastic and volcanoclastic
sedimentary rocks that are intercalated with and overlie the CRBG (Waters 1961, 
Swanson et al. 1979) The Ellensburg stratigraphy of the Hanford Site has been discussed in
RHO-BWI-ST-14, Subsurface Geology of the Cold Creek Syncline, in Geological Society of 
America Special Paper 239, Volcanism and Tectonism in the Columbia River Flood-Basalt
Province (Reidel et al. 1989a), and in Bulletin 77, Selected Papers on the Geology of Washington
(Fecht et al. 1987) At the Hanford Site, the Ellensburg Formation is mixed with sediments
deposited by the ancestral Clearwater River and Columbia River

Ringold Formation Sediments continued to be deposited in most synclinal valleys of the
central Columbia Basin including the Hanford Site, long after the eruptions of the CRBG these
sediments are the Ringold Formation Although exposures of the Ringold Formation are limited
to the White Bluffs on the east side of the Hanford Site, isolated exposures on the west side of the
Hanford Site, and the Smyrna and Taunton Benches within the Othello Basin, extensive data on
the Ringold Formation have been obtained from boreholes at the Hanford Site

The Ringold Formation at the Hanford Site is up to 607 ft thick in the deepest part of the
Cold Creek syncline south of the 200 West Area and 558 ft thick in the western Wahluke syncline
near the 100 B Area The Ringold Formation pinches out against the Gable Mountain,
Yakima Ridge Saddle Mountains, and Rattlesnake Mountain anticlines This formation is present
under the CSB site

The Ringold Formation consists of semi-indurated clay, silt, pedogenically altered sediment,
fine- to coarse-grained sand, and granule to cobble gravel Ringold strata typically are below the
water table and the textural variations of the strata influence groundwater flow The Ringold
Formation historically has been divided into a variety of units, facies types and cycles
(Newcomb 1958, RHO-BWI-ST-4 RHO-ST-23 SD-BWI-DP-039 and DOE/RW-0164)
However these terminologies have proven to be of limited use because they are too generalized
to account for significant local stratigraphic variation or because they were defined in detail for
relatively small areas and do not account for basinwide stratigraphic variation
(WHC-SA-0740-FP WHC-SD-EN-EE-004)

Recent studies of the Ringold Formation in the Hanford Area indicate it contains significant
stratigraphic variations (WHC-SA-0740-FP WHC-SD-EN-EE-004) that are best described on
the basis of sediment facies Sediment facies in the Ringold Formation are defined on the basis of
lithology, stratification, and pedogenic alteration

- The fluvial gravel facies consists of clast-supported granule to cobble gravels with a
sandy matrix and intercalated sands and muds Clast composition is variable but
typically includes basalt quartzite, porphyritic volcanics and greenstone Sands
generally are quartzo-feldspathic with less than 25% basalt content Bedforms have
low angle to planar stratification, massive bedding, wide shallow channels, and large-scale cross-bedding. The facies was deposited in a gravelly fluvial braidplain characterized by wide, shallow, shifting channels.

- The fluvial sand facies consists of quartz-feldspathic sands, cross-bedded and cross-laminated sands that are intercalated with lenticular silty sands, clays, and thin gravels. These sands usually contain less than 15% basaltic lithic fragments, and fining upwards sequences are common. Strata of this type were deposited in wide, shallow channels.

- The overbank facies consists of laminated to massive silt, silty fine-grained sand, and paleosols containing variable amounts of pedogenic calcium carbonate. Overbank deposits occur as thin lenticular interbeds in the gravels and sands and as thick laterally continuous sequences. These sediments record deposition in proximal levee to more distal floodplain conditions.

- The lacustrine facies is characterized by plane laminated to massive clay with thin silt and silty sand interbeds displaying some soft-sediment deformation. Deposits coarsen upwards. Strata were deposited in a lake under standing water to deltaic conditions.

- The alluvial fan facies is characterized by massive to crudely stratified, weathered to unweathered basaltic detritus. These deposits generally are found around the periphery of the Pasco Basin and record deposition by debris flows in alluvial fan settings and in sidestreams draining into the Pasco Basin.

The lower half of the Ringold Formation is the main unconfined aquifer under the Hanford Site and contains five separate stratigraphic intervals dominated by the fluvial gravels facies. These gravels, designated units A, B, C, D, and E (Figure 1-21), are separated by intervals containing deposits typical of the overbank and lacustrine facies (WHC-SD-EN-EE-004). The lowermost of the fine-grained sequences overlying unit A is designated the Lower Mud sequence. The uppermost gravel unit, unit E, grades upwards into interbedded fluvial sand and overbank deposits that are in turn overlain by lacustrine-dominated strata. Fluvial gravel units A and E correspond to the lower basal and middle Ringold units respectively as defined in DOE/RW-0164, Site Characterization Plan Reference Repository Location Hanford Site Washington. Gravel units B, C, and D do not correlate to any previously defined units (WHC-SD-EN-EE-004). The Lower Mud sequence corresponds to the upper basal unit and lower unit as defined by DOE/RW-0164.

The upper part of the Ringold Formation consists of the sequence of fluvial sands, overbank deposits, and lacustrine sediments overlying unit E. These sediments correspond to the upper unit as originally defined in "Ringold Formation of the Pleistocene Age in the Type Locality, The White Bluffs, Washington," (Newcomb 1958) along the White Bluffs in the eastern Pasco Basin. The fluvial sand facies is the principal facies of the upper part under the CSB.
The CRBG lies approximately 527 ft beneath the 100 K Area. Overlying the CRBG is the Ringold Formation.

The Ringold Formation is about 493 ft thick and consists of the fluvial gravels and sands of units A, B, C, and E, lacustrine and fluvial overbank deposits, and palesols (WHC-SD-EN-TI-011) (Figure 1-21). Unit A, the lowermost unit, is approximately 23 ft thick and consists of fluvial gravel facies grading upward into sand associations. Overlying unit A is the Lower Mud unit. The Lower Mud unit is approximately 105 ft thick. Unit B is approximately 92 ft thick and consists predominantly of sand. Overlying unit B is a 209-ft-thick sequence of muds and sandy muds, typically displaying characteristics of palesols and fluvial overbank deposits. The sequence has three parts: an upper and a lower part that are predominantly silt to sandy silt, and a middle section of gravelly sand. The uppermost unit of the Ringold Formation at the 100 K Area is the coarse-grained unit E, which is predominantly composed of the fluvial gravel and fluvial sand facies. The unconfined portion of the uppermost aquifer system occurs in this unit at the 100 K Area. The known thickness of unit E ranges from 64 to 141 ft.

The Hanford formation at the 100 K Area is a wedge that decreases in thickness toward the Columbia River. It is approximately 120 to 130 ft thick. The Hanford formation pinches out from southeast to northwest across the 100 K Area. The gravel-dominated facies predominates in the Hanford formation throughout the 100 K Area. Boulder gravel is often found in the upper 20 to 50 ft. The sand-dominated facies occurs locally in a few intervals, but it is not thick enough or extensive enough to correlate from borehole to borehole (Figure 1-22). The silt-dominated facies has not been identified in the 100 K Area.

Holocene deposits in the study area are dominated by Columbia River deposits and eolian deposits. Columbia River deposits consist of gravels and coarse-grained sands deposited in channels and silts and fine sands deposited in overbank area. Eolian deposits consist dominantly of less than 3 ft of silty, fine-grained sands that blanket much of the area except in locations where they were removed for construction purposes. In many locations, eolian deposits are only a thin blanket (<1 ft).

The 100 K Area is geologically different than surrounding areas (100 B, 100 C, and 100 N Areas) because the Ringold Formation is exposed, not only along the banks of the Columbia River, but also from the river to 1200 ft or more away from the river to the southeast.

Quaternary Stratigraphy of the Pasco Basin. Quaternary sediments as much as 328 ft thick within the Pasco Basin overlie the Ringold Formation. The most extensive of these is the Pleistocene-aged Hanford formation, which is about 50 ft thick at the K Basins and CVDF (Figure 1-21). Locally the Hanford formation and underlying Ringold Formation are separated by several laterally discontinuous and informally defined units. These units are the Plio-Pleistocene unit, the pre-Missoula gravels, and the early Palouse soil (Figure 1-21) but they are absent at the SNF Project facilities.

Quaternary Alluvium. Fluvial deposits from major rivers (Yakima, Snake, Columbia) are represented in the Pasco Basin ranging in age from Tertiary to present (Baker et al 1991). There
are two main alluvial units that are recognized at the Hanford Site: the Plio-Pleistocene unit and the pre-Missoula gravels. Neither of these units is present at the K Basins and CVDF. See Section A1 4.3 in Annex A for discussions related to the CSB.

Overlying the tilted and truncated Ringold Formation in an unconformable relationship in the western Cold Creek syncline in the vicinity of 200 West Area is the laterally discontinuous Plio-Pleistocene unit (DOE/RW-0164). The Plio-Pleistocene unit appears to be correlative to other sidestream alluvial and pedogenic deposits found near the base of the ridges bounding the Pasco Basin on the north, west, and south. These sidestream alluvial and pedogenic deposits are inferred to have a late Pliocene to early Pleistocene age on the basis of stratigraphic position and the magnetic polarity of interfingering loess units.

In the central Pasco Basin, mainstream alluvium lies stratigraphically between the Ringold Formation and the Hanford formation. A thick sheet of well-rounded and well-sorted quartzose to gneissic clast-supported pebble to cobble gravel with a quartzo-feldspathic sand matrix gravel, informally called the "pre-Missoula gravels," overlies the Ringold Formation in much of the central Pasco Basin. Based on magnetic polarity and stratigraphic position, this unit is interpreted to be early Pleistocene. Mainstream alluvium of probable early Pleistocene age is exposed along Cold Creek and the Yakima Bluffs. It is unclear whether the pre-Missoula gravels overlie or interfinger with the early Palouse soil and Plio-Pleistocene unit. The pre-Missoula gravels are interpreted as mainstream deposits in the Columbia River.

**Eolian Deposits.** Loess deposits at Hanford contain a detailed Quaternary record. Five units are represented within the Pasco Basin (WHC-MR-0391). These units are informally referred to as L1 through L5 and differentiated on the basis of position relative to other stratigraphic units, color, soil development, and paleomagnetic polarity.

The main eolian unit in the subsurface at the Hanford Site is referred to as the early Palouse soil. The early Palouse soil consists of up to 66 ft of massive, brown-yellow, compact loess-like silt and minor fine-grained sand (RHO-ST-23, DOE/RW-0164). Granule-sized grains consisting primarily of basalt are common in this unit. These deposits overlie the Plio-Pleistocene unit (Figure 1-21) in the western Cold Creek syncline around the 200 West Area but are absent in the 200 East Area. The unit is differentiated from overlying graded rhythmites (Hanford formation) by greater calcium carbonate content, massive structure, and high natural gamma response in geophysical logs (DOE/RW-0164). The upper contact of the unit is poorly defined and it may grade up-section into silty strata commonly found in the lower part of the Hanford formation. Because of a predominantly reversed polarity, the unit is inferred to be early Pleistocene in age.

**Hanford Formation.** The Hanford formation is the informal name given to all cataclysmic flood deposits of the Pleistocene. This is the main stratigraphic unit at the surface of the SNF Project facilities. The Hanford formation is thickest in the vicinity of 200 West and 200 East Areas where it is up to 200 ft thick. Hanford deposits are absent on ridges above approximately 1250 ft above sea level, the highest level of cataclysmic flooding in the Pasco Basin (RHO-BW-SA-563A).
The Hanford formation consists of pebble to boulder gravel, fine- to coarse-grained sand and silt. These deposits are divided into three facies: gravel-dominated, sand-dominated, and silty. These facies are referred to as coarse-grained deposits, plane-laminated sand facies, and rhythmite facies, respectively, in RHO-BW-SA-563A, *Quaternary Geology of the Pasco Basin, Washington*. The rhythmite facies are also referred to as the "Touchet Beds." The Hanford formation is thickest in the vicinity of 200 West and 200 East Areas, where it is up to 200 ft thick. Hanford deposits are absent on ridges above approximately 1,250 ft above sea level, the highest level of catastrophic flooding in the Pasco Basin (RHO-BW-SA-563A).

- The gravel-dominated facies generally consists of coarse-grained basaltic sand and granule to boulder gravel. These deposits display massive bedding, plane to low-angle bedding, and large-scale planar cross-bedding in outcrop. The gravel facies dominates the Hanford formation in the 100 Areas north of Gable Mountain. The gravel-dominated facies was deposited by high-energy flood waters in or immediately adjacent to the main catastrophic flood channelways.

- The sand-dominated facies consists of fine- to coarse-grained sand and granule gravel displaying plane lamination and bedding and less commonly plane bedding and channel-fill sequences in outcrop. This facies is most common in the central Cold Creek syncline and in the central to southern parts of the 200 East and 200 West Areas. The laminated sand facies was deposited adjacent to main flood channelways during the waning stages of flooding. The facies is transitional between the gravel-dominated facies and the rhythmite facies.

- The silty facies consists of thinly bedded, plane laminated, and ripple cross-laminated silt and fine- to coarse-grained sand that commonly displays normally graded rhythms a few centimeters to several tens of centimeters thick (RHO-BWI-ST-4 DOE/RW-0164). This facies is found throughout the central, southern, and western Cold Creek syncline within and south of the 200 East and West Areas. These sediments were deposited under slackwater conditions and in back-flooded areas (DOE/RW-0164).

**Volcanic Ash Deposits** Volcanism in the Cascade Range has been active throughout the Pleistocene Epoch (approximately 2 million years before present to 10,000 years before present) and the Holocene Epoch (10,000 years before present to present). The eruption history of the Holocene best characterizes the most likely types of activity in the next 100 years. Many of the volcanoes in the Cascade Range have been active in the last 10,000 years, including Mount Mazama (Crater Lake) and Mount Hood in Oregon and Mount St. Helens, Mount Adams, and Mount Rainier in Washington State. Quaternary sediments recorded these eruptions in the form of ash deposits that are interlayered with the sediments.

The Hanford Site is approximately 95 mi from Mount Adams, 110 mi from Mount Rainier, and 125 mi from Mount St. Helens, the three closest active volcanoes. At these distances, the tephra (ash) is the only volcanic product to reach the Site and, thus, the only volcanic hazard at the Hanford Site (Figure 1-23). Mount St. Helens has been considerably more active throughout...
the Holocene than Mount Rainier or Mount Adams, which is the least active of the three. Less
than 0.4 in of ash was deposited on parts of the Hanford Site during the 1980 Mount St Helens
eruption.

1433 History of Cataclysmic Flooding in the Pasco Basin Cataclysmic floods inundated the
Pasco Basin several times during the Pleistocene when ice dams failed in northern Washington.
Net erosion by these floods was minimal and probably associated with only the earliest floods,
later floods only partially incised into older flood deposits before backfilling. During the three
major flood episodes there were probably numerous individual flood events. Deciphering the
history of cataclysmic flooding in the Pasco Basin is complicated, not only by floods from multiple
sources but also because the paths of Missoula floodwaters migrated and changed course with
the advance and retreat of the Cordilleran Ice Sheet. The best preserved record is that of the last
Missoula flood, which apparently came down the Columbia River. The uppermost 50 ft of
sediments at the 100 K Area are flood deposits.

1434 Geologic Structures of the Columbia Basin and Hanford Site The geologic structure
of the Pacific Northwest is controlled by a basement rock assemblage of accreted terranes fused
onto the structurally complex North American craton from the early Mesozoic to early Cenozoic.
The accreted terranes form the backbone of the Cascade Range, Okanogan Highlands, and the
Blue Mountains. The terranes are now mostly covered by extensive cover of Cenozoic rocks that
were folded and faulted in a north-south oriented compressive regime. North-south compression
is continuing today east of the Cascades portion of the Pacific Northwest and this pattern of
Cenozoic deformation is expected to continue into the future.

The Columbia Basin is a structurally and topographically low area surrounded by mountains
ranging in age from the late Mesozoic to Recent (May 5-18). The Columbia Basin has two
major structural subdivisions or subprovinces: the YFB and the Palouse Slope (Figure 1-18).
The YFB is a series of anticlinal ridges and synclinal valleys in the western and central parts of
the Columbia Basin. The Palouse Slope forms the eastern part of the Columbia Basin and is mainly
a westward-tilting paleoslope. The Hanford Site and the CVDF are in the eastern part of the YFB.
The western boundary of the Palouse Slope is at the eastern boundary of the Hanford Site.

The Blue Mountains subprovince of the Columbia River flood-basalt province is a
northeast-trending anticlinorium that extends 155 mi from the Oregon Cascades to Idaho and
forms the southern border of the Columbia Basin and the southern part of the Columbia Plateau.

14341 Major Structural Features of the Columbia Basin The main structural
features of the Columbia Basin are the YFB and two major cross-cutting structures: the Olympic
Wallowa lineament (OWL) and the Hog Ranch-Naneum Ridge anticline (HR-NR). The OWL
passes along the southern boundary of Hanford and the HR-NR anticline forms the western
structural boundary of the Pasco Basin and Hanford Site.

The Olympic-Wallowa Lineament The OWL (Figure 1-24) is a major topographic
feature in Washington and Oregon that crosscuts the Columbia Basin and forms the southern
boundary of the Hanford Site. This alignment of structural features parallels prebasalt structural
trends along the northwest margin of the Columbia Basin, but it has not been linked to any individual structure (Campbell 1989; Reidel and Campbell 1989).

Northwest of the CRBG margin, numerous northwest- and north-trending faults and shear zones of the Strait Creek fault system lie subparallel to the OWL. The Snoqualmie batholith intrudes these faults but is not cut by them, indicating that any possible movement along the OWL at the western margin of the Columbia Basin must be older than the batholith, 17 to 19.7 Ma (DOE/RW-0164).

The structural significance of the OWL has been called into question by two recent geophysical studies. Neither a seismic profiling survey (Jarchow 1991) nor a gravity survey (Saltus 1993) could find any obvious geophysical signature for the OWL below the CRBG.

**Hog Ranch-Naneum Ridge Anticline** The NR-HR anticline is the western structural boundary of the Pasco Basin, the basin containing the Hanford Site (Figure 1-24). The HR-NR anticline is a broad south-trending anticline in the CRBG that crosses the YFB in a north-south direction. This south-plunging structure passes through five Yakima folds and the OWL. The HR-NR anticline was active in late to middle Miocene as demonstrated by thinning of basalt flows across it (Reidel et al. 1989b), but the east-trending Yakima folds show no apparent offset by the cross structure (Campbell 1989; Keinle et al. 1977; Reidel et al. 1989b), nor is the HR-NR anticline offset where the OWL-Cle Elum-Wallula deformed zone (CLEW) crosses it. Growth of the HR-NR anticline continued from the Miocene to Recent and is now marked by the highest structural points along the ridges that cross it.

**The Yakima Fold Belt** The YFB subprovince covers about 5,400 mi² of the western Columbia Basin (Figures 1-19 and 1-24) and formed as basalt flows and intercalated sediments were folded and faulted under north-south directed compression. The reader is referred to Tables 1-17 and 1-18 and to the compilation of structural features for the Columbia Basin by Tolan and Reidel (1989). The Hanford Site lies in the Pasco Basin, which is one of the larger structural basins near the eastern limit of the YFB. The YFB gives the Hanford Site its principal physiographic features and has been the primary factor influencing the geohydrologic conditions at the Hanford Site.

The YFB consists of asymmetrical anticlinal ridges and synclinal valleys. The anticlines are typically segmented and usually have a north vergence, although some folds have a south vergence. Synclines are typically asymmetrical with a gently dipping north limb and a steeply dipping south limb. Fold length is variable ranging from several miles to over 62 mi; fold wavelengths range from several miles to as much as 12 mi. Structural relief is typically about 2,000 ft but varies along the length of the fold. The greatest structural relief along the Frenchman Hills, the Saddle Mountains, Umtanum Ridge, and Yakima Ridge occurs where these folds intersect the north-south trending HR-NR anticline (Reidel et al. 1989b).

RAW = Rattlesnake Mountain to Wallula Gap

fsar01 sar 1-48 November 1999
In general, the axial trends produce a "fanning" pattern across the fold belt (Figure 1-24). Anticlines on the western side of the fold belt generally have a N 50° E trend (Open File Report 79-1363). Anticlines in the central part of the fold belt have east-west trends except along the OWL where a N 50° W trend predominates.

Within the Hanford Site and surrounding area, the geometry of the anticlines typically consists of steeply dipping to overturned north flanks and gently dipping (< 5°) south flanks. Exceptions, however, include the doubly plunging anticlines within the Rattlesnake-Wallula alignment of the CLEW and the conjugate box-fold geometry of parts of the anticlines such as the Smyrna segment of the Saddle Mountains (Reidel 1984). The main variable in fold profiles is the width of the gently dipping limb. The widths of the gently dipping limbs vary from as little as 3 mi to as much as 22 mi.

Segmentation of the anticlines is common throughout the fold belt and is defined by abrupt changes in fold geometry or by places where regional folds die out and become a series of doubly plunging anticlines. Segment lengths are variable but average about 7 mi (ranging from 3 to 22 mi) near the Hanford Site, some of the larger segments contain subtler changes in geometry, such as different amplitudes, that could also be considered segment boundaries. Segment boundaries are often marked by cross or tear faults that trend N 20° W to north and display a principal component of strike-slip movement (e.g., Saddle Mountains [Reidel 1984]). Near Hanford these cross faults are confined to the anticlinal folds and usually occur only on the steeper limb, dying out onto the gentler limb.

Segment boundaries may also be marked by relatively undeformed areas along the fold trend where two fold segments plunge toward each other. For example, the Yakima River follows a segment boundary where it crosses the Rattlesnake-Wallula alignment at the southeast termination of Rattlesnake Mountain (Figure 1-24).

The steep limb of the asymmetrical anticlines is almost always faulted. Near the Hanford Site the steep limb is typically the northern flank, but elsewhere as at the Columbia Hills (Open File Report 79-1363) the south limb is faulted. Where exposed, these frontal fault zones have been found to be imbricated thrusts as, for example, at Rattlesnake Mountain, Umtanum Ridge near Priest Rapids Dam (Bentley in Open File Report 79-1363) the Horse Heaven Hills (RHO-BWI-SA-344 P) and the Saddle Mountains near Sentinel Gap (Reidel 1984).

Yakima folds have emergent thrust faults at the ground surface. The tops of the youngest lava flows at the earth's surface serve as a plane that becomes a low angle thrust fault, the structural attitude of the surface flow controls the angle of the emergent fault plane. This type of apparent structural control led many investigators to conclude that faults associated with the Yakima Folds are low-angle thrust faults with detachment surfaces either within the CRBG, in the sediments below the basalts or at the basalt-sediment contact. Where erosion provides deeper exposures into the cores of folds, the frontal faults are observed to be reverse faults (e.g., the Columbia water gap in the Frenchman hills, 45° south [Grolier and Bingham 1978], the Columbia Hills at Rock Creek, Washington, 50°-70° north [Open File Report 79-1363]).
Hydrocarbon exploration boreholes provide direct evidence for the dips of these frontal faults. Reidel et al. (1989b) have shown that the Saddle Mountains fault must dip more than 60° where the Shell-ARCO BN 1-9 borehole was drilled. Drilling of the Umtanum fault near Priest Rapids Dam (DOE/RW-0164) suggests that this fault dips southward under the ridge with a dip of at least 30° to 40° but perhaps as high as 60° (Price and Watkinson 1989).

Although it is difficult to assess, total shortening increases from east to west across the YFB. At about 120° longitude, it is estimated to be greater than 9 mi but less than 16 mi (Reidel et al. 1989b) or about 5% (Table 1-17). Typically, shortening on an individual anticline caused by folding is approximately 0.5 to 1.0 mi. The amount of shortening on faults expressed at the surface is generally unknown. Estimates range from several hundreds of meters to as much as 1.9 mi (Table 1-18).

14342 Structure of the Hanford Site. The Cold Creek syncline (Figure 1-25) lies between the Umtanum Ridge-Gable Mountain uplift and the Yakima Ridge uplift, and is an asymmetric and relatively flat-bottomed structure. The 200 Areas lie on the northern flank, and the bedrock dips gently (approximately 5°) to the south. The 300 Area lies at the eastern end of the Cold Creek syncline where it merges with the Pasco syncline.

The Wahluke syncline (Figure 1-25) is the principal structural unit that contains the 100 Areas and the CVDF. The Wahluke syncline is an asymmetric and relatively flat-bottomed structure similar to the Cold Creek syncline. The northern limb dips gently (approximately 5°) to the south. The steepest limb is adjacent to the Umtanum Ridge-Gable Mountain structure.

The Umtanum Ridge-Gable Mountain structural trend is a segmented anticlinal ridge extending for a length of 68 mi in an east-west direction. It passes north of the 200 and 300 Areas and south of the 100 Areas. From the west, the Umtanum Ridge plunges eastward and joins the Gable Mountain-Gable Butte segment just east of the western boundary of the Hanford Site. The easternmost segment, the Southeast anticline, trends southeast off the eastern boundary of the Gable Mountain-Gable Butte segment. Gable Mountain and Gable Butte are two topographically isolated anticlinal ridges that are composed of a series of northwest trending, doubly plunging, en echelon anticlines, synclines and associated faults.

The Yakima Ridge uplift extends from west of Yakima, Washington, to the center of the Pasco Basin, where it forms the southern boundary of the Cold Creek syncline south of 200 West Area (Figure 1-25). The easternmost surface expression of the Yakima Ridge uplift is represented by an anticline that plunges eastward into the Pasco Basin (Tolan and Reidel 1989). The eastern extension of Yakima Ridge is mostly buried beneath late Cenozoic sediments and has much less structural relief than the rest of Yakima Ridge.

The 200 and 300 Areas are situated on the south flank of the Umtanum-Gable Mountain anticline where the Miocene-aged basalt bedrock dips to the southwest into the Cold Creek syncline. The 100 Areas lie north of the Umtanum Ridge-Gable Mountain anticline in the Wahluke syncline. The deepest parts of the Cold Creek syncline the Wye Barricade depression...
and the Cold Creek depression are approximately 7.5 mi southeast of the 200 Areas and under the 200 West Area respectively.

1435 Geology of the 100 K Area The 100 K Area and vicinity is underlain by the CRBG and intercalated Ellensburg Formation, the Ringold Formation, the Hanford formation, and Holocene deposits. The 100 K Area is near the axis of the Wahluke syncline. See Section A1 4 3 in Annex A for discussion of 200 East Area geology that relates to the CSB.

1436 Tectonic Development of the Hanford Site A seismic hazards analysis of the Hanford Site (WHC-SD-W236A-T1-002) has shown that the geologic history of the Hanford Site from the Precambrian to the present and the resulting geologic structures significantly impact the hazards analysis. This section summarizes the principal geologic events in the development of the Site geology.

The present structure of the Columbia Basin is the product of north-south compression that began in the early Tertiary before the eruption of the CRBG and continues today. The Columbia Basin is composed of two fundamental subprovinces, the Palouse Slope and the YFB. The Palouse Slope is a stable, undeformed area overlying the old continental craton. The YFB overlies a large pre-basalt basin that has been subsiding since the early Tertiary. The pre-CRBG sedimentary basin and CRBG basin are divided by the HR-NR anticline. The edge of the old continental craton lies at the junction of the two structural subprovinces and is presently marked by the Ice Harbor dike swarm of the CRBG.

The pattern of deformation in the Columbia Basin has been dominated by north-south compression and subsidence. The YFB is the principal product of these. Deformation has controlled the location of the Columbia River system since the late Miocene as well as the depositional pattern of the post-basalt sediments. The rates of deformation in the Columbia Basin have declined since the early Tertiary. The rate of regional subsidence of the basin and the rate of local uplift on the anticlinal ridges have both declined. The present rate of ridge growth is estimated at 0.0016 in/yr and the rate of subsidence in the basin is estimated at 0.0001 in/yr.

Microseismicity, high in situ stress conditions, and the geometry of Quaternary-Holocene faulting indicate that the basin is still experiencing north-south compression. Although known late Cenozoic faults are found exclusively on the anticlinal ridges, earthquake focal mechanisms and strain measurements suggest that most stress release is occurring in the synclinal areas. No earthquake events have been shown to be related to known faults. The high in situ stress in the Cold Creek syncline explains the microseismicity in the region, but the absence of microseismicity associated with the anticlinal ridges may result from weakened fault zones lubricated with groundwater that have a component of a seismic or below-detection-limit seismic slip or the fault zones may be locked up.

14361 The Pre-Miocene Columbia Basin The beginning of the development of the Pacific Northwest can be traced to the late Precambrian rifting of the Proterozoic supercontinent when plates that were to become part of either Siberia or Australia separated from North America. The western edge of the North American craton in Washington was near the present...
119° longitude trending north-south in the vicinity of the present Ice Harbor Dam and near the eastern border of the Hanford Site. Between the initial rifting and early Mesozoic time, eastern Washington was a passive margin accumulating sediments along the coast through most of the Paleozoic and early Mesozoic.

When Pangea began to separate in the Triassic, the western coast of North America became an active continental margin with a subduction zone forming along the cratonic boundary. By the late Jurassic, microcontinents and exotic terranes that formed at great distances from North America began to be accreted onto the old craton, expanding the North American continent westward. Washington and the west coast of North America grew by accreting other terranes until at least the Eocene. Presently, these accreted terranes form the crystalline basement of the Hanford Site.

The process of subduction and accretion resulted in suturing of these exotic terranes by the intrusion of batholiths beginning in the Cretaceous and continuing into the Eocene. At the same time, most of eastern Washington was uplifted. Streams and rivers eroded these uplands and deposited the sediments along the edge of the continental shelf. The accretion also resulted in successive westward repositionings of the subduction zone until the present position was reached.

The Cenozoic saw the initiation of extensive volcanism throughout the Pacific Northwest along north-south trending volcanic arcs and in areas where extension occurred during the Eocene. In the Columbia Basin, the Eocene and early Oligocene saw rapid subsidence caused by extension accompanied by infilling of continental sediments and volcanic rocks.

Before the eruption of the CRBG in Miocene time, the Columbia Basin had two distinct parts. The eastern basin was underlain by ancient cratonic rocks that formed a stable gently dipping slope to the west. The western portion of the Columbia Basin was an area underlain by the accreted terranes of the Mesozoic which were overlain by continental volcanic rocks and continental sediments that accumulated in a rapidly subsiding basin during the early part of the Cenozoic. The Hanford Site is along the boundary of these two parts of the Columbia Basin. In "Crustal Structure of the Columbia Plateau – Evidence for Continental Rifting" (Catchings and Mooney 1988), Catchings and Mooney interpreted the basin underlying the western part as a failed rift based on seismic refraction survey. Other studies (RHO-BW-SA-289P, RHO-BW-SA-435P), however, question this interpretation. These studies did not find evidence for a rift basin in the deep crust or mantle.

Tertiary sedimentary and volcanioclastic rocks extend beyond the margin of the CRBG and form part of the Cascade Range (Reidel et al. 1994). In addition, there is no known fault zone along the western margin of the basin as suggested in the rift model. The pre-CRBG sediments that continue across the present Cascade Range were arched upward during intrusion and uplift of the Cascade Range beginning about 12 Ma to form the present western edge of the Columbia Basin. This supports the previously mentioned geophysical studies and suggests that the Columbia Basin is not a rift basin but perhaps simply a back-arc basin. The concept of a rift basin has a significant impact on the seismic hazards of the Site (WHC-SD-W236A-TI-002).
14362 Miocene Columbia Basin  Beginning about 17 Ma and continuing until about 6 Ma, flood-basalt flows of the CRBG began erupting from linear vent systems in eastern Washington, northeast Oregon, and western Idaho. The greatest volume (85%) of basalt was erupted between 16.5 and 15.5 Ma with waning eruptions until 6 Ma. The basalt eruptions were huge by comparison to eruptions today, individual flows contained as much as 1,200 m$^3$ of basalt (Reidel et al. 1989b). The average hiatus between eruptions was as long as 20,000 years.

Borehole, geophysical, and stratigraphic data (Catchings and Mooney 1988; Reidel et al. 1989b) indicate that the CRBG is thinner on the Palouse Slope than in the YFB. The CRBG ranges from 1,640 to 4,920 ft thick on the Palouse Slope but abruptly thickens to as much as 13,125 ft in the Pasco Basin area under the Hanford Site (Reidel et al. 1989b). Regional thickness patterns for both the CRBG and underlying Tertiary sediments indicate that the pre-CRBG basin where the Hanford Site is located began subsiding again. By far the most significant tectonic activity was continued subsidence in the basin. The subaerial nature of the CRBG indicates that subsidence continued as long as basalt was being erupted and that basalt accumulation kept pace with subsidence (Reidel et al. 1989a and 1989b). Subsidence rates from 17 to 15.6 Ma were approximately 0.4 in/yr initially and decreased to 0.001 in/yr in the late Miocene (Reidel et al. 1989b).

During the eruption of the CRBG, the anticlinal ridges were topographic highs against which the basalt flows thinned as they were emplaced (Reidel 1984; Reidel et al. 1989b). Detailed analysis of borehole and field data (Reidel 1984, Reidel et al. 1989b) established a quantitative relationship between flow thickness and fold growth rates. During the initial eruption of the CRBG (17 to 15.6 Ma), the ridges grew at about 0.01 in/yr, and the rate decreased to about 0.002 in/yr during the waning phases (15.6 to 10.5 Ma) (Reidel 1984, Reidel et al. 1989b).

By the end of the massive eruptions of the CRBG (8.5 Ma) most of the Columbia Basin was a shallow, bowl-shaped nearly featureless plain. The massive eruptions had buried most of the structural and topographic relief in the western part of the Columbia Basin, only the anticlinal ridges that were not buried by younger flows stood above the plain. Across this plain flowed the ancestral Columbia River and its main tributaries including the Salmon-Clearwater, Yakima, and Palouse Rivers.

14363 The Late-Miocene to Middle-Pliocene Columbia Basin  The post-CRBG tectonic history of the Columbia Basin and Hanford Site is recorded in the Yakima folds and post-CRBG sediments. Alluvial-lacustrine sediments deposited primarily by the Columbia River system show that the Yakima folds were growing and displacing river channels during the late Miocene and Pliocene (Fecht et al. 1987).

Progressive changes in the distribution of post-CRBG sedimentary facies provide one of the best records of the post-CRBG tectonic history of the Columbia Basin and Hanford Site. Ridge uplift and basin subsidence are recorded by progressive lateral shifts in these depositional environments over time (Fecht et al. 1987, Smith 1988, WHC-SD-EN-TI-008, Reidel et al. 1994).
During the waning phases of CRBG eruptions (12.5 to 8.5 Ma) the Columbia River flowed south across the YFB. Before approximately 8 Ma, the post-CRBG pre-Ringold channel of the Columbia River flowed across the western Pasco Basin, entering at Sentinel Gap and exiting near the southwestern side of Hanford, from there it flowed southwest toward Goldendale. About 8 Ma the Columbia River began to shift eastward onto the Hanford Site flowing south through Gable Gap and occupying a water gap over the eastern end of Rattlesnake Mountain near Benton City, Washington (Fecht et al. 1987). By middle Ringold time (approximately 6 Ma), the Columbia River shifted position again, exiting the Pasco Basin at Wallula Gap as it does now (Fecht et al. 1987).

About 3.4 Ma, regional uplift in western North America caused incision of the Columbia River system that resulted in the removal of over 328 ft of Ringold section across the Hanford Site. This regional incision and erosion produced the White Bluffs along the Columbia River on the eastern boundary of the Hanford Site.

14364 Quaternary Deformation in the Columbia Basin. Uplifted and faulted Ringold and coeval sediments flank most ridges in the central Columbia Basin (Reidel 1984, Reidel et al. 1989b). Deformed Pliocene-Pleistocene sediments also are found on many ridges. Younger glaciofluvial sediments of the Hanford formation locally record some of the youngest deformation in the Columbia Basin.

Evidence for continued growth of the YFB in the Quaternary is mainly restricted to the frontal fault zones. Although not common, evidence of young faulting or suspected young faulting has been found at many locations across the YFB (see Tables 1-19 and 1-20). Young faults have been described at Toppenish Ridge, at Union Gap in Ahtanum Ridge, on Gable Mountain along Umtanum Ridge, in the Columbia Hills anticline, and along the CLEW. Although age relationships are not fully understood, they suggest that faulting has continued since the last catastrophic flood (approximately 13,000 years before present).

1437 Contemporary Stress and Strain

14371 Seismicity. Seismic monitoring at Hanford began when the U.S. Geological Survey installed a small array of seismograph stations around the Hanford Site in the summer of 1969. In 1982 a closely spaced seismic network was installed at the Hanford Site to characterize the microseismicity on the Site for a possible high-level waste repository. This operated until 1988. In 1988 the number of stations in the network was reduced. Earthquakes of magnitudes 1.0 (Coda Amplitude Magnitude) and larger currently can be detected and located at the Hanford Site and earthquakes of magnitude 2.5 and larger are detected and located throughout most of eastern Washington.

Past seismic hazard studies at the Hanford Site have shown that earthquakes can be related to three crustal layers and five general sources (Tables 1-21 and 1-22). All layers and sources are monitored at the Site except the Cascadia Subduction Zone, which is monitored by the University of Washington.

**Vertical Patterns** There are three horizontal layers of seismicity (seismic stratigraphy) related to the stratigraphy of the Hanford Site and vicinity (Table 1-21) the CRBG the prebasalt sediments, and the crystalline basement. About 75% of the earthquakes have originated in the CRBG layer. The prebasalt sedimentary layer has had 8% of the events and the crystalline basement has had 17%.

**Shallow Earthquakes in the Basalt** The majority of the seismicity at the Hanford Site and the surrounding area comes from the basalt layer that extends from the surface to approximately 2.5 m under the Site.

**Earthquakes in Sedimentary Rock below the Basalt** The seismicity in the pre-CRBD sedimentary rock appears to be confined to the top 1.9 m. The seismicity of this sedimentary layer at the Hanford Site is relatively low when compared to the basalt layer but may be related to localized detachment zones related to the growth of the anticlinal structures.

**Earthquakes in the Crystalline Basement** Deep earthquakes below 6.2 m appear to be concentrated in the western and southwestern portions of the Hanford Site. The deepest earthquakes located below the Site are shallower than 18.6 m.
Using first-motion data from the Eastern Washington Regional Network and from the Basalt Waste Isolation Project, focal mechanisms show faulting that strikes between N 30° W and N 80° W. Although the strike is consistently west-northwest, the throw on the assumed faults varies. These data indicate reverse faults or strike-slip faults.

**Spatial Patterns** Past studies at the Hanford Site have concluded that there are five different tectonic environments (earthquake sources) where earthquakes can occur near the Hanford Site and in the Columbia Basin of eastern Washington (Table 1-22):

1. Reverse/thrust faults in the CRBG associated with major anticlinal ridges such as Rattlesnake Mountain, Yakima Ridge, and Umtanum Ridge

2. Secondary faults occurring on the major anticlinal ridges

3. Small geographic areas of unknown geologic structure that produce clusters of events (swarms) usually in the CRBG in synclinal valleys

4. Basement source structures, although earthquakes cannot be directly tied to a mapped fault because very little is known about geologic structures in the crystalline basement beneath the Hanford Site

5. The Cascadia Subduction Zone, which recently has been postulated to be capable of producing a magnitude 9 earthquake.

**Floating Earthquakes** A "floating" earthquake within the tectonic environment covering the entire Columbia Basin, including the Hanford Site, has been considered. A floating earthquake is one that, for seismic design purposes, can happen anywhere in a tectonic province and is not associated with any known geologic structure. It can be floated anywhere in the province.

**Earthquake Swarm Areas** The major source of earthquakes at the Hanford Site is swarm activity in the syncline of the YFB. There are three general areas of significant swarm activity: the Wooded Island swarm area, Coyote Rapids swarm area, and the Saddle Mountains swarm area (Figure 1-26).

The Wooded Island swarm area, located near the 300 Area, occurs at the eastern edge of the YFB where it abuts against the Palouse Slope. This boundary marks the suture zone between the old accreted terranes to the west and the stable Precambrian-Paleozoic craton to the east (Reidel et al. 1994). This zone is marked by an abrupt increase in the thickness of the basalt and subbasalt sediment over the accreted terranes and abrupt thinning of the basalt and sediment over the craton.

The Coyote Rapids Swarm Area is located at the horn of the Columbia between 100 K and 100 N areas. It occurs over no known geologic structure. The K Basins and CVDF are located in the southern portion of this swarm. The swarm lies at the intersection of two paleoslopes that make a northeast-southwest trough extending from Spokane, Washington, to the Columbia Gorge. This zone may be an old basement weakness zone, but there is no known reason for the
swarm to occur in its present position. The largest earthquake recorded on the Hanford Site has a magnitude of 3.8 and was a part of the Coyote Rapids Swarm Area.

The Saddle Mountains Swarm Area is located along the north side of the Saddle Mountains. The swarm area is located north of the Saddle Mountains fault zone in an area that has no mapped geologic structures. There is evidence for recent (post-13,000 years) faulting on the Saddle Mountain fault (Table 1-19), but there is no evidence for faults at the swarm. The cause of the earthquake swarm is not known at this time.

**Magnitude of Earthquakes** Earthquake activity at Hanford and in the Columbia Basin is summarized in Tables 1-23, 1-24, and 1-25. Since July 1982, approximately 650 earthquakes between magnitude 0 and 3.8 have been recorded on and around the Hanford Site. The pattern of earthquake activity between 1990 and 1995 is shown in Figure 1-27. The greatest seismic activity is in the low-magnitude range, with only 5 events exceeding a magnitude of 3.0. The largest magnitude earthquake on the Hanford Site was a 3.8 magnitude earthquake on October 25, 1971, in the Coyote Rapids Swarm Area (Figure 1-28) (Table 1-25). The largest recent, felt earthquake was a 3.3 magnitude earthquake on June 12, 1995, in the Wooded Island swarm area. The largest regional earthquake was the 5.7 Milton-Freewater earthquake on July 16, 1936 (Table 1-24). This earthquake occurred 62 mi southeast of the Hanford Site. The 1936 Milton-Freewater earthquake was estimated to have a peak acceleration of 0.03 g at the Hanford Site.

**14372 Contemporary Stress in the Cold Creek Syncline** Contemporary stress in the Cold Creek syncline is expressed principally as horizontal shortening and subsidence. Geodetic surveys (Open File Report 84-797) were performed across the Pasco Basin to determine rates of shortening. The data suggest north-south shortening. The rate of shortening is not statistically significant at the 95% confidence level, however, and the measurements are within the error limits of the recording instruments.

Contemporary stress measurements were performed at the Hanford Site as part of the Basalt Waste Isolation Project. Core disking and spalling in boreholes drilled in the Cold Creek syncline indicate relatively high in situ stress (DOE/RW-0164). Hydraulic fracturing tests were conducted in boreholes in the Cold Creek syncline at a depth of about 0.6 mi (DOE/RW-0164). The results also indicated high in situ stress. The maximum horizontal stress ranges from 7,630 to 9,780 lbf/in² and the minimum horizontal stress ranges from 4,400 to 5,180 lbf/in², with a mean horizontal to vertical ratio of 1.77 ± 0.20. The mean orientation of induced fractures and the direction of the maximum horizontal stress is consistent with north-south compression (DOE/RW-0164).

*Modified Mercalli Intensity

Latitude and longitude are used to define the location of historical earthquakes. Some times and coordinates have been modified from the original source times and coordinates to better reflect the possible error of these early earthquakes.

LT = local time
MB = body wave magnitude
ML = local magnitude
MS = surface wave magnitude

*Reflects the total period of recorded swarm activity and may include more than one swarm period

1437 Subsidence  Subsidence has been continuing in the Pasco Basin and Hanford Site since at least the Eocene. Estimates of subsidence since the middle Miocene (17 Ma) indicate the rates of subsidence have declined. From 17 to about 15.6 Ma, the rate of subsidence was about 0.3 to 0.4 m/yr. This decreased to about 0.01 m/yr from 15.6 to 14.5 Ma. The present rate of ridge growth is estimated at 0.0015 m/yr and the rate of subsidence in the basin is estimated at 0.0001 m/yr.

The pattern of subsidence in the Cold Creek syncline is shown in Figure 1-24. There are two broad areas of subsidence in the Cold Creek syncline: the Wye Barricade depression and the Cold Creek Depression. Both areas have had a long slow history of subsidence (Reidel et al. 1989b). Both areas are away from the 200 Areas and the CSB site.

1438 Geologic Hazards  The geologic hazards that affect the performance of the SNF Project facilities have been assessed based on the geologic data addressed in previous sections. These hazards are discussed below and where appropriate quantified for use in the structural evaluations and safety analyses. Geologic hazard assessments for the CVDF and the CSB are found in Section 1438 of the facility FSAR Annexes.
Seismic Hazard Assessment

A seismic hazard analysis has been completed for the Hanford Site (WHC-SD-W236A-TI-002). The Washington Public Power Supply System conducted previous seismic hazard analyses for WNP-1, WNP-4, and WNP-2, which also are located on the Hanford Site (Power et al. 1981). The study was later applied to the DOE-held areas within the Hanford Site by Woodward-Clyde Consultants (WHC-MR-0023). The following discussion is based on WHC-SD-W236A-TI-002 Proportional Seismic Hazard Analysis DOE Hanford Site Washington, the most recent seismic hazard analysis. It incorporates seismo-tectonic data and interpretations that postdate the Washington Public Power Supply System's earlier assessment and are discussed in previous sections of this report. The details of the source models and attenuation relationships used in the hazard assessment are included in WHC-SD-W236A-TI-002.

The potential seismic sources determined to be the major contributors to the seismic hazard in and around the Hanford Site are crustal sources and Cascadia Subduction Zone earthquakes in western Washington State. The crustal sources are:

- Fault sources related to the Yakima folds
- Shallow basalt sources that account for the observed seismicity within the CRBG and not associated with the anticlines
- Crystalline basement source

The site response characteristics of the soils underlying the Hanford Site are similar to those represented in the empirical strong motion database from California. This was determined by comparing the relative response of characteristic Hanford Site soil profiles and dynamic soil properties with those of California deep-soil strong-motion recording stations. Time histories representative of the events contributing to the Hanford Site hazard were used for ground motion input (WHC-SD-W236A-TI-002, Appendix A).

The mean seismic hazard curves for the 100 K Area are shown in Figures 1-29 and 1-30 and illustrate the contributions of individual folds to the hazard. The relative contribution of crustal and Cascadia Subduction sources at the 100 K Area is illustrated in Figure 1-31 and the relative contribution of the three crustal sources for the same location is shown in Figure 1-32.

The performance category 3 horizontal and vertical equal-hazard response spectra were developed for the CVDF site. These are shown at 5% damping for performance category 3 in Figure 1-33. These spectra are the enveloping spectra for the 200 Areas and the 100 K Area. More detail and additional damping values are presented in WHC-SD-W236A-TI-002. The design basis earthquake for the K Basin's safety-class structures is defined in HPS-SDC-4 as an event producing a maximum horizontal ground acceleration of 0.2 g simultaneously with a vertical ground acceleration of 0.13 g.

The remaining 100 K structures were designed and evaluated to Uniform Building Code criteria in effect at the time of their design.
14382 Volcanic Hazard Assessment  Two types of volcanic hazards have affected the Hanford Site in the past 20 million years

- Continental flood basalt volcanism that produced the CRBG, which underlies the Hanford Site, outcropping in the surrounding ridges

- Volcanism associated with the Cascade Range

Several volcanoes in the Cascade Range are currently considered active, but activity associated with flood basalt volcanism has ceased The flood basalt volcanism that produced the CRBG occurred between 17 million and 6 million years before present Most of the lava was extruded during the first 2 to 2.5 million years of the 11-million-year volcanic episode Flood basalt volcanism has not recurred during the last 6 million years, suggesting that the tectonic processes that created the episode have ceased The recurrence of Columbia River basin volcanism is not considered to be a credible volcanic hazard (DOERW-0164)

Volcanism in the Cascade Range has been active throughout the Pleistocene Epoch (approximately 2 million years before present to 10 000 years before present) and through the Holocene Epoch (10 000 years before present to present) The eruption history of the Holocene best characterizes the most likely types of activity in the next 100 years Many of the volcanoes in the Cascade Range have been active in the last 10 000 years including Mount Mazama (Crater Lake) and Mount Hood in Oregon and Mount St Helens, Mount Adams and Mount Rainier in Washington state (Figure 1-23) The Hanford Site is approximately 95 mi from Mount Adams 110 mi from Mount Rainier, and 125 mi from Mount St Helens the three closest active volcanoes At these distances the tephra (ash) is the only hazard Mount St Helens has been considerably more active throughout the Holocene than Mount Rainier or Mount Adams, which is the least active of the three Ashfall at the Hanford Site during the May 18 1980, eruption of Mount St Helens ranged from a trace in the southern part of the Site to about 0.5 in in the 100 Areas

Probabilistic volcanic hazard studies of the Cascade Range have been completed by the U.S. Geological Survey (Open File Report 87-297, Open File Report 95-492) Figure 1-23 illustrates the annual probability of exceeding 0.4 in of volcanic ash accumulation in Washington and Oregon following the eruption of a major Cascade Range volcano and the annual probability of exceeding 4 in of volcanic ash accumulation Figure 1-34 presents this information as a volcanic ash hazard curve for the Hanford Site The design basis ground ash load for safety class SSCs is the same as that for Energy Northwest's WNP-2, 24 lb/ft²

14383 Subsurface Stability  The SNF Project facilities are constructed on flood sediments the youngest sediments being approximately 13 000 years old There are no areas of potential surface or subsurface subsidence, uplift, or collapse except for the low geologic deformation discussed in Section 1436 With the exception of the loose, surficial wind-deposited silt, soils are competent and form good foundations Geotechnical studies have been completed in and around the 100 K Area (WHC-SD-NR-ER-093 Redpath 1994) The water table in the 100 K Area is approximately 75 ft below ground surface in the relatively
compact and moderately well cemented unit of the Rmgold Formation. See Section A1.4.3 in Annex A for the discussion of subsurface stability at the CSB

1.5 NATURAL PHENOMENA THREATS

See Sections 1.5 of the facility FSAR Annexes for a discussion of the natural phenomena design criteria used for their design.

1.6 EXTERNAL HUMAN-GENERATED THREATS

This section identifies and investigates potential human-generated threats to SNF Project operation. The main threats are aircraft crashes and transportation accidents. See Section 1.6 of the facility FSAR Annexes for facility-specific evaluations.

1.6.1 Aircraft Activity

Two airports serving commercial and military aircraft are located within 35 mi of the K Basins and CVDF site and within 30 mi of the CSB site. The closest is the Richland Airport 21 mi south-southeast of the CSB. This airport has two 4,000-ft runways, one with a 010°/190° orientation and the other with a 070°/250° orientation. Runway capability is about 30,000 lb per point of contact. Visual flight rule landings are standard Federal Aviation Administration non-control-tower patterns. Federal arrivals and instrument approaches and departures are shown on Figure 1-35. In March 1998 approximately 77 aircraft were based at the airport. The reported number of operations per year is 22,400. All operations are by general aviation aircraft (Santos 1998).

The Tri-Cities Airport in Pasco is 34 mi to the southeast of the K Basins and CVDF and 29 mi from the CSB. The Federal Aviation Administration operates the air traffic control tower and airport radar approval control facility. The airport has two 7,700-ft crossing runways with 120°/300° and 030°/210° orientations. The latter has a 4,430-ft parallel runway. Runway 30 has a very high-frequency omnirange instrument approach, and runway 21R has an instrument landing system and is an instrument approach runway. In March 1998 about 108 aircraft were based at the airport. Total operations are reported as 74,000 per year with 68% general aviation, 29% commercial aviation (air taxis, air carriers), and 3% military aircraft. Commercial carriers operate a total of about 26 flights (arrivals and departures) per day.

Both NUREG-0800, Standard Review Plan, and DOE-STD-3014-96 provide methodology to evaluate and assess the significance of aircraft crash risk on facility safety. For the SNF Project, the methodology in DOE-STD-3014-96 is more conservative than that in NUREG-0800 because NUREG-0800 includes the assumption that protection provided in nuclear power plant
design for tornado-generated missiles is adequate for protection against general aviation light aircraft crashes. This is not a valid assumption for the CSB and CVDF. Therefore, the methodology of DOE-STD-3014-96 is used to evaluate the potential for aircraft crash into the CSB.

DOE-STD-3014-96 provides methodology to conservatively evaluate and assess the significance of aircraft crash risk on facility safety. The CVDF and CSB meet the standard's guidelines for applicability because they contain enough radioactive material to be classified as a hazard category 2 facilities according to the criteria established in DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480 23 Nuclear Safety Analysis Reports*.

The approach used in DOE-STD-3014-96 includes methodology to evaluate the frequency of aircraft impact into the facility. If the frequency of aircraft impact, calculated according to the methodology given in the standard exceeds $10^{-6}$/yr, the analysis proceeds to a consideration of whether those aircraft that have a high impact frequency could actually do damage resulting in potential releases from the facility. Using that methodology, the frequency of aircraft impact into the CVDF and CSB has been assessed (Beary 1997b).

The methodology provided in DOE-STD-3014-96 considers two contributors to the overall frequency of aircraft crashes: (1) the frequency of crashes resulting from nearby airport activity (i.e., takeoffs and landings) and (2) the frequency of crashes during overflights of the facility. Only runways within about 24 mi of the facility are included on the crash location probability tables given in Appendix B of DOE-STD-3014-96. Activities on runways at greater distances are not considered potential contributors to the frequency of a crash at the facility location for any category of aircraft. For calculating the frequency of crashes from aircraft flying over the site, DOE-STD-3014-96 provides DOE site-specific frequency data, in crashes per square mile per year centered at the site for various classes of aircraft.

For both the nearby airports and the overflight activities, DOE-STD-3014-96 bases the calculation of frequency of aircraft crash into a facility on a "four factor formula" that considers:

1. The number of aircraft operations at nearby airports and overflying the site (N)
2. The probability that an aircraft will crash (P)
3. The conditional probability that, given a crash, the aircraft crashes into a one-square-mile area where the facility is located ($f(x\ y)$)
4. The site-specific effective area of the facility ($A_{\text{eff}}$)

The formula is applied individually to each category of aircraft for both the nearby airports and the overflight activities. The overall frequency of aircraft crash into the facility is the sum of the frequencies calculated for all categories of aircraft and for all operational modes.
To evaluate the frequency of crashes that impact the facility from overflight operations, Tables B-14 and B-15 of DOE-STD-3014-96 give generic values of NFf(x,y) in crashes per square mile per year centered at various DOE sites, including the Hanford Site for five categories of aircraft. The values are based on the historic record for aircraft crashes in the continental United States.

The site-specific values of NFf(x,y) for overflight operations given for the Hanford Site by aircraft category are as follows:

- General aviation: $1 \times 10^{-4}$ crashes/yr/mi²
- Air carrier: $1 \times 10^{-7}$ crashes/yr/mi²
- Air taxi: $1 \times 10^{-6}$ crashes/yr/mi²
- Large military: $1 \times 10^{-7}$ crashes/yr/mi²
- Small military: $4 \times 10^{-8}$ crashes/yr/mi²

For both the nearby airport and the overflight operations, the NFf(x,y) for each category of aircraft is multiplied by an effective area, $A_{eff}$, representing the ground surface area within which an unobstructed aircraft, were it to crash within the area, would impact the facility either by flying or skidding into the facility. The effective area depends not only on the length, width, and height of the facility, but also on the aircraft's wingspan, the flight path angle, the heading angle relative to the heading of the facility, and the length of the skid. Therefore, an effective area is calculated for each category of aircraft.

Formulas for calculating the effective area of the facility are given in Appendix B of DOE-STD-3014-96. The effective area has two terms: the effective fly-in area $A_f$ and the effective skid area $A_s$.

$$A_{eff} = A_f + A_s$$

and

$$A_f = (WS + R) H \cot \phi + \frac{2 LW WS}{R} + LW$$

$$A_s = (WS + R) S$$

where

- $WS$ = aircraft wingspan
- $R$ = length of the diagonal of the facility $(L^2 + W^2)^{0.5}$
- $H$ = facility height
\[ \cot \phi = \text{mean of the cotangent of the aircraft impact angle} \]

\[ L = \text{facility length} \]

\[ W = \text{facility width} \]

\[ S = \text{aircraft skid distance} \]

See Sections 1-6 of the facility FSAR Annexes for the results of the calculations for the SNF Project facilities.

An analysis of the risk from helicopter accidents to the CSB and the CVDF was performed. The analysis was based on results of studies documented in the safety analysis reports for other Hanford Site facilities, Savannah River Site facilities, and for the NRC-licensed WNP-2.

Table 1-26 summarizes the studies examined, the study results, and the inferences the results provide relative to the SNF Project's design adequacy for protection against helicopter crashes.

The studies examined showed a consistently low frequency of impact and of penetration probability following impact (the latter despite the use of different algorithms for the calculation). Some of the studies addressed only crash frequencies and some addressed only damage probabilities. Three of the studies addressed aircraft in general but not helicopters specifically.

The combined results of the seven studies examined indicate a very conservative estimate of the frequency of helicopter crashes at close to \( 1 \times 10^{-6} \) per year. Those studies that specifically addressed penetration of the protective barriers showed this capability to be completely negligible. Therefore, the risk to SNF Project facilities of safety from helicopter crashes is very low. It can be conservatively concluded that the helicopter crash frequency is less than \( 1 \times 10^{-7} \) per year.

### 1-6.2 Other Transportation Accidents

A rail spur that passes by the K Basins and CVDF. This spur has not seen recent use and will not be used in support of K Basins Path Forward activities. The switch that would route trains on the spur is normally locked in the position that would route trains away from the 100 K Area (WHC-SD-WM-SAR-062).

Accidents that might occur on State Highway 240, such as explosions or toxic chemical releases, are judged to present a negligible risk to the SNF Project facilities because of the distance between the facility and the highway. At its closest approach, the distance is about 6 mi from the K Basins and CVDF and 5 mi from the CSB. NRC Regulatory Guide 1.78, *Assumptions for Evaluating the Habitability of a Nuclear Power Plant Control Room During a Postulated Hazardous Chemical Release* provides useful guidance on evaluating chemicals stored or situated at distances greater than 5 mi from the facility. It states that they need not be considered...

because if a release occurs at such a distance, atmospheric dispersion will dilute and disperse the incoming plume to such a degree that there should be sufficient time for the operators to take appropriate action. In addition the probability of the plume remaining within a given sector for a long time is quite small. Because CSB is 5 mi from Highway 240 an evaluation was performed (see Section A 1 6 2 in Annex A).

NRC Regulatory Guide 1 78 also provides useful guidance for the evaluation of potential accidents involving hazardous chemicals that might be shipped past the SNF Project facilities on Route 4 North and the Hanford Site railroad. NRC Regulatory Guide 1 78 does not require control room habitability analysis for shipments less frequent than 10/yr for truck traffic, 30/yr for rail traffic or 50/yr for barge traffic. Neither the truck nor rail guidelines are exceeded for shipments of a quantity that could present a risk to the SNF Project facilities. Sections 3 3 of the facility FSAR Annexes address this hazard from the perspective of safety of workers and capability to maintain the facility in a safe state. Barge shipment on the Columbia River does not routinely occur above the Port of Benton barge facility as discussed in Section 1 3 1.

Regulatory Guide 1 91, Evaluations of Explosions Postulated to Occur on Transportation Routes Near Nuclear Power Plants, describes a method for determining distances from critical plant structures beyond which any explosion that might occur on a railway, highway, or navigable waterway is not likely to have an adverse effect on plant operation or to prevent safe shutdown. The method is based upon an NRC staff judgement that for structures of concern an acceptable overpressurization limit from such explosions can be conservatively chosen at 1 lb/in². Although not stated in the Regulatory Guide, it is assumed that the 1 lb/in² value was established for structures that are designed to withstand the severe natural phenomena loadings that are typical for safety-related structures of nuclear power plants.

1 7 NEARBY FACILITIES

See Sections 1 7 of the facility FSAR Annexes for discussions of facilities near the SNF Project facilities.

1 8 VALIDITY OF EXISTING ENVIRONMENTAL ANALYSES

No significant discrepancies have been identified between the site characteristic assumptions made in this chapter and those made in the SNF Project Environmental Impact Statement (DOE/EIS-0245F).

20 FACILITY DESCRIPTION

21 INTRODUCTION

This chapter provides an integrated overview description of the final hazard category 2 Spent Nuclear Fuel (SNF) Project facilities, processes, and operations. Facility-specific descriptions of the individual SNF Project facilities and processes are provided in the facility annexes (Annex A, Canister Storage Building [CSB], Annex B, Cold Vacuum Drying Facility [CVDF] and Annex D, 200 East Area Interim Storage Area [ISA]) to this SNF Project Final Safety Analysis Report (FSAR). Descriptions of the SNF Project-related facilities and processes at the K Basins are provided in WHC-SD-WM-SAR-062 K Basins Final Safety Analysis Report.

22 REQUIREMENTS

The requirements that form the basis for the design of SNF Project facilities are found in HNF-SD-SNF-RD-001, Spent Nuclear Fuel Project Standards/Requirements Identification Document. Specific requirements applicable to this chapter include the following:

- U.S. Department of Energy (DOE) Order 5400.1, General Environmental Protection Program
- DOE Order 5480.7A, ‘Fire Protection’
- DOE Order 5480.24, Nuclear Criticality Safety
- DOE Order 5480.28, Natural Phenomena Hazards Mitigation
- DOE Order 6430.1A, General Design Criteria
- ANSI/ACI 349-85, Code Requirements for Nuclear Safety Related Concrete Structures

November 1999
- ANSI/AISC N690-94 *Specification for the Design, Fabrication and Erection of Steel Safety-Related Structures for Nuclear Facilities*
- ANSI/ANS-57 1-1992 *Design Requirements for Light Water Reactor Fuel Handling System*
- ANSI/ANS-57 9-1992, *Design Criteria for an Independent Spent Fuel Storage Installation (Dry Type)*
- ANSI/ASME 30 17 *Overhead and Gantry Cranes (Top Running Bridge, Single Girder, Underhung Hoist)*
- ANSI/ASME B30 10, *Safety Standard for Hooks*
- ANSI/ASME B30 16, *Overhead Hoist (Underhung)*
- ANSI/ASME HST-1M, *Performance Standard for Overhead Electric Wire Chain Hoists*
- ASCE-7-93 *Minimum Design Loads for Building and Other Structures*
- ASME B30 20-1993 *Below-the-Hook Lifting Devices*
- ASME *Boiler and Pressure Vessel Code (ASME 1995)*
- ASTM C 1055 *Standard Guide for Heated System Surface Conditions that Produce Contact Burn Injuries*

Additional requirements that apply only to a specific facility are identified in the applicable facility FSAR Annex.
A requirement for new SNF Project facilities to achieve nuclear safety equivalency comparable to US Nuclear Regulatory Commission licensed facilities was established in 1995 (Sellers 1995) This requirement has been implemented for the CVDF and CSB Further discussion of these requirements is provided in Section 3.3 of this SNF Project FSAR

2.3 FACILITY OVERVIEW

The SNF Project is involved with consolidation and safe interim storage of the spent fuels that are located on the Hanford Site These fuels are treated as two groups The first is that group know as K Basins SNF This group requires retrieval from underwater storage, cleaning, packaging into storage containers, dewatering, inerting, and transport to the interim storage location. The second group is the SNF currently dry-stored in several locations on the Hanford Site This group will be transported to a common dry storage location in the 200 East Area

For the K Basins SNF WHC-SD-SNF-SP-005 Hanford Spent Nuclear Fuel Project Integrated Process Strategy established the technical framework for constructing facilities and implementing processes that are compatible with DOE goals. This process strategy has subsequently evolved to the current technical baseline based on implementation of the Baseline Change Request, SNF-98-006, Simplified SNF Project Baseline SNF-98-006 describes process and design approaches for moving SNF from the K Basins in water-filled multi-canister overpack (MCO) containers, vacuum drying the fuel at the CVDF, a new facility constructed near the K Basins, and moving the SNF in sealed MCOs to the CSB, a new dry interim storage facility located in the Hanford Site 200 East Area

2.3.1 K Basins Spent Nuclear Fuel

New systems, equipment, and facilities are being constructed and modifications are being made to the K Basins to support the removal of the K Basin spent fuel sludge, and debris. The new systems include the fuel retrieval system, sludge removal system, debris removal system, integrated water treatment system, and cask loadout system. Modification upgrades are also being made to the K Basins to allow installation of these systems and to provide related infrastructure support. The integrated water treatment system upgrade will handle the increased need for treated water to support the new systems and to maintain basin water quality during in-basin activities. The end result of these processes is SNF loaded into water-filled MCOs and moved out of the K Basins. Detailed descriptions of the K Basin systems and processes are provided in the K Basin FSAR (WHC-SD-WM-SAR-062)

The CVDF has been constructed near the K Basins to accept loaded water-filled MCOs and to remove the free water. The CVDF contains process bays in which water is removed from the MCOs. CVDF processing systems control the temperature of the MCO contents, minimize oxygen concentrations via helium inerting, establish vacuum and purge for drying, and use controlled and filtered ventilation to control emissions. Detailed descriptions of the CVDF systems and processes are provided in Annex B to this SNF Project FSAR
The CSB has been constructed in the 200 East Area to accept dry MCOs for interim storage of up to 40 years. The CSB will store the MCOs in vertical tubes in the first of three below-ground vaults. The CSB contains processing systems for receipt and handling of the MCOs, sampling of a selected number of MCOs, welding permanent caps on the MCOs, and heating, ventilation and air conditioning to control temperature and monitor emissions. Detailed descriptions of the CSB systems and processes are provided in Annex A to this SNF Project FSAR.

The MCO is a key component in the packaging, transport, drying, and interim storage processes for the K Basin SNF. The MCO is a cylinder, approximately 14 ft long and 2 ft in diameter. Each MCO is capable of holding up to six baskets of fuel and scrap. Approximately 400 MCOs will be used for interim storage of the SNF. The MCO is of robust design, capable of withstanding various drop scenarios and containing internal pressures of up to 450 lb/in² gauge with the welded cover cap in place. As a prudent action, monitoring a small number of the first MCOs shipped to the CSB for a period of up to 2 years will provide data indicating the internal gas generation rate and pressure buildup to show that the SNF Project process meets long-term storage requirements.

The MCO provides primary confinement for the SNF during processing and storage. In the CVDF it serves as part of the primary processing vessel. Because the MCO plays an integral part in the design, operations, and safety functions for the entire SNF Project, a separate document has been prepared to describe the MCO design and technical issues in an integrated fashion for the entire SNF Project. This detailed description of the MCO is provided in HNF-SD-SNF-SARR-005 Multi-Canister Overpack Topical Report.

Transportation of the MCOs from the K Basins to the CVDF and from the CVDF to the CSB is described in HNF-SD-TP-SARP-017, Safety Analysis Report for Packaging (Onsite) Multi-Canister Overpack Cask. The packaging and venting requirements during transport are addressed in the facility annexes to this SNF Project FSAR. The interface with transport functions at each facility and the transport of the MCO between facilities is addressed in the SNF Project FSAR with annexes or the K Basins FSAR (WHC-SD-WM-SAR-062).

2.3.2 Other Spent Nuclear Fuel

The 200 East Area ISA has been constructed a few hundred feet west of the CSB in the 200 East Area. The ISA is a relatively simple facility consisting of concrete and gravel pads with fencing and lighting. The ISA will be used to store non-defense reactor SNF housed in above-ground dry cask storage systems. Three different SNF types will be stored in three different dry cask systems. Detailed descriptions of the ISA, SNF types, and dry cask systems are provided in Annex D to this SNF Project FSAR.
2 4 FACILITY STRUCTURE

For an overview of the basic facility-specific buildings and structures, including construction details such as basic floor plans, equipment layout, construction materials, controlling dimensions, and dimensions significant to the hazard and accident analyses, see the facility FSAR Annexes or the K Basins FSAR (WHC-SD-WM-SAR-062).

2 5 PROCESS DESCRIPTION

The major process steps involved in moving K Basin SNF to interim storage are shown in Figure 2-1. At the K Basins, spent fuel assemblies are removed from the existing canisters, cleaned and placed into specially designed baskets that are loaded into an MCO. The MCO is filled with water, the MCO shield plug is installed, and the MCO is transported in a cask to the CVDF. At the CVDF, the MCO is drained of water, vacuum dried, leak tested and inerted with helium. The mechanical sealing of the MCO is completed and the MCO is leak tested and transported to the CSB. At the CSB, the MCO is received, and those that have been designated for sampling over a 2-year time span are moved to storage tubes. All other MCOs are queued for permanent sealing, which is achieved by welding an end cap in place. An MCO designated for sampling will have an end cap welded in place at the end of the sampling period. After welding, the MCO is placed in interim storage within long vertical tubes.

Non-defense reactor SNF currently dry-stored in several locations on the Hanford Site will be transported to the ISA and stored in above-ground dry cask storage systems.

2 5 1 Technical and Safety Discussion for K Basins Spent Nuclear Fuel

2 5 1 1 Safety Interfaces Between Facilities. Figure 2-2 shows the key SNF subproject safety interfaces and identifies the major safety assumptions applicable to those interfaces. The figure shows the safety analysis documents (HNF-3553 Annex A, Annex B and Annex D and WHC-SD-WM-SAR-062) outlined with a dotted line where the major interface issues are discussed. The MCO Topical Report HNF-SD-SNF-SARR-005) also is shown as technical support to the K Basin FSAR and to both the CSB FSAR (Annex A) and the CVDF FSAR (Annex B). While the safety analysis report for packaging (HNF-SD-TP-SARP-017) is not explicitly shown in the figure, the major safety assumptions of the report are included with the major process flow arrows between facilities. The K Basins processes and fuel transportation controls ensure that the MCOs transferred from the K Basins to the CVDF meet the following interface criteria:

- Limit the number of scrap baskets to two per MCO
- Load the MCO in accordance with the loading procedures
- Follow the prescribed cleaning procedures
- Keep transit time within the prescribed 24-hour shipping window during shipment of the MCO to the CVDF

- Follow the prescribed MCO drying, testing, and cask inerting and sealing procedures

During the drying process at the CVDF, the mass of free water is reduced to less than 0.2 kg. This mass is not actually measured at the completion of drying but process controls and the results of proof-of-dryness testing provide evidence that the drying process has been successful. A mathematical correlation was developed and calibrated using test data that modeled residual free water after vacuum drying (HNF-1851). This correlation and the process controls for temperature and pressure, which ensure conditions consistent with the model and no introduction of additional water, are adequate to meet the interface criteria of <0.2 kg of free water. A proof-of-dryness test is used to demonstrate that initial conditions for the correlation are met and fuel reaction rates are limited.

The safety analysis for the CSB is based on upper limits of particulate and water in the MCO. Evaluations were made for low nominal and upper limits of the residual particulate mass, generated particulate mass, and bound water (HNF-1527, HNF-1523). The worst-case conditions have been used in the safety analyses. Accidents at the CSB are based on 64 kg of particulate and 464 kg of bound water (in addition to free water as discussed below). The upper limit on residual particulate assumes no effectiveness for the cleaning process.

2.5.1.2 Key Spent Nuclear Fuel Project Safety Considerations. The SNF Project safety basis and the related safety analysis report accident analyses for the K Basins, CVDF, and CSB consider the following:

- MCO and confinement barrier integrity (including drops)
- MCO overpressurization
- Fuel reactivity and corrosion behavior
- Hydrogen generation and potential for deflagration or detonation
- Oxygen generation and reactivity with MCO contents
- Product end state and ability to seal the MCO (applies for interim storage)

Technical issues have been identified through a combination of systems engineering safety analysis and technology acquisition program activities. To support the SNF Project’s schedule objectives, the SNF Project is organized into several subprojects. However, the major technical issues tend to cut across many of the subprojects. Each of the SNF Project facility FSAR Annexes and the K Basins FSAR (WHC-SD-WM-SAR-062) address a comprehensive set of equipment failures, design and construction defects, operator errors, natural phenomena hazards (e.g., seismic, wind), external events (e.g., fire), and process hazards that could challenge safety barriers or defense-in-depth mitigating features.
Table 2-1 identifies the process characteristics and related potential hazards that drive the safety analysis for the SNF Project involving K Basin spent fuel handling, processing, and storage. Six major categories of process-related hazards are identified in Table 2-1.

$^d$ $H_2$ and $O_2$ can react explosively with each other and can react with MCO contents to form hydrides and oxides.

MCO = multi canister overpack

The retained water inventory (free water plus chemically bound water) drives the process control strategy for all of the accidents except nuclear criticality. Process and administrative controls are established to optimize process efficiency and to maintain process operations within an acceptable safety envelope. Analyses have been performed and documented that address each of the major process-related hazards. Models have been developed and conservative enabling assumptions have been established when necessary to allow analysis to proceed without impacting project schedules. Characterization and testing required to verify enabling assumptions have been performed and documented.

Nuclear criticality controls are in place to maintain $k_{eff}$ less than or equal to 0.98 in the K Basins or 0.95 in the MCO and the new SNF Project facilities. These controls include mass and geometry controls in the K Basins and CVDF processing and geometry and moderator control in the CSB.

Table 2-2 relates the potential hazards identified in Table 2-1 with the steps used in processing the K Basin SNF and identifies the technical analyses that are needed to address these hazards and to estimate the effect of these hazards on the process. The effects on the processes include criticality radiolysis, hydrogen deflagration and detonation reactions with the fuel.

CSB = Canister Storage Building
CVDF = Cold Vacuum Drying Facility
MCO = multi-canister overpack

2.5.1.2.1 Multi-Canister Overpack Integrity  Maintaining MCO integrity is a primary safety function. The two principal risks to MCO integrity are MCO overpressurization and deflagration or detonation within the MCO. Only these two key technical issues, which have required characterization or testing to sufficiently resolve important technical uncertainties, are summarized here. Other issues and assumptions relating to the safety basis are discussed in the facility FSAR Annexes.

Multi-Canister Overpack Pressure Retention  The pressure retention function is one of the primary safety features of the MCO. Pressure buildup can be due to temperature rise,
radiolytic gas generation, or fuel corrosion reactions. However, the principal source of pressure rise is hydrogen gas generated during a water-uranium corrosion reaction. Water inventory in the MCO can come from free water, waters of hydration of several MCO and fuel element constituents, and chemically bound water. The principal focus of the SNF Project processes is to limit the particulate as a source of waters of hydration and chemically bound water and to remove most of the free water.

Figure 2-3 reflects the MCO pressurization safety basis summary. This figure depicts the amounts of particulate loaded in an MCO at K Basins and generated during transportation and drying, the amounts of water in an MCO after drying in the CVDF, and MCO pressure contributions from MCO contents stored for 40 years. The first column in Figure 2-3 shows the total particulate content (64 kg) within a bounding MCO and the way in which it is distributed between generated particulate, aluminum hydroxide and uranium oxide (HNF-1527). The center column of Figure 2-3 shows how the particulate in the first column contributes to the water content (4.84 kg) of an MCO shipped to the CSB (HNF-1523). Notice that the aluminum hydroxide (hydrated water) contributes the largest amount of water. Also included in the water total is the 200 g of residual water estimated as an upper bounding limit to remain in the MCO after CVDF drying operations. The last column in Figure 2-3 depicts the estimated pressure for an MCO after 40 years of storage (62 lb/in² gauge), showing the relative amounts of pressure contributed by the internal water hydrates, and aluminum hydroxide components (HNF-SD-SNF-TI-040). Estimates from the nominal calculations show an expected pressure of less than 16 lb/in² gauge. The third column also shows the MCO design margins present for the mechanically sealed MCO (150 lb/in² gauge) and the welded MCO (450 lb/in² gauge).

Hydrogen and Oxygen Concentrations in a Multi-Canister Overpack. Following cold vacuum drying, the MCO is sealed for interim storage with a helium atmosphere slightly above atmospheric pressure. Hydrogen is generated by radiolytic and chemical processes. Hydrogen concentrations over the 40-year storage period are expected to be significant. Oxygen is also generated by radiolysis of aluminum hydroxide and metal oxide hydrates (U, Fe, Al) that are contained in an MCO.

Lower flammability limits of oxygen and hydrogen were established as a safety basis criterion for acceptable oxygen buildup. Since oxygen is consumed by reaction with exposed fuel elements and fuel scrap, the safety basis strategy has been to demonstrate that inherent oxygen gettering within the MCO sufficiently reduces the oxygen concentration and therefore the risk of deflagration or detonation. Exposed uranium is the principal oxygen gettering material within the MCOs. Consequently, the number of scrap baskets within an MCO is a key variable related to the oxygen gettering scenarios. The worst-case scenario is an MCO containing intact fuel with no exposed uranium and zero scrap baskets. As stated in HNF-SD-SNF-TI-040, MCO Internal Gas Composition and Pressure During Interim Storage, there is no combination of high MCO power, water content, and reaction area that results in oxygen concentrations above the lower flammability limit. Under best-estimate water inventories, a worst-case oxygen concentration of no more than 0.75% is predicted. It was concluded that oxygen concentrations throughout the 40-year storage period for MCOs containing either zero, one, or two scrap baskets will not reach.
the minimum concentration needed to support combustion (4%) The technical basis for the oxygen gettering safety basis is addressed in HNF-SD-SNF-TI-040

2 5 1 2 2 Summary of Accident Scenarios and Preventative and Mitigative Features

Key facilities and process physical barriers have been identified and evaluated for K Basins SNF retrieval MCO transport and processing and interim storage This barrier evaluation identified the accidents of concern that are applicable for each of the major process elements The key prevention mitigation or control features identified in Figure 2-4, are required to sufficiently reduce the risk of the important safety accidents for each major process element Monitoring and measurements also identified in Figure 2-4 provide the feedback needed to ensure that treatment transport or storage operations are maintained within the established operating design basis envelopes However the monitoring system is not a safety basis feature

The identified safety envelopes system design features and process and administrative controls establish sufficient safety margins to provide safe and environmentally sound management of K Basin SNF The facility FSARs for the CSB (HNF-3553 Annex A) CVDF (HNF-3553 Annex B) and K Basins (WHC-SD-WM-SAR-062) define the equipment and control features needed to prevent or mitigate the consequences of accidents

2 5 1 3 Technical Documentation

The fundamental technical data used to support the safety basis for the processing and sealed storage of MCOs is documented in HNF-SD-SNF-TI-015, Spent Nuclear Fuel Project Technical Databook Data required for support of the safety basis that is not available through literature review has been developed through an SNF Project engineering studies characterization efforts and process equipment test programs Although hundreds of documents have been produced the Technical Databook (HNF-SD-SNF-TI-015) directly references 23 documents that provide key technical baseline support The Technical Databook is revised periodically as needed to update parameters with new information or the results from new analyses It is issued as a controlled document with tracked distribution of the numbered copies

The 23 documents referenced directly by the Technical Databook (HNF-SD-SNF-TI-015) address engineering studies and analyses and characterization and testing results that have been used to support the SNF Project safety analysis process beyond the key technical data provided in the Technical Databook Some of the documents characterize the K Basins SNF with respect to mass surface area and decay heat Basic physical properties and conditions such as emissivity and climatological data are identified Other documents provide information on reaction rates that affect corrosion particulate and gas generation and water availability MCO pressures and temperatures based on the feed material process conditions and potential accident conditions also are provided

2 5 1 4 Closure of Major Technical Issues

The process hazard assessment and safety analysis processes identified key process hazards and technical issues that required resolution to ensure safe efficient implementation of SNF Project objectives The technical basis for resolution has been determined for the following topics
Zero, one, and two scrap baskets in an MCO meet safety and design basis boundaries based on updated calculations (HNF-2877)

An upper limit on free residual water has been established at 200 g per MCO (HNF-2882)

Additional methods of oxygen control, such as added gettering, fuel mixing or cladding removal, are not required to keep oxygen below the lower flammability level (HNF-3036)

The bounding value for aluminum hydroxide is 10.6 kg/MCO (HNF-3256)

The worst-case oxygen levels in an MCO will be below the lower flammability level during 40 years of storage for MCOs containing zero, one, or two scrap baskets (HNF-2876)

A limited approach to monitoring has been established that focuses on temperature pressure, and gas composition measurement of four to six MCOs for up to 2 years (HNF-3354)

Reaction rate and particulate generation assumptions are sufficiently conservative to bound observed fuel crumbling for the temperature condition that could be experienced by fuel elements during the vacuum drying process. Fuel crumbling has been observed in some tests, which raises a potential concern that this phenomena may occur in the MCO and increase the reactive surface area and the rate of heat generation during processing. The information from crumbling observed during testing does not impact the SNF Project safety basis and is bounded by conservatisms for reaction rates used in the safety analysis. Crumbling was not observed at the temperature and moisture conditions expected during MCO processing. When crumbling occurred, changes in reaction rate were not detectable within the limits of data uncertainty. The safety basis for interim storage depends on the integrity of the MCO and the limited supply of reactants rather than on reactive surface area.

Numerous scenarios have been analyzed for various combinations of cask-MCO and MCO drops during handling in the K Basins and the CSB. The results of these analyses are reported in the K Basins FSAR (WHC-SD-WM-SAR-062) and in the SNF Project FSAR annexes (HNF-3553, Annexes A and B).

2515 Margins of Safety and Conservatisms Significant design margins and safety analysis conservatisms are incorporated in the SNF Project process design and operational approach to safety. These conservatisms ensure that a robust margin of safety is provided for all phases of the process for removal processing and storage of K Basins SNF. A brief discussion of the key safety margins is provided in the paragraphs that follow.
**Particulate not Removed by Fuel Cleaning** The bounding quantities of aluminum hydroxide and uranium oxide particulate affect the pressurization of and oxygen buildup in the sealed MCO during the 40-year storage period. The quantity of fuel particulate available for release during an accident scenario also affects the radiological release calculations performed as part of the safety analysis. The significant removal of particulate during fuel washing or handling that occurs during fuel retrieval is not assumed in determining the bounding particulate and water content in an MCO. It is highly likely that fuel washing will be much more effective than is assumed by the safety basis, and this represents a substantial conservatism in the safety case. Nominal estimates of expected particulate content in an MCO quantify the probable magnitude of this conservatism—the bounding quantity is 64 kg compared to the nominal estimated value of 8 kg.

**Generated Particulate** The quantity of fuel particulate generated within an MCO after the fuel is loaded in an MCO, but before free water is removed, is conservatively calculated for the CVDF design basis accidents. The corrosion rates used for estimating the generated particulate that could be available for dispersion in certain accident scenarios is a factor of 22 higher than the nominal literature values and corrosion rates measured under prototypical atmospheric conditions by the SNF Project characterization program.

**Multi-Canister Overpack Pressurization** Chemical and radiolytic processes result in increasing pressure in a sealed MCO during interim storage at the CSB. The safety case bounding pressure expected during the 40-year storage period is <5.2 atm absolute (76.4 lb/in² absolute, or 62 lb/in² gauge). Nominal calculations of expected pressure estimate a value <16 lb/in² gauge (bounding/nominal ratio = 4.7).

**Multi-Canister Overpack Pressurization Retention Capability** With the cover cap welded in place, the MCO is estimated to have a pressurization retention capability between 1,000 to 1,300 lb/in² gauge (HNF-SD-SNF-SARR-005). This capability represents a very large margin of safety above the bounding estimated pressure of 5.2 atm absolute (76.4 lb/in² absolute). This ratio of pressure retention capability and maximum credible pressure buildup creates a bounding-to-failure margin of between 13.2 and 17.1 ([68.8 atm - 9.4 atm]/5.2 atm, or more than an order of magnitude of margin). The structural margins associated with the MCO design also provide a margin related to the potential for hydrogen burn in an MCO.

**Oxygen Concentration in a Sealed Multi-Canister Overpack** Bounding estimates of the end-of-life oxygen concentration are below a conservatively chosen lower flammability limit for all MCOs that contain one or more scrap baskets. In order to compute values that approach the hydrogen–oxygen flammability limit, the worst-case particulate and water content, fuel and scrap reactive surface area, fuel decay power, and radiolysis rate must all be assumed. Simultaneously achieving bounding safety basis values for all of these parameters in a single MCO is a significant conservatism in the safety case. HNF-SD-SNF-TI-040 documents sensitivity analyses showing the impact on the end-of-life oxygen concentrations.

**Radiological Release Calculations (Gaseous and Liquid)** Appropriately conservative parameters and calculational methods are used for SNF Project safety analyses. The degree of
conservatism and the appropriateness of assumptions used for radiological release computations were evaluated in Letter DESH 9852617 R2, *Contract Number 80232764-9-K004 — Spent Nuclear Fuel Project Safety Analysis Conservatism* (Segrest 1998)

2.5.2 Spent Nuclear Fuel Project Authorization Basis

Authorization basis is defined in DOE Order 5480.21, *Unreviewed Safety Questions* and DOE Order 5480.23, *Nuclear Safety Analysis Reports*, as follows:

*Authorization Basis* Those aspects of the facility design basis and operational requirements relied upon by DOE to authorize operation. These aspects are considered to be important to the safety of facility operations. The authorization basis is described in documents such as the facility Safety Analysis Report and other safety analyses. Hazard Classification Documents, the Technical Safety Requirements, DOE-issued safety evaluation reports, and facility-specific commitments made in order to comply with DOE Orders or policies.

This definition encompasses aspects of the facility safety basis, related technical information, technical issues, and safety analyses and other safety documentation. It also includes the design basis for the facilities. These are usually summed up in the facility FSAR and a small number of other documents. The discussion below will expand on each of these areas and arrive at the definition of the authorization basis documentation for each facility.

2.5.2.1 Spent Nuclear Fuel Project Safety Basis

Safety basis is defined in DOE Order 5480.23 as follows:

*Safety Basis* means the combination of information relating to the control of hazards at a nuclear facility (including design, engineering analyses, and administrative controls) upon which DOE depends for its conclusion that activities at the facility can be conducted safely.

The safety basis for the SNF Project's new facilities is described in this FSAR. The safety basis for the K Basins is described in WHC-SD-WM-SAR-062.

Numerous documents have been developed to support the SNF Project. The major documents that comprise the core information and analysis are summarized in this section. Figure 2-2 shows the relationship between the key facility subproject FSARs (HNF-3553, Annex A and Annex B) and the MCO Topical Report (HNF-SD-SNF-SARR-005). Figure 2-2 illustrates that the MCO Topical Report is a major reference in the safety basis of the new facilities and of the modifications to the K Basins. The MCO Topical Report is used to provide a single description of the MCO and its contents. This ensures that the different SNF Project safety analysis documents that discuss the MCO all use the same description of the MCO. The SNF Project elected to modify and update the existing K Basin FSAR (WHC-SD-WM-SAR-062) to address the canister unloading, fuel cleaning, and MCO loading operations. These were added...
to the prior functions that were already addressed by the K Basins FSAR (WHC-SD-WM-SAR-062) The CVDF and the CSB as well as the ISA, are addressed by this SNF Project FSAR and its annexes

2522 Other Safety Analysis Documents In addition to the SNF Project FSAR and its annexes several other safety documents have been developed that are important to the safety and authorization basis Most of the safety documentation was developed in concert with technical design basis documents that have been developed concurrently

The interface between the safety documentation process and the technical or design basis documents for the K Basins SNF is through the SNF Project Technical Databook (HNF-SD-SNF-TI-015) and the MCO Topical Report (HNF-SD-SNF-SARR-005) The MCO Topical Report (HNF-SD-SNF-SARR-005) is not an FSAR but is a summary document that integrates the issues design data and safety data that are common to each of the subprojects The characterization program literature reviews, engineering studies analyses, and communication documents all flow down to support the SNF Project Technical Databook and the MCO Topical Report These two documents form the foundation for the technical input for the safety documentation process

Additional safety analysis documents include the following

- The hazard analyses for each of the SNF Project FSAR Annexes and the K Basins FSAR
- The fire hazard analyses
- The criticality safety evaluation reports
- The safety analysis reports for packaging

Hazard analyses were performed and are documented separately for each of the SNF Project subprojects

In addition, an interface hazard analysis was conducted to identify and assess conditions or events occurring at one location or facility that could subsequently impact safety during cask-MCO transport or operations at another location or facility. The interface hazard analysis is documented in HNF-5245, Spent Nuclear Fuel Project Facility Interface Hazard Analysis for Production Reactor Fuel. This document assigns responsibility for analyzing new hazardous conditions if not previously identified, to the appropriate SNF Project groups or facilities to ensure development of adequate safety and operational controls using the formal DOE hazard analysis and safety analysis processes. No new hazards were identified during the interface hazard analysis that challenge the present K Basins, CVDF, and CSB FSARs, MCO Topical Report, or safety analysis report for packaging safety documentation.

Fire hazard analyses were performed and are documented separately for each of the SNF Project subprojects:

- WHC-SD-SNF-FHA-001, Fire Hazards Analysis for the K Basins Facilities at 100K Area
- HNF-SD-SNF-FHA-002, Final Fire Hazard Analysis for the Canister Storage Building
- SNF-4268, Fire Hazard Analysis for the Cold Vacuum Drying Facility
- SNF-4932, Fire Hazard Analysis for the 200 Area Interim Storage Area

Criticality safety is discussed in the SNF Project FSAR and its Annexes (HNF-3553 Annexes A, B and D), in the K Basins FSAR (WHC-SD-WM-SAR-062) and in the safety analysis reports for packaging (HNF-SD-TP-SARP-017, WHC-SD-TP-SARP-010, NAC-E-804 and WHC-SD-TP-SARP-008). Criticality events under normal and accident conditions for various MCO configurations are analyzed in HNF-SD-SNF-CSER-005, Criticality Safety Evaluation Report for the Multi-Canister Overpack. Activities related to fuel storage, fuel handling equipment, and fuel handling activities in the K Basins are evaluated in HNF-SD-SNF-CSER-010, Criticality Safety Evaluation Report for the Storage and Removal of Spent Nuclear Fuel from K Basin. Criticality evaluations for specific systems are provided in HNF-SD-SNF-CSER-011, Criticality Safety Evaluation Report for the K West Basin Integrated Water Treatment System, and in HNF-SD-SNF-CSER-006, Criticality Safety Evaluation Report for the Cold Vacuum Drying Facility's Process Water Handling System. Criticality evaluations for the handling and storage of sealed casks in the ISA are documented in several additional reports (WHC-SD-FV792-DA-004, WHC-SD-FF-CSER-002, WHC-SD-FF-CSER-003, WHC-SD-FF-CSER-004, WHC-SD-FF-CSER-006, WHC-SD-SQA-CSA-30006, WHC-SD-FF-CSER-007, HNF-3499).

November 1999
HNF-SD-TP-SARP-017 addresses the safety concerns for transport of MCOs between each of the SNF Project facilities. While FSAR Annexes A and B and HNF-SD-TP-SARP-017 are stand-alone documents, safety assumptions that are required for safe transport are established as constraints to the facility delivering an MCO and cask system for transport. The receiving areas at the CSB and CVDF have safe receiving, unloading, inspection, and storage requirements in order to meet the delivery assumptions in HNF-SD-TP-SARP-017. Other interfaces may be required in the event of a delayed shipment, such as a means of retrieving the cask for timely transport or cooling. WHC-SD-TP-SARP-010, Safety Analysis Report for Packaging (Onsite) Interim Storage Cask, NAC-E-804 Safety Analysis Report for the NFS-4/NAC-1 Spent-Fuel Shipping Cask, and WHC-SD-TP-SARP-008, Safety Analysis Report for Packaging NRF TRIGA Packaging, address the safety concerns for transport of non-defense reactor SNF to the ISA.

2 5 2 3 Design Basis Design basis is defined in DOE Order 5480.21 as follows:

**Design Basis** The set of requirements that bound the design of systems, structures, and components within the facility. These design requirements include consideration of safety, plant availability, efficiency, reliability, and maintainability. Some aspects of the design basis are important to safety, although others are not.

The design descriptions are contained in Chapter 2.0 of each SNF Project FSAR annex and of the K Basins FSAR. The discussion of how that design meets the requirements is included in Chapter 4.0 of each SNF Project FSAR annex and of the K Basins FSAR.

2 5 2 4 Authorization Basis Documentation Requirements for the authorization basis documentation are contained in DOE Order 5480.23 and include the safety analysis reports, technical safety requirements, and safety evaluation report. Because the MCO Topical Report (HNF-SD-SNF-SARR-005) contains basic design information related to the MCO and its contents and is referenced by SNF Project FSARs, it becomes part of the facility authorization basis.

During the design and construction of the new SNF Project systems, processes, and facilities, phased safety analysis documents were prepared, and reviewed and approved by DOE in order to authorize procurement of components and systems or to authorize construction. These documents were prepared in phases that supported the installation of specific equipment or the construction of defined portions of the new facilities. The safety analysis documents grew into the following safety analysis reports that contained information required by the DOE orders for preliminary safety analysis reports:

- HNF-SD-SNF-SAR-002, Safety Analysis Report for the Cold Vacuum Drying Facility Phase 2 Supporting Installation of Process Systems
- HNF-SD-SNF-RPT-004, Canister Storage Building (CSB) Safety Analysis Report Phase 3 Safety Analysis Documentation Supporting CSB Construction
The phased preliminary safety analysis reports authorize the procurement, installation, construction, and testing of the components, systems, and structures of the SNF Project's new facilities.

This SNF Project FSAR (HNF-3553) is a document that meets the content requirements and format guidelines of DOE Order 5480.23 and DOE-STD-3009-94, *Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports*, for an FSAR and is used to authorize the final testing and operation of the SNF Project's new facilities. It contains applicable information from the phased safety analysis report documents along with new information that addresses operation of the facilities. This FSAR comprises several volumes; the first of which contains the information that applies to all of the new facilities. The other volumes (annexes) of this FSAR contain facility-specific information. Following DOE review of this FSAR and a specific facility annex, issuance of the safety evaluation report for the specific facility, the SNF Project FSAR, Volume 1, and the applicable annex volume become the primary authorization document that controls further testing, any need modification, and operations of the facility. At that time, the phased preliminary safety analysis document will no longer control activities within the facility.

Facility authorization agreements will be documented and approved. These agreements will list the documentation that establishes the facility authorization basis. It is expected that the following documents will provide the operations authorization basis:

- For the K Basins
  - K Basins FSAR (WHC-SD-WM-SAR-062)
  - K Basins Technical Safety Requirements (HNF-SD-SNF-TSR-001)
  - DOE Richland Operations Office Safety Evaluation Report
  - MCO Topical Report (HNF-SD-SNF-SARR-005)

- For the CSB
  - CSB FSAR (HNF-3553 and Annex A)
  - CSB Technical Safety Requirements (HNF-3672)
  - DOE, Richland Operations Office, Safety Evaluation Report
  - MCO Topical Report (HNF-SD-SNF-SARR-005)

- For the CVDF
  - CVDF FSAR (HNF-3553 and Annex B)
  - CVDF Technical Safety Requirements (HNF-3673)
  - DOE Richland Operations Office Safety Evaluation Report
  - MCO Topical Report (HNF-SD-SNF-SARR-005)
For the ISA

- ISA FSAR (HNF-3553 and Annex D)
- ISA Technical Safety Requirements (SNF-5047)
- DOE, Richland Operations Office Safety Evaluation Report

HNF-SD-TP-SARP-017 is the authorization basis document for transportation of loaded MOCS between SNF Project facilities. As such, there are interfacing requirements between it and facility FSARs (WHC-SD-WM-SAR-062 and HNF-3553, Annexes A and B) and the MCO Topical Report (HNF-SD-SNF-SARR-005). WHC-SD-TP-SARP-010 NAC-E-804, and WHC-SD-TP-SARP-008 are the authorization basis documents for transportation of sealed casks to the 200 East Area ISA.

2.6 CONFINEMENT SYSTEMS

For the K Basins SNF, the three major components or systems that comprise the key confinement barriers of the safety basis are (1) the MCO-transport cask system, (2) the cold vacuum drying processing system, and (3) the multi-zoned building and ventilation and filtration systems associated with the SNF Project facilities. Except during vacuum processing, the MCO provides the primary confinement barrier for the SNF Project. The MCO has various roles depending on the process function being performed. During some operations, the MCO is vented or open, while during others, it is sealed or welded closed. Table 2-3 summarizes the MCO conditions at various stages of MCO processing. For facility-specific identification and description of structures, systems, and components that perform confinement functions, see facility FSAR Annexes A and B and the MCO Topical Report (HNF-SD-SNF-SARR-005).

Each of the dry storage systems used for interim storage of non-defense reactor SNF at the 200 East ISA is described in Annex D of this FSAR.

2.7 SAFETY SUPPORT SYSTEMS

For facility-specific identification and description of the principal safety support systems, see the K Basins FSAR (WHC-SD-WM-SAR-062) and the SNF Project FSAR Annexes.

2.8 UTILITY DISTRIBUTION SYSTEMS

The Bonneville Power Administration (BPA) provides the main source of power to the Hanford Site by means of a major substation known as Midway. The BPA Midway Substation which is located near Priest Rapids Dam has three 230-kV buses. Each BPA Midway bus section is supplied by a line from the Priest Rapids generating station. BPA Midway buses No. 1 and No. 3 are also supplied by lines that are connected to the Grand Coulee 230-kV Substation and to 230-kV substations in the lower Columbia River power system. The Grand Coulee and lower...

Columbia River Substations are interconnected to the BPA 500-kV transmission system. The BPA 500-kV and 230-kV transmission systems are interconnected to all the Columbia and Snake River hydroelectric generating stations and northwest steam generating plants and are also interconnected to California and British Columbia power network systems.

In addition to supplying power to the Hanford Site and other U.S. Department of Energy substations, the Hanford Site 230-kV loop normally supplies power to Ashe and White Bluffs Substations. However, if both Midway power sources are lost, sufficient power for normal operations will flow into the Hanford Site 230-kV loop from the Ashe Substation. Figure 2-5 shows the onsite transmission lines.

Power from the Ashe Substation into the Hanford Site 230-kV loop is supplied by a 115-kV line connected to the White Bluffs Substation. One 115-kV line at the White Bluffs Substation is connected to the BPA Franklin Substation. The other 115-kV line is connected to the BPA Benton Switch Substation.

Power is fed by two 230-kV lines to the 230–13.8 kV A-8 substation located near the intersection of the Yakima Barricade and 100 N highways (Route 11A and Route 4 North, respectively). The 251-W Building adjacent to the A-8 Substation contains the switchgear and control equipment. The A-8 Substation distributes 13.8 kV through overhead lines. The power is then distributed to SNF Project facilities.

For details of the facility-specific power system and components such as transformers, motor control centers, and uninterrupted power supply, see the K Basins FSAR (WHC-SD-WM-SAR-062) and the SNF Project FSAR Annexes.

2.9 AUXILIARY SYSTEMS AND SUPPORT FACILITIES

For other auxiliary and support systems in the SNF Project facilities, see the K Basins FSAR (WHC-SD-WM-SAR-062) and the SNF Project FSAR Annexes.

Fuel Retrieval and MCO/Cask Loading

Key Physical Barriers
- Water and basin structure
- Building and ventilation system

Important Accident Considerations/Scenarios
- Dropped loads
- Criticality
- Fuel flashing/rapid underwater corrosion
- Natural phenomena and external events

Key Prevention, Mitigation and Control Features
- Cleaning process controls (affects sealed storage)
- Scrap and fuel loading procedures (affects sealed storage)
- Criticality controls
- Load lifting controls/procedures
- Basin water temperature control/heat sink
- Cask inerting and sealing procedures
- Limited fuel basket queueing (<30 days)

Key Phenomena and Analysis Results
- Particulate generation during transport
- Corrosion reaction rates
- Conditions for hydrate formation

Key Monitoring/Measurements
- Basin temperature

Transfer to CVD

Key Physical Barriers
- Sealed cask/vented MCO

Important Accident Considerations/Scenarios
- Runaway corrosion/temperature transient
- $H_2$ pressure build up
- $H_2$ deflagration
- Natural phenomena and external events

Key Phenomena and Analysis Results
- Particulate generation during transport
- Corrosion reaction rates
- Conditions for hydrate formation

Key Prevention, Mitigation and Control Features
- Limited transfer duration (<24 hours)
- Water heat sink in MCO/cask (cask annulus water level)
- Back up cooling if shipping delayed
- Transfer procedures

Key Monitoring/Measurements
- Transfer time window
- Cask pressure measured at receipt

November 1999
Figure 2-4 Spent Nuclear Fuel Project Facilities and Process Physical Barriers (Sheet 2 of 3)

Key Physical Barriers:
- MCO and vacuum purge system boundary
- Multi-zoned building and ventilation system

Important Accident Considerations/Scenarios:
- Runaway corrosion / temperature transient
- U/O_2 reaction (air ingress)
- Gas release and liquid release
- H_2 deflagration (internal and external to MCO)
- Natural phenomena & external events

Key Phenomena and Analysis Results:
- Particulate generation
- Corrosion reaction rates
- Conditions for hydrate formation
- Fuel crumbling

Key Prevention, Mitigation, and Control Features:
- CVD removal of free water (affects sealed storage)
- Inert gas purge and pressure control (SC helium)
- MCO temperature control (tempered water annulus)
- MCO and cask meeting sealing (mechanical)
- Process system and building ventilation
- Structural configuration

Key Monitoring/Measurements:
- In-process measurements
- CVD residual free water removal vacuum hold
- MCO and cask post insertion leak tests

Key Physical Barriers:
- Sealed MCO (mechanical)
- Sealed cask

Important Accident Considerations/Scenarios:
- Gas pressure build up MCO overpressure
- H_2 deflagration (within MCO)
- MCO degradation and leaking
- U/O_2 reaction (air ingress)
- H_2 deflagration in cask
- Natural phenomena and external events
- Transportation loads

Key Phenomena and Analysis Results:
- Limited particulate content
- Limited particulate water content

Key Prevention, Mitigation, and Control Features:
- Inerted MCO (pressure > atmosphere)
- O_2 gettering by uranium (no getter added)
- CVD removal of free water
- Transfer procedures

Key Monitoring/Measurements:
- Cask pressure

3 0 HAZARD AND ACCIDENT ANALYSES

3 1 INTRODUCTION

The purpose of this chapter is to provide an overview of the process used to systematically identify and assess hazards to evaluate the potential internal, external, and natural phenomena events that can cause the identified hazards to develop into accidents. The results of this hazard identification and assessment process specific to individual Spent Nuclear Fuel (SNF) Project facilities are provided in the facility annexes to the SNF Project Final Safety Analysis Report (FSAR). Hazard analysis considers the complete spectrum of accidents that may occur because of facility operations, analyzes potential accident consequences to the public and workers, estimates likelihood of occurrence, identifies and assesses associated preventive and mitigative features, identifies potential safety structures, systems, and components (SSCs), and identifies a selected subset of accidents designated design basis accidents (DBAs), to be formally defined in accident analyses. Subsequent accident analyses evaluate these DBAs for comparison with release limits and evaluation guidelines to identify and assess the adequacy of all safety SSCs. These analyses pave the way for the development of the technical safety requirements (TSRs) and the needed emergency response plans.

When the FSAR is approved by the U.S. Department of Energy (DOE), it will establish the authorization basis for the SNF Project. Changes to the facility during operations will be reviewed to ensure they do not affect the authorization basis. This review process is described in Chapter 17.0 and is termed the unreviewed safety question process. When activities or projects result in a positive unreviewed safety question evaluation, an authorization basis change package will be developed. This package will include text changes for the SNF Project FSAR, the appropriate FSAR Annexes, and the TSR documents (as required). The changes will be for DOE review and approval.

This chapter describes the methodology for and approach to hazard and accident analyses. The facility FSAR Annexes cover hazard identification, facility hazard classification, hazard evaluation, and accident analyses. Products of the FSAR Annexes include the following:

- Identification of hazardous materials and energy sources present by type, quantity, form, and location
- Facility hazard classification, including segmentation in accordance with DOE-STD-1027-92, *Hazard Categorization and Accident Analysis Techniques for Compliance with DOE Order 5480.23 Nuclear Safety Analysis Reports*
- Identification in the hazard analysis of the spectrum of potential accidents at the facility in terms of largely qualitative consequence and frequency estimates and a summary of this activity that includes
  - Identification of planned design and operational safety improvements
Summary of defense in depth and other items needing TSR coverage in accordance with DOE Order 5480.22 *Technical Safety Requirements*

Summary of the significant worker safety features including identification of safety-significant SSCs for worker safety and any relevant programs to be covered under TSR administrative controls

Summary of design and operational features that reduce the potential for large material releases to the environment

Identification of the limited set of unique and representative accidents (i.e., DBAs) to be assessed further in accident analyses

Accident analyses of DBAs identified in the hazard analysis and a summary of this activity that includes for each accident analyzed the following:

- Estimation of source term and consequence
- Documentation of the rationale for binning frequency of occurrence in a broad range in hazard analysis (detailed probability calculations not required)
- Documentation of accident assumptions and identification of safety-class and safety-significant SSCs based on evaluation guidelines

Several major accident types were considered in the SNF Project hazard and accident analyses. Project safety basis accidents considered include the following:

- Multi-canister overpack (MCO) overpressurization or leakage
- Rapid corrosion or temperature transient (H₂O–uranium)
- Uranium metal or uranium hydride burn (O₂–uranium)
- Radiological releases during processing and treatment
- Hydrogen combustion or explosion
- Nuclear criticality
- Dropped loads that cause cold vacuum drying system breach (radiological release)
- Transport accidents (HNF-SD-TP-SARP-017)
- MCO or fuel overheating
- Natural phenomena and external events (e.g., fire)
- MCO mechanical breach or significant geometry changes caused by shear drop, or collision impact forces

Based on a comprehensive hazard analysis process, representative DBAs are selected for in-depth analysis. The DBA represents a bounding case for a category of events. The analysis process results in identification of safety-class and safety-significant SSCs and the functional requirements needed to prevent or mitigate potential accident sequences and to ensure that the facilities can be operated in a safe, controlled manner. The analysis also identifies a set of controls (i.e., TSRs) that ensure all identified vulnerabilities associated with the operation of the facility have been adequately addressed. The comprehensive hazard and safety analyses results for each phase of the SNF Project are documented, with preventive or mitigative features, in the facility FSAR Annexes.

The SNF Project product specification (HNF-SD-SNF-OCD-001) provides the limiting values of all key parameters. Based on limiting values assumed in the hazard and DBA analyses, the SNF Project has interface requirements among its facilities to ensure that where the different facilities rely on certain functional performance requirements to be satisfied, those performance requirements will be met. For example, the Cold Vacuum Drying Facility (CVDF) assumes that the MCO is loaded with at most two scrap baskets, where scrap baskets may only be loaded at the top and bottom of the MCO. The Canister Storage Building (CSB) requires that an MCO delivered from the CVDF to the CSB contain less than 200 g of free water and confine combustible hydrogen gases within the mechanically sealed MCOs.

### 3.2 REQUIREMENTS

The requirements that form the basis for performing hazard and accident analyses to establish the safety basis of SNF Project facilities are found in HNF-SD-SNF-RD-001, *Spent Nuclear Fuel Project Standards/Requirements Identification Document*. Specific requirements applicable for this chapter include the following:

- DOE Order 5480 22, *Technical Safety Requirements*
- DOE Order 5480 23, *Nuclear Safety Analysis Reports*
- DOE Order 6430 1A, *General Design Criteria*

In Letter 95-SFD-167, *Implementation of the K Basins Spent Nuclear Fuel Project (SNFP) Regulatory Policy* (Sellers 1995), DOE established the requirement for new SNF Project
facilities to achieve "nuclear safety equivalency" to comparable U S Nuclear Regulatory Commission (NRC)-licensed facilities. The SNF Project identified the NRC requirements that were needed in addition to existing and applicable DOE requirements to establish nuclear safety equivalency. These NRC requirements and the process used to identify them are documented in HNF-SD-SNF-DB-003, Spent Nuclear Fuel Project Path Forward Additional NRC Requirements, WHC-SD-SNF-DB-009, Canister Storage Building Natural Phenomena Hazards and WHC-SD-SNF-DB-010, Cold Vacuum Drying System Natural Phenomena Hazards. These documents establish design requirements to be met for the new SNF Project facilities to achieve this equivalency.

The following NRC rule and guidance were considered in the development of HNF-SD-SNF-DB-003, WHC-SD-SNF-DB-009 and WHC-SD-SNF-DB-010 and have particular significance to Chapter 3. However they do not by themselves establish requirements for the facilities or the Chapter 3 accident analyses:

- Title 10 Code of Federal Regulations, Part 72, "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel and High-Level Radioactive Waste" (10 CFR 72)
- NRC Regulatory Guide 3 26 Standard Format and Content of Safety Analysis Reports for Fuel Reprocessing Plants
- NRC Regulatory Guide 3 48 Standard Format and Content for the Safety Analysis Report for an Independent Spent Fuel Storage Installation or Monitored Retrievable Storage Installation (Dry Storage)

3.3 HAZARD ANALYSIS

Hazard identification and evaluation can provide a thorough, predominantly qualitative evaluation of the spectrum of risks to the public, workers and the environment from accidents involving the hazards identified in the analysis. The hazard analysis determines the material system MCO handling, processing, storage and facility characteristics that can produce undesirable consequences, followed by the assessment of hazardous situations associated with a process or activity. Largely qualitative techniques are used to pinpoint weaknesses in design or operation of the facility (MCO processing, handling, or storage) that could lead to accidents. The hazard analysis examines the complete spectrum of potential accidents that could expose members of the public, onsite workers, facility workers and the environment to hazardous materials. A selection process is used to identify accidents with the potential to cause unacceptable consequences. These accidents are further analyzed, and a set of controls is selected and implemented to ensure that the facility can be designed, constructed, operated, and decommissioned safely and to meet DOE requirements. This section presents the methodology used to perform the SNF Project hazard analysis and to identify the resulting candidate accidents selected for more comprehensive analyses in subsections of Section 3.4.2 of the facility FSAR Annexes.
Hazard analyses were prepared to support the phased safety analysis reports. Final hazard analyses were performed to support the accident analyses by providing a basis for selecting representative and bounding DBAs. The final hazard analyses systematically reviewed the final designs to identify any additional hazardous materials or energy sources that have the potential to initiate an accident that may require further review or analysis. A specific and comprehensive analysis of all fire hazards associated with the facilities have been completed and augment the standard hazard analysis.

The revised hazard analyses were prepared using baseline design information identified in Chapters 20 of the facility FSAR Annexes, system design descriptions, and other design requirements documents, including relevant design drawings, design calculations, supporting documents, and operational plans.

3.3.1 Methodology

This section describes the methodology used to identify and evaluate the SNF Project facilities hazards. The hazard evaluation process identifies hazardous conditions, determines causes and preventive and mitigative features, and qualitatively estimates the consequences and frequencies of occurrence. The results of the application of this methodology are presented in the facility FSAR Annexes. The hazard analysis was based on American Institute of Chemical Engineers methodology that conforms with the guidance provided by DOE-STD-3009-94 which implements the requirements of DOE Order 5480.23.

3.3.1.1 Hazard Identification

The hazard analyses considered events occurring during normal operations at the facilities to ensure that there were no adverse consequences for the public or the workforce or contamination of the environment. The hazard analysis identified all conditions that could occur during normal operations and during abnormal and accident conditions at the facility. The hazard analysis therefore focused on hazardous conditions created by equipment failures, errors, or other accidents leading to release of hazardous material in the facility.

A hazard is defined in DOE Order 5480.23 as a source of danger (i.e., material energy source or operation) with the potential to cause illness, injury, or death to personnel or damage to an operation or to the environment (without regard for the likelihood or credibility of accident scenarios or consequence mitigation). Hazard identification for the SNF Project facilities was based on examination of the major building areas in the facility designs. The processes and activities that can take place within each area were identified. A hazardous material/energy source checklist, provided in Table 3-1, was based on a standard table and modified to include facility-specific concerns. This table was used to group potentially hazardous materials and energy sources as they were identified in each of the major building areas. An alpha-numeric designator was assigned to each hazardous material and energy source identified. The designator combined the acronym for the building area, the designation letter for the general hazard group, and the hazard number for the specific type cause, or source. For example, AA-A-01 identifies an electrical source in the administrative area, specifically battery banks. If a single hazard could result in more than one consequence, different features may be needed to prevent or mitigate each.

- November 1999
consequence. Such possibilities, discussed in separate rows in the hazard evaluation table, are distinguished by appending a lowercase letter to the final hazard number (e.g., AA-A-01a, AA-A-01b, and AA-A-01c).

Identified hazards were grouped by their general form (e.g., electrical, thermal, friction) and by specific type, cause, or source (e.g., motors, power tools, wiring). The hazards were further identified by determining hazardous conditions resulting from the hazardous material or energy source, establishing accident initiators or causes, and defining resultant accident sequences.

The hazardous materials and energy sources with the potential to cause an uncontrolled release of radioactive or other hazardous material were screened from those that present only standard industrial hazards. Standard industrial hazards are defined in DOE-STD-3009-94 as those hazards that “are routinely encountered in general industry and construction and for which national consensus codes and/or standards (e.g., Occupational Safety and Health Administration, transportation safety) exist to guide safe design and operation without the need for special analysis to define safe design and/or operational parameters.” These standard industrial hazards were dismissed from further analysis in the facility FSAR Annexes. Standard industrial hazards that can contribute to the uncontrolled release of radioactive or hazardous material, and the remaining hazards from the hazardous material/energy source checklist that were not dismissed represent hazards requiring further characterization and evaluation as potential accident analysis candidates.

### 3.3.1.2 Hazard Evaluation

The hazard evaluation was a structured and systematic examination of the SNF Project facilities and operations described in Chapter 2.0 of each facility FSAR Annex. Standard industry (American Institute of Chemical Engineers) hazard evaluation techniques were used. The hazard evaluation was performed by a team of cognizant SNF Project operations and engineering personnel, safety analysts familiar with the SNF Project, and technical experts in specialty areas.

A preliminary hazard analysis (PHA) technique is used to analyze facility operations and situations that are primarily operations driven. A PHA focuses in a general way on the hazardous materials and major process areas of a plant. The PHA technique normally is used in the preliminary phase of plant development for cases where experience provides little or no insight into potential safety problems. The technique also may be helpful when analyzing large existing facilities or prioritizing hazards when circumstances prevent a more extensive technique from being used.

In the PHA, lists of hazards and generic hazardous situations are examined to determine whether any apply to the facility being analyzed using the following process characteristics:

- Raw materials
- Intermediate and final products (and their reactivity)
- Plant equipment
- Facility layout
- Operating environment
- Operational activities (e.g., testing, maintenance)
- Interfaces among system components
- Energy sources

A PHA yields a qualitative description of the hazards related to a process design. A PHA also provides a qualitative ranking of hazardous situations that can be used to prioritize recommendations for reducing or eliminating hazards in subsequent phases of the life cycle of the process. Using the PHA technique requires that analysts have access to available plant design criteria, equipment specifications, material specifications, and other sources of information.

Each hazard evaluation was performed using a table to record the specific building location and hazard as described in Section 3.3.1.1 and the evaluation factors identified in this section. Each hazardous condition was reviewed to determine causes for the hazard, potential accidents that could result from the presence of each hazard, and consequences to the public offsite, collocated and facility workers onsite, the environment, or the specific facility. Safety features, segregated into engineering and administrative features, were identified for each hazard based on preventing or mitigating the consequences. Qualitative estimates of the frequency and consequences of the hazardous condition were assigned.

The hazard evaluation included the following information:

- Hazardous condition
- Cause
- Frequency
- Consequence

Potential hazardous conditions (excluding those identified as common industrial hazards) are developed based on the hazards identified and the application of the hazard evaluation methods described above. The description of each hazardous condition includes release of material from a location as the result of an event.

The hazard evaluation tables contain descriptions of causes for hazardous conditions. The identification of causes was based on the hazard identification results, reviews of the systems and historical event data, and other sources of information (existing safety documentation), including discussions with experienced facility personnel. The causes of hazardous conditions include internal events, external events, and natural phenomena events. Single and multiple failures (equipment and human errors) were considered as well as common-cause failures. Both human errors of commission and omission (i.e., human reliability) have been identified as potential causes or contributors to hazardous conditions. The potential causes of a postulated hazardous condition are identified to support a qualitative frequency evaluation.
The assessment of the consequence for each hazardous condition was a qualitative judgment. The assessment took into consideration the impact of passive features (e.g., structures, barriers) listed in the hazard analysis but not the impact of active features or planned controls (e.g., valves, shipping restrictions). The qualitative criteria for consequence assessments are as follows:

**S3**
On the basis of material at risk and causes postulated, there is sufficient material and release energy to affect a receptor at the nearest point of uncontrolled public access.

**S2**
On the basis of material at risk and causes postulated, there is sufficient material and energy to affect an onsite receptor (collocated worker) 100 m from the source of the release.

**S1**
On the basis of material at risk and causes postulated, the release is confined to the facility and affects facility workers.

**S0**
On the basis of material at risk and causes postulated, there is insufficient material released to affect facility workers.

The more severe consequence categories encompass the less severe consequence categories. For example, a hazardous condition assessed as having onsite consequences (S2) is also considered to have facility worker consequences (S1).

The assessment of frequency also was a qualitative judgment. The assessment took into consideration the impact of designed passive features (e.g., structures, barriers) but not the impact of active features or planned controls (e.g., valves, shipping restrictions). The frequency assessments were based on initiating event frequencies of a per year basis. The qualitative criteria for frequency assessments are as follows:

**F3**
The hazardous condition based on the causes postulated is anticipated to occur during the facility's lifetime ($10^2$ to $10^1$ per year).

**F2**
The hazardous condition based on the causes postulated is foreseeable, but unlikely ($10^{-4}$ to $10^{-2}$ per year).

**F1**
The hazardous condition based on the causes postulated is perhaps possible but extremely unlikely ($10^{-6}$ to $10^{-4}$ per year).

**F0**
The hazardous condition based on the causes postulated is considered too improbable ($<10^{-4}$ per year) to warrant further consideration.
3.3.2 Hazard Analysis Results

The results of the hazard analysis were used in the selection of DBAs. Analysis of the unmitigated consequences of the DBAs was used to identify safety function SSCs and to determine their classification. Events identified by the hazard analysis as having significant consequences to offsite and onsite receptors were assigned to risk bins organized by major building area. Figure 3-1 (which is based on Figure 3-3 in DOE-STD-3009-94) presents the likelihood and consequence ranking matrix. In terms of the risk binning process, the accidents chosen from the hazard analysis for further analysis as DBAs were all events identified in consequence categories S3 and S2. Events identified in frequency category F3 as having S1 or S2 consequences are not ignored, they are reviewed and addressed as abnormal events as described in Section 3.3.3 'Methodology for Abnormal Event Identification, Analysis, and Documentation'. These events also are discussed in Section 3.3.3, "Worker Safety." Consistent with DOE-STD-3009-94, the events located in risk bins represent "situations of concern," or "situations of major concern." These events were evaluated as candidate DBAs. The final list of candidate DBAs, sorted by risk ranking, formed the basis for the selection of DBAs analyzed in Sections 3.4 of the facility FSAR Annexes. DBA selection is addressed in Section 3.3.2.5.

The design SSC functions and facility controls used in the final hazard analysis were checked against the up-to-date specific facility designs described in Chapters 2.0, 4.0, and 5.0 in the facility FSAR Annexes.

3.3.2.1 Hazard Identification

Completed facility-specific hazard analysis tables are shown in Sections 3.3.2.1 of the facility FSAR Annexes. As described in Section 3.3.1.1, the hazards were identified by form (e.g., electrical, thermal, friction), type (e.g., motors, power tools, wiring), and building location. The radionuclide content of the special nuclear material is the main inventory of hazardous material in the K Basins, CVDF, and CSB. The toxicological hazards of the radionuclide inventory were reviewed. As described in Section 3.4.1.1, the radiological guidelines are more limiting than the toxicological guidelines for the release of SNF particulate. The radioactive particulate on SNF is primarily oxides of uranium which are not expected to change under current accident conditions. Other hazardous material identified by the hazard identification process includes pyrophoric metals and hydrides, oxidizers, hydrogen, diesel fuel, and other flammable or combustible materials. The specific characteristics of these hazards are identified in detail in the hazard analysis as documented in the facility FSAR Annexes. Specific and comprehensive analyses of fire hazards associated with SNF Project facilities have been completed to augment the standard hazard analyses.

The CVDF and the CSB do not have operating histories, so major hazards resulting from facility operations cannot be identified or summarized as suggested by DOE-STD-3009-94. K Basins operating history is limited to movements of fuel canisters with manual canister grappling tools that have been factored into the K Basins hazard analysis. However, the spent fuel handling and storage activities are similar to those of independent spent fuel storage installations issued materials licenses under 10 CFR 72. Similarity exists in that these independent spent fuel storage installations must handle SNF containers similar to the SNF Project's.
transportation casks and MCOs. The 10 CFR 72 dockets, including notices of violations issued and reported under 10 CFR 72.75, “Reporting Requirements for Specific Events and Conditions” were reviewed. The facilities reviewed included Fort St. Vrain, H.B. Robinson, Pacific Sierra Nuclear, Vectra-Pacific Nuclear Fuel, Oconee, Prairie Island, Calvert Cliffs, Surry, Point Beach and several facilities licensed under 10 CFR 72. Major hazards from similar independent spent fuel storage installations were considered when performing the hazard analyses for the SNF Project facilities. These hazards include generation of combustible gases, failure of confinement barriers, defects in cask integrity, and the spread of external contamination.

3.3.2.2 Final Hazard Classification. In accordance with DOE-STD-1027-92, the final hazard categorization for each of the SNF Project facilities was performed based on the facility’s final hazard analysis and accident analyses. The final categorizations are based on the unmitigated releases of materials at risk causing the DBAs for the specific facility as described in Sections 3.4 of the facility FSAR Annexes. The facility material inventories were compared against the DOE-STD-1027-92 threshold quantities and final facility hazard categorizations were determined as described in Sections 3.3.2.2 of the facility FSAR Annexes.

3.3.2.3 Hazard Evaluation. The final facility hazard analyses characterized hazards not considered to be standard industrial hazards in the context of the actual SNF processing, handling, and storage to be performed in SNF Project facilities. For example, while an MCO is being handled and stored in a storage tube, a number of initiating events may put the MCO radionuclide inventory at risk. These initiating events were listed and the characterization information identified for the energy sources related to the initiating event. The characterized hazards were entered in the hazard analysis tables by facility area. Each hazardous condition was then identified and recorded along with the potential accidents arising from the presence of the hazardous condition, potential causes and consequences of the hazardous condition, existing design features to prevent the condition or mitigate the consequences, administrative features planned to prevent the hazardous condition or mitigate the consequences, and qualitative estimates of the frequency and consequences of the hazardous condition.

The hazard groupings described in Section 3.3.1.1 provide for systematic evaluation of the hazards based upon common release phenomena. The qualitative severity of the hazard consequence categories described in Section 3.3.1.2 considers the potential impact of the hazard on the offsite public, collocated onsite worker, and the facility worker. The hazard analysis also examined the potential for environmental contamination and listed those preventive or mitigative features that are already a part of the design.

3.3.2.3.1 Planned Design and Operational Safety Improvements. According to DOE-STD-3009-94, this section discusses commitments (resulting from the hazard evaluation) for the planned major design fuel handling and cleaning, MCO loading, MCO handling, or MCO storage improvements for the specific facility that are not yet implemented. In general, because the facility design and accident analyses were developed in parallel, the opportunity to provide feedback for design consideration has been available. As the hazard evaluation and specific accident analyses have progressed for each of the SNF Project facilities, cost-effective modifications that improve safety have been incorporated into the design. Therefore, in general...
there are no outstanding major improvements for improved safety planned as a result of the hazard evaluation that are not part of the current design and planned facility operations (MCO processing, handling or storage) at the SNF Project facilities.

### 3.3.2.2 Defense in Depth

The SNF Project is committed to protecting the health and safety of the environment, workers, and the public through its commitment to and implementation of numerous environmental, safety, and health programs. These activities are identified and discussed in the programmatic chapters of the FSAR. In particular, HNF-3552, *Spent Nuclear Fuel Project Execution Plan*, describes these efforts to ensure a “defense-in-depth” approach to project implementation. A summary of fundamental points relevant to the concept of defense in depth is as follows:

- **Builds layers of defense** against releases of hazardous materials (radiological and toxic chemical) to reduce reliance on any one layer.

- **Can be considered independent of functional classification of feature** (i.e., core features are expected to be safety class and safety significant as required, but not all defense-in-depth features are required to be safety class or safety significant).

- **Includes barriers to hazardous releases and protection of those barriers**
  - Barriers can be physical (design features) and operational (administrative controls).
  - Barriers depend upon high-quality design and construction and competent operating personnel.
  - Innermost layers of defense are preferably highest quality, highest reliability barriers.

- **Provides protective functions that are some combination of passive design features, automatic design features, design features required to alert operators to action, and programmatic features** (e.g., procedures, training, and TSRs).

- **Outer layers of defense (barriers) may provide**
  - Diverse control of a hazard already controlled by inner barriers.
  - Additional hazard mitigation should inner barriers fail.
  - Protection of the inner barriers to prevent their failure.

All SSCs are designed in accordance with applicable codes and standards with a high degree of reliability and simplicity. The designs also encompass human factors considerations to ensure that operations can be conducted safely.
Safety-Significant Structures, Systems, and Components  This section in the facility FSAR Annexes identifies defense-in-depth SSCs for the SNF Project facilities as safety-significant SSCs. Safety-significant SSCs are predominantly required to prevent or mitigate consequences of postulated accident events to the collocated onsite worker. In addition, DOE-STD-3009-94 suggests that SSCs be designated as safety significant if they play a key role in defense in depth (or worker safety). The severity of the event being prevented or mitigated and the number of barriers present are provided in the standard as guidance for the identification of defense-in-depth safety-significant SSCs.

Technical Safety Requirements  This section in the facility FSAR Annexes identifies defense-in-depth SSCs requiring TSR coverage. All identified TSRs have been chosen in relation to postulated accident events that would challenge accident consequence evaluation guidelines for offsite public and collocated onsite worker receptors. The identified TSRs are indicated in the DBA sections and are further explained in Chapters 5 of the facility FSAR Annexes. In addition, criticality prevention features are controlled by TSRs as identified in Chapters 5 of the facility FSAR Annexes.

3.3.2.3.3 Worker Safety  This section in the facility FSAR Annexes identifies significant worker safety-related SSCs and TSRs based solely on worker safety considerations. Worker safety for the SNF Project facilities is ensured by a combination of design features that reduce exposure to radioactive, toxic, and industrial hazards and by institutional practices that, in total, provide adequate protection of workers from these hazards. Protection of the facility worker from standard industrial hazards identified for the SNF Project facilities is achieved through adherence to the institutional safety programs described in this safety analysis report and documented in lower-tier documents such as health and safety plans and job hazard analyses. Such industrial hazards do not require specific safety-significant SSCs or TSR-level administrative features. Therefore, in accordance with the guidance of DOE-STD-3009-94, the remainder of this section deals with protecting workers from the hazards of facility operation exclusive of standard industrial hazards.

The hazard analyses in the facility FSAR Annexes provide an overview of the major features protecting facility workers at their respective facilities. Worker safety features are an integral part of facility design and operation. The major features of worker protection are identified in tables in the facility FSAR Annexes and are categorized by hazard. The hazard location and the potential accident and consequence are identified along with protective features including passive, active, and administrative features. As discussed in the facility FSAR Annexes, the controls identified in the analysis of the DBAs in conjunction with the safety features identified in the hazard analysis and the institutional programs, are demonstrated to be adequate to ensure worker safety.

Protection Against Releases  The hazard analysis was used to develop a list of anticipated conditions that could result in releases affecting only facility workers (i.e., hazardous conditions identified as frequency category F3 and consequence category S1 and having no controls). These hazardous conditions are presented in the individual facility FSAR Annexes and November 1999.
were reviewed to determine whether they represented potential for serious injury or death to the worker. Any such conditions were determined to be safety significant for worker safety.

33234 Environmental Protection This section of the facility FSAR Annexes identifies the external hazards and the means for their prevention and mitigation. The external hazards associated with each facility’s operation all involve the potential release of contaminants. The release pathway for contaminants is only via the air to the boundaries and receptors discussed in Sections 1313 of the facility FSAR Annexes. Liquid release hazards or accidents, such as contaminant releases to the ground or groundwater, are the key hazards to be considered in protecting the environment and are identified in the facility FSAR Annexes. In general, in SNF Project facilities where liquid releases are possible, they are contained by design of the facility. However, the potential exists for the release of large quantities of contaminated water from the K Basins to the environment. Potential environmental consequences, including offsite releases, and required prevention and mitigation features are discussed in subsections of Section 342 of the facility FSAR Annexes. Implementation of the prevention and mitigation features will prevent large releases that could have significant environmental impact.

In general, the SNF Project facilities minimize or do not use toxic chemicals during operations. However, the toxicological hazards of the radionuclide inventory were reviewed, as described in Section 3411, and it was shown that for all accidents involving the release of spent fuel particles and for all frequency ranges, the radiological guidelines are more limiting than the toxicological guidelines (i.e., SSCs and controls necessary to limit radiological risk to within guidelines are more than adequate to limit toxicological risk to within toxicological limits) (HNF-SD-SNF-TI-059).

In general, the SNF Project facility features that protect the onsite collocated worker and public against radiological exposure also serve to prevent and mitigate radiological release to the environment. In addition, sitewide programs for environmental monitoring provide for assessment of the impact of facility releases. Normal MCO processing, handling, and storage activities are expected to have a minor impact on the local and regional environment.

33235 Accident Selection This section of the facility FSAR Annexes provides the results of the accident selection process based on the hazard analysis process. The methodology for the selection of DBAs is specified by DOE Order 5480-23, which states that DBAs are classes of accidents that are used to provide the design basis parameters for release barriers and mitigating systems. As such, this is a common requirement among the SNF Project facilities and is described below.

The representative and bounding conditions in turn define an envelope of operations that is used to evaluate safe operation of the facility, both in terms of its initial startup and operating lifetime and during the evaluation of facility modifications using the unreviewed safety question determination process. The basic accident selection methodology used for SNF Project facilities and documented in the facility FSAR Annexes is as follows.
Use the hazard analysis to identify hazards and postulate accident scenarios for each operational area of the facility (hazards that have the possibility of affecting other operational areas of the facility are either evaluated within the operational area in which they originate or are referred to the other area for further evaluation).

- Make preliminary evaluations of frequencies and consequences for these events.
- Organize the events having significant consequences into categories.
- Choose a bounding event representing the most severe consequence and highest risk scenario, from each of these categories for further analysis as a DBA.
- Consider also the less severe events that pose unique and important phenomenological challenges to the facility.

Candidate accidents are selected by binning the identified hazards in terms of frequency, consequence, and risk. The frequency and consequence categories that are used in this binning process are defined in Section 3.3.1.2. The final set of candidate accidents resulting from the hazard binning process is presented in Section 3.3.2.3.5 of the facility FSAR Annexes and contains all identified category S3 and S2 events. All of these events and the controls selected for their prevention and mitigation, are described in DBA discussions in subsections of Section 3.4.2 of the facility FSAR Annexes. The selected DBAs then establish the functional requirements that the safety-class and safety-significant SSCs must meet.

3.3.3 Methodology for Abnormal Event Identification, Analysis, and Documentation

The DOE orders are the controlling requirements for the SNF Project; however, additional NRC criteria were established in the Concurrence with the K-Basins Spent Nuclear Fuel Project Policy on Nuclear Safety Requirements (Grumbly 1995) (hereafter referred to as the Policy). The Policy required new SNF Project facilities to achieve “nuclear safety equivalency” to comparable NRC-licensed facilities. NRC equivalency requirements were identified in WHC-SD-SNF-DB-002 Spent Nuclear Fuel Project Path Forward Nuclear Safety Equivalency to Comparable NRC-Licensed Facilities and HNF-SD-SNF-DB-003.

Specific NRC equivalency requirements of interest are those associated with facility conditions not analyzed as “normal operations or accidents” as required by the DOE safety analysis process. These conditions, described as “off-normal operations or abnormal operations” in the NRC documentation, are expected to occur during the lifetime of the facility but do not result in radiological releases outside the facility. Facility worker exposure to ionizing radiation while responding to abnormal events will be controlled by site and facility radiological protection and ALARA (as low as reasonably achievable) requirements.

This section describes the process used to identify, analyze, and document abnormal events fitting the NRC profile for “off-normal or abnormal operations.” This requirement for inclusion
of abnormal operations is part of the NRC equivalency requirements identified in HNF-SD-SNF-DB-003. The process builds upon the discussion in Section 3.3.1.2 and is diagramed in Figure 3-2.

This section also discusses implementation of NRC nuclear safety equivalency ANSI/ANS-57 9-1992 *Design Criteria for an Independent Spent Fuel Storage Installation (Dry Type)* and ANSI/ANS-57 2-1983, *Design Requirements for Light Water Reactor Spent Fuel Storage Facilities at Nuclear Power Plants*, present a set of events for consideration in the design and accident analyses for a spent fuel storage installation. The discussion in this section uses the terminology of ANSI/ANS-57 9-1992 but the terminology of ANSI/ANS-57 2-1983 also applies. Table 3-2 defines the event frequency that is related to each of the events outlined in these standards and relates the terminology used in ANSI/ANS-57 9-1992 to the terminology used in ANSI/ANS-57 2-1983.

*ANSI/ANS 57 9 1992 1992 Design Criteria for an Independent Spent Fuel Storage Installation (Dry Type)*
American Nuclear Society La Grange Park Illinois

This section is limited to consideration of abnormal and accident conditions. Design event I occurrences are associated with normal operation. Protection of the facility worker from normal and abnormal events will be addressed in Chapters 7 and 8 of the facility FSAR Annexes as suggested by DOE-STD-3009-94. Chapter 7 also contains a summary of the calculations performed to determine the impact of normal operations upon members of the public. Facility loadings experienced during design event I conditions (i.e., normal operation) such as dead and live weight, pressure, and thermal loading will be discussed in Chapters 2 and 4 of the facility FSAR Annexes as suggested by DOE-STD-3009-94. Similar loadings for the MCO are discussed in HNF-SD-SNF-SARR-005, *Multi-Canister Overpack Topical Report*. Design event II, III, and IV occurrences are identified by the hazard identification process discussed in Section 3.3.1. Facility-specific consequence analyses for design event II, III, and IV hazards are performed as discussed in Section 3.3.3 of the facility FSAR Annexes.

Design events II and III are associated with abnormal events. Abnormal events are operating conditions resulting from situations outside of normal operations, where normal operations are defined by process flow diagrams, system design descriptions, and operation and maintenance procedures. This category encompasses abnormal, upset, and off-normal operations from malfunctions of systems, operating conditions, or operator errors. This category applies to events that are expected to occur annually or several times during the lifetime of the facility. Expected consequences of abnormal events can include an increase in occupational exposure of workers or guidelines.

Design events IV are associated with accident occurrences. Accidents are addressed in Section 3.4 of the SNF Project FSAR.

### 3.3.1 Use of Facility Hazard Analysis Results

Consistent with the DOE Order 5480.23 and DOE-STD-3009-94 qualitative likelihood and severity classifications, frequency and consequence rankings were assigned to each hazardous condition during the hazard analysis process. The frequency and consequence rankings are described in Section 3.3.2.

The frequency/consequence matrix from DOE-STD-3009-94 and the definition from Section 3.3.2 were used to identify events fitting the NRC off-normal or abnormal operations profile. Hazard analysis tables, containing the frequency and consequence rankings for hazardous conditions and potential accidents or events, are included in SNF Project facility-specific hazard analysis report.

Hazardous conditions and their associated potential accidents or events that fall into boxes identified as F3 and part of F2 (frequencies from annually to once per 100 years) and S0 or S1 are likely to occur during the facility design lifetime. SNF Project facility design lifetimes are 40 years for the CSB and less than 5 years for the CVDF and the K Basins. These events have been analyzed in the category of abnormal events. The specific identification and analysis of these events is further described in the SNF Project facility-specific FSAR Annexes.

### 3.3.2 Abnormal Events Binning

Abnormal events identified by the above process were binned into groups having similar operational impact on the facility. While there are numerous...
ways to bin events the SNF Project determined that grouping events according to their operational impact provided a logical connection to operational-related procedures and the steps necessary to return the facility and process to normal operations. For each bin the following format and descriptive information is provided:

**Event** The event, or events, having similar operational impacts including the location of event type of failure or mis-operation and system or systems involved

**Postulated Cause of Event** The occurrences that could initiate the event or events under consideration

**Detection of Event** The means or methods (e.g., visual or audible alarms or routine inspections) to detect events

**Analysis of Effects and Consequences** The consequences of the event, or events, under consideration

**Corrective Actions** Corrective actions necessary to return to a normal situation

Chapter 7.0 of this volume and the facility FSAR Annexes contain the results of calculations of the impact of abnormal events on members of the public.

### 3.4 ACCIDENT ANALYSIS

This section presents the methodology for formal development and analysis of the potential accidents at the SNF Project facilities. Results and development of preventive and mitigative features are provided in the facility FSAR Annexes.

#### 3.4.1 Methodology

This section presents the methodology used to develop the potential accidents described in the facility FSAR Annexes. The accident analysis for each DBA starts with a description of the accident scenario with the major assumptions identified. The accident source term is then determined. Source terms for the accidents have been obtained through phenomenological and system response calculations. Once a source term has been determined, onsite and offsite consequences are calculated for the atmospheric transport pathway. These consequences are then compared to evaluation guidelines for onsite consequences or release limits for offsite consequences for the identification of safety-class SSCs and TSRs.

#### 3.4.1.1 Source Term Composition (Radiological and Toxicological)

The bounding source term considered for the accident analyses is based on data for the fuel in the K East and K West Basins given in HNF-SD-SNF-SARR-005, HNF-SD-SNF-TI-009, 105-K Basin Material Design Basis Feed Description for Spent Nuclear Fuel Project Facilities defines an inventory for safety
analysis by considering inventories of Mark IV, Mark IA, and single-pass reactor fuel in the K Basins. High-burnup Mark IV fuel, the fuel type that results in the highest estimated dose to people exposed to the material, was selected as the bounding inventory for radiological dose calculations. Nuclear accountability records give the basis for the quantity, exposure variation and decay time variation of the stored fuel. The radionuclide inventory was estimated from these data.

The MCO contains finely divided particulate material associated with oxidation of the fuel. This material includes an oxide layer on the fuel and particulate remaining on fuel surfaces and in crevices after fuel washing and racking into the MCO as well as expected increases in oxidation products that occur during queuing at the K Basins and processing at the CVDF. The particulate inventory of the MCO dominates the airborne release. The radionuclide inventory of the sludge also is bounded by the high-burnup Mark IV fuel. The radionuclide content of sludge, based on sample analyses, is reported in Volume 2 of HNF-SD-SNF-TI-009. Comparison of the observed activity of sludge samples (activity per mass of uranium) with high burnup Mark IA fuel indicates that Mark IA fuel bounds the sludge observations for sludge samples.

Because any environmental release of SNF could have toxicological as well as radiological effects, both are computed for comparison with risk evaluation guidelines. From this comparison, the predominant risk of the spent fuel particles can be determined, and controls can be identified that prevent or mitigate both risks, thus simplifying the analysis and presentation. A detailed comparison of the toxicological and radiological hazards presented by the spent fuel particles has been performed (HNF-SD-SNF-TI-059). The basic assumptions used to show that the radiological risk guidelines are more limiting than the toxicological risk guidelines are listed below:

- The risk evaluation guidelines for toxicological and radiological hazards (Sellers 1997) are the foundation for determining the severity of a postulated airborne release under accident conditions. Both sets of guidelines cover onsite and offsite receptors and distinguish three accident frequency categories. The projected radiological consequences of an accident must be less than the appropriate radiological guideline. Similarly, the toxicological consequences of an accident must be less than the corresponding toxicological guideline.

- The primary material released under accident conditions is SNF particulate matter, which is mostly oxides of uranium. The safety basis composition of SNF (HNF-SD-SNF-TI-015) was used in the comparison. It is assumed that the bounding case accidents do not introduce toxic chemicals in addition to the particulate or change the relative toxicological versus radiological hazard of the particulate inventory used in the comparison (i.e., the particulate is assumed to be a single material with both radiological and toxicological effects). Note that chemical forms were assumed that would be most limiting. For added conservatism, the radiological dose factors were the largest allowed, and the air concentration limits were the smallest allowed. It has been shown that the radiological guidelines will be exceeded for a smaller mass of particulate released than the toxicological guidelines.
Because SNF contains no corrosive chemicals, a conservative exposure averaging time of 15 minutes was used in the calculation of average air concentration. Note that the time-weighted permissible exposure limit is based on an 8-hour averaging time while the emergency response planning guidelines are based on a 1-hour averaging time.

Air transport for very short durations is normally computed using a puff model. For the distances from release locations to the Site boundary, release durations less than 8 minutes could be modeled this way. Since the air concentration averaging time is 15 minutes, the puff model is not appropriate. Air transport is represented with a plume model for all release durations.

Long exposure times are a concern for chemical hazards. The air concentration guidelines use values with defined exposure times. If these times are exceeded, there is a potential for increased risk to the individuals downwind. The air concentration guidelines were conservatively reduced by the ratio of the assumed averaging time (15 minutes) to the release duration to account for this possibility.

3.4.1.2 Consequence Analysis. Radiological inhalation dose consequences for each analyzed accident were based on the following factors:

- Mass of material available for release
- Airborne release fraction (or airborne release rate and release time) and respirable fraction
- Leak path factor
- Atmospheric transport and dispersion of airborne particles
- Duration of exposure
- Breathing rates
- Dose conversion factors

The radiological dose to a maximum receptor of interest is typically determined by using the following equation:

\[ D = M \times \frac{Y}{Q'} \times BR \times UD \]
where

\[ D = \text{effective dose equivalent (rem)} \]
\[ M = \text{mass of respirable airborne material released (g)} \]
\[ \chi/Q' = \text{time-integrated atmospheric transport factor (s/m}^3) \]
\[ BR = \text{breathing rate (m}^3/\text{s})^1 \]
\[ UD = \text{dose per unit mass of radioactive material inhaled (rem/g)}^2 \]

The mass of respirable material released \((M)\) is determined by the specific accident scenario. The quantity is a function of the total airborne release fraction (or airborne release rate times release time) the respirable fraction and the leak path factor of any passive structural enclosure that may cause deposition of an airborne release before the release enters the atmosphere. The leak path factor is based on a time-integrated calculation of aerosol deposition within and release from an enclosure of given dimensions with specified leakage area pressure and temperature differentials. The mass of respirable radioactive particulate released \((M)\) during this is calculated using the following equation

\[ M = (\text{MAR})(\text{DR})(\text{RF})(\text{LPF}) \]

where

\[ \text{MAR} = \text{material at risk (kg)} \]
\[ \text{DR} = \text{damage ratio (conservatively assumed to be 1)} \]
\[ \text{RF} = \text{release fraction} \]
\[ \text{LPF} = \text{leak path factor (conservatively set to 1)} \]

The specific value of each parameter is determined in the individual DBA analyses and based on the physical phenomena of the accident. The composition of the material released \((M)\) is assumed to be the same as that of the K Basins fuel used to determine the unit dose \((UD)\). The accident conditions, as well as processing activities, are assumed to have minimal effect on the relative amounts of the various nuclides (HNF-SD-SNF-TI-059).

The atmospheric transport factor \((\chi/Q')\) is based on specific release conditions (e.g., ground level or elevated long or short duration) and the receptor's distance from the release. The atmospheric transport factor is the time-integrated normalized air concentration at the receptor's location. The transport factor includes the dilution of an airborne contaminant caused by atmospheric mixing and turbulence. The air transport values used have been generated using the GHQ computer program (WHC-SD-GN-SWD-30002 WHC-SD-GN-SWD-30003).

---

\(^1\)The 12-hour breathing rate is \(3.33 \times 10^{-4}\) m²/s and the 24-hour breathing rate is \(2.64 \times 10^{-4}\) m²/s (HNF-SD-SNF-TI-059).

\(^2\)4.38 \times 10^5\) rem/g uranium (HNF-SD-SNF-TI-059).
Specific air transport values used to determine onsite and offsite consequences are provided in the facility FSAR Annexes.

Air transport factors are calculated using methods found in NRC Regulatory Guide 1 145, *Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants*. In each wind direction, the observed frequencies of particular wind speed and stability class combinations are used to compute a value that is exceeded only 0.5% of the time. This is repeated for all 16 compass directions to determine the worst-case location. In addition, the overall site value (exceeded only 5.0% of the time) was computed. For SNF Project facilities, the sector maximum (0.5%) is always greater than the overall site value (5.0%) for ground-level releases (HNF-SD-SNF-TI-009).

Exposures to the collocated worker onsite are bounded by the individual at the 100 m location. The risk evaluation guidelines apply to this individual. Exposures to members of the public are bounded by the individuals located on Washington State Highway 240 and at the Hanford Site boundary. For assessment purposes, DOE has directed (Sellers 1996) that the Hanford Site boundary be considered the location of the offsite receptor. Consequences at the Highway 240 location are included for reference only. Note that distances to the Hanford Site boundary and to the nearest public access locations onsite were computed using the methodology described in NRC Regulatory Guide 1 145. In this approach, the shortest distance in a 45° sector centered on the direction of interest is chosen for each of the 16 compass directions. Table 3-3 shows the maximum individual locations and air transport factors for ground-level releases.

The consequence dose analyses used in these accidents conservatively ignore adjustment of the air transport factors for the finite size of the source (i.e., building wake effects) or for the elevation of the release above ground level (i.e., stack effects). The outlet stack heights are less than twice the height of the building, which is an insufficient height to take credit for these effects. However, the duration of the release does affect the air transport values. Durations less than 1 hour use a point source model. Durations from 1 hour to 2 hours add the effect of plume meander. Air transport factors for longer periods (i.e., 12 and 24 hours) are calculated from the 2-hour and annual average values according to the method in NRC Regulatory Guide 1 145.

For accident analyses without controls, dose calculations for the maximum onsite individual assume that the individual remains at a distance of 100 m (328 ft) for the duration of plume passage up to a maximum of 12 hours. The 12-hour maximum duration is chosen because it is the normal shift for operating personnel. Dose calculations for the maximum offsite individual assume that the individual remains at the worst-case distance for the duration of plume passage up to a maximum of 24 hours. The 24-hour maximum duration is judged to be an appropriate endpoint for consequence calculations based on the premise that the offsite individual can be notified and appropriate corrective action taken within 24 hours of the start of the accident. For accident analyses with controls, a different exposure duration may be used based on a demonstrated ability to detect the accident and protect the receptor.

The 12 and 24 hour values are computed by interpolation. The rest are computed by GXQ (WHC SD GN SWD 30002 1995 GXQ Program Users Guide Rev 1 Westinghouse Hanford Company Richland Washington) All GXQ runs use a release height and receptor height of zero meters.<br><sup>a</sup>Use of K West represents bounding values for both K Basins.<br><sup>b</sup>For the Canister Storage Building  this receptor is located 100 m ESE.<br><sup>c</sup>For the Canister Storage Building  this receptor is located 12 670 m E.<br><sup>d</sup>For the Canister Storage Building  this receptor is located 17 390 m ESE.<br><sup>e</sup>NA = not applicable.
Inhalation rates (BR) for the reference man (ICRP Publication 23) are used. The light activity breathing rate $(3.33 \times 10^{-4} \text{ m}^3/\text{s})$ normally applies during the first 16 hours of the day when the person is assumed to be awake. The resting breathing rate $(1.24 \times 10^{-4} \text{ m}^3/\text{s})$ applies during the last 8 hours of the day when the person is assumed to be asleep. The 24-hour average breathing rate is $2.64 \times 10^{-4} \text{ m}^3/\text{s}$.

The dose per unit mass of radioactive material is the 50-year dose commitment for all relevant exposure pathways per gram of radioactive material inhaled. The major radiation exposure pathway for the identified accidents is inhalation of radioactive material. Dose contributions from the submersion pathway were calculated and found to be negligible with respect to the total dose for the radionuclides of interest (Hey 1995). Doses from groundshine also are expected to be negligible because most of the radionuclides of interest are alpha emitters. Therefore, the doses from groundshine and submersion are not included in the radiological dose calculations.

Potential doses from the ingestion pathway are not considered because DOE, state, and federal emergency preparedness plans limit ingestion of contaminated food in the event of an accident. DOE/RL-94-02, *Hanford Emergency Response Plan*, governs emergency response for all Hanford Site facilities. The primary determinant of exposure from the ingestion pathway is the effectiveness of public health measures (i.e., interdiction) rather than the severity of the accident itself. Ingestion, if it occurs, involves a relatively slow-to-develop pathway and is not considered an immediate threat to an exposed population in the same sense as the inhalation pathway. In addition, calculations in HNF-SD-SNF-TI-059, *A Discussion on the Methodology for Calculating Radiological and Toxicological Consequences for the Spent Nuclear Fuel Project at the Hanford Site*, show that the contribution of ingestion to the total dose is negligible compared to the inhalation contribution.

The composition of the K Basins fuel decayed to May 31, 1998 was used to determine the committed effective dose equivalent per gram $(4.38 \times 10^5 \text{ rem/g})$ of respirable release (HNF-SD-SNF-TI-059). Isotopes of plutonium, americium, and curium constitute 99.5% of the total inhalation dose. The values for the dose per unit respirable radioactive material inhaled (UD) are the product of the activities and the dose conversion factor found in EPA Federal Guidance Report Number 11 *Limiting Values of Radionuclide Intake and Air Concentration and Dose Conversion Factors for Inhalation Submersion and Ingestion*. The dose conversion factor for tritium was increased by 50% to account for skin absorption (ICRP Publication 30). The committed effective dose equivalent for $^{40}$Kr is the submersion dose factor from EPA Federal Guidance Report Number 12 *Manual of Protective Action Guides and Protective Actions for Nuclear Incidents*. The value of the dose conversion factor divided by the light activity breathing rate.

**3.4.3 Toxicological Effects** The SNF is primarily uranium metal, which is known to have toxicological effects. Plutonium and other transuranic heavy metals also are present in small quantities but add little to the overall toxicity of the fuel. For example, if the toxic air concentration limits for uranium are applied to neptunium, plutonium, americium, and curium, the sum-of-fractions' indicator of toxicity increases about 0.2% (HNF-SD-SNF-TI-059). Thus, the uranium content of SNF controls the potential health impacts downwind following a postulated accident.
accident. Uranium acts like many heavy metals to damage one or more internal organs of individuals exposed to high air concentrations. The toxicity depends on the solubility of the uranium, with more soluble compounds being a greater hazard because they are transferred from the respiratory tract into the blood more quickly. The chemical form, of radiological isotopes that is most soluble (toxic) was assumed when determining the toxicological effects.

No routine chemical processes are conducted in the SNF Project facilities. Purging and backfilling the MCOs involves the use of an inert gas (helium). Some chemicals such as those used for equipment decontamination, may be used occasionally (HNF-SD-SNF-CM-001). However, there are no chemical inventories of concern for safety analysis considerations.

3.4.1.4 Frequency Estimates. The frequency and consequence of each design basis or evaluation basis accident is to be evaluated to determine the effectiveness of selected preventive and mitigative controls. Thus each DBA is evaluated and a frequency assessment made to determine the frequency of the initiating event and subsequent probabilities of failures required to result in the identified consequence. This evaluation of the frequency of the total accident scenario is documented for each DBA represented in the accident analysis. The frequency and consequence for each DBA are then used to determine whether the identified controls are sufficient to meet DOE guidelines. This process develops quantitative frequencies for the DBAs and results in qualitative probabilities for the remaining accidents identified in the hazard analysis.

3.4.1.5 Risk Guidelines. The DOE-recommended radiological risk evaluation guidelines (Sellers 1997) are shown in Table 3-4. These risk evaluation guidelines are used for identifying safety-class and safety-significant SSCs, they implement the guidance of DOE Order 6430.1A, Section 1300.14 ‘Guidance on Limiting Exposure of the Public,’ and are consistent with the graded approach to safety required by DOE Order 5480.23.

Note: All doses are committed effective dose equivalents.

According to HNF-PRO-704, *Hazard and Accident Analysis Process*, satisfaction of the radiological evaluation guidelines in HNF-PRO-704 meets the goals of SEN-35-91 *Nuclear Safety Policy*. However, the guidelines used by the SNF Project (Sellers 1997) are more conservative and more restrictive and bound by the guidelines specified in HNF-PRO-704, Table D-1. As such, satisfaction of the SNF Project radiological evaluation guidelines (Sellers 1997) will meet the goals of SEN-35-91. As discussed in future sections, the mitigated DBAs using the identified preventive and mitigative SSC features met the SNF Project radiological evaluation guidelines (Sellers 1997) and, consequently, the goals of SEN-35-91.

3.4.1.6 Safety Structures, Systems, and Components

"Safety class" and "safety significant," as related to safety SSCs, are defined consistently for the SNF Project. Safety-class SSCs prevent or mitigate releases to the public that would otherwise exceed the offsite radiological evaluation limits or they prevent accidental nuclear criticality. Specifically, DOE Order 6430.1A Section 1300-3.2 states, "Safety-class items are systems components and structures, including portions of process systems whose failure could adversely affect the environment or safety and health of the public. Specifically, safety-class items are those systems components and structures with the following characteristics:

- Those whose failure would produce exposure consequences that would exceed the guidelines in Section 1300-1.4, Guidance on Limiting Exposure of the Public at the site boundary or nearest point of public access
- Those required to maintain operating parameters within the safety limits specified in the operational safety requirements during normal operations and anticipated operational occurrences
- Those required for nuclear criticality safety
- Those required to monitor the release of radioactive materials to the environment during and after a DBA
- Those required to achieve and maintain the facility in a safe shutdown condition
- Those that control the safety-class items described above [DOE Order 6430.1A, Section 1300-3.2, Safety Class Items]

A safety-class SSC satisfies the criteria of DOE Order 6430.1A (Sellers 1997) if the SSC does one of the following:

1. Prevents or mitigates offsite doses in excess of 500 mrem (5 mSv) total effective dose equivalent
2. Places or maintains an operating process in a safe condition that prevents or mitigates offsite doses in excess of 500 mrem (5 mSv) total effective dose equivalent
3 Monitors the release of radioactive materials to the environment during and after accidents in which the monitor's output initiates emergency response plan actions or operator actions to place the operating process in a safe condition in accordance with criterion 2

4 Maintains criticality controls

5 Supports the safety function of a safety-class SSC, this includes control and monitoring functions (e.g. operating air, electrical power, instrumentation)

Safety-significant SSCs prevent or mitigate releases of radiological materials or toxic chemicals to onsite workers. This includes barriers that are judged to substantially contribute to defense in depth independent of quantitative analysis. Safety significant also describes worker safety SSCs that protect the facility worker from serious injury caused by hazards not controlled by institutional safety programs. Specifically HNF-PRO-704 implements criteria for safety-significant SSCs as follows:

6 Prevents or mitigates a radiological dose or chemical exposure that challenges the risk evaluation guidelines in Letter 97-SFD-172 (Sellers 1997)

7 Places or maintains an operating process in a safe condition that prevents or mitigates consequences that exceed criterion 6 listed above

8 Prevents or mitigates exposure in excess of 5 rem (50 mSv) total effective dose equivalent or an airborne concentration in excess of Emergency Response Planning Guidelines-2 limit to facility operators who are relied on to achieve the safe condition of criterion 2 or criterion 7 listed above

9 Monitors the release of radioactive and/or hazardous materials to the environment during and after accidents where the monitor's output initiates emergency response plan actions or operator actions to place the operating process in a safe condition in accordance with criterion 7

10 Supports the safety function of a safety-significant SSC this includes control and monitoring functions (e.g. operating air, electrical power, instrumentation)

11 Prevents or mitigates an acute fatality to a facility worker or serious injury to a group of workers, except where the SSCs are controlled through an implemented institutional safety or radiation protection program

12 Provides defense-in-depth prevention or mitigation of an uncontrolled release of radioactive and/or hazardous material deemed significant in the safety analysis

For each accident scenario, the airborne radiological dose calculated using the methods described here is compared with the appropriate onsite and offsite evaluation guidelines and
limits If the radiological dose for the unmitigated case exceeds the guideline, mitigating safety features with appropriate safety-class and/or safety-significant functional classification, are described. The dose consequences are recalculated taking appropriate credit for the mitigating safety features to verify that the mitigated doses satisfy the guidelines.

3.4.1.7 Multi-Canister Overpack Particulate Inventory and Other Common Design Basis Accident Assumptions

The safety basis MCO particulate inventory used in the accident analyses and other assumptions has some relevance to all the DBAs and is listed here to establish consistency between individual accident analysis chapters.

- The safety basis loose particulate inventory is 0 kg immediately after washing at the K Basins.
- The safety basis particulate inventory for an MCO is 15 kg at the end of draining at the CVDF and up to 25 kg after processing.
- The safety basis particulate inventory for an MCO at the CSB after 40 years of storage is 34 kg (HNF-SD-SNF-TI-015).

3.4.2 Design Basis Accidents

According to DOE Order 5480.23, DBAs are those accidents that are postulated for the purpose of establishing functional requirements for safety-class and safety-significant SSCs. The DBAs have been analyzed to quantify consequences and compare them with evaluation guidelines. The process is iterative, starting by taking no credit for mitigative features and comparing the results to the evaluation guidelines. Credit is then taken for safety SSCs that prevent or mitigate the consequences to show that the results are below the evaluation guidelines. The process continues after the evaluation guidelines are met by identifying other SSCs that, while not designated as safety class, provide additional mitigative features as defense in depth. Finally, identified safety-class or safety-significant SSCs must be defined to have safety functions to meet the applicable functional preventive or mitigative requirements (if any) to address the consequences of the DBA. The DBAs, the quantified consequences, and the comparisons with evaluation guidelines are provided in the facility FSAR Annexes. In addition, each individual DBA section references a supporting calculational note that provides more detail.

3.4.3 Beyond Design Basis Accidents

DOE Order 5480.23 Attachment 1, paragraph 4 f (3)(d) currently requires consideration of beyond DBAs for nuclear facilities but presents no clear guidelines as to how or to what criteria they should be evaluated and judged. DOE-STD-3009-94 indicates that the purpose of beyond DBA presentation is to gain insight into the magnitude of these events particularly if they are close in frequency to pertinent DBAs but beyond the credible range and have consequences that exceed evaluation guidelines. While these events would be beyond...
requirements of further safety-class or safety-significant functions, they might provide guidance on the prioritization of long-term safety improvements for a facility. The Standard specifically excludes evaluation of human-generated external events as beyond DBAs. Beyond DBAs address issues such as the following:

- Breach of a low-heat MCO during receiving caused by excessively cold weather and resulting ice formation
- Collapse of the building superstructure as a result of natural phenomena hazards of a frequency lower than the facility's current natural phenomena hazard design basis events
- DBAs currently included in Sections 3 4 2 of the facility FSAR Annexes with the assumption that safety-class SSCs currently credited have failed. Examining the unmitigated consequences of these events as presented in the facility FSAR Annexes provides insight into the magnitude of the consequences of the events.

The results from analyses of beyond DBAs are provided in the facility FSAR Annexes.

4 0 SAFETY STRUCTURES, SYSTEMS, AND COMPONENTS

4 1 INTRODUCTION

The purpose of this chapter is to provide a general overview description of the methodology and criteria used to identify and select Spent Nuclear Fuel (SNF) Project structures, systems, and components (SSCs) that are necessary to ensure public and onsite worker safety, provide defense-in-depth, or contribute to facility worker safety or institutional control as identified in Chapter 3 0. Additional information specific to individual SNF Project facilities is provided in the facility annexes to the SNF Project Final Safety Analysis Report (FSAR). This chapter is organized and prepared in accordance with the requirements of DOE Order 5480 23, Nuclear Safety Analysis Reports, as amplified by DOE-STD-3009-94, Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports.

The SNF Project facilities are designated hazard category 2 nuclear facilities with the potential for an accident resulting in significant onsite and offsite consequences. Hazard category 2 facilities are designed with safety-significant SSCs to provide protection to the onsite workers, and as appropriate, safety-class SSCs to provide protection to the offsite public. The public protection function requires that safety-class SSCs receive more formality to establish functional requirements and performance criteria than safety-significant SSCs.

Each accident analysis section in Chapters 3 0 of the facility FSAR Annexes concludes with a summary of safety SSCs that provides the basis for FSAR Annex Chapters 4 0. A summary listing of the accident categories and the designated safety SSCs that prevent or mitigate their consequences is provided in the facility FSAR Annexes. Also provided are a summary list of the safety SSCs identified and the level of safety provided for each accident category. Many SSCs provide a safety function for prevention or mitigation of more than one accident. Detailed definitions of safety-class and safety-significant SSCs are provided in Section 3 4 1 6.

4 2 REQUIREMENTS

The requirements that form the basis for selection of safety SSCs are found in HNF-SD-SNF-RD-001, Spent Nuclear Fuel Project Standards/Requirements Identification Document. The specific requirements applicable to this chapter include:

- DOE Order 6430 1A, General Design Criteria
- DOE Order 5480 23, Nuclear Safety Analysis Reports
- DOE Order 5480 28, Natural Phenomena Hazards Mitigation
- DOE Letter 97-SFD-172, Risk Evaluation Guidelines (REGs) to Ensure Inherently Safer Designs (Sellers 1997)
In Letter 95-SFD-167 Implementation of the K Basins Spent Nuclear Fuel Project (SNFP) Regulatory Policy (Sellers 1995) the U.S. Department of Energy (DOE) establishes the requirement that new SNF Project facilities such as the Cold Vacuum Drying Facility and Canister Storage Building achieve "nuclear safety equivalency" to comparable U.S. Nuclear Regulatory Commission (NRC)-licensed facilities. The SNF Project identified the NRC requirements that were needed in addition to existing and applicable DOE requirements to establish nuclear safety equivalency. These NRC requirements and the process used to identify them are documented in HNF-SD-SNF-DB-003 spent Nuclear Fuel Project Path Forward Additional NRC Requirements WHC-SD-SNF-DB-010, Cold Vacuum Drying System Natural Phenomena Hazards and in NRC Regulatory Guide 3.48, Standard Format and Content for the Safety Analysis Report for an Independent Spent Fuel Storage Installation or Monitored Retrievable Storage Installation (Dry Storage). These documents establish specific design requirements for the Cold Vacuum Drying Facility and Canister Storage Building.

4.3 SAFETY-CLASS STRUCTURES, SYSTEMS, AND COMPONENTS

The following paragraphs describe the processes used to identify safety-class SSCs for the SNF Project facilities. Refer to the facility FSAR Annexes for the specific safety-class SSCs. Hazard category 2 facilities do not normally have the consequence potential associated with high hazard facilities such as Class A reactors. As described in DOE-STD-3009-94 for the SNF Project facilities the same level of information is not expected to be provided in the FSAR as is expected for Class A reactors. The facility FSAR Annexes include determination of safety functions and functional requirements for safety SSCs and designation of performance criteria. The FSAR is focused on identifying functional requirements that, in general, are neither absolute nor subject to fine safety margin resolution. Associated performance criteria are only defined for critical operational aspects of SSCs and not general design requirements. Safety analyses and design information for the safety-class SSCs are provided in each facility FSAR Annex. In accordance with DOE Order 6430.1A, safety-class SSCs are subject to appropriately higher quality design, fabrication, and test standards and codes to assure reliability and allow credit for capabilities assumed in the safety analysis. Safety-class SSCs are designed to the Boiler and Pressure Vessel Code Section III Class II (ASME 1995), or to other comparable safety-related codes and standards appropriate for the system being designed. See the facility FSAR Annexes for specific applicable codes and standards.

DOE Letter 97-SFD-172 (Sellers 1997) states that identification of safety-class engineered safety features for the SNF Project shall remain consistent with DOE Order 6430.1A. This Order defines safety-class SSCs including portions of process systems as those SSCs whose failure could adversely affect the environment or the health and safety of the public. Detailed definitions of safety-class SSCs are provided in Section 34.16.

The SSCs credited with a safety-class function in Chapters 30 of the facility FSAR Annexes are detailed in Sections 4.3 of the facility FSAR Annexes. The sections also include details regarding the representative and bounding accident for each safety-class SSC, safety
function codes and standards, system description, functional requirements system evaluation, and controls (technical safety requirements)

DOE Order 6430 1A identifies aspects related to safety-class SSCs that must be addressed to a higher quality standard. These are described in the following paragraphs.

**Single-Failure Criterion and Redundancy**

The design shall ensure that a single failure (as defined in DOE Order 6430 1A) does not result in the loss of capability of a safety-class system to accomplish its required safety functions. To protect against single failures, the design shall include appropriate redundancy and shall consider diversity to minimize the possibility of concurrent common-mode failures of redundant items.

**Equipment Environment Considerations**

- **General**

  Safety-class items shall be designed to withstand the effects of, and be compatible with, the environmental conditions associated with operation, maintenance, shutdown testing, and accidents. The environmental capability of equipment shall be demonstrated by appropriate testing, analysis, and operating experience, or other methods that can be supported by auditable documentation or a combination of these methods.

- **Environmental Qualification of Equipment**

  Equipment qualification shall provide assurance that safety-class items will be capable of performing required safety functions under design basis accident conditions. The qualification shall demonstrate that the equipment can at a minimum perform for the period of time that its safety functions are required. Environmental temperature, pressure, and humidity shall be based on the most severe postulated accident affecting the particular item.

- **Equipment Operability Qualification**

  Testing or a combination of testing and analysis shall be the preferred method of demonstrating the operability of fluid system components, mechanical equipment, instrumentation, and electrical equipment that are required to operate during and following a design basis earthquake.
Maintenance

The design shall consider the maintainability factors peculiar to the specific equipment to be used in the facility. Facility design shall provide for routine maintenance, repair, or replacement of equipment subject to failure.

Safety-class items shall be designed to allow inspection, maintenance, and testing to ensure their continued functioning, readiness for operation, and accuracy.

The design of all process equipment shall include features to minimize self-contamination of the equipment, piping, and confinement areas. The design of process equipment shall also include features to minimize the spread of contamination out of local areas.

Testing

The design shall include provisions for periodic testing of monitoring, surveillance, and alarm systems. In addition, the design shall provide the capability to periodically test under simulated emergency conditions safety-class items required to function under emergency conditions.

4.4 SAFETY-SIGNIFICANT STRUCTURES, SYSTEMS, AND COMPONENTS

DOE-STD-3009-94 states that in general, safety-class SSCs require more formality in establishing functional requirements and performance criteria than safety-significant SSCs because of their public protection function. For hazard category 2 facilities, there is potential for an accident resulting in significant onsite consequences which may have consequences offsite. These facilities characteristically have safety-significant SSCs. SSCs designated as safety significant are designed to meet the single-failure criteria of safety-class SSCs and secondary confinement where the potential exists for significant onsite consequences which may have offsite consequences. As with safety-class SSCs, safety-significant performance criteria are only defined for critical aspects of SSCs not general design.

DOE Letter 97-SFD-172 (Sellers 1997) provides a rigid definition of safety-significant SSCs. This letter states that NRC Regulatory Guide 3.48 requires an evaluation of accidents to workers (defined in the letter to be collocated worker within the controlled area). Location of the collocated worker varies at the Hanford Site. Consequently, the determination is made that the collocated worker be 100 m from the facility or that distance which results in the maximum calculated exposure to the collocated worker thereby allowing minimization of actual exposures. This location will be used for the designation of safety-significant SSCs to protect collocated workers and to provide defense in depth. DOE Letter 97-SFD-172 (Sellers 1997) further states that identification of safety-significant engineered safety features shall remain consistent with DOE-STD-3009-94 but with the additional conservatism to address the collocated worker.
Finally, the letter states that onsite risk evaluation guidelines will be employed to identify safety-significant SSCs to protect the collocated workers.

DOE Order 6430 1A identifies several aspects related to safety-class SSCs that must be addressed to a higher quality standard (see Section 4 3). These aspects related to design, qualification, operability, maintenance, and testing are applied to the extent possible to safety-significant SSCs.

The SSCs credited with a safety-significant function in Chapters 3 0 of the facility FSAR Annexes are detailed in Sections 4 4 of the facility FSAR Annexes or are combined in annex Sections 4 3 and 4 4 as appropriate for ease of presentation.

5.0 DERIVATION OF TECHNICAL SAFETY REQUIREMENTS

5.1 INTRODUCTION

This Chapter consists of summaries and references to pertinent sections of the safety analysis report that are used to describe design and administrative features needed to prevent or reduce the consequences of an accident. The Safety Limits, Limiting Control Settings (LCSs), Limiting Conditions for Operation (LCOs), Surveillance Requirements, Administrative Controls (ACs) and Design Features form the basis of the Technical Safety Requirement (TSR) document and provide the logical link between the TSRs and the safety analysis report.

As discussed in Chapter 3.0 of the facility annexes to the Spent Nuclear Fuel (SNF) Project Final Safety Analysis Report (FSAR), a hazard categorization process assessed the hazardous material inventory at risk for release, unmitigated by any safety features. The TSRs for each of the facilities were developed based on the graded approach applied to the hazard and accident analyses and the final hazard category 2 designation for SNF Project facilities.

This Chapter includes the following information:

- Qualitative and quantitative TSR selection criteria
- Derivation logic for minimum staffing levels
- Identification of TSR interfaces with other Hanford Site facilities

The facility FSAR Annexes include the following facility-specific information:

- Operational modes that designate distinguishable facility configurations and operational conditions
- Derivation discussion of the TSR controls selected
- A table that links the Chapter 3.0 accident analyses and the TSRs
- A list of Design Features not covered by the TSRs

The necessary and sufficient preventive and mitigative features determined to be essential in Chapter 3.0, "Hazard and Accident Analyses," and described in Chapter 4.0 "Safety Structures, Systems and Components," are identified in the facility FSAR Annex chapters. Information necessary for preparing the separate TSR document required by U.S. Department of Energy (DOE) Order 5480.22, "Technical Safety Requirements," also is provided in these chapters.

TSRs define acceptable conditions, safe boundaries, and management or ACs that ensure safe operation of a nuclear facility and reduce the potential risk to the public and onsite workers from uncontrolled releases of radioactive material or from radiation exposures caused by inadvertent criticality (DOE Order 5480.22). As established in Chapter 3.0 of the facility FSAR...
Annexes the toxicological hazards of the radionuclide inventory are bounded by the radiological consequences. Therefore, control of the radiological risk similarly controls any lesser risk from toxicological hazards.

5.2 REQUIREMENTS

The requirements that form the basis for developing TSRs are found in HNF-SD-SNFRD-001, *Spent Nuclear Fuel Project Standards/Requirements Identification Document*. Specific requirements applicable for this Chapter include the following:

5.3 TECHNICAL SAFETY REQUIREMENTS COVERAGE

The TSRs for analyzed hazards and accidents are summarized in Tables 5-1 of the facility FSAR Annexes. This table lists TSR controls in accordance with the accident analyses for each facility FSAR Annex. Chapter 3. Table 5-1 is written to provide a road map from the respective accident analysis section to the relevant subheadings within Section 5.5 of the facility FSAR Annexes, where derivation details are arranged by TSR control.

The necessary and sufficient TSR controls are established based upon consideration for public safety, significant defense in depth, significant worker safety, and for maintaining radiological consequences below risk guidelines.

5.3.1 Criteria

Chapter 3.0, Section 3.3.1 details the control selection process from initial hazard analysis identification to selection of hardware or administrative programs for controls. Guidance for selecting TSR candidates is found in Appendix A of HNF-PRO-700, *Safety Analysis and Technical Safety Requirements*. The criteria used for selecting TSR candidate controls are outlined in Section 5.3.11 and the criteria for determining the level of selected controls are outlined in Sections 5.3.1.2 and 5.3.1.3. Generalized criteria may be found in DOE orders. The following criteria, while considered to meet the generalized order criteria, reflect an interpretive base determined by coordination with other DOE site TSR writing personnel, a...
DOE-sponsored TSR training course, contractor procedures (HNF-PRO-700) reactor standard technical specifications (NUREG-1431), and site expertise

5 3 1 1 Control Selection Criteria  The following elements were considered in the selection of controls

- Analysis Assumptions — Controls were selected to protect major analysis assumptions if the assumption significantly affected consequences

- Incredible Accidents — Controls were selected if required to prevent an accident (i.e., caused the accident to be judged incredible) when an unmitigated consequence analysis was not performed

- Sensitivity Analysis — Controls were selected for less significant analysis assumptions if variability of the assumption significantly affected consequences

- Optimization — Controls were selected that could address multiple accidents to minimize implementation costs

- Priorities — Controls were selected first to prevent, then to mitigate first to involve passive systems, then to involve actively engineered systems, and first to use engineered controls then to use administrative programs

- Practical Safety-Class and Safety-Significant Designation — Controls were selected that would have value in being designated safety class or safety significant

- Risk Guidelines — Controls were identified that would bring the frequency or consequences within onsite risk evaluation guidelines and/or offsite accident release limits identified in Chapter 3.0 of the facility FSAR Annexes

- Human Factors — Controls were selected that took into account human factors considerations

- Facility Worker Safety — Controls were selected that would not significantly increase exposures to the facility worker or would significantly minimize serious risk to facility workers as discussed in Chapter 3.0

- Significant Defense-in-Depth — Controls were selected from the suite of defense-in-depth items if they significantly minimized risk as discussed in Chapter 3.0

- Operational Flexibility — Controls were selected that minimized the need for additional operators or maintenance personnel

5 3 1 2 Safety Limits and Limiting Control Settings  DOE-STD-3009-94 states that SLs [Safety Limits], if used, are reserved for a small set of extremely significant features that prevent
potentially major offsite impact. Hanford Site-specific procedures extend this SL applicability to those features that prevent potentially major onsite impact as well. Criteria for the selection of Safety Limits are established as the following set of elements which must be all true before a Safety Limit is selected for any of the defined bounding accidents:

- A primary passive barrier failed (e.g., multi-canister overpack [MCO])
- Passive barrier failure was the direct result of exceeding a physical parameter (e.g., system pressures sufficient to cause catastrophic failure of the MCO)
- This physical parameter can be directly measured by field personnel (e.g., tempered water temperatures)
- Radiological consequences without controls exceeds either onsite risk evaluation guidelines or offsite accident release limits
- The physical parameter limit prevents an accident from occurring rather than mitigating an accident after it has already occurred.

LCSs are setpoints on safety systems that control process variables to prevent exceeding Safety Limits. The specific setpoints are chosen such that if exceeded, sufficient time is available to automatically or manually correct the condition before exceeding Safety Limits. The LCSs are normally combined with their respective LCOs. By combining the LCSs with the LCOs, the LCS setpoint becomes part of the operability of the system. Furthermore, safety is enhanced by placing the applicability actions, and surveillance for a system in a single location, and the complexity of the TSR document is reduced.

5.3.1.3 Limiting Conditions for Operations and Administrative Controls Controls for accidents and hazards exceeding offsite or onsite risk guidelines which are not candidates for Safety Limits according to the criteria listed above are candidates for either LCOs or ACs. ACs are considered equally important to the control philosophy as LCOs. They are not treated as less meaningful controls for safety.

LCOs are prepared for systems, equipment, or conditions that provide safety functions and meet one or more of the following descriptions:

- Installed instrumentation that is used to detect and indicate a criticality accident or a significant degradation of physical barriers to the release of radiological material.
- Structures, systems, and components (SSCs) that are relied upon in the safety analyses to prevent or mitigate accidents or transients that involve the assumed failure or present a challenge to, the integrity of a physical barrier to the release of radiological or hazardous material.
- Process variables or environmental or facility conditions that are initial conditions for those design basis accidents or transient analyses that involve the assumed failure of or present a challenge to, the integrity of a physical barrier

- Experiments and experimental facilities that could provide a path through barriers to the release of radiological or hazardous material or that affect criticality safety

- Systems and equipment that are used for handling fissile material when identified in the accident analyses as being part of the primary success path to providing an acceptable risk of facility operations

In addition, ACs are established as necessary to support operating limits provided by Safety Limits, LCSs and LCOs and to provide requirements that maintain the safety basis of the facility as described in the safety basis documentation

The requirements contained in Chapters 6 through 17 that form the basis for the AC programs are contractual requirements. Many of the programs may be administered by contractor organizations that are outside of the SNF Project organizational structure. The minimum requirements for each AC program are found in the program key elements section of the TSR document. However, a noncompliance within a specific procedure that implements an AC program is not necessarily a TSR violation. A TSR violation occurs as a result of failure to comply with an AC program (not necessarily individual implementing procedures) or the intent of an AC program

5.4.4 Surveillance Requirements Each LCO identified in the facility FSAR Annexes (Section 5.5.X) includes the information necessary to derive the appropriate surveillance requirements

5.3.2 Safety Structures, Systems, and Components not Provided with Technical Safety Requirement Coverage

The safety-class and safety-significant SSCs that have not been provided with TSR coverage are identified in the facility FSAR Annexes. All other safety SSCs are provided with TSR coverage with an LCO or are included in an AC program. The bases for not providing TSR coverage are provided in the facility FSAR Annexes

5.4 DERIVATION OF FACILITY MODES

5.4.1 Operational Modes

The facility operational modes for the SNF Project facilities are identified to indicate overall facility status. See Sections 5.4.1 of the facility FSAR Annexes for the facility-specific mode definitions
5 4 2 Minimum Staffing Levels

The minimum operations shift complement in the facility modes is established in each facility FSAR Annex and is based upon the minimum staff in each mode considered adequate to perform the minimum safety functions necessary to protect the health and safety of the public onsite workers, and the environment during normal operations, and abnormal and emergency conditions. Consideration is given to the human factors principles addressed in Chapter 13 that guide day-to-day operations.

Determination of the minimum staff is based on ensuring that the following safety criteria are met:

- TSR compliance
- Emergency initial notification and initial response

The minimum staff does not include individuals necessary to fulfill the SNF Project mission goals and objectives, or to meet all other safety, environmental and authorization basis requirements and commitments.

Qualification training for the minimum staff (managers, engineers, operators, and health physics technicians) is addressed in Chapter 12. The program for TSR, emergency, and alarm response administrative procedures is also addressed in Chapter 12. Emergency response is addressed in Chapter 15. The bases for determining the minimum staff are provided in the following paragraphs:

Normal Operations — The minimum staff during normal operations is necessary to (1) safely operate the facility, (2) perform required TSR surveillance to ensure minimum TSR compliance (3) provide radiological control, and (4) perform maintenance of safety SSCs. Surveillance, such as system calibrations and functional tests, and AC program commitments are planned and scheduled to ensure TSR compliance.

Abnormal Conditions — The minimum staff during abnormal conditions is necessary to perform required actions specified in LCO action statements with completion times of "immediately" or less than 8 hours to ensure TSR compliance. Hanford Site experience has shown that additional staff could be provided within 8 hours if needed (considering the most adverse weather and travel conditions) to ensure all LCO completion times are met. LCO completion times of "immediately" imply the highest sense of urgency and are given top priority over all other activities. The minimum staff is not given tasks that could interfere with meeting TSR requirements.

Emergency Conditions — The minimum staff during emergency conditions is necessary to respond to the spectrum of accidents analyzed in Chapter 3 of the facility FSAR Annexes. The minimum staff must make prompt initial notifications and implement initial protective actions to preclude or reduce the exposure of individuals affected by hazards or unsafe conditions.
conditions during an emergency. Specific functions that must be performed by the minimum staff in an emergency include:

- Implementation of alarm response, plant response, and emergency management procedures
- Classification of events
- Initial prompt notifications
- Performance of administrative functions, such as preparing occurrence reports
- Communication of facility status and response to questions
- Support for the U.S. Department of Energy, Richland Operations Office (DOE-RL) Emergency Operations Center

5.5 TECHNICAL SAFETY REQUIREMENT DERIVATION

This section details level of control and derivation bases for the TSRs. This section is organized by control and includes a derivation discussion for those surveillance associated with each specific control. It can be used as an interface to link the accident analyses and the TSRs. It defines the reasons controls were chosen, including details about AC bases that are not discussed in the TSR document. Tables 5-1 of the facility FSAR Annexes provide a road map between the accidents in Chapters 30 and the TSR controls derived from them.

All controls are discussed within their applicable facility FSAR Annexes except for Sections AC 5.1 through 5.6 of the separate TSR documents. AC 5.1, "Purpose," AC 5.2, "Contractor Responsibility," and AC 5.3, "Compliance," define the need for subsequent AC provisions and clarify responsibility according to good management practice. AC 5.4, "Technical Safety Requirement Violation," AC 5.5, "Occurrence Reporting," and AC 5.6, "Organization," satisfy the requirements of DOE Order 5480.22 Section 9.3 (5). This DOE order section requires ACs for reporting deviations and identifying staffing requirements. Worker safety program requirements are addressed in other FSAR sections based on design and operations information.

5.6 DESIGN FEATURES

Design Features are those features not covered elsewhere in the TSRs that, if altered or modified, would have a significant effect on safety. Design Features are normally permanently built-in features that do not require or infrequently require maintenance or surveillance and are
normally not subject to change by operations personnel. The categories of Design Features to be addressed in accordance with DOE Order 5480.22 include the following:

- Vital passive components such as piping, vessels, supports, confinement structures, and containers
- Configuration and physical arrangement of the facility where safety is a concern including site characteristics such as the locations of public access roads, collocated facilities, facility area boundaries, site boundaries, and distances to the nearest residences
- Building materials if the safe operation of the facility depends on any component being constructed of a particular material

Changes to Design Features are considered significant modifications. The unreviewed safety question process ensures that changes to Design Features are appropriately analyzed and controlled so that they do not adversely affect safe operation of the facility. The configuration management system that controls changes to Design Features is discussed in Chapter 17.0, "Management, Organization and Institutional Safety Provisions."

Design Features for each of the facilities that, if altered or modified, would have a significant effect on safe operation are identified in the facility FSAR Annexes. Descriptions of these Design Features are provided in Chapter 2.0, "Facility Description." The safety functions they perform are provided in Chapter 4.0, "Safety Structures, Systems and Components."

5.7 INTERFACES WITH TECHNICAL SAFETY REQUIREMENTS FROM OTHER FACILITIES

The SNF Project facilities interface with each other and separate Hanford Site facilities both physically and administratively. These interfaces include utilities, fire protection, emergency preparedness, waste management, and SNF material transfers. SNF Project programs will be put in place to ensure that interactions with other facilities and their safety requirements do not affect the SNF Project facilities safety basis and do not exceed the safety analyses requirements.

The following discussion includes a description of the utilities, fire protection, emergency preparedness, and waste management interfaces and applicable safety programs. The SNF material transfers section includes a description of the transfer interfaces and TSRs required between SNF Project facilities the material is being transferred to or received from.
571 Utilities

The interfacing utilities include water and electrical power. The service water distribution system is the source of water for the Cold Vacuum Drying Facility (CVDF) and the Canister Storage Building (CSB) fire protection systems. Electrical power to the SNF Project facilities is supplied by the Hanford Site commercial power distribution system.

There are no utility interface requirements that affect the SNF Project facilities safety basis.

572 Fire Protection

The SNF Project fire protection program discussed in Chapter 11 interfaces with the Hanford Fire Department DOE-RL, and the Emergency Preparedness Program, discussed in Chapter 15. The fire protection program is established to meet the objectives of DOE Order 5480.7A, Fire Protection, to minimize the potential for a fire, ensure that fire does not cause an onsite or offsite release of radiological and other hazardous material that would threaten public health or the environment, provide an acceptable level of personnel life safety from fire, protect process control and safety systems from fire, ensure vital DOE programs do not experience unacceptable delays, and minimize property damage. The fire protection program is implemented through the Hanford Site policies and procedures on fire protection. An overview of the fire protection program is provided in HNF-PRO-340, Fire Protection Program Overview.

There are no fire protection interface requirements that affect the SNF Project safety basis.

573 Emergency Preparedness

The scope of the emergency preparedness program (see Chapter 15) ensures that appropriate actions are taken to protect the health and safety of the workers, the public, and the environment. Personnel at each facility are responsible for responding to all emergencies involving their facility and activities. The interfaces between the SNF Project facilities and other emergency organizations are described in DOE/RL-94-02, Hanford Emergency Response Plan, which applies to all Hanford Site employees and facilities. Under this plan, the contractor emergency response organization and the DOE-RL emergency response organization provide guidance to SNF Project facility personnel and oversee the response actions. DOE-RL interfaces with onsite emergency response organizations and offsite agencies including the DOE-Headquarters emergency management team.

There are no emergency preparedness interface requirements that affect the SNF Project facilities safety basis.
5.7.4 Facility Waste Management Program

The SNF Project waste management program (see Chapter 9.0) focuses on (1) protecting the workers, the public, and the environment, (2) ensuring proper management of waste from its point of generation to its final disposition, (3) ensuring compliance with applicable federal and state regulations, and (4) ensuring that radioactive and hazardous material exposure is as low as reasonably achievable. To accomplish these objectives, the waste management program contains the following basic elements:

- Plans and procedures governing waste designation, segregation, packaging, monitoring, treatment, storage, transportation, disposal, recordkeeping, and reporting
- Policies and programs for employee training, audits, and inspections
- Waste minimization goals and practices that reduce the volume of radioactive and hazardous waste and the spread of contamination

All waste transfers from the SNF Project facilities are controlled by procedures that meet the requirements specified in the appropriate DOE orders, Hanford Site requirements, federal and state regulations, and industry standards. WHC-EP-0063-04 Hanford Site Solid Waste Acceptance Criteria also identifies requirements for radioactive wastes and dangerous wastes as defined in WAC 173-303 "Dangerous Waste Regulations."

There are no waste management interface requirements that affect the SNF Project facilities safety basis.

5.7.5 Receipt and Transfer of Spent Nuclear Fuel

The SNF Project interfaces between the facilities through the receipt of SNF at CVDF from the K Basins and the transfer of the dried fuel from the CVDF to the CSB. This section describes the SNF material transfers between the K Basins, CVDF, and CSB, and applicable controls.

5.7.5.1 Spent Nuclear Fuel Transfers from K Basins to the Cold Vacuum Drying Facility
The K Basins send SNF to the CVDF that meets the criteria and assumptions identified in Chapter B3.0 of Annex B, the CVDF FSAR. The K Basins will send SNF to the CVDF in accordance with established controls that require a program to maintain consistency between the K Basins TSRs and the TSRs of interfacing facilities through the use of approved and controlled operating specifications and procedures. WHC-SD-WM-SAR-062 K Basins Safety Analysis Report does the following:

- Establishes maximum shipping temperatures to ensure the initial conditions and assumptions used in the CVDF safety analysis are valid.
• Establishes MCO basket loading controls and overall MCO loading controls to ensure the initial conditions and assumptions used in the CVDF and CSB safety analyses are valid.

• Establishes requirements for shipping preparations (such as cask-MCO void space purging requirements) to ensure the initial conditions and assumptions used in the CVDF safety analysis are valid.

• Defines the initiation of a shipping window to ensure that transfers from K Basins to the CVDF are adequately controlled such that the receipt pressure assumptions within the CVDF accident analyses are protected (Annex B, the CVDF FSAR, defines the completion point of the shipping window).

5.7.5.2 Spent Nuclear Fuel Transfers from the Cold Vacuum Drying Facility to the Canister Storage Building  The CVDF sends SNF to the CSB that meets the criteria and assumptions identified in Chapter A3.0 of Annex A the CSB FSAR. The only parameters of concern identified in Annex A are MCO seal leakage rates and maximum bulk water content. The CVDF will send SNF to the CSB in accordance with established controls that require a program to maintain consistency between the CVDF TSRs and the TSRs of interfacing facilities through the use of approved and controlled operating specifications and procedures. Annex B, the CVDF FSAR, does the following:

• Requires that proper testing be conducted to establish that the MCO water content is within acceptable levels to ensure that key parameters assumed in the CSB safety analysis are protected.

• Establishes a maximum MCO leak rate to protect leak rate assumptions in the CSB safety analysis.

6.0 PREVENTION OF INADVERTENT CRITICALITY

6.1 INTRODUCTION

This chapter provides the information necessary to document the Spent Nuclear Fuel (SNF) Project criticality prevention program. The material presented in this chapter is intended to describe the essential features of the inadvertent criticality prevention program as they relate to facility safety and to demonstrate its compliance with DOE Order 5480.24 Nuclear Criticality Safety. The SNF Project facilities (K Basins Cold Vacuum Drying Facility [CVDF], the Canister Storage Building [CSB], and the Interim Storage Area [ISA]) are classified as hazard category 2 facilities and have sufficient fissile materials to require a criticality prevention program.

In preparing the evaluations a graded approach was taken that factors in the low enrichment, storage configuration, and inventory limits of the stored N Reactor fuel. N Reactor fuel has a maximum initial enrichment of 1.25 wt% $^{235}$U, and other initial enrichments are 0.95 wt% $^{235}$U and 0.71 wt% $^{235}$U. The storage, handling, decapping, and repackaging of N Reactor fuel into shipping containers in the K Basins have been evaluated for potential nuclear criticality accidents and found to be safe and within the limits established for the fuel storage basins to meet nuclear criticality safety criteria (WHC-SD-WM-SAR-062). Fuel processing at the CVDF and long-term interim fuel storage at the CSB have also been determined to be safe and within the limits established to meet nuclear criticality safety criteria (see Annex B, the CVDF final safety analysis report [FSAR] and Annex A, the CSB FSAR). The buildup of fissile material in sludge, ion exchange modules, cartridge and sand filters, and K East Basin sandfilter backwash pits has been evaluated and the fissile material configurations were found to be critically favorable for all postulated event sequences and material arrangements (WHC-SD-WM-SAR-062).

Transportation of loaded multi-canister overpacks (MCOs) is discussed in HNF-SD-TP-SARP-017 Safety Analysis Report for Packaging Onsite Multi-Canister Overpack Cask. The single pass reactor fuel stored at the K Basins is currently not authorized to be processed at the CVDF or stored in the CSB.

The ISA is used to store sealed casks of SNF. Four types of SNF will be stored at the ISA.

- Fast Flux Test Facility (FFTF) fuel
- Test Reactor and Isotope Production General Atomics (TRIGA)$^1$ reactor fuel
- Pressurized water reactor fuel
- Boiling water reactor fuel

The storage and handling of the FFTF, TRIGA, and light water reactor (LWR) fuels at the ISA has been evaluated for potential nuclear criticality accidents and determined to be safe and within the limits established to meet nuclear criticality safety criteria (see HNF-3553 Annex D). Transportation of the storage casks to the ISA is discussed in WHC-SD-TP-SARP-008, Safety.

See the facility FSAR Annexes for specific evaluations regarding the potential for criticality and the associated engineering and administrative controls

6.2 REQUIREMENTS

The requirements for SNF Project facility criticality prevention are listed in HNF-SD-SNF-RD-001, Spent Nuclear Fuel Project Standards/Requirements Identification Document. The specific requirements applicable to this chapter include:

- Title 10, Code of Federal Regulations, Part 72, "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel and High-Level Radioactive Waste" (10 CFR 72), specifically Section 72 124, "Criteria for Nuclear Criticality Safety"
- DOE Order 5480 24, Nuclear Criticality Safety
- DOE Order 5480 20A, Personnel Selection Qualification and Training Requirements for DOE Nuclear Facilities
- DOE Order 6430 1A, General Design Criteria
- ANSI/ANS-8 1-1983 Nuclear Criticality Safety in Operations with Fissionable Materials Outside Reactors
- ANSI/ANS-8 3-1997 Criticality Accident Alarm System

6.3 CRITICALITY CONCERNS

6.3.1 Criticality Hazards

The criticality hazards discussed in this section involve the fissionable materials in the N Reactor fuel and fuel scrap that is stored in the Hanford Site K Basins. The SNF that is loaded in the MCOs may be in the form of intact fuel elements, partial fuel elements, or pieces of fuel scrap larger than 0.25 in. In addition, these fuel forms may contain fuel oxides and other corrosion products. A description of the N Reactor fuel elements is provided in Table 6-1. The types and quantities of N Reactor fuel analyzed for criticality concerns are described in...

Some Mark IV fuel (designated Mark IVB) contains natural uranium (0.71 wt % $^{235}\text{U}$) in both the outer and inner tubes.

$^a$ Twelve Mark IA fuel assemblies are 66 294 cm (26 1 in) long.
Most fissionable materials involved were initially at one of two enrichments before irradiation: 0.95 wt% or 1.25 wt% $^{235}\text{U}$. Operations procedures at the K Basins ensure that the fuel is segregated by enrichment and loaded in accordance with the limits described in WHC-SD-WM-SAR-062, K Basins Safety Analysis Report. Existing floor sludge and any material removed from the fuel during the cleaning process are discussed in WHC-SD-WM-SAR-062.

The fuel stored at the ISA is contained in sealed casks. Fuel from the FFTF has the highest initial enrichment, 29.28 wt% plutonium with a minimum of 11.63 wt% $^{240}\text{Pu}$. All fuel is in the form of intact assemblies, fuel pins, or fuel elements, and there are no pieces of fuel or fuel scrap as with the N Reactor fuel. Chapter 2.0 of HNF-3553, Spent Nuclear Fuel Project Final Safety Analysis Report, Annex D, “200 Area Intermediate Storage Area Final Safety Analysis Report,” contains a description of these casks and the different fuel design characteristics.

**6.3.1.1 N Reactor Fuel** The vast majority of the 2,100 metric tons of irradiated fuel stored in the K Basins is from the N Reactor. N Reactor fuel has a tube-within-tube design and was fabricated in two basic fuel assembly types, designated Mark IV and Mark IA. Mark IV fuel assemblies have a preirradiation enrichment of 0.95 wt% $^{235}\text{U}$ in both inner and outer elements and a maximum uranium mass of 23.4 kg. The assemblies have an outside diameter of 2.43 in and a length of 17.4 to 26.1 in. Mark IA fuel assemblies have a preirradiation enrichment of 1.25 wt% $^{235}\text{U}$ in the outer element, 0.95 wt% $^{235}\text{U}$ in the inner element, and a maximum uranium mass of 16.7 kg. They have an outside diameter of 2.40 in and a length of 14.9 to 26.1 in. There are 12 Mark IA fuel assemblies that are 26.1 in long, and they will be loaded into a Mark IV basket according to the requirements specified in WHC-SD-WM-SAR-062.

Table 6-1 provides a detailed listing of the N Reactor fuel dimensions and weights. Only the enrichment of unirradiated fuel, before it was loaded in the N Reactor, is given in the table. Analyses performed for N Reactor fuel cover both intact fuel assemblies, inner and outer fuel elements, and pieces of fuel assemblies. If possible, these pieces of fuel assemblies will be assembled into composite assemblies and loaded into fuel baskets. The criticality analysis performed for the contingency of dropping an MCO in which the fuel in all of the MCO baskets rubblizes into optimal scrap, bounds any loading of composite or partial assemblies. Pieces of fuel assemblies that cannot be assembled into composite assemblies were modeled as scrap (see Section 6.3.1.2).

Analyses on the effects of burnup and fission products decay showed that the unirradiated N Reactor fuel is neutronically more reactive (higher infinite criticality factor $k_\infty$) than irradiated fuel in spite of the presence of plutonium products in the SNF (HNF-SD-SNF-CSER-005). Reduced uranium enrichment and the presence of decayed or stable fission products more than compensate for any increase in $k_\infty$ attributable to the plutonium content in the SNF. Analysis of the effect on $k_\infty$ of fission product decay over a long period of time (e.g., 100 years or more) is described in HNF-SD-SNF-CSER-005, Criticality Safety Evaluation Report for the...
*Multi-Canister Overpack* and provides further justification for use of the unirradiated fuel characteristics in the analyses presented in this chapter. Because most of the fuel stored in the K Basins is irradiated, this is conservative for criticality analysis. Only 0.072% of the fuel is unirradiated.

Also stored in the K Basins are fuel types Mark IB, IC, IVB, and IVC. Mark IB and IVB have preirradiation enrichments of 0.71 wt% $^{235}$U and Mark IC has a preirradiation enrichment of 0.95 wt% $^{235}$U. There are no special handling requirements for these fuel types. The Mark IVC fuel has a preirradiation enrichment of 1.15 wt% $^{235}$U in the outer element and 0.95 wt% $^{235}$U in the inner element. No Mark IVC fuel is currently stored in the K Basins.

### 6.3.2 Reactor Fuel Scrap

The SNF that is to be shipped to the CSB is stored in the K East and K West Basins. A significant fraction of the fuel assemblies are assumed to be in a highly damaged or corroded condition, resulting in sludge and broken elements in the canisters. Canister sludge and fine particles of broken fuel are removed during the cleaning cycle of the fuel retrieval operation and are flushed to the integrated water treatment system. Any particulate material that is left after cleaning is classified as fuel scrap for the purpose of criticality analyses and will be loaded into the scrap baskets. It also is anticipated that removal from existing canisters, cleaning, and repacking of seemingly intact fuel assemblies in the K Basins could generate an additional amount of scrap fuel. Particulate that comes off of the fuel as it is dumped on the fuel retrieval system table will be swept into a scrap basket. The fuel will then be sorted. Broken pieces of the fuel assemblies that cannot be assembled into composite assemblies will be treated as scrap and packed separately in baskets specifically designed for loading scrap into the MCOs, as depicted in Figure 6-1. The Mark IA scrap basket has a center post similar to that of a Mark IA fuel basket, shown in Figure 6-2.

A region around the center of both scrap basket types is provided to collect fine pieces of scrap (this region is around the center post of the Mark IA scrap basket). Because the scrap was modeled as optimally sized spaced and moderated, the criticality analyses performed are bounding for all scrap loadings. Mark IV fuel assemblies and scrap are in the K West and K East Basins. A small amount of Mark IA fuel and scrap is stored in the K East Basin and the majority is stored in the K West Basin. Fine particulate material that falls through the perforated base plates of both the fuel and scrap baskets may build up on the floor of the basins. The scrap basket loading limits are based on analysis of spills of optimized scrap to the basin floor over a layer of this fine particulate. The fine particulate also was modeled as optimized scrap.

### 6.3.3 Suspended Uranium Dioxide

While in storage and after being loaded into the MCO, the SNF corrodes forming $\text{UO}_2$. Some of this $\text{UO}_2$ could be removed with the water as small suspended particles. This has been modeled as $\text{UO}_2$ enriched to 1.25 wt% $^{235}$U suspended in water, optimally moderated and reflected (HNF-SD-SNF-CSER-006). The results of the analysis are discussed in Chapter B6.0 of the CVDF FSAR (HNF-3553 Annex B).

### 6.3.4 Fast Flux Test Facility Fuel

Fuel consists of both standard driver fuel assemblies and test assemblies used to test both materials and fuel forms. All of the driver fuel assemblies and most of the test assemblies contain mixed oxide fuel containing $\text{UO}_2$ and $\text{PuO}_2$ in pellet form and...
clad with stainless steel or other experimental steel cladding. Slight variations in fuel enrichment exist but all are bounded by the maximum enrichment of 29.28 wt% plutonium with a minimum enrichment of 11.63 wt% $^{239}$Pu. The uranium in the mixed oxide fuel is either natural or depleted $^{235}$U. Many of the test assemblies were disassembled for post-irradiation testing. The fuel pins from these assemblies are contained in Ident-69 (ID69) pin containers. ID69 is the print designation for pin containers that fit in various locations in the interim examination and maintenance cell at the FFTF, there is more than one type of ID69 container. All SNF from the FFTF is contained in interim storage casks (ISCs) that will be shipped to the ISA. Included in the FFTF inventory are several test assemblies containing sodium-bonded uranium–zirconium metal fuel. This fuel is currently not authorized for storage at the ISA.

6.3.5 Test Reactor and Isotope Production General Atomics Fuel

TRIGA fuel is a ceramic zirconium hydride–uranium fuel with 8.5 wt% uranium content enriched to 20 wt% $^{235}$U. Elements are clad with either stainless steel or aluminum. Two fuel follower control rods also are to be stored at the ISA. The $^{235}$U content is listed in HNF-3553, Annex D, Table D2-4. The fuel is contained in Neutron Radiography Facility TRIGA casks and the fuel follower control rods are contained in U.S. Department of Transportation-6M casks. All these casks are contained in a Rad-Vault described in HNF-3553, Annex D, Section D2.3.

6.3.6 Commercial Light Water Reactor Fuel

The commercial LWR fuel consists of pressurized water reactor fuel assemblies and some boiling water reactor fuel pins which are zircaloy-clad $\text{UO}_2$ fuel enriched to a maximum of 3.6 wt% $^{235}$U. Fuel assemblies from the Point Beach and Calvert Cliffs facilities also were examined at Hanford. This fuel is stored in Nuclear Assurance Corporation (NAC)-1 casks.

6.3.2 Criticality Analysis

Table 6-2 shows the criticality issues for each facility. The specifics of the criticality analyses are discussed in the criticality safety evaluation reports written for SNF operations and are summarized in the facility FSAR Annexes.

An MCO is 166-in long with a 24-in outside diameter and a 0.5-in wall thickness. A total of five Mark IV fuel baskets or six Mark IA fuel baskets may be loaded into an MCO. The dimensions of the baskets are such that the total stack height of the baskets inside the MCO is about the same regardless of the type of basket. A shield plug assembly, consisting of a stainless steel plug, filters, and filter guard plate, is installed in the MCO after loading.

Rad-Vault is a trademark of Chem-Nuclear Systems, Incorporated.

MCO = multi canister overpack
TRIGA = Test Reactor and Isotope Production General Atomics (fuel)
The normal condition is to have each type of SNF contained in baskets designated for that type of fuel (see Figures 6-1 and 6-2) and the baskets in turn stacked in an MCO (see Figure 6-3). The Mark IA fuel basket holds 48 Mark IA fuel assemblies and has a center post specifically designed for criticality control. This post is a hollow stainless steel bar with an outside diameter of 6.625 in and an inner diameter of 1.75 in to allow for the insertion of the long axial process tube for vacuum drying. The Mark IA scrap basket has a similar center post. The Mark IV fuel basket holds 54 fuel assemblies and has a central tube with a 2.64x1 outside diameter for installation of the long axial process tube to vacuum dry the fuel in the MCO at the CVDF. The designs of the MCO and fuel baskets are more fully summarized in HNF-SD-SNF-SARR-005, Multi-Canister Overpack Topical Report.

Each MCO may be loaded in one of three configurations:

- All fuel baskets
- One scrap basket with four or five fuel baskets
- Two scrap baskets and three or four fuel baskets

As discussed in WHC-SD-WM-SAR-062, the fuel basket loading is limited by the design of the fuel baskets. There is no minimum loading requirement for either Mark IA or Mark IV fuel assemblies. The Mark IA and Mark IV scrap baskets have administratively controlled maximum loading limits of 575 kg and 980 kg, respectively. These limits are discussed in WHC-SD-WM-SAR-062.

For criticality analyses of MCOs under normal conditions, each MCO was assumed to contain two scrap baskets, one at the top and one at the bottom, as shown in Figure 6-3, using the fuel basket loading with the highest $k_{eff}$. This loading was determined to contain partially loaded fuel baskets in the configurations shown in Figures 6-4 and 6-5. The Mark IA fuel basket contained 47 fuel assemblies with an empty location in the middle row, and the Mark IV basket contained 53 complete fuel assemblies with an inner element only in the outer row.

Each ISC contains a single core component container (CCC) that may hold a maximum of seven FFTF driver fuel assemblies or test assemblies. A CCC may only hold six ID69 pin containers because they are too long to fit in the central tube of the CCC. Several ISC loadings may be considered to be normal and these are discussed in HNF-3553 Annex D Section D6 3 3 1 1.

The normal loading for the TRIGA fuel cask contains 18 fuel elements, and the Rad-Vault contains six casks. Two U.S. Department of Transportation-6M casks, each containing a single fuel follower control rod, also may be loaded in the Rad-Vault. The center location of the Rad-Vault contains an empty 55-gal drum and the casks are loaded around the outer wall of the vault. Details of the models are discussed in HNF-3553 Annex D Section D6 3 3 2 1.

Similar to the ISCs, the NAC-1 casks have different loadings that may be considered to be normal. These are also discussed in HNF-3553 Annex D Section D6 3 3 3 1.

November 1999
6.3.3 Criticality Criteria and Assumptions

6.3.3.1 Criteria for Acceptable Criticality Determinations  The criticality prevention criterion is that the effective neutron multiplication factor ($k_{\text{eff}}$) shall not exceed $k_{\text{limit}}$ ($k_{\text{eff}} \leq 0.95$ for a loaded MCO) including allowances for all uncertainties and meeting all single contingencies. For criticality safety, the double contingency principle requires that process design incorporate sufficient factors of safety such that at least two unlikely independent, or concurrent changes occur before a criticality accident is possible. The analyses presented in the annexes to this FSAR demonstrate that the double contingency principle is satisfied by showing that the allowed configurations of fissile material in all components and systems will not exceed the $k_{\text{limit}}$ for the violation of any single contingency. The criterion that $k_{\text{limit}}$ not exceed 0.95 for all types and locations of storage casks is based on implementing the US Nuclear Regulatory Commission equivalency requirements described in HNF-SD-SNF-DB-003, Spent Nuclear Fuel Project Path Forward Additional NRC Requirements, and on the US Department of Energy’s policy that new SNF Project facilities achieve a level of nuclear safety equivalent to that of comparable facilities licensed by the US Nuclear Regulatory Commission (Sellers 1995). The criticality prevention criterion may be stated as follows:

\[ k_{\text{eff}} = k_{\text{calc}} - \Delta k_{\text{bias}} + (\sigma_b^2 + \sigma_c^2 + \sigma_d^2 + \sigma_e^2 + \sigma_T^2)^{1/2} \leq k_{\text{limit}} \]

where:

\[ k_{\text{eff}} = \text{calculated effective neutron multiplication constant corrected for bias and uncertainties} \]
\[ k_{\text{calc}} = \text{calculated } k_{\text{eff}} \]
\[ \Delta k_{\text{bias}} = \text{methods bias} \]
\[ \sigma_b = \text{bias uncertainty} \]
\[ \sigma_c = \text{calculational uncertainty} \]
\[ \sigma_d = \text{uncertainty in } k_{\text{eff}} \text{ due to dimensional tolerances} \]
\[ \sigma_e = \text{uncertainty in } k_{\text{eff}} \text{ due to enrichment tolerances} \]
\[ \sigma_T = \text{uncertainty in } k_{\text{eff}} \text{ due to temperature variations} \]

No uncertainty is calculated for variations in the position of the scrap basket in the MCO. This is because the scrap basket is modeled such that the scrap is as close as possible to the bottom of the fuel basket and the scrap basket sides are expanded as widely as possible to conserve mass. The dimensions used exceed the manufacturing tolerances for the basket.

The calculated $k_{\text{eff}}$ must be at the 95% confidence level. For a one-sided distribution, this level is obtained by multiplying the total statistical uncertainty by 1.645 except for $\sigma_b$, which is multiplied by a factor of 2. Applying the factors to get the upper bound of $k_{\text{eff}}$ at the 95% confidence level results in the following equation:

\[ k_{\text{eff}} = k_{\text{calc}} - \Delta k_{\text{bias}} + [(2\sigma_b)^2 + (1.645^2[\sigma_c^2 + \sigma_d^2 + \sigma_e^2 + \sigma_T^2])]^{1/2} \leq k_{\text{limit}} \]
The above formula is generic for all those represented in the facility FSAR Annexes. For all calculations involving SNF in the MCO, the values of the $k_{\text{eff}}$ equation parameters are as follows:

- $\Delta k_{\text{bus}} = -0.0004$ (HNF-SD-SNF-ANAL-013)
- $\sigma_b = 0.005$ (HNF-SD-SNF-ANAL-013)
- $\sigma_d = 0.000546$ (HNF-SD-SNF-CSER-005)
- $\sigma_c = 0.00154$ (HNF-SD-SNF-CSER-005)
- $\sigma_T = 0.00081$ (HNF-SD-SNF-CSER-005)

For a loaded MCO, the equation simplifies to:

$$k_{\text{eff}} = k_{\text{calc}} + 0.0004 + \left[ (0.01)^2 + (1.645)^2 (0.002083^2) \right]^{1/4} \leq 0.95$$

Calculations for the ISCs used the MONK6A and MONK6B codes. No uncertainties were calculated for parameter variations. Instead, fuel enrichments and component dimensions were used that give the largest $k_{\text{eff}}$ values. The equation in this case is as follows:

$$k_{\text{eff}} = k_{\text{calc}} - \Delta k_{\text{bus}} + (2\sigma_b)^2$$

This reduces to the following equation:

$$k_{\text{eff}} = k_{\text{calc}} + 0.015$$

where $(2\sigma_b)^2 - \Delta k_{\text{bus}} = 0.015$ (WHC-SD-SQA-CSWD-20015).

TRIGA fuel was analyzed using MCNP, MONK6B, and WIMS-E/GOLF codes. The application of the uncertainties and biases for each code is discussed in HNF-3553, Annex D, Section D6 3.3.2.1.

The calculations for the LWR fuel in the NAC-1 casks were performed with MCNP and KENO-Va/Seale 4.2. Section D6 3.3.1 of HNF-3553, Annex D, discusses the application of the uncertainties and biases for these analyses.

### 6.3.3.2 Analysis Assumptions for the N Reactor Fuel

All criticality analyses for the CSB CVDF and K Basins are based on conservative assumptions for determining the worst-case normal and credible accident conditions. These assumptions are listed below and are common to all the analyses:

- Optimal moderation for the scrap baskets
- Optimal scrap size (unless controlled)
- Optimal spacing
- Maximum enrichment
- Unirradiated fuel (no burnup)
The assumption of optimal moderation is applied to fuel whenever the fuel geometry is not constrained by the storage canisters MCO fuel baskets, or MCO structure. During abnormal events the fuel was also modeled as optimally moderated and spaced unless constrained by safety class components. If the fuel was assumed to rubblize, it was considered to be scrap. Fuel scrap and floor sludge were always assumed to be optimally configured. The sludge in the integrated water treatment system was modeled as being optimally moderated and spaced based on the maximum particle size of 550 μm. This size is controlled by the safety-class screens on the knockout pots.

6.3.3 Analysis Assumptions for the Fast Flux Test Facility Fuel. The criticality analysis for the FFTF fuel in the ISCs is based on the following set of assumptions:

- The fuel modeled is outer driver fuel, Type 41, with 29.28 wt% plutonium and 11.63 wt% 240Pu, which is the highest total plutonium enrichment for any of the FFTF fuel pins.
- Unirradiated fuel was modeled, no credit was taken for burnup.
- The radial dividers in the ID69 pin containers were neglected (resulting in a positive bias in $k_{eff}$).

A corrosion phenomenon that has been observed for nuclear fuel irradiated in a sodium-cooled reactor and exposed to the corrosive environment of cleaning the residual sodium from the assemblies is called hot-cell rot. This has been observed to occur at other facilities when cleaned assemblies have been stored for long periods of time. Hot-cell rot has not been observed with assemblies from FFTF. For the purpose of this analysis, hot-cell rot was assumed to occur and fuel pins and/or assembly ducts suffer a complete structural failure. Hot-cell rot was not considered credible for ID69 pin containers or CCCs.

6.3.4 Analysis Assumptions for the Test Reactor and Isotope Production General Atomics Fuel. Because different codes were used for the analysis of the TRIGA fuel, the assumptions are not presented in this section. HNF-3553 Annex D Section D6 3 3 2 1 discusses all the models used in the analysis.

6.3.5 Analysis Assumptions for the Light Water Reactor Fuel. The criticality analysis for the LWR fuel in the NAC-1 casks is based on the following set of assumptions:

- Unirradiated fuel was modeled; no credit was taken for burnup.
- The zircaloy cladding was neglected.
- Enrichment for all pins in the model was taken as the highest actual value for any single pin in the assembly.
The casks containing the Point Beach assemblies have a maximum of 179 pins with 3.2 wt% enrichment.

The cask containing the Calvert Cliffs full assembly has a maximum enrichment of 2.72 wt%.

The cask containing the Calvert Cliffs partial assembly has a maximum enrichment of 2.73 wt%.

6.4 CRITICALITY CONTROLS

The requirements for determining engineered and administrative criticality controls are provided by DOE Order 5480.24 and are implemented using the guidance of HNF-PRO-537, Criticality Safety Control of Fissionable Material.

6.4.1 Engineering Controls

The preferred method of ensuring criticality safety is to use passive engineered controls although active engineered controls are also acceptable.

- Engineered controls for the MCOs include features such as the 6 625-in. center post for the Mark IA fuel and scrap baskets and the internal diameter for the MCO.
- Engineered controls in the K Basins include the canisters and components in the fuel retrieval system.
- Engineered controls for the ISCs include both the ISC and the CCC, which are designed to maintain structural integrity for all design basis accidents.
- For the TRIGA fuel, the engineered features include the Neutron Radiography Facility cask, which may hold a maximum of eighteen fuel elements.
- The engineered control for the LWR fuel is the inner pipe containing the loose fuel pins in the NAC-1 cask.

See the facility FSAR Annexes for specific engineering controls.

Configuration control of equipment used to store, handle, transport, and process SNF is maintained in accordance with the guidance of HNF-PRO-544, Criticality Plant Configuration Control. A facility safety equipment list designates all equipment that may impact criticality safety as safety-class equipment. Before work on the equipment, a work authorization is processed, including review by the facility criticality safety representative (CSR) and approval by the facility.
safety organization Chapter 17 of the SNF Project FSAR provides a general description of the SNF Project configuration control program

6.4.2 Administrative Controls

Administrative controls in addition to engineering controls are implemented at each facility to ensure criticality safety. Types of controls are basket loading limits and MCO loading limits. The ISC has administrative controls on loading, and the administrative control for the LWR fuel requires loose fuel pins be loaded into the inner pipe. Administrative controls for the TRIGA fuel include limits on loading the Rad-Vault and spacing between the Rad-Vault and other fuel. See the facility FSAR Annexes for specific administrative controls.

Administrative control of processes and system configurations important to criticality safety is maintained in accordance with the guidance of HNF-PRO-544. Proposed changes to design or process configurations are reviewed by the CSR to ensure that such a change can be performed under an approved evaluation and criticality prevention specification. All changes that impact criticality safety are documented and include proper approval designation.

6.4.3 Application of Double Contingency Principle

The double contingency principle, as defined in DOE Order 5480.24 states that designs shall incorporate sufficient factors of safety to require at least two unlikely independent and concurrent changes in process conditions before a criticality accident is possible. DOE Order 6430.1A Chapter 13 Section 1320, delineates criteria for irradiated fissile material storage facilities. It provides no specific guidance on double contingency but references 10 CFR 72 for further guidance. The double contingency criterion delineated in paragraph 10 CFR 72.124 (a) is similar to the one quoted in DOE-STD-3009-94 Preparation Guide for US Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports.

The design and operation of each facility has been analyzed and engineered, and administrative controls implemented, to ensure the double contingency principle is satisfied. These controls are reported in the facility FSAR annexes. All facility FSAR Annexes purport to satisfy the double contingency requirement by ensuring that any single failure shall not result in criticality. For conservatism, the safety analyses were based on unirradiated fuel (initial enrichment) critical mass parameters. Normal operating conditions for each facility were identified. Potential error or failure situations were developed using the guidelines of Appendix A of HNF-PRO-539 Criticality Safety Evaluations and by evaluating the operations at each facility.
6.5 CRITICALITY PROTECTION PROGRAM

This section presents an overview of the organizational structure and interfaces and the technical and administrative practices of the criticality protection policy and programs for the SNF Project operations. An overview of the criticality safety management program for the SNF Project is shown in Figure 6-6. Each facility is responsible for developing its own criticality safety program in accordance with the requirements of DOE Order 5480.24

6.5.1 Criticality Safety Organization

The organizational responsibilities for criticality safety are described in HNF-PRO-334, Criticality Safety General Requirements. The procedure identifies the organizational elements responsible for individual aspects of the criticality safety and defines the responsibilities of the overall facility management and the operators who handle the fissionable material (i.e., the SNF). The procedure also defines the responsibilities of the engineering organization that performs criticality analyses to establish criticality safety parameters for each individual facility. The SNF Project Safety Review Board provides oversight of all criticality matters. The organization and its responsibilities are described in Chapter 11.0 of the SNF Project FSAR.

The CSR conducts periodic facility inspections and reviews modifications to operating procedures and facility equipment for impact on criticality safety. The CSR also provides information for or conducts the required criticality safety meetings for the operators, prepares criticality prevention specifications and postings, and serves as a point of contact for all criticality safety-related issues.

6.5.2 Criticality Safety Plans and Procedures

The criticality safety plans and procedures for SNF Project operations were developed as required by DOE Order 5480.24. Each facility develops its procedures to comply with the above plans. The general process for preparation, review, approval, distribution, and use of SNF Project procedures is described in Chapter 12.0 of the SNF Project FSAR.

Included in the procedures are provisions for posting criticality safety limits, material and operational controls, review of operations, emergency evacuation, and guidelines for permitting fire fighting water or other moderating materials used to suppress fires within or adjacent to moderation control areas. The general fire fighting provisions are described in Chapter 11.0 of the SNF Project FSAR.

6.5.3 Criticality Safety Training

Criticality safety training requirements are provided in DOE Order 5480.24. The guidance of HNF-PRO-538, Criticality Safety Training, has been used to develop a training program for
the SNF Project operations organization. This program ensures that operators, supervisors, and managers involved in the control, handling, storage, or transfer of the SNF in the MCOs understand their responsibilities for preventing criticalities. The training program ensures that the knowledge and experience profile of all management personnel is commensurate with their assigned responsibilities and that they are aware of the criticality risks involved and the preventive and corrective actions required in performing their responsibilities. The general process for training SNF Project workers is described in Chapter 120 of the SNF Project FSAR.

The Hanford Site training organization provides formal criticality safety training classes for fissile material handlers and managers and engineers. This formal classroom training, which includes written examinations with a minimum passing grade, is required every two years. General topics covered in the formal classroom training include the following:

- Basic criticality principles (consequences of a criticality accident, safety factors for \( k_{\text{eff}} \), and responsibilities for contingency prevention)
- Labeling and posting
- Emergency procedures and required responses

On-the-job facility-specific continuing training is provided through periodic safety meetings as considered necessary by the supervisors and managers with the guidance of HNF-PRO-538. As a part of this training, the facility CSR provides quarterly criticality safety training information to the managers and operators for their review. Annually, the CSR conducts a safety meeting for managers and operators to review this criticality safety training information and present new material as appropriate. Time is allowed during the facility-specific training for the discussion of unusual occurrences and work-oriented problems. Changes to procedures and process standards (which contain the criticality prevention specifications), technical safety requirements, management requirements, and procedures, and emergency procedures, also are addressed.

In addition to the periodic training sessions, each manager of personnel who handle SNF packages is responsible for on-the-job training of those personnel. The workers are not only trained in the use of facility-related procedures and process standards but also in the actual use of equipment to perform the various jobs.

Formal training records that verify satisfactory completion of formal training are maintained by the training organization. The records for job-specific orientation and periodic training are established and maintained by facility management.

### 6.5.4 Determination of Operational Nuclear Criticality Limits

For SNF Project facilities, HNF-SD-SNF-DB-003, in accordance with U.S. Department of Energy policy for U.S. Nuclear Regulatory Commission equivalency (Sellers 1995) requires that \( k_{\text{eff}} \) shall not exceed 0.95 for the CSB, CVDF, and MCO loading (0.98 for SNF in the K Basins).
until loaded into an MCO) The $k_{\text{eff}}$ shall not exceed 0.95 at the ISA. These calculational $k_{\text{eff}}$ limits provide an adequate margin of safety with respect to a criticality $k_{\text{eff}}$ of 1.0.

Criticality safety evaluations are performed in accordance with the guidance of HNF-PRO-537. Unless otherwise stated, all calculations used to verify compliance with the limits were performed using the Monte Carlo computer code MCNP (LA-12625). MCNP is used internationally and has been extensively tested with the ENDF/B-V-based cross sections. Use of other verified and validated codes to verify compliance will be discussed in the affected criticality safety evaluation reports.

The bias and uncertainty for MCNP calculations of low-enriched uranium systems were derived in HNF-SD-SNF-ANAL-013 *MCNP4B Criticality Validation and Bias for Low-Enriched Uranium Systems* and the uncertainties due to dimensional and enrichment tolerances were derived in HNF-SD-SNF-CSER-005. As described in Chapters 6.0 of the facility FSAR Annexes, in HNF-SD-SNF-CSER-005, the calculated values of $k_{\text{eff}}$ are corrected for biases in MCNP and for the dimensional and material uncertainties. WIMS-E validation and MONK6A and 6B validations are described in WHC-IP-0840-FMEF *Validation of WIMS-E for Prediction of Uranium Plutonium Nitrate Solution Critical Masses*, WHC-SD-SQA-CSWD-20015, *MONK6A Pu Validation* and WHC-SD-SQA-CWSD-20019 *MONK6B Pu Validation*. The application of biases and uncertainties is discussed in HNF-3553, Annex D, Section D6.0.

Analyses also are performed to account for operator error contingencies, such as loading Mark 1A material into a Mark IV basket or misloading ISCs, to ensure that the criticality criteria are not violated by those contingencies thus meeting the requirements of DOE Order 5480 23, *Nuclear Safety Analysis Reports* paragraph 4 f(3)(d)& item a, d and e. The limits are established by the criticality safety evaluation reports which are used to develop the criticality specifications that are identified in the technical safety requirements document for each of the SNF Project facilities.

### 6.5.5 Criticality Safety Inspections and Audits

Criticality safety inspections, audits, and assessments are performed at the SNF Project facilities in accordance with the guidance of HNF-PRO-548 *Criticality Safety Inspections and Assessments*. The SNF Project nuclear safety organization periodically verifies and validates that the facility is implementing the criticality safety program adequately. The current DOE Hanford Site contractor Nuclear Safety organization and the Criticality and Shielding organization conduct independent inspections, and make recommendations for program improvements for all Hanford Site nuclear facilities as shown in Figure 6-6 for the SNF Project.

Criticality safety inspections are performed routinely at the facility. The CSR performs monthly or more frequent inspections to verify correct fuel storage thus meeting the requirement of DOE Order 5480 23 paragraph 4 f(3)(d)&, item f and the guidance of HNF-PRO-548.
The criticality safety inspection and assessment reports are maintained in accordance with the SNF Project records management program described in Chapter 17.0 of the SNF Project FSAR. These records are available for review during assessments and also for review of trending for nonconformances.

6.5.6 Criticality Infraction Reporting and Follow-Up

The criticality infraction reporting and follow-up program provides for safe recovery from criticality safety program nonconformances. The underlying principle of the program is to not make a nonconforming situation worse and to prevent recurrence. The nonconforming situation is stabilized as necessary notifications are made, and following evaluation a recovery plan may be developed, approved, and implemented. A long-term corrective action plan may be developed and lessons learned may be incorporated into the facility safety analysis. The nonconformance actions are documented and the records retained in accordance with the SNF project records management program.

The manager of SNF Project Operations is responsible for developing procedures on reporting and follow-up of criticality infractions at SNF Project facilities. The procedures are developed in accordance with the guidelines provided in HNF-PRO-549 “Criticality Safety Nonconformance Response” and HNF-PRO-060 “Reporting Occurrences and Processing Operations Information.”

6.6 CRITICALITY INSTRUMENTATION

Criticality alarm and detection systems are not required for any of the SNF Project facilities. Each facility FSAR Annex contains the specific discussions relating to criticality instrumentation requirements and justification for not requiring criticality alarm and detection systems.

7 0 RADIATION PROTECTION

7 1 INTRODUCTION

This chapter describes the safety policies, procedures, designs, and other considerations relative to radiation protection that maintain radiation exposures as low as reasonably achievable (ALARA) at the Spent Nuclear Fuel (SNF) Project facilities. Credible radiological hazards are identified in Chapters 30 of the facility annexes to the SNF Project Final Safety Analysis Report (FSAR) and are not detailed in this chapter. The radiation protection program elements described in this chapter are designed to minimize potential exposure from radiological accidents and to minimize occupational exposures resulting from normal and off-normal operations.

In those cases where policies, programs, and practices important to safe operation are described in detail in other documents, the information is summarized in this chapter and the documents are referenced. The detailed programs and procedures described in referenced documents may be changed without further U.S. Department of Energy (DOE) approval to the extent that the changes do not constitute an unreviewed safety question as defined by DOE Order 5480.21, Unreviewed Safety Questions.

7 2 REQUIREMENTS

The requirements that form the basis for the radiation protection program are found in HNF-SD-SNF-RD-001 Spent Nuclear Fuel Project Standards/Requirements Identification Document. The specific requirements applicable to this chapter include:

- Title 10 Code of Federal Regulations Part 835, "Occupational Radiation Protection" (10 CFR 835)

7 3 RADIATION PROTECTION PROGRAM AND ORGANIZATION

7 3 1 Radiation Protection Program Elements

The radiation protection program for the SNF Project protects against the basic types of radiological hazards including the following that could affect occupational exposure:

- Contamination with radioactive material
- Ionizing radiation emitted from the multi-canister overpack (MCO) pipes, equipment, or other radiation sources

November 1999
Potential releases of radioactive aerosols, gases, or particles that could become airborne and affect occupational exposure, either by inhalation or external exposure.

Chapters 30 of the facility FSAR Annexes contain a summary of the hazards associated with the SNF Project facilities. The SNF Project radiation protection program is implemented in accordance with standards/requirements identification document (S/RID) Section 11 (HNF-SD-SNF-RD-001), 10 CFR 835, and HSRCM-1, *Hanford Site Radiological Control Manual* to protect against those hazards and against unnecessary radiation exposures from any radiation source in the SNF Project facilities. Table 7-1 identifies the primary elements of the radiation protection program.

### 7.3.2 Radiological Control Organization

Radiation protection organizational requirements are mandated by HSRCM-1. The requirements mandate that a radiological control manager be appointed who is responsible for overseeing a radiation protection program. Field work is performed by radiological control.
technicians supported by professional staff. Qualifications and staffing are consistent with the requirements contained in 10 CFR 835. Specific staffing assignments within the radiological control organization are subject to the discretion of the radiological control manager based on activities to support safe operation of SNF Project facilities.

7.4 ALARA POLICY AND PROGRAM

Minimizing radiation exposure to levels that are ALARA is a fundamental principle of radiation protection. 10 CFR 835.101, "Radiation Protection Programs," mandates formal plans and measures for applying the ALARA process in controlling occupational radiation exposure. To support a comprehensive ALARA program, a review of applicable U.S. Nuclear Regulatory Commission (NRC) documents was made by the SNF Project organization. As a result of this review, sections of NRC Regulatory Guide 8.8, Information Relevant to Ensuring that Occupational Radiation Exposures at Nuclear Power Stations will be as Low as is Reasonably Achievable, are to be applied in the Cold Vacuum Drying Facility (CVDF) and Canister Storage Building (CSB) designs as applicable and address piping systems that carry radioactive materials. Regulatory Guide 8.8 is listed as an additional requirement in HNF-SD-SNF-DB-003, Spent Nuclear Fuel Project Path Forward, Additional NRC Requirements. Each facility FSAR Annex addresses this design requirement.

ALARA policy during facility operations and/or design is described in the following:

- HNF-PRO-1618, ALARA Policy and Management Commitment
- HNF-PRO-1619, ALARA Organization and Responsibilities
- HNF-PRO-1620, ALARA Program Scope
- HNF-PRO-1621, ALARA Decision-Making Methods
- HNF-PRO-1629, Administrative Control Levels
- HNF-PRO-1631, ALARA Training
- HNF-PRO-1633, ALARA Program Records
- HSRCM-1, Hanford Site Radiological Control Manual
- SNF Project administrative procedures

The radiation protection program governing facility activities follows these policies by implementing ALARA into all facets of radiological work. These policies specifically commit SNF Project organizations to limiting radiation exposures to ALARA levels and acknowledge that the primary method used to achieve ALARA objectives is physical design features. The SNF Project incorporated ALARA principles early on in the design of the CVDF and CSB and in the K Basins modifications.
741 Program Administration

Essential elements of an acceptable occupational ALARA program are defined in DOE G4441-1-2 *Occupational ALARA Program Guide for Use with Title 10 Code of Federal Regulations Part 835 Occupational Radiation Protection* The essential elements as implemented in the SNF Project ALARA program are defined as follows:

- Management commitment
- Assigning specific responsibilities
- Establishing challenging administrative control levels
- Establishing radiological performance goals
- Conducting ALARA training
- Establishing plans and procedures
- Performing internal reviews and audits
- Using optimization methodology to reduce exposure
- Performing radiological design reviews
- Performing radiological work planning
- Maintaining ALARA records

General criteria for an ALARA committee are detailed in HSRCM-1, Article 138 The ALARA program implemented at the SNF Project facilities is documented in SNF Project administrative procedures, which establish lines of responsibility for ensuring that ALARA practices are administered properly.

742 Radiological Design

7421 Requirements The basic elements of radiological (ALARA) design as required by 10 CFR 835 HSRCM-1, and HNF-SP-1145, *Fluor Daniel Hanford Radiation Protection Program, Implementation of Title 10 Code of Federal Regulations Part 835* are summarized below:

- Measures must be taken to keep radiation exposures ALARA by the combination of facility and equipment design and administrative controls The primary methods shall be physical design features, administrative controls shall be used only as supplemental methods to keep exposures ALARA (10 CFR 835 1001(a))

- Physical design features must be demonstrated to be impractical before administrative controls can be used to maintain radiation exposures ALARA (10 CFR 835 1001(b))

- Dose reduction, contamination reduction, and waste minimization features are to be incorporated into the design at the earliest planning stages (HSRCM-1)
Radiological design reviews must ensure the integration of appropriate methods and considerations during the design phase to maintain exposures ALARA during the construction, modification, and operation of the equipment and facility.

During the design phase, optimization methods must be used in developing and justifying facility design and physical controls to ensure that exposure is maintained ALARA during subsequent maintenance and operations (10 CFR 835 1002(a)).

"The design objective for controlling personnel exposure from external sources of radiation in areas of continuous occupational occupancy (2,000 hours per year) shall be to maintain exposure levels below an average of 0.5 mrem (5 microsieverts) per hour and as far below this average as is reasonably achievable" (10 CFR 835 1002(b)).

Actions must be taken to meet the design objective for exposure rates in areas not continuously occupied; this design objective is for exposure rates to be ALARA, and less than exposure rates that would result in an occupational worker receiving more than 20% of the applicable standard in 10 CFR 835 202, 'Occupational Exposure Limits for General Employees' (10 CFR 835 1002(b)).

Actions must be taken to meet the design objective for the control of airborne radioactive material; this design objective is to normally avoid the release of radioactive material to the workplace atmosphere, and in any case to control the inhalation of radioactive material to levels that are ALARA (10 CFR 835 1002(c)).

The design of the facility and the selection of materials shall include features that facilitate operations, maintenance, decontamination, and decommissioning (10 CFR 835 1002(d)).

7 4 2 2 Design  For facility-specific radiological design considerations see the facility FSAR Annexes. Radiological design considerations that affect exposures at all SNF Project facilities are described in Section 10 of HNF-SD-SNF-SARR-005 Multi-Canister Overpack Topical Report.

7 4 3 Performance Goals and Indicators

HSRCM-1 establishes methods for assessing the effectiveness of the radiological protection program including ALARA measures. Under this program, the SNF Project organization has established a system for defining and tracking specific radiological performance goals and performance indicators.
7.4.4 Radiological Work Planning

The planning of radiological work is a key element in the ALARA program. Radiological work at the SNF Project facilities will be planned in compliance with 10 CFR 835 requirements in accordance with HSRCM-1. Radiological activities are subject to planning steps (described in HSRCM-1, Articles 312 and 313) that include formal radiological review, senior management review, ALARA committee review, prejob briefing, enhanced management oversight, and post-job review.

7.4.5 Radiological Work Documentation and Reviews

SNF Project facilities integrate ALARA into the planning, conduct, and post-job reviews of all radiological work in compliance with 10 CFR 835 and HSRCM-1. Key features of this system are discussed in the following subsections.

7.4.5.1 Prejob ALARA Review
A prejob ALARA review ensures that necessary ALARA considerations have been included in the prejob planning to ensure that exposures are minimized. The ALARA Management Worksheet, or its equivalent, documents prejob ALARA considerations, ALARA practices, and the estimated collective dose. The trigger levels (HSRCM-1, Article 312) for deciding on the use of an ALARA Management Worksheet, and thus a more detailed ALARA review, are structured to ensure that the necessary level of attention is given to each task, job, or project.

7.4.5.2 Conduct of Work in Progress
Radiological work is periodically monitored to ensure proper implementation of controls identified in the ALARA Management Worksheet. Review of work in progress includes monitoring and comparing collective dose accumulation and contamination levels with prejob estimates.

7.4.5.3 Post-job ALARA Review
A formal post-job ALARA review occurs whenever job-specific trigger levels (HSRCM-1, Article 352) are reached. This review compares actual doses with prejob estimates, evaluates the effectiveness of ALARA controls, documents lessons learned, and provides recommendations for similar activities.

7.4.5.4 Internal ALARA Program Reviews and Work Practice Assessments
As mandated by 10 CFR 835 102, “Internal Audits,” the SNF Project conducts an internal audit of its ALARA program at an appropriate frequency and at least once every three years. The internal reviews examine details of radiological work, including items such as work control preparation, prejob briefings, conduct of work, and applied ALARA techniques, post-job briefings, and follow-up discussions.

7.4.5.5 ALARA Records
10 CFR 835 704(b), “Administrative Records,” mandates maintaining ALARA documentation. The SNF Project facilities maintain documentation demonstrating the effectiveness of the ALARA program as described in HSRCM-1, Article 742.
7.5 RADIOLOGICAL PROTECTION TRAINING

Radiological protection training requirements are mandated by 10 CFR 835, Sections 901, 902, and 903. Training requirements are implemented by HSRCM-1, Articles 611 to 657. The general criteria for radiological protection training are detailed below.

7.5.1 General Employee Training

All general employees are trained in radiation safety before receiving occupational exposure during access to controlled areas within the SNF Project facilities. The knowledge of radiation safety possessed by general employees is verified by examination. Retraining is provided when there is a significant change to radiation protection policies and procedures that affects general employees and at intervals not to exceed two years. Allowance may be made for previous DOE training on generic radiation safety topics (i.e., those not specific to a site or facility) provided the training was received at another DOE site or facility within the past two years. Documentation of the previous training shall clearly identify the individual's name, date of training, topics covered, and name of the certifying individual.

7.5.2 Radiological Worker Training

The SNF Project radiological worker training and retraining programs familiarize workers with the fundamentals of radiation protection and the ALARA process and are conducted at intervals not to exceed two years. 10 CFR 835 902 requires a training and retraining program for radiological workers and requires retraining on at least a two-year basis. Radiological worker training not specific to a given site or facility may be waived provided that this training has been received at another DOE site or facility within the past two years and provided that proof-of-training in the form of a certification document containing the individual's name, date of training and specific topics covered and it is certified by an appropriate official. Training includes both classroom and applied training. The knowledge of radiation safety possessed by radiological workers is verified by examination before an unsupervised assignment. The level of training is commensurate with each worker's assignment.

7.5.3 Radiological Control Technician Training

Training and retraining programs for radiological control technicians to familiarize them with the fundamentals of radiation protection and the proper procedures for maintaining exposures ALARA are established and conducted at intervals not to exceed two years. Training includes classroom and applied training. The training either precedes performance of tasks assigned to radiological control technicians or is concurrent with such task assignments if the individual is accompanied by and under the supervision of a trained individual.
The required level of knowledge of radiation safety possessed by radiological control technicians is verified to meet requirements by examination, including on-the-job evaluations before any unsupervised work assignment. The training program includes procedures specific to the individual SNF Project facilities. The level of training is commensurate with the technician's assignment. Records of training are monitored and checked to assure only qualified technicians perform assigned duties. Allowance may be made for previous DOE training on generic radiation safety topics (i.e., those not specific to a site or facility), provided the training was received at another DOE site or facility within the past two years. Documentation of the previous training shall clearly identify the individual's name, date of training, topics covered, and name of the certifying individual.

7.6 RADIATION EXPOSURE CONTROL

The radiation protection program is designed to protect workers from hazards associated with:

- External exposure to radiation
- Spread of radioactive contamination
- Inhalation or ingestion of radioactive materials

The primary engineered mechanisms for ensuring exposure control are shielding from direct radiation and ventilation control of airborne radioactive material. Administrative and monitoring controls for ensuring exposure control include radiological access control, workplace monitoring, and automated radiation area monitors equipped with local alarm annunciators.

HNF-SD-SNF-DB-003 requires that the CVDF and CSB incorporate, as applicable, the following NRC requirements:

- Apply the radiological exposure criteria of Title 10, Code of Federal Regulations, Part 72, "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel and High-Level Radioactive Waste," Section 72 104 "Criteria for Radioactive Materials in Effluents and Direct Radiation from an ISFSI or MRS (10 CFR 72 104), to the design and safety analyses.

- Apply the hourly dose limit of Title 10 Code of Federal Regulations, Part 20, "Standards for Protection Against Radiation," Section 20 1301 "Dose Limits for Individual Members of the Public" (10 CFR 20 1301) to the design and safety analysis.

- Incorporate control devices for access to high-radiation areas that conform to the requirements of 10 CFR 20, Section 20 1601, 'Control of Access to High Radiation Areas.'
The 10 CFR 20 1301 hourly dose limit of 0.002 rem (2.0 x 10^{-5} Sv) to the public has been incorporated into the CSB and CVDF designs and safety analyses. This hourly dose limit is assumed to be from external sources for any unrestricted area during normal operations and anticipated occurrences. The 10 CFR 20 1601 requirement for access control devices for high-radiation areas (≥ 0.1 rem/hr at 30 cm) has been applied to the design of the CVDF as discussed in Annex B. The radiological exposure annual dose criteria of 10 CFR 72 104 also have been incorporated into the designs. These criteria apply to design measures to protect any offsite public individual during normal operations and anticipated occurrences both from direct radiation and planned discharges of radioactive materials. These annual dose equivalent criteria are 25 mrem (0.25 mSv) to the whole body, 75 mrem (0.75 mSv) to the thyroid, and 25 mrem (0.25 mSv) to any other critical organ. (Note that existing DOE requirements are 25 mrem [0.25 mSv] to the whole body and 75 mrem [0.75 mSv] to any other critical organ.) The calculated dose to the public from radioactive material releases during normal operation is provided in the radioactive emissions notice of construction for each facility. The dose to the public from direct shine is exceedingly low owing to the low radiation levels at the facilities during operation. The totals of these values are much lower than the 10 CFR 72 104 limits. Refer to Chapter 7.0 of the facility annexes for further description of the dose levels to the public.

7 6 1 Occupational Dose Limits and Administrative Control Levels

Dose limits are derived from 10 CFR 835, Sections 202, 206, 207, and 208. To keep exposures ALARA and to minimize the possibility of exceeding legal personnel exposure limits, the SNF Project has adopted administrative control levels for those exposures that may be received by the workers and visitors. The SNF Project administrative control levels for individuals shown in Table 7-2, are substantially below the regulatory limits shown in Table 7-3 and are multitiered, with increasing levels of authority required to approve higher administrative control levels.

7 6 2 Radiological Practices

Engineered controls are the primary methods used to prevent unnecessary exposure of personnel to radiological hazards. Engineered controls, such as bulk shielding, shielding plugs, canister caps, and shielded work stations, are used to reduce exposure to penetrating radiation from the stored SNF. Exposure to sources of airborne contamination is reduced by sealing potential airborne sources from the atmosphere. Building design, permanent shielding, and confinement systems are described in Chapters 2.0 of the facility FSAR Annexes. Safety and safety-related structures, systems, and components are described in Chapters 4.0 of the facility FSAR Annexes. Technical safety requirements relating to the facility's safety-related structures systems, and components are described in Chapters 5.0 of the facility FSAR Annexes.

Note: Levels are from Title 10 Code of Federal Regulations Part 835 Occupational Radiation Protection (10 CFR 835) Refer to 10 CFR 835 for additional detailed information that applies to these limits

General methods for controlling exposure include precautions for conducting radiological tasks and personnel protective equipment. Protocols are established for designating and posting radiological areas and for labeling radioactive material. Entry and exit controls are established and radiological work permits (RWPs) are used to control radiological work. For high-risk radiological work, stay times may be specified and incorporated during radiological work planning processes.
7.6.2.1 Precautions for Conducting Radiological Tasks

Work scopes involving radioactive materials are governed by facility procedures that are approved by facility management. Radiological procedures undergo a review by the radiological control organization to help ensure that all actions necessary to maintain exposure ALARA are incorporated into the procedural steps.

7.6.2.2 Personnel Protective Equipment

Personnel protective equipment includes protective clothing and/or respiratory protection. The amount and type of protective equipment used for a specific task are commensurate with the radiological hazards associated with the task. Specific requirements for protective equipment are identified on the applicable RWPs.

7.6.2.3 Permanent Shielding

Facility-specific permanent shielding is addressed in the facility FSAR Annexes.

7.6.2.4 Multi-Canister Overpack and Transportation Cask Shielding

The MCO transportation cask is designed to minimize dose rates to facility personnel during transfer and processing of the MCO. During processing at the CVDF, the cask lid is removed and the shield plug minimizes the dose to facility personnel during connection and disconnection of the process lines. The SNF Project CSB ALARA Analysis 09 (Transmittal FDP-788) reports that the maximum anticipated personnel dose from the MCOs will be less than 1 rem per year, which meets the 5 rem per year limit required by Section 11.1 of the SNF Project S/RID (HNF-SD-SNF-RD-001) and in 10 CFR 835.202.

An MCO shield plug dose rate analysis has been performed (HNF-SD-SNF-CN-026) to estimate neutron and gamma doses near the MCO. The final ALARA analyses provided with the final facility designs will define whether new shielding or tools are necessary to protect facility personnel. Neutron monitoring will be conducted during initial operations to characterize neutron dose rates. Based on the review of the initial dosimetry and neutron monitoring results, monitoring of the neutron doses may be discontinued. See HNF-SD-SNF-SARR-005 for a more complete description of cask-MCO shielding. Dosimetry records for personnel working near the uncovered MCO will be maintained for beta-gamma and neutron exposures unless neutron dosimetry is discontinued.

7.6.2.5 Radiological Posting and Labeling

Radiological areas are posted in accordance with 10 CFR 835 and S/RID Section 11.1 (HNF-SD-SNF-RD-001) criteria that are summarized in Tables 7-4 and 7-5. Specifications for the color, size, and dimensions of the signs are defined in HSRCM-1.

Posting radioactive material areas is performed in accordance with Article 236 of HSRCM-1. Radiological buffer areas are established within controlled areas to provide secondary boundaries to minimize the spread of contamination and to limit doses to general employees who have not been trained as radiological workers. It is not required that radiological buffer areas be established around inactive or secured contamination areas. The need for radiological buffer areas in conjunction with radioactive material areas is evaluated on a case-by-case basis by the radiological control organization.

DAC = derived air concentration
dpm = disintegrations per minute
RWP = radiological work permit

7.6.2.6 Radiological Access Controls  Radiological access controls are administered in accordance with the requirements of Section 11.1 of the SNF Project S/RID (HNF-SD-SNF-RD-001) and of 10 CFR 835, as discussed below. Access control is maintained for each radiological area to a degree commensurate with the existing and potential radiological hazards within the area. One or more of the following methods is used to ensure access control:

- Signs and barricades
- Control devices on entrances
- Conspicuous visual and/or audible alarms
- Locked entrance ways
- Administrative controls

The FSAR annexes provide additional detail on the specific access control methods to be used at the individual facilities.

Administrative procedures are written to demonstrate compliance with 10 CFR 835 and include actions essential to ensure the effectiveness and operability of barricades, devices, alarms and locks. Authorizations are required to perform specific work within radiological areas and are affiliated with procedures that include specific radiation protection measures.

Access control authorizations are administered in conjunction with computerized database systems that enable supervisors and individuals to assess their to-date exposure and exposure levels. This information is provided as a tool to be used in determining and administering stay times in radiological areas for the purpose of using exposure effectively and in accordance with ALARA principles. Entryways to high radiation areas (>0 1 rem/h at 30 cm) will be locked or...
guarded at all times. No controls are installed that would prevent rapid evacuation of personnel under emergency conditions [10 CFR 835 501(e) and 10 CFR 835 502(c)].

7 6 2 7 Radiological Work Permits The RWP is the administrative radiological control tool for intended work activities at SNF Project facilities. The RWP is used as specified in HSRCM-1, Article 321, to govern entries into radiological areas and to control all radiological work. RWPs are issued by the radiological control organization and are used by radiological workers. The permits define the protective clothing requirements, maximum allowable contamination and radiation levels, respiratory protection requirements, dosimetry requirements, radiological worker training requirements, and special precautions relative to job-specific activities. RWPs generally are prepared in conjunction with work planning activities and/or procedure development efforts and are part of the work package. RWPs are updated if radiological conditions change to the extent that protective requirements need modification. They also provide a mechanism to relate worker exposure to specific work activities.

7 6 3 Dosimetry

External dosimetry is provided to and used by all radiological workers who, under typical conditions, are likely to receive exposures that trigger one or more of the criteria identified in Table 7-6. These criteria comply with the requirements of S/RID Section 11 1 (HNF-SD-SNF-RD-001) and 10 CFR 835 402 "Individual Monitoring."

Personnel working at SNF Project facilities are not expected to receive occupation radiological exposure from internally deposited radioactive material. To minimize airborne contamination, which could lead to internal deposition, the facility designs incorporate area...
ventilation systems and/or spot ventilation systems in key locations. Chapters 20 and 70 of the facility FSAR Annexes contain facility-specific ventilation systems information. Radiological workers who meet trigger levels (identified in Table 7-7) for potential internal deposition are included in a bioassay program consistent with the requirements in 10 CFR 835 and HSRCM-1.

</table>

The radiological control organization issues supplemental dosimetry on a job-specific basis in accordance with the applicable RWPs. Hanford Site standard dosimetry exchanges are coordinated with the central dosimetry organization on a schedule that is commensurate with the anticipated annual exposure for each radiological worker (annually as a minimum). Personnel working near an MCO that has the cask lid removed will have their beta-gamma and neutron exposures recorded. Based on the review of the initial dosimetry results, monitoring of neutron doses may be discontinued.

### 7.6.4 Respiratory Protection

Respiratory protection criteria are described in HSRCM-1. Use of respiratory protection is reduced to the minimum level practicable by implementing engineering controls and work practices to contain radioactivity at the source. The facility designs do not require routine respirator use except at the K Basins. Radiological monitoring during initial MCO processing will validate the design intent relative to respirator use. Respirator use may be required during certain maintenance and overhaul activities at SNF Project facilities not considered to be normal routine operations. The radiological control organization performs reviews of procedures during the planning stages for radiological work. Specific engineering controls are implemented on a job-specific basis and are commensurate with the degree of hazard associated with the anticipated work scope.
Standards and requirements for implementing a respiratory protection program and associated training of personnel are driven by HSRCM-1. Respiratory protection described in this safety analysis report is not the safety analysis basis for preventing inhalation of radionuclides among radiological workers. The engineering controls associated with the design of the SNF Project facilities are designed to prevent the introduction of radioactive airborne contaminants into the work environment. Engineering controls represent the primary basis for ensuring radiological safety of workers.

The Respiratory Protection Program (HNF-PRO-120) applies to nonemergency activities that require respiratory protection for hazards including radiological, chemical, and particulate. The Respiratory Protection Program governs the purchase, selection, issuance and control, use, maintenance, and quality assurance for all respirators used by SNF Project workers. Medical qualification for respirator wearers is identified through the worker job task analysis processes and the occupational medical provider is responsible for the medical evaluation and qualification of respirator wearers. Respiratory protection complies with the requirements of 29 CFR 1910.134 and HSRCM-1.

The SNF Project respiratory protection program complies with the respiratory protection standards published in ANSI Z88.2-1992, *Respiratory Protection*, and includes the following elements:

- A written policy statement
- Guidance on proper selection of equipment, based on the hazard
- Requirements for fitting, use, cleaning, storage, inspection, and maintenance of respiratory equipment
- Use of respiratory protection equipment that has the approval of the National Institute for Occupational Safety and Health

The type of respirator to be used is specified in writing on the applicable job hazard analysis maintenance procedure, operating procedure, or job-specific permit.

### 7.7 Radiological Monitoring

Section 11.1 of the SNF Project S/RID (HNF-SD-SNF-RD-001) 10 CFR 835.401 and 10 CFR 20 define the required program for radiological monitoring and surveys. HSRCM-1 Article 551 specifies that scheduled radiation survey task descriptions provide the field direction to radiological control technicians performing required surveillances. These task descriptions schedule the specific regions of the facility to be surveyed and the types and frequencies of surveys to be performed and clarify the minimum documentation requirements for completed surveillances. Task descriptions are written to satisfy the requirements of HSRCM-1.
7.7.1 Radiation Exposure Surveys

Radiation exposure survey programs are established in accordance with 10 CFR 835 401 and are based on potential radiological conditions, probability of change in conditions, and area occupancy factors.

7.7.2 Contamination Surveys

Contamination survey programs are established in accordance with 10 CFR 835 401 and 10 CFR 835 404. All radiological areas, as defined by HSRCM-1, will be routinely surveyed based on type of radiological area, probability of change in conditions, potential for the spread of contamination, and area occupancy factors.

In addition to these routine contamination survey programs, surveys also are performed:

- During initial entry into known or suspected contamination areas
- Periodically during work involving the potential for radioactive contamination
- At the completion of work involving the potential for radioactive contamination
- As specified by RWPs and scheduled radiation survey task descriptions
- Following a leak or spill of radioactive materials

7.7.3 Monitoring for Radioactive Airborne Contaminants

Criteria for monitoring radioactive airborne contaminants are mandated by Section 111 of the SNF Project S/RID (HNF-SD-SNF-RD-001) and by 10 CFR 835 403. Selection of air monitoring equipment is based on the specific job being monitored. Air monitoring equipment includes portable and fixed air sampling equipment and continuous air monitors.

Air sampling equipment is used in occupied areas where, under normal operating conditions, a person is likely to receive an annual intake of 2% or more of the specified annual limit-of-intake values (40 DAC [derived concentration] hours).

Continuous air monitoring equipment is installed in occupied areas where a person without respiratory protection may be exposed to a concentration of radioactivity in air exceeding 1 DAC or where there is a need to alert potentially exposed workers to unexpected increases in the airborne radioactive material levels.

7.7.4 Monitoring Records

Required surveillances are documented, and the survey records are subject to the records retention criteria of 10 CFR 835 703. Data collected during radiological monitoring activities are recorded according to procedure and made available to appropriate staff for responding to action...
levels, assessing the effectiveness of radiological protection programs, preparing lessons-learned information, and archiving.

7.8 RADIOLOGICAL PROTECTION INSTRUMENTATION

In accordance with 10 CFR 835.401, instruments used for monitoring and contamination control shall be

- Periodically maintained and calibrated on an established frequency of at least once per year
- Appropriate for the types, levels, and energies of the radiation encountered
- Appropriate for existing environmental conditions
- Routinely tested for operability

General criteria for radiological instrumentation are provided by HSRCM-1, Articles 551 through 564.

7.8.1 Selection and Placement Criteria

7.8.1.1 Air Sampling Equipment  In general, air sampling equipment is located in the vicinity of workers to provide an indication of the airborne radioactive material levels to which the workers are exposed. Air monitoring equipment is used in situations where airborne radioactivity levels can fluctuate and early detection of airborne radioactivity could prevent or minimize inhalation of radioactivity by personnel. Air sampling equipment placement criteria are documented in HSRCM-1, Article 555, and the facility technical basis document. The criteria in these documents are based on airflow patterns in the facility, work activity, quantity and type of contamination present or anticipated, and the location of workers.

7.8.1.2 Area Radiation Monitoring  Monitoring of radiation in the workplace is performed using stationary (area) and portable radiation instruments. S/RID Section 11.1 (HNF-SD-SNF-RD-001) require monitoring of individuals and areas to accomplish the following objectives:

- Detect changes in radiological conditions
- Detect gradual buildup of radioactive material in the workplace
- Verify the effectiveness of engineering and process controls in containing radioactive material and reducing radiation exposure
• Document radiological conditions

• Demonstrate compliance to requirements

Area radiation monitors are designed into SNF Project facilities or are added to the facility based on these criteria. The specific location of area radiation monitors is described in the facility FSAR Annexes. Monitoring instruments in SNF Project facilities are equipped to warn radiological workers of adverse radiological conditions so they can evacuate the effected region in time to minimize their exposure. Monitoring with portable instruments is performed utilizing appropriately selected, maintained and calibrated instruments. These instruments are appropriate to the radiations encountered and the environmental conditions and are routinely tested for operability.

7 8 1 3 Automated Personnel Monitors SNF Project facilities S/RID Section 111 (HNF-SD-SNF-RD-001) require that monitoring to detect and prevent the spread of contamination be performed by personnel exiting radiological areas. Instruments and techniques used for this monitoring are required to be effective in controlling contamination. At SNF Project facilities automated personnel contamination monitors are provided for personnel monitoring and contamination control in addition to portable instruments at commonly used egress points. These devices include beta–gamma detection, as appropriate. The exact locations of personnel survey devices are subject to considerations that include background interference, radiological postings, and egress pathways. General criteria for personnel release surveys are defined by HSRCM-1, Article 338. See the facility FSAR Annexes for specific applications of automated personnel monitors.

7 8 1 4 Portable and Laboratory Radiation Monitoring Equipment A variety of portable and laboratory equipment is used at SNF Project facilities. General criteria for radiological instrumentation are addressed by HSRCM-1, Articles 551 to 564.

7 8 2 Types of Detectors

A summary of the different kinds of radiation detection instruments used at SNF Project facilities is presented below:

• Body frisker
• Hand and foot monitors
• Portal monitors
• Area radiation monitors
• Fixed head air samplers
• Beta–gamma continuous air monitors
• Alpha continuous air monitors

This is a general list. Specific application of instrument types is addressed in the facility FSAR Annexes.
7.8.3 Instrument Calibration

Radiation protection instrumentation is calibrated in accordance with Section 11.1 of the SNF Project S/RID (HNF-SD-SNF-RD-001) and 10 CFR 835 401(c). Calibrations are performed at least annually in accordance with established procedures that meet the requirements of ANSI N323, *Radiation Protection Instrumentation Test and Calibration*. All calibrations use National Institute of Standards and Technology-traceable sources. Standard radiation sources are used to routinely check instruments in the field. Administrative controls, procedures, and training ensure the instruments used are appropriate for the type(s), levels, and energies of the radiation(s) encountered and are appropriate for existing environmental conditions.

7.8.4 Quality Assurance for Calibration and Maintenance

The SNF Project quality assurance program is based on Title 10 *Code of Federal Regulations*, Part 830, "Nuclear Safety Management." Section 830.120 "Quality Assurance Requirements" (10 CFR 830.120). Radiological instruments are selected to be appropriate for the field conditions and environment in which they are expected to operate, and they are used to measure only the radiation for which their calibrations are valid.

Calibrations are performed using National Institute of Standards and Technology-traceable standards and procedures developed for each radiological instrument type. Keeping the calibration of instruments current is ensured by affixing a label or tag with the date of calibration and the date recalibration is due. For instruments whose "as found" readings indicate that the instrument may have been used while out of calibration, immediate notification of the out-of-calibration condition is made to the appropriate radiological control organization office. The radiological control organization office reviews any measurements performed with the instrument while it was suspected of being out of calibration.

A program for preventive and corrective maintenance of radiological instruments has been established. The components and procedural recommendations used for preventive and corrective maintenance are at least as stringent as those specified by the instrument's manufacturer. After any preventive or corrective maintenance or any adjustment that voids the previous calibration, radiological instruments undergo calibration before use.

7.9 RADIOLOGICAL PROTECTION RECORD KEEPING

Radiological protection record keeping requirements are mandated by SNF Project facility S/RID Section 11.1 (HNF-SD-SNF-RD-001). Table 7.8 identifies the primary records that are applicable to radiation protection and a general overview of how these records are integrated into the facility record system. Radiological protection records that relate to the operation of the radiological protection program (e.g., RWPs, ALARA reviews, radiological surveys, and radiological problem reports) are maintained by the SNF Project radiological control organization according to SNF Project administrative procedures and quality assurance manuals.

8 0 HA ZA RD OUS MATERI AL PRO TE C T I ON

8 1 I NTRO DUC T I ON

This chapter addresses the major provisions of the occupational safety and health program as it applies to hazardous material protection for the Spent Nuclear Fuel (SNF) Project. Hazardous material, as defined in U.S. Department of Energy (DOE) Order 5480 23, *Nuclear Safety Analysis Reports*, is "any solid, liquid, or gaseous material that is toxic, explosive, flammable, corrosive, or otherwise physically or biologically threatening to health. Oil is excluded from this definition." This chapter contains sufficient information to demonstrate compliance with applicable requirements for control of personnel exposures to hazardous materials.

The SNF Project is cognizant of the requirements applicable to a hazardous material protection program. An effective SNF Project occupational safety and health program will be used to control onsite worker exposures to hazardous materials and will provide the protection necessary to control exposures to the general public.

8 2 R EQ UIRE ME NTS

The requirements that form the basis for the hazardous material protection program are found in the SNF Project standards/requirements identification document (S/RID) (HNF-SD-SNF-RD-001). The specific requirements applicable to this chapter include:

- DOE Order 5480 4 *Environmental Protection Safety and Health Protection Standards*
- DOE Order 5480 8A, *Contract Occupational Medical Program*
- DOE Order 5480 9A, *Construction Project Safety and Health Management*
- DOE Order 5480 10, *Contractor Industrial Hygiene Program*
- DOE Order 5483 1A, *Occupational Safety and Health Program for DOE Contractor Employees at Government Owned Contractor-Operated Facilities*
8.3 HAZARDOUS MATERIAL PROTECTION PROGRAM AND ORGANIZATION

The SNF Project has an established, visible, and comprehensive occupational safety and health program that implements the occupational health and safety requirements and guidelines of DOE Order 5480.10 as well as other relevant DOE and DOE Richland Operations Office directives described in Section 8.2. The goal of the SNF Project occupational safety and health program is to control worker exposure to work hazards within the limits prescribed by DOE and by professional occupational safety and health practices and principles. The primary objective is to provide a workplace free from or protected against hazards likely to cause injury, illness, impaired health and well-being, or significant discomfort or inefficiency among workers or the community.

The occupational safety and health program uses the Occupational Safety and Health Administration (OSHA) permissible exposure limits (PELs) and the American Conference of Governmental Industrial Hygienists (ACGIH) threshold limit values (TLVs) to provide guidance on controlling exposures and protecting the worker. Where a lower published exposure limit exists, the SNF Project will use that limit, according to the hierarchy published in DOE Order 5480.10. Workers will be knowledgeable of such limits and standards and of SNF Project policies and procedures through applicable training (see Section 8.5). All SNF Project employees are instructed to observe DOE-prescribed OSHA standards applicable to this work and report promptly any conditions that may lead to a violation of these standards in accordance with DOE Order 5483.1A. The Hanford Fire Department acts as the incident command agency for emergency incidents involving hazardous materials.

The SNF Project implements the hazardous material protection program based on the requirements of HNF-MP-003, *Integrated Environment Safety and Health Management System Plan*. More detailed guidance is provided in SNF Project administrative procedures.

The SNF Project's occupational safety and health organization is responsible for administering the occupational safety and health program. The SNF Project Occupational Safety and Health Manager reports directly to the SNF Project Vice President/Project Director's office, who has ultimate responsibility for the hazardous material program implementation. This includes responsibility for establishing the occupational safety and health program in accordance with DOE requirements and other applicable requirements documents and providing appropriate resources to support the occupational safety and health programs.

The SNF Project implementing procedures reflect the management commitment and worker involvement facets of the DOE Voluntary Protection Program (VPP) provided in DOE/EH-0433, *U.S. Department of Energy Voluntary Protection Program* and in HNF-MP-003. Safety training of SNF Project management and workers places an emphasis on the elements of the VPP, and workers are encouraged to actively participate in VPP initiatives.

The administrative activities and responsibilities of the support organization are summarized in the following sections.
8.3.1 Organizational Structure

The effectiveness of the hazardous material program depends on the formal definition and communication of organizational structure, responsibilities, and authorities through the application of organization charts and job descriptions. The organizational structure of the SNF Project, including staffing levels and qualifications, positions of authority, responsibilities, and interfaces with other safety organizations and facility operations, is discussed in Chapter 17. Basic rights and responsibilities of SNF Project personnel are also described in HNF-PRO-074 Safety Responsibilities. Therefore, this section summarizes the responsibilities of the organizations with regard to the SNF Project occupational safety and health program in accordance with requirements of Section 19.0 of the SNF Project S/RID (HNF-SD-SNF-RD-001). Management self-assessments will be used by management to verify that the requirements are being met and/or implemented and will be used to measure performance objectives.

8.3.1.1 Spent Nuclear Fuel Project Operations Managers. The SNF Project Operations Managers bear full responsibility and accountability for providing workers a safe and healthy working environment. The SNF Project Operations Managers report to the SNF Project Vice President/Project Director's office and have the following hazardous material protection program responsibilities:

- Establish and maintain safe conditions in the workplace.
- Identify and monitor, on a regular basis, the hazards and associated risks that may exist at the facility.
- Account for modifications and changes that may occur to the equipment and/or processes.
- Provide all workers with the hazard information and training necessary to perform their jobs in a safe and healthy manner.
- Ensure that workers have all necessary medical clearances for their jobs and enforce all medical work restrictions.
- Ensure that workers assigned to tasks involving hazardous materials have the appropriate training required for the job.
- Promptly inform the occupational safety and health organization of any operation or condition that appears to present a hazard to workers.
- Provide personal protective equipment as specified by the occupational safety and health organization and ensure that workers wear this equipment and undergo training to use it properly.
• Provide funding for occupational safety and health assessments and hazard control

• Take appropriate disciplinary action for violations of health and safety rules

• Promptly respond to formal occupational safety and health recommendations for needed control measures

• Perform accident investigations

• Incorporate provisions for protection of the public, workers and environment into the conduct of operations program

• Identify the procedures and controls that must be followed to guard against the hazards

• Conduct operations consistent with established health and safety procedures

• Develop and implement a chemical management program

• Provide a hazard communication program

• Perform SNF Project emergency planning and response actions as defined in Chapter 15

• Include industrial hygiene staff in the design review process whenever new construction or remodeling of an existing process is planned

• Request industry hygiene staff to evaluate effectiveness of proposed environment control equipment and approve procedure for use

8.3.1.2 Spent Nuclear Fuel Project Occupational Safety and Health Manager The SNF Project Occupational Safety and Health Manager has the following responsibilities

• Develop and administer programs to control and minimize health and safety hazards and to promote continuous improvement in safety and health performance

• Provide safety and health expertise, assistance and support for SNF Project operations and activities

• Maintain safety and health records and administrative controls and coordinate with Hanford Site service organizations as necessary

• Provide and manage resources to design and implement occupational safety and health programs
• Ensure that applicable requirements are integrated into the occupational safety and health program and the procedures and standards of other applicable organizations

• Procure and maintain hazardous material monitoring instrumentation

• Review and evaluate Hanford Site and SNF Project facility-specific training programs to ensure adequacy of occupational safety and health components with the occupational safety and health organization participating, as necessary, as subject matter experts in training program development and delivery

• Support professional development of the occupational safety and health organization staff by sending the staff to onsite and offsite technical training and encourage individual initiative by supporting efforts to obtain necessary certification

8 3 1 3 Spent Nuclear Fuel Project Engineering Manager (Chief Engineer) The SNF Project Chief Engineer/Director has the following responsibilities

• Provide assistance and support in hazard assessments, hazard posting, and container labeling

• Provide technical support to the maintenance of the facility's hazardous chemical product lists and interface with work control and operating facilities as requested

• Use established approved engineering procedures to minimize exposures to harmful environmental factors or stresses

• Notify the occupational safety and health organization whenever new operations or processes are to be introduced so that potential hazards may be evaluated in the planning stage

• Obtain occupational safety and health program approval for new installations and equipment before its initial use

8 3 1 4 Spent Nuclear Fuel Project Technical Training SNF Project technical training is responsible for establishing, conducting and administering the training program for SNF Project facility managers to ensure that all workers meet the hazardous material protection training requirements of their assigned tasks

8 3 1 5 Spent Nuclear Fuel Project Workers Each worker is responsible for recognizing and promptly notifying management of events and conditions that could have adverse safety or environmental implications. Workers are also responsible for obeying all oral and written hazardous material control instructions and procedures conscientiously applying all health and safety training in daily activities, and properly using all prescribed personal protective equipment. In addition, SNF Project workers have the following specific responsibilities...
Observe the Master Safety Rules
Perform work in accordance with the specified work instructions, work procedures, and standard operating procedures
Use all prescribed personal protective equipment
Actively support programs designed to protect workers
Stop work to prevent or control hazards considered to be an immediate threat
Work defensively and be vigilant that coworkers do not put themselves at risk
Submit ideas for safety and health improvements to management
Report injuries and medically imposed work restrictions to the immediate manager in a timely manner

**8 3 1 6 Occupational Medical Services Contractor** An external organization is contracted by DOE to provide occupational medical services. As described in Section 8 6 3 and Chapter 17 0, the SNF Project relies on this occupational medical support organization for the following services

- Performing preplacement health appraisals, periodic health examinations, and health education programs
- Providing appropriate physical examinations for workers who work with, or are exposed to, hazardous agents or materials
- Maintaining records of occupational illnesses in accordance with the requirements of Title 29, *Code of Federal Regulations* Part 1904, Recording and Reporting Occupational Injuries and Illnesses (29 CFR 1904)
- Setting medical restrictions for workers whenever warranted by examination findings and ensuring that the restricted worker's management is notified of the restrictions
- Ensuring that the bioassay and medical monitoring programs are responsive to the requirements of 29 CFR 1910 120 and 29 CFR 1910 Subpart Z
- Consulting with the industrial hygiene staff on the need for job-related medical examinations or bioassays
- Assisting in performance of workplace hazard evaluations as requested
8317  Spent Nuclear Fuel Project Industrial Hygiene  As required by Section 19.2 of the SNF Project S/RID (HNF-SD-SNF-RD-001), the SNF Project industrial hygiene staff is professionally qualified, adequately staffed and has sufficient time and authority to design and implement the industrial hygiene program. Industrial hygiene has the following responsibilities:

- Alerting the industrial hygiene staff to all suspected occupational illnesses to facilitate early evaluation and correction of problems.
- Maintaining medical records in accordance with the applicable OSHA and DOE requirements.
- Providing first aid services including diagnosis and treatment of non-life threatening medical events.
- Providing technical assistance in areas such as chemical exposure assessment and collection of personal monitoring data to ensure necessary calculations to determine exposure and recommend appropriate hazard controls.
- Notify workers on results of personal exposure monitoring.
- Recommend workers to applicable managers to be included in medical surveillance programs.
- Exercise the traditional tenets of industrial hygiene in anticipating, recognizing, evaluating, and controlling hazards in the work place.
- Assist in the preparation, review, and approval of job hazard analyses (JHAs), job safety analyses (JSAs), automated JHAs, automated employee job task analyses (EJTAs), work plans and packages, preventive maintenance actions, plant operating procedures, and other technical and operations-related documents where industrial hygiene is a potential issue.
- Review the material safety data sheets (MSDSs) for toxic materials and new safety products or related equipment materials purchases.
- Communicate hazard information to workers and their managers so the workers and managers can perform their jobs safely.
- Provide for the collection and analysis of necessary samples and ensure that instrumentation is properly calibrated, used, and maintained.
- Collect and maintain accurate and precise information on occupational health hazards and preserve and maintain the information in a centralized system.
HNF-3553 REV 0

- Develop occupational safety and health program criteria and the standards necessary to ensure proper identification, evaluation, and control of workplace health hazards.
- Conduct periodic audits and appraisals to monitor compliance with the requirements of the occupational safety and health procedures and to evaluate the overall effectiveness of the program.
- Approve hazardous material requisitions and sign the purchase requisition to indicate approval before the material is purchased.
- Verify conformance to chemical management requirements such as safe storage, usage, tracking, and substitutions of less hazardous chemicals.
- Interface with DOE Richland Operations Office to assess and resolve concerns.

8 3 1 8 Spent Nuclear Fuel Project Chemical Management Point of Contact: The chemical management point of contact has the following responsibilities:
- Provide technical support and expertise in assisting SNF Project and activities.
- Provide pre-acquisition reviews of material and service requests to determine if less hazardous substitutes are available or if item is already in stock and current inventory can be used.
- Provide information with regards to chemical inventories, chemical usage, and chemical release information for required reporting of hazardous chemicals.
- Communicate hazard information to workers and their managers so the workers and managers can perform their jobs safely.
- Verify conformance to chemical management requirements such as safe acquisition, transportation, storage, usage, tracking, and substitutions of less hazardous chemicals.
- Act as point of contact for all chemical management issues involving other Project Hanford Management Contract Major Subcontractors, subcontractors, and all other non-SNF Project personnel conducting work at SNF Project facilities.
- Maintain the facility’s hazardous chemical product lists and provide lists to work control and project facilities.

8 3 1 9 Contracts: The SNF Project Contracts organization has the following occupational safety and health responsibilities:
- Control the purchase and distribution of potentially hazardous materials.
Obtain assistance from the occupational safety and health department when hazardous materials are requested.

Ensure that MSDSs are received with each shipment from the chemical manufacturer or supplier and submitted to the MSDS coordinator (see Section 8.10.5).

Ensure that contractors and subcontractors performing potentially hazardous work in SNF Project facilities are obligated to comply with the mandatory occupational safety and health standards of DOE Order 5480.4.

8.3.10 U.S. Department of Energy, Richland Operations Office  According to DOE Order 5480.1B *Environmental Safety and Health Program for Department of Energy Operations*, the heads of DOE field offices are responsible for ensuring that all operations under their jurisdiction are carried out in a manner consistent with sound safety and health practices and in accordance with all applicable DOE regulatory requirements. This responsibility includes the requirement by DOE to appraise the hazardous material protection program and the entire facility in accordance with DOE Order 5482.1B *Environment Safety and Health Appraisal Program* and other applicable regulatory requirements.

8.3.2 Staffing Levels and Qualifications

The SNF Project occupational safety and health organization is staffed by qualified and experienced personnel who are trained in the anticipation, recognition, evaluation, and control of occupational safety and health hazards in the work environment in accordance with Section 1912 of the SNF Project S/RID (HNF-SD-SNF-RD-001). Formal qualification criteria are established to define the experience, education, capability, and training required to perform a designated position. There are established requirements for periodic performance reviews, evaluations, and updates of qualification and requalification criteria. As indicated in Chapter 170, minimum education and experience requirements for management and workers meet the requirements of Section 4.0 of the SNF Project S/RID. SNF Project management determines the basic educational and experience criteria for the occupational safety and health staff positions (also see Section 8.5).

The occupational safety and health organization determines the basic educational and experience criteria for employees assigned to industrial hygiene staff positions. Industrial hygiene personnel must have a Bachelor of Science degree and industrial hygiene safety experience. Area industrial hygiene technicians must have a high school diploma. Certification (certified industrial hygienist or occupational health and safety technician by the American Board of Industrial Hygiene or certified safety professional by the Board of Certified Safety Professionals) is highly desired. Requirements for being a fully qualified safety professional include completion of a contractor qualification program and a minimum of two years related experience.
8.4 ALARA POLICY AND PROGRAMS

While there is no established formal SNF Project as-low-as-reasonably-achievable (ALARA) program for nonradiological hazardous materials, the SNF Project has expanded the classic concept of ALARA principles (i.e., minimization of radiological exposures) to the application of exposure minimization for hazardous substances and conditions. SNF Project policy is to limit human exposures to radiation and hazardous materials to levels below federal and state regulatory limits and further to levels ALARA. Therefore, ongoing programs promote reduction of exposures to chemical hazards, ionizing and nonionizing radiation, and other physical hazards through education and worker involvement. Many of the same principles and work practices that are specified in the ALARA program described in Chapter 7.0 also are used to minimize exposures to nonradiological hazardous materials.

The hazardous material exposure control program, discussed in Section 8.6, and the hazard communication program, discussed in Section 8.10, are provisions of the SNF Project occupational safety and health program directed at limiting exposures to hazardous materials to ALARA levels. Engineering and administrative controls, work practices, and personal protective equipment are instituted to reduce and maintain personnel exposures to or below the PELs for substances regulated by 29 CFR 1910 Subpart Z or TLVs from ACGIH whichever is more conservative.

The following work practices are used for hazardous materials protection at the SNF Project facilities:

- Prejob planning
- Job monitoring
- Post-job reviews
- Chemical exposure control
- Lessons-learned reviews
- Cost–benefit analysis worksheets
- Project and task planning, design, and reviews
- ALARA awareness
- Training

Chemical exposures in the workplace are further controlled by:

- Requirements of the purchasing process for chemical agents
- Requirements for handling of chemicals
- Chemical monitoring
- Hazard communication program
- Substituting nonhazardous or less hazardous chemicals
- Records and reporting

A summary for most of the above contributions that each practice provides to implementation of ALARA concepts is provided in Table 8-1.

November 1999
The occupational safety and health program includes the following additional provisions:

- Exposures to hazardous materials are controlled within the PELs established by OSHA and the TLVs established by the ACGIH. Where a lower published exposure limit exists, the SNF Project will use that limit, according to the hierarchy published in DOE Order 5480.10.

- Routine work hazards are identified and communicated to workers through morning meetings, safety meetings, and routine worker–supervisor communication.

- Workers are involved with both the prejob planning process and prejob walkdowns whenever possible.

- Prejob briefings are held for nonroutine work to communicate hazards and controls to workers who will perform the task.

- Hazard information is communicated to the affected workers for routine work using an existing ("standing") JHA, JSA, automated JHA, approved procedure safety meeting, or routine worker–supervisor work discussion.
Nonroutine tasks require generation of a job-specific JHA, JSA or a computer-based qualitative JHA or the use of a permit, approved procedure, or prejob safety meeting to address the anticipated hazards and control measures of the task.

A hazard communication program provides workers and management with up-to-date accurate and timely information on hazards in their workplace and ways to reduce those hazards.

The occupational safety and health program is integrated into the SNF Project assessment process, which includes independent assessments, audits, and surveillances, management assessments, management workplace walkthroughs and on-the-job supervision.

Workplace hazard monitoring is conducted to detect physical or biological hazards or for any operation that can reasonably be expected to result in worker exposures equal to or greater than the action level for that chemical or substance.

An automated job task analysis is performed to support collection of the data necessary for a risk-based approach to medical qualification and monitoring. Information collected represents a compilation of hazards and exposures associated with routine work activities as well as hazards associated with nonroutine work activities that can be predicted or anticipated. Hazard and exposure information for nonroutine activities that cannot be predicted or anticipated are identified through JHAs, JSAs, and automated JHAs and incorporated into approved procedures.

Qualitative exposure assessments are conducted to assess the potential for occupational exposure of workers to chemical, physical, and biological hazards to evaluate and recommend control measures for potential hazards to communicate information regarding chemical, physical, and biological exposure hazards and controls to line management, and to document the qualitative exposure assessment results.

Chemicals are properly handled and stored.

Nonhazardous or less hazardous chemicals are substituted whenever possible.

A program will be implemented to minimize occupational exposure to chemical carcinogens as required by Section 1912 of the SNF Project S/RID (HNF-SD-SNF-RD-001).

Safety plans or standard operating procedures will describe the use of chemical carcinogens and the procedures used to contain exposure. The occupational safety and health organization will review and approve these documents.
SNF Project implementing procedures will establish emergency actions involving chemical carcinogens (e.g., cleanup of spills or accidental releases).

Notices of hazardous chemicals and physical and biological agents known to be present in the work area are posted.

Chemical agents that are brought into a facility are controlled by requiring that the hazards associated with the agents be determined before purchase, by requiring MSDSs from all manufacturers or suppliers, and by monitoring the workplace.

Any hazardous material or hazardous process that creates a potential worker exposure or oxygen-deficient atmosphere is reviewed and evaluated. This includes evacuating and reinerting the multi-canister overpacks.

Workers have access to and are trained to use MSDSs.

The SNF Project oversees contractor and subcontractor activities at SNF Project facilities to minimize exposures to hazardous materials through worksite inspections following the requirements of the SNF Project S/RID. Subcontractors are required to identify any chemicals or products that they will furnish to complete their work and are required to provide MSDSs for those chemicals prior to use.

DOE Order 5480.10, Revision 0, Section 9b, 'Introduction,' describes an industrial hygiene program designed to preserve employee health and well-being. Ergonomics is proposed as either an environmental factor or stressor under this program (e.g., body position in relation to task, repetitive motion, and mental or physical fatigue). For purposes of the SNF Project, the occupational safety and health concept of ergonomics is captured in Chapter 13 of Human factors engineering includes ergonomics as design criteria to consider in the project design. Human engineering includes human capabilities and limitations that must be considered in the design, with trade-offs appropriately considered as applicable based on such factors as safety risks, costs, benefits, and expediency.

The applicable ergonomics requirements of DOE Order 5480.10 will be included and developed further in the human engineering program plan (SNF-4399).

INEL-95/0117, Human Factors Engineering Checklists for Application in the SAR Process, contains a series of 19 human factors checklists that support analyses of DOE reactor and nonreactor facilities and activities. Many of these checklists contain ergonomics criteria (e.g., physical accessibility) and are included in the SNF Project human factors engineering analyses and findings reports.
8.5 HAZARDOUS MATERIAL TRAINING

Access to SNF Project facilities is limited during fuel handling operations. During staging and interim storage modes, the SNF Project facilities are expected to require only periodic monitoring by SNF Project workers. Therefore, only a few selected SNF Project workers assigned such monitoring duties are required to have specialized hazardous material training. Workers will perform only those tasks for which they have received the proper training. As the SNF Project mission changes, SNF Project management will review the training requirements and modify worker training requirements accordingly.

The SNF Project has an established hazardous material training program that complies with the requirements of 29 CFR 1910 and applicable provisions of DOE Order 5480.10. Occupational safety and health staff are trained in anticipating, recognizing, evaluating, and controlling hazards in the work environment. All workers are provided with initial general training on recognizing and minimizing job-related hazards. The process by which training is developed is discussed in Chapter 12.

SNF Project management provides training, professional education, and certification opportunities necessary to support, maintain, and enhance industrial hygiene staff proficiency to meet or exceed DOE industrial hygiene training objectives and goals. Program elements include needs assessment, definition of training objectives, training plans and implementation and evaluation of program effectiveness. Training is appropriate for the assigned tasks and level of responsibilities. Training also addresses hazards described in DOE-prescribed OSHA standards as well as those for which no PEL or other requirement has yet been established. The contractor integrates DOE-mandated training objectives into training programs as appropriate for each level of qualification for professional industrial hygiene staff, line management and supervision, and other workers.

The safety and health requirements of Section 19 of the SNF Project S/RID (HNF-SD-SNF-RD-001) ensure that all contracted or subcontracted activities are conducted in a safe manner. Significant activities involving safety are identified so that proper procurement or contract clauses will be included. Subcontractors will address the activities in their safety plans and safety professionals can assist in controlling risks. The SNF Project construction manager is responsible to ensure that subcontractor work groups are provided with the training, resources, and technical support necessary to perform their assigned safety and health duties. SNF Project implementing procedures provide information on implementation of the training requirements.

SNF Project facility managers are responsible for ensuring that workers assigned to any task involving hazardous materials are trained in the safety and health hazards associated with such hazardous materials. Workers receive on-the-job, area-specific training for the chemical hazards they work with that are present in their work areas. This training includes the following topics:

- How to recognize the presence or release of hazardous chemicals in the work area
Safe work practices for the chemical agents present in the workplace and work area

Controls that have been implemented to ensure exposures are reduced to below OSHA-established limits or limits set by the ACGIH

Information about the physical and health hazards of any chemicals present in the work area

Procedures and safety requirements that workers can use to protect themselves from hazards

Instructions for use of personal protective equipment in accordance with 29 CFR 1910.132 "General Requirements"

Response to chemical emergencies, such as a release, fire, or explosion

Specific training courses that cover the above topics include

- General Employee Training. This training provides the worker dealing with hazardous material and/or waste with the fundamentals for use and disposal of hazardous material. Information is provided on federal and hazardous communication programs, the use of MSDSs, labeling, requirements for manufacturers, Hanford Site labels, general chemical handling, safety, health effects, waste minimization, waste management regulations, the SNF Project's waste management system, and an overview of mixed waste requirements. Hazard communication and waste management awareness training introduces workers to federal laws governing chemical safety in the workplace. This safety training is mandated for general industry by 29 CFR 1910.1200, "Hazard Communication."

- Advanced General Employee Training. This training series provides the advanced general worker dealing with hazardous material and/or waste with detailed information for use and disposal of hazardous material. Course material covers various topics including regulatory requirements, waste characterization, waste storage disposal, packaging of dangerous or mixed waste, and preparation of packages for shipping.

- Hazardous Waste Site Supervisor/Manager Training. This training provides safety management training required for supervisors and managers of hazardous waste sites or operations covered by 29 CFR 1910.120, "Hazardous Waste Operations and Emergency Response."

- Hazardous Waste Operations. This training is a 24- or 40-hour hazardous waste operations course (depending on specific job requirements) that meets the requirements of 29 CFR 1910.120.
SNF Project facility managers are responsible for determining the mandatory task-specific training requirements for their workers. Examples of training include:

- **Confined Space Entry** Confined-space entry training is mandatory for permit-required, confined-space entry supervisors, attendants, and entrants. The course covers basic awareness of confined space hazards, entry permits, recognition of air contaminant over-exposure or oxygen deficiency symptoms, and emergency response requirements.

- **Fall Protection** Fall protection training is designed for workers protected by fall prevention systems and for users of personal fall arrest systems. The course covers a program overview, fall protection requirements at the SNF Project facilities, hands-on equipment inspection, and proper use of a variety of personal fall arrest systems.

- **Behavior-Based Safety Training** Behavior-based safety training contains elements of the VPP, conduct of operations, ALARA program, and total quality.

- **Asbestos Control** Asbestos control training covers recognition and identification of asbestos-containing materials and a review of applicable regulations, asbestos exposure hazards, chronic health effects, protective clothing, respiratory protection, waste disposal, and abatement techniques.

- **Hazards Recognition** Hazards recognition training provides OSHA-based training for recognizing hazards for general workers and supports requirements of the OSHA VPP.

- **Manager Safety Training** Manager safety training provides training in basic emergency medical care with emphasis on Hanford Site-specific implementation of safety standards and the VPP and includes discussion of relevant health and safety issues.

- **Medic First Aid** Medic first aid training provides instruction in basic emergency medical care with emphasis on developing ten basic skills: primary assessment, one-rescuer adult cardiopulmonary resuscitation, obstructed airway management, bleeding control, shock management, illness assessment, injury assessment, set-up and barriers, rescue breathing, and circle of care.

- **Noise Control** Noise control training provides OSHA training that meets requirements for workers exposed to excessive noise in the workplace.

The SNF Project training program establishes mandatory retraining for certain safety-related topics and procedures. It is the responsibility of SNF Project facility management to ensure workers are retrained within the time allowed by the course requirements for any specific training subject. The retraining sequence for each course is published in the SNF Project training program and is tracked on the computer-based training matrix database. As stated in...
Section 8.4 many of the same principles and work practices that are specified in the radiological ALARA program are used to minimize exposures to nonradiological hazardous materials. ALARA training will be provided to workers involved in minimizing hazardous materials. In addition to the above training, workers at SNF Project facilities will take training courses required for working at a Comprehensive Environmental Response Compensation and Liability Act (CERCLA) of 1980 site in accordance with 29 CFR 1910.120. Subcontractors are required to have training equivalent to that required for SNF Project staff members.

8.6 HAZARDOUS MATERIAL EXPOSURE CONTROL

Occupational exposures to hazardous materials and the spread of hazardous material contamination are controlled by a combination of engineered, operational, and administrative controls and by the use of personal protective clothing and equipment. Every effort is made to eliminate the hazards first through positive means or engineering controls before using administrative controls and personal protective equipment. Administrative controls include establishment of work zones to minimize the spread of contamination and implementation of procedures, training, and technical safety requirements. Engineering controls include confinement ventilation equipment layout, and high-efficiency particulate air filter placement.

HNF-MP-003 describes the philosophy and policies that provide reasonable assurance that the SNF Project facilities and activities are designed, constructed, and operated in a manner that ensure protection of workers, the public, and the environment. The key safety management concepts regarding hazardous materials are based on the following safety concepts:

- **Defense-in-depth** — Design facilities to provide multiple levels of defense against undue exposures to the workers and the public.
- **Maintain compliance with the authorization envelope** including using the least toxic chemicals or products that will provide the desired result.
- **Minimize exposures** — Keep exposures ALARA.
- **Hazard and/or safety analyses** — Define the hazardous aspects of the activity and the features needed to render the probability of inadvertent exposure of workers and the public extremely low.
- **Clear delineation of safety responsibility** — Define and exercise responsibility, when using hazardous materials, to ensure the safety of workers and the public and to protect the environment.

As described in HNF-MP-003, the following safety practices and requirements embody these fundamental safety concepts.
Prevention requirements that pertain to hazard analysis prevent undue exposures whether from normal or abnormal conditions attendant to the work activity or from unusual but credible events. Hazard analysis is also used to identify chemical incompatibilities and reactions that must be controlled.

- Use of materials that have the least adverse impact on workers, the public, and the environment but will provide the desired results.

- Preservation requirements to preserve the designed-in capability of the structures, systems, and components that are important to nuclear safety and to protection of the environment.

- Mitigation requirements that reflect possibilities for operational mishaps, human- or nature-caused and the emergency response capabilities needed to regain control and mitigate the consequences of dispersed hazardous material if released beyond the immediate design barriers.

- Management requirements that address the need for detailed procedures and trained and qualified workers to integrate, manage, and execute the safety functions.

An independent review is conducted to ensure that the requirements selected as the basis for new SNF Project facilities provide an acceptable level of worker safety, public health, and safety and protection of the environment.

### 8.6.1 Hazardous Material Identification Program

The industrial hygiene staff will identify and document existing and potential occupational health hazards in accordance with requirements of DOE Order 5480 10. This is performed through:

- Knowledge and assessment of the operations
- Periodic walkthrough surveys
- Information provided by inter-organizational communications
- Review of proposed projects, facilities, engineering plans, and specifications
- Maintenance of a hazards inventory or tracking system

Hazardous materials in the workplace are identified by several mechanisms including:

- Hazard communication program
- Hazardous materials and hazardous waste labeling
- Inventory of chemicals
- Facility modification assessments
- General employee health and safety training
- Hazardous materials characterization activities
- Ongoing and continuous source monitoring
- Worker and work area monitoring
- Potential hazard and accident analysis

Prejob planning, including the performance of a JHA, JSA, or automated JHA ensures that potential health and safety hazards are identified and controlled. The JHA, JSA, or automated JHA is performed through the combined efforts of a team (management and workers) finding potential hazards and then eliminating or minimizing them before the job starts. This process results in determining the best way to perform a job safely for both routine and nonroutine work activities. Involvement of workers and technical support organizations (e.g., occupational safety and health and radiological) in both hazard identification and hazard control components is essential to the hazard analysis process. All work activities will receive adequate planning so that potential hazards and accidents are identified and specific precautions are applied. The following steps are included in the JHA, JSA, or automated JHA process:

- Determine the scope and general description of activities to be performed
- Break the job or task down into separate steps or components in the order of planned occurrence
- Identify and assess all known or potential hazards associated with the job or task and areas where workers may be exposed to hazardous conditions
- Determine effective measures to remove or control the potential hazard
- Document and secure approval of appropriate organization functions including Occupational Safety and Health, Fire Protection, Nuclear Safety, Radiological Control, and Environmental Protection
- Participate in a prejob safety meeting using the JHA and/or JSA and other safety-related material relevant to the job or task
- Perform the job or task in accordance with the approved JHA and/or JSA

As needed, the JSA is supplemented by a qualitative exposure assessment of the operations activities, and tasks that present a significant potential for occupational exposure to chemical, physical, and biological hazards. The qualitative exposure assessment is intended to assess the potential for occupational exposure of workers to chemical, physical, and biological hazards, evaluate and recommend control measures for potential hazards, communicate information regarding chemical, physical, and biological exposure hazards, and controls to workers and line management, and document the qualitative exposure assessment. A qualitative exposure assessment includes provisions for conducting occupational safety and health walkthroughs of operations and activities to identify exposure agents and their sources, identify where and when in the operation or activity (e.g., step, stage, location) exposures could occur, and identify control measures.
As discussed in Chapter 30, an assessment team conducted a hazard analysis to identify potential hazards to the SNF Project facility worker, collocated worker, the public, and the environment. Use of the hazard analysis study to identify worker safety concerns and potential accidents satisfies the process safety management guidelines in 29 CFR 1910.119 "Process Safety Management of Highly Hazardous Chemicals," relative to evaluating hazards of a process.

Process safety management is an integrated approach to hazard identification and risk management.

The SNF Project also has a well-defined, systematic approach to performing industrial safety and health comprehensive baseline hazard assessments. Comprehensive baseline hazard assessments are conducted in accordance with SNF Project implementing procedures to identify workplace hazards, evaluate controls and their effectiveness, and to verify effective implementation of applicable safety requirements. Comprehensive baseline hazard assessments and abatement of identified hazards are performed with direct worker involvement. Results of assessments are submitted to the responsible operations managers and their assigned workers.

Chapter 30 describes the evaluation methodology for identifying hazards. To identify potential SNF Project hazards, the processes and activities that will take place within each area of SNF Project facilities were determined. A standardized hazardous material and energy source checklist was used to group potentially hazardous materials and energy sources as they were identified in each area. The hazards were further identified by determining hazardous conditions resulting from the hazardous material or energy source, establishing accident initiators or causes, and defining resultant accident sequences.

Worker safety features are an integral part of facility design. The major features of worker protection are identified and categorized by hazard. The hazard location, potential accident, and consequences are identified along with protective features, including passive, active, and administrative features. The SNF Project uses defense-in-depth engineered and administrative features that provide layers of protection to workers from those hazards. Defense-in-depth engineered features include those that function as:

- Barriers to contain uncontrolled hazardous material or energy release
- Preventive systems to protect those barriers
- Systems to mitigate uncontrolled hazardous material or energy release upon barrier failure

8.6.2 Administrative Limits

SNF Project policy requires that personnel exposure to hazardous materials be maintained at less than the OSHA and ACGIH airborne concentration limits. Personnel exposures to hazardous materials are controlled within the PELs and TLVs. Where OSHA and ACGIH have not established limits, recommendations by other agencies such as the National Institute for...
Occupational Safety and Health and the American Industrial Hygiene Associations, are considered in developing an exposure limit. Guidelines on evaluation and control are developed using the best available information and the professional judgement of the safety and health specialist. In the absence of any recommended limits, nonroutine exposure limits are prescribed on a case-by-case basis for the particular hazard. The occupational safety and health staff will establish these limits conservatively using a combination of factors derived from professional experience and knowledge, available data, and an assessment of the particular situation.

8.6.3 Occupational Medical Programs

The Hanford Site occupational medical contractor is responsible for providing an effective, appropriate, medical surveillance program, including maintaining all associated records and documents. Bioassay requirements are specified by the occupational safety and health organization for workers who have the potential for exposure to heavy metals, carcinogens, or compounds for which the ACGIH has specified biological exposure indices. Bioassay and medical monitoring programs are responsive to the requirements of 29 CFR 1910.120 and 29 CFR 1910 Subpart Z.

The automated EJTA provides the primary mechanism to ensure that workers have the appropriate medical qualification, training, and exposure monitoring based on their assigned job functions and the hazards to which they may be exposed. The EJTA also:

- Satisfies specific Americans with Disabilities Act of 1990 and Fitness for Duty data needs
- Identifies the need for additional employee exposure assessments and monitoring data
- Aids in determining the necessary health and safety training

The job task analysis in conjunction with the automated JHA and exposure monitoring and reporting provides the primary data input components to the Hanford Site occupational health process. In addition to providing essential data for medical qualification and monitoring, the Hanford Site occupational health process effectively supports other occupational medical qualification monitoring, and evaluations and preplacement, voluntary periodic, return to work and termination health examinations, which are specified by the SNF Project S/RID (HNF-SD-SNF-RD-001).

The specifics of the occupational medical program provided for the workforce are described in the memorandum of agreement between the occupational medical contractor, and Fluor Daniel Hanford, Incorporated. The occupational medical contractor schedules workers for medical qualification examinations and medical monitoring based on data provided through the EJTA.
Removes workers from medical program placement when warranted based on EJTA information and other relevant medical information

- Reports results of medical examinations and monitoring to workers and line management
- Maintains medical records in accordance with the applicable OSHA and DOE requirements
- Provides first aid services, including diagnosis and treatment of non-life threatening events
- Performs treatment following accidents, injuries or illnesses
- Conducts worker medical examinations and evaluations in accordance with the S/RID
- Provides fitness for duty on workers for all conditions that may influence performance or work suitability
- Provides medical input into the Fluor Daniel Hanford Incorporated Environmental, Safety Health and Quality organization procedures
- Conducts worksite assessments

All SNF Project workers have the right to review their EJTA, JHA they are working or have worked on and their own medical records maintained by the occupational health contractor

**8.6.4 Respiratory Protection**

The SNF Project is committed to minimizing the inhalation of air contaminated with dusts, mists, fumes, gases, vapors, toxic substances and radionuclides in accordance with the requirements of Sections 19 3 2 and 19 4 1 of the SNF Project S/RID (HNF-SD-SNF-RD-001) which provide hazards controls and health examinations. These cover various hazardous materials, personal protective equipment, environmental controls, materials handling and storage, medical and first aid, work place inspections for hazardous conditions and other similar controls. The primary means of achieving this goal is to prevent or mitigate the hazardous condition at the source. Every reasonable effort is made to achieve this objective by using engineering and administrative controls such as enclosures, ventilation or process modification in accordance with ANSI Z88.2-1992 *Respiratory Protection*. Personal protective equipment requirements in accordance with 29 CFR 1910 are stated in job planning documents including JHAs, JSAs, maintenance procedures, operating procedures, and job-specific permits. These job planning documents include the consideration of normal, abnormal, and accident conditions.
Assessments are performed of work areas and work activities by the occupational medical contractor in accordance with Section 19 4 1 in the SNF Project S/RID (HNF-SD-SNF-RD-001) to determine the presence or likelihood of hazards. This will include a review of materials, processes, and procedures with an emphasis on physical, chemical, and biological hazards. Frequency of worksite visits is determined by the occupational medical director taking into account factors such as the size of the workforce, number and types of operations, nature and amounts of physical, chemical, or biological agents, accident and incident rate, and occupational illness and disability rate.

Prior to the health examinations, the SNF Project management will provide a summary of potential exposures to hazardous agents or tasks and any worksite exposures in excess of OSHA and DOE PELS pertaining to the employees to be examined. Recommendations will be provided to management for corrective action or preventive measures.

The occupational health examiner will perform a number of medical evaluations in accordance with DOE Order 5480 8A, including:

- Preplacement evaluations
- Medical surveillance examinations and health monitoring
- Qualification examinations
- Return-to-work health evaluations
- Termination health evaluations
- Medical monitoring

Section 19 3 2 (29 CFR 1910 134) and Section 19 4 1 in the SNF Project S/RID (HNF-SD-SNF-RD-001) provide the requirements for the respiratory protection program for radiological and nonradiological hazards, which will be implemented by SNF Project implementing procedures. Also see Section 8 6 1, which presents the details for identifying potential hazardous materials in the workplace. For nonradiological hazards, industrial hygienists will:

- Evaluate hazards and select respiratory protection to be used by workers for SNF Project activities involving hazardous materials
- Evaluate hazards and conduct hazardous material exposure assessment as required to ensure adequacy of respiratory protection
- Support line management, respirator issuers, and respirator wearers in ensuring the proper application control, issue, use, cleaning, maintenance, repair, and care for respirators/cartridges at the worksite
- Maintain applicable documentation and records
- Serve as initial point of contact for any issue resolution
- Order cartridges/canisters as needed for specific applications involving hazardous materials

### 8.6.5 Bioassay Program

SNF Project implementing procedures describe the process for implementing the internal dosimetry program and bioassay program, including specific actions and responsibilities of Fluor Daniel Radiological Protection, major subcontractor organizations and Battelle Pacific Northwest Dosimetry Operations in accordance with Title 10, *Code of Federal Regulations*, Part 835, 'Occupational Radiation Protection,' Section 835.402 'Individual Monitoring' (10 CFR 835), and HSRCM-1, *Hanford Site Radiological Control Manual* The need for a baseline or routine bioassay examination may be triggered by a potential for internal exposure in which prejob planning or the radiation work permit indicate that a bioassay examination is required for:

- New employee
- Rehire
- Vendor
- Visitor
- Subcontractor employee
- Employee returning from a leave of absence

In addition, special examinations are initiated if a worker is exposed to the following:

- Radioactive contamination on the worker or potentially in a wound
- Airborne contamination where the worker could have received greater than or equal to 10 derived air concentration hours of internal exposure (after calculating for respiratory protection factors)

If the indicators indicate contamination by transuranic radioisotopes (plutonium, americium) or if an uptake of transuranic isotopes is considered possible, an on-call occupational health contractor physician is notified that the test criteria and test results support use of diethylene triamine penta acetic acid therapy. Results of the testing in the form of internal dose evaluation reports (accident) routine results report (less than decisional levels), and routine results report (greater than investigative levels) is discussed with the manager and worker including the health and safety implications of the results. An occurrence report including test results, is developed and presented to the worker and DOE.

Workers may be restricted from radiological work for any of the following reasons:

- Failing to submit required routine bioassay samples
- Missing a scheduled in vivo test

8-25 November 1999
Experiencing a suspect or uncertain dose requiring further evaluation to assess
Any other assessed situation that could result in undetected internal dose

A report is prepared periodically (about annually) by Pacific Northwest National Laboratory that supplies information to support decisions made in assigning routine bioassay requirements in radiation work permit preparation. Reports consist of the following information:

- Identifies what routine bioassays are required for standard work activities
- Identifies exceptions to the bioassay criteria for standard work activities
- Contains characterization data or other determinations necessary to support the conclusions
- Applicable radiological work permit guidance
- May contain process flow charts, waste characterization or other available documents
- Applicable internal dosimetry technical basis guidance
- Considers what radionuclides are most likely to be dispersed in an accident (i.e., contamination that is resuspendable is more important for routine bioassay planning than material that is fixed and unlikely to contribute to a worker intake)
- Includes a discussion on the use of air sample analysis and tech smears of material likely to be resuspended

8.7 HAZARDOUS MATERIAL MONITORING

This section provides summaries of the hazardous material sampling and monitoring programs that are conducted internally and externally for SNF Project facilities in accordance with Section 19.3 of the SNF Project S/RID (HNF-SD-SNF-RD-001). Additional details of the program are presented in the following subsections.

8.7.1 Workplace Monitoring and Sampling Program

The SNF Project administrative procedures describe the process for implementing the workplace monitoring and sampling program. The objectives of the workplace monitoring and sampling program are to provide a rational basis for selecting appropriate levels of personal protective equipment and work practice controls, documenting personnel exposure levels and verifying that the implemented hazard control procedures are adequate and appropriate for actual facility conditions. SNF Project occupational safety and health manuals and procedures address
monitoring for workplace hazards. See Section 8.4 for a discussion of the SNF Project policies and programs for maintaining nonradiological hazardous materials. ALARA. Also see Section 8.6.1, which provides details on prejob planning, developing a JHA, JSA, or automated JHA, worker and work area monitoring, identifying potential hazards, involvement of workers and technical support organizations in hazard identification, and hazard control processes.

8.7.2 External Monitoring and Sampling Program

The SNF Project administrative procedures describe the process for implementing the external monitoring and sampling program. The principal function of the external monitoring and sampling program is to detect, quantify, evaluate, and, where possible, predict impacts associated with routine as well as accidental or unintended releases of radioactive as well as nonradioactive constituents to the environment. Monitoring programs also are directed at maintaining compliance with environmental permits from the Washington State Department of Health and with other applicable regulations. The monitoring programs are directed at atmospheric, physical and biological parameters both on and off the site. As required by Section 19.3.1 of the SNF Project S/RID (HNF-SD-SNF-RD-001), the industrial hygiene staff is responsible to determine the type and frequency of periodic monitoring that is performed to ensure the maintenance of satisfactory conditions. The industrial hygiene staff also determines the type and frequency of periodic monitoring, including continuing adequacy of controls, need for additional controls or recommendations for maintenance or reemphasis of administrative controls.

Section 20.3 of the SNF Project S/RID (HNF-SD-SNF-RD-001) presents requirements for environmental monitoring, surveillance, and inspection activities applicable to the SNF Project. Environmental surveillance includes sampling and analyzing environmental media to detect and quantify potential contaminants and to assess their human health significance. This includes sampling of air, surface water, soil, and vegetation. The environmental monitoring activities are performed independently of the occupational safety and health organization's monitoring activities by the SNF Project environmental monitoring organization.

A preoperational environmental monitoring study will be initiated prior to startup of SNF Project facilities in accordance with Section 20.3 of the SNF Project S/RID (HNF-SD-SNF-RD-001). This will be completed between one and two years prior to startup so as to include any seasonal changes. This study will include the following:

- Characterization of existing physical, chemical, and biological conditions that could be affected
- Establishment of background levels of radioactive and chemical components
Characterization of pertinent environmental and ecological parameters

Identification of potential pathways for human exposure or environmental impact as a basis for determining the nature and extent of the subsequent routine operational and effluent monitoring and environmental surveillance programs.

An environmental monitoring plan will be developed for each SNF Project. This will contain rational and design material for the monitoring program, extent and frequency of monitoring and measurements, procedures for laboratory analyses, quality assurance requirements, program implementation procedures, and direction for preparation and disposition of the reports. The plan will be reviewed annually and updated as necessary.

Analytical models to perform dose evaluations will be appropriate for:

- Emission characterizations (e.g., gas, liquid or particle, depositing or nondepositing buoyant or nonbuoyant)
- Mode or release (e.g., stack or vent, crib or pond, continuous or intermittent)
- Environmental transport medium (e.g., air or water)
- Exposure pathway (e.g., inhalation, ingestion of food, water, or milk, direct radiation)

Information will be updated as necessary to document significant changes that could affect dose evaluations.

SNF Project implementing procedures will include the above and related requirements of Sections 20.4 and 20.5 of the SNF Project S/RID (HNF-SD-SNF-RD-001).

Section 20.6 of the SNF Project S/RID (HNF-SD-SNF-RD-001) present recordkeeping, reports, and notification requirements. Responsibilities and response actions to be initiated in the event of an accidental routine or nonroutine release of a solid, liquid, or airborne substance that includes radioactive hazardous or dangerous wastes, hazardous or extremely hazardous substances, polychlorinated biphenyls, or oil petroleum products are contained in SNF Project implementing procedures. Such releases are immediately reported regardless of the quantity except for small drips that can be immediately wiped up. The SNF Project is responsible for implementing actions to clean up and properly dispose of spilled material in accordance with the applicable federal, state, and local codes and regulations. This procedure also presents requirements for reporting chemical information pursuant to the Emergency Planning and Community Right-To-Know Act of 1986.
8.8 HAZARDOUS MATERIAL PROTECTION INSTRUMENTATION

Direct-reading instrumentation and other hazardous protection instruments are maintained in a pool. The instruments in the pool are treated as sitewide resources and are loaned to Hanford Site workers on an as-needed basis. The occupational safety and health organization assists the SNF Project facility industrial hygienists and technicians with preuse and postuse calibrations. A database is used to track the status and location of instruments being used, and status-indicating tags are used to control instruments requiring service and repair. Periodic, routine maintenance of the direct-reading instrumentation within the pool is the responsibility of the instrument pool organization. Calibrations are performed at an onsite laboratory or approved offsite laboratory using National Institute of Standards and Technology traceable standards. The types of standards (e.g., calibration gases, thermometers) and calibration technique, if performed onsite, meet manufacturer's specifications.

In addition to direct-reading field instruments, many types of personal monitors that require field sampling followed by laboratory analysis of samples are used. Field-sampling equipment is controlled in the same manner as the direct-reading instruments.

Typical direct-reading instruments available for workplace monitoring are listed in Table 8-2. SNF Project facility industrial hygienists and technicians will use the appropriate instrumentation for personnel protection. For several of the analytes listed, various types of instruments are available for sampling and monitoring.

The calibration and/or functional status of each direct-reading instrument is checked and documented by the person responsible for the equipment before and after each use. The calibration and/or functional status of each direct-reading instrument is checked and verified to be within established limits or the manufacturer's manual guidance. The results of this check are documented by the user daily and prior to use. All instrument field calibration data and monitoring results are recorded in a daily monitoring, if taken. As discussed in Chapter 14.0 each organization responsible for using measuring and testing equipment uses controlled procedures for calibration and control of that equipment. Any measuring and testing equipment used for acceptance testing, verification, or data collection are subject to these controls. These controls will provide for calibration and adjustment at specified intervals to maintain accuracy within necessary limits.

An SNF Project quality assurance program plan provides specific details that describe the activities and quality assurance controls for measuring and testing equipment for the SNF Project facilities. As discussed in Chapter 10.0, the SNF Project in-service surveillance program will contain provisions for testing and calibration, and control and calibration of measuring and testing equipment. Additional details of the program for the control and calibration of measuring and testing equipment are required by Section 10.1 of the SNF Project S/RID (HNF-SD-SNF-RD-001).

**Toxics** = CO₂, HCN, CO, NO₂, H₂O, SO₂, and NH₃.

*The GC instrument is portable in principle but because of its weight it is typically used in a laboratory setting.

CL = chemiluminescence
ES = electrochemical sensor
FID = flame ionization detector
FL = fluorescence
GC = gas chromatograph
GF = gold film
IR = infrared
LEL = lower explosive limit (e.g., for oxygen, hydrogen, and methane)
PID = photo ionization detector
ppb = part per billion (range of 1 to 1,000 parts per billion by volume)
ppm = part per million (range of 1 to 1,000 parts per million by volume)
Safety and health specialists determine instrument use number of instruments and placement under normal and emergency conditions by drawing upon their skills and experience and by using data from a qualitative hazard analysis or baseline hazard assessment. The requirements for hazardous material protection instrumentation at the SNF Project facilities are based on the following:

- Type of work being performed
- Contaminant to be sampled or monitored
- Regulatory requirements (PELs or TLVs) for the contaminant
- Worker exposure levels or concentrations of hazardous substances
- Results of periodic work condition evaluations verifying that the selected levels of protection and control measures are appropriate

Direct-reading instruments are used for personal and area monitoring while work activities are being performed. Personal breathing zones are sampled using sorbent or filter media to confirm that exposure levels are within the regulatory exposure levels.

### 8.9 Hazardous Material Protection Record Keeping

The SNF Project has an established document control and records management program that ensures records are maintained in compliance with Sections 18 and 181 through 183 of the SNF Project S/RID (HNF-SD-SNF-RD-001). The activities and controls for SNF Project records are presented in a SNF Project quality assurance program plan.

Health and safety data and information are collected, maintained, and retrieved in a systematic manner that ensures data quality. The SNF Project hazard communication program requires that all monitoring data written reports of field evaluations, recommendations for corrective actions, and closures of actions be recorded and retained pursuant to Section 196 of the SNF Project S/RID (HNF-SD-SNF-RD-001).

Records shall be (1) adequate and proper that are created and maintained for all activities under the contract and (2) established in accordance with a records management program that provides approval of all records dispositioned by the National Archives and Records Administration. An approved records disposition schedule will be developed for every records service.

As required by Section 1961 of the SNF Project S/RID (HNF-SD-SNF-RD-001), all employees or former employees have access to their personal safety, health, and medical records consistent with the *Freedom of Information Act* and the *Privacy Act of 1974*.
If requested by the worker, occupational monitoring data are reported directly to the worker monitored. As required by Section 1931 of the SNF Project S/RID (HNF-SD-SNF-RD-001), the SNF Project management will inform workers of the existence, location, and availability of workplace-related medical and exposure records. These records are maintained by the Fluor Daniel Hanford, Incorporated Environmental Safety, Health and Quality organization and are provided to a worker or worker's representative, within 15 days of a request. Distribution of personal exposure monitoring data is governed by Section 1931 of the S/RID.

Data resulting from occupational monitoring will be easily retrievable. Monitoring data shall be tabulated along with information on the location and operation monitored, the identity and job classification of the employees associated with the operations, estimated time-weighted average or short-term exposure levels, and a reference to the sampling and analytical methods used in accordance with Section 1961 of the SNF Project S/RID (HNF-SD-SNF-RD-001). Data generated to provide information on worker and public hazardous material protection are reviewed for adequacy by qualified staff authorized for release and use by management, and distributed to those workers who request the information. Occupational monitoring data are reviewed before inclusion in the Hanford Site occupational safety and health exposure database. Reviews consist of data validation (to ensure that appropriate monitoring methods were employed), confirmation that instruments used were within calibration specifications, and data transcription checks (to ensure that the data are free of technical and clerical errors). The data are interpreted by comparing the validated monitoring data with recognized national standards to assess compliance and to determine whether engineering, administrative, or personal protective controls are needed to protect workers from assessed hazards.

The SNF Project is responsible for recording and reporting recordable occupational illnesses and injuries in accordance with the requirements of Section 1922 of the SNF Project S/RID (HNF-SD-SNF-RD-001). Records of employee exposure to toxic materials or harmful physical agents will be maintained in perpetuity. Records of violations of DOE-prescribed OSHA standards noted during inspections will be maintained. Retention periods will be established in accordance with the SNF Project S/RID requirements.

The SNF Project will post DOE forms 5480 2 and 5480 3 or DOE forms EV-632 and EV-632S. Posting will be sufficient to permit employees to observe the information on the way to or from their places of employment.

8.10 HAZARD COMMUNICATION PROGRAM

The hazard communication program applies to the purchase, receipt, transportation, use, and storage of hazardous chemicals and products. Specific elements of the program include area definitions and postings, chemical labeling, chemical product lists, and MSDSs. A description of the program and worker responsibilities is contained in SNF Project implementing procedures.
An inventory of potential occupational health chemical, physical, and biological hazards in SNF Project facilities will be maintained by location and/or job category of users and indicate when the hazards were present. The industrial hygiene staff evaluation of potential health hazards will be documented in written reports and deficiencies will be identified with recommended corrective actions. These reports and responses by SNF Project management will be retained in accordance with the records management program.

The purpose of the hazard communication program is to ensure that SNF Project workers are informed of these hazards and are provided with adequate information and training to know and understand the use of the necessary protective measures. The primary goal of the program is to provide adequate information to allow these materials or agents to be used, handled, stored, and disposed of safely. SNF Project personnel are required to promptly notify the Hanford Fire Department of any hazardous material spills or incidents requiring response by the Hanford Fire Department's hazardous materials response team. The SNF Project also maintains an ongoing dialogue with the Hanford Fire Department so the fire department is aware of unique or special hazards related to the SNF Project. This dialogue is required by SNF Project implementing procedures.

The SNF Project purchasing organization will participate as requested by the industrial hygiene staff to ensure that potentially hazardous material or equipment being procured are adequately identified, evaluated, and controlled. In addition, they will ensure compliance with the mandatory industrial hygiene standards in Section 1932 of the SNF Project S/RID (HNF-SD-SNF-RD-001) and make provisions to allow the industrial hygiene staff to monitor compliance.

8.10.1 Hazard Posting in Work Areas

Chemical and physical hazard information is posted in each specific work area location within the SNF Project facilities to advise workers of the hazards that are present in the workplace. The posting includes flammable, corrosive, reactive, toxic, and carcinogenic chemicals that are used or stored within the area. Informational postings also include other workplace hazards, such as physical or biological hazards. In addition to hazard warnings, hazard postings provide information on the location of MSDSs and spill cleanup materials. It is the responsibility of each worker to observe the hazard postings and to comply with the indicated requirements.

8.10.2 Chemical Management

A chemical management program has been established as required by the integrated environment, safety, health, and quality management system. Objectives that are achieved by this program include the following:

- Assure compliance with applicable regulatory and statutory requirements.
- Protect the worker, public, and environment
- Implement a consistent approach to the management of chemicals among the Project Hanford Management Contract Team and its subcontractors
- Incorporate the chemical management system requirements agreed to by the Hanford Site major prime contractors

An SNF Project implementing procedure has been developed that applies to all chemical management operations associated with the acquisition, storage, use, transportation, and final disposition of chemicals. This procedure also includes the Project Hanford Management Contract Team roles and responsibilities and key implementing procedures that establish requirements for chemical management. Chemical management requirements will be applied on a graded approach.

8.10.3 Chemical Labeling

The SNF Project hazard communication program will require that the manufacturer's labels and appropriate warnings be legible on all purchased hazardous chemical primary containers. The manufacturer's label on the original chemical container will not be removed or defaced. As a minimum, the manufacturer's label indicates the manufacturer's name and address, identity of the hazardous chemical, associated health and safety hazards, product or chemical name, appropriate hazard warnings, and special precautions. If a container is inadequately labeled, the label is corrected immediately by the person discovering the situation unless the contents are unknown. If the contents are unknown or improperly or inadequately identified, the contents are identified before use or disposal.

If a hazardous chemical is transferred from a primary container to another (secondary) container, the secondary container is labeled with a Hanford Site hazard label in accordance with established procedures. The Hanford Site label shows the MSDS number and numerical hazard rating. The Hanford Site label includes the name of the chemical and the product or trade name. Hazards are color coded as follows:

- Health hazard – blue
- Fire hazard – red
- Reactivity hazard – yellow
- Other hazards – white

The hazard severity identification includes:

- 0 – minimal or no hazard
- 1 – slight hazard
- 2 – moderate hazard
- 3 – serious hazard
- 4 – severe hazard
Chemical materials transferred from the original container into smaller, portable containers are not required to be labeled as long as their subsequent use is limited to the immediate use of the worker who performs the transfer.

8 10 4 Chemical Product List

All chemical products stored or used in SNF Project facilities are listed on the facility-specific chemical product list. The list identifies the product by providing the following information:

- Chemical name
- Site medical contractor-assigned MSDS identification number
- Manufacturer's number
- Determination of whether the product is a carcinogen
- Determination of whether the product, if disposed of, is a regulated waste
- Date received or placed in inventory
- Locations approved for use or storage

The facility's chemical product list is maintained by the engineering organization. A copy of the chemical product list is kept with the facility's MSDS files. Any chemicals not on the list are reviewed before they are ordered to determine whether a suitable substitute product could be bought that will perform the same function while reducing potential exposure to hazardous chemicals. To ensure that disposal requirements are known in advance of purchase of a new chemical, a waste summary and a waste specification record or hazardous waste disposal analysis record is prepared and approved. Procurement of a known or suspected carcinogen or other hazardous product will require justification, in writing, describing the reason a less hazardous chemical cannot be used. Training and information is provided for those using and handling a new chemical before the chemical is brought into the facility.

Chemical tracking is performed by the occupational safety and health organization to provide information about the storage location, product name, manufacturer, chemical constituents, physical state, container description, and total quantity for all chemical products stored in facilities that maintain an inventory of hazardous chemicals. Regular inspections are made of chemical storage areas and facilities to ensure container integrity, compatibility, adequate separation, temperature, moisture, and humidity control. Outdated material is disposed of properly. Any contaminated decomposed, or altered material is considered highly unstable and potentially hazardous. If such materials are found, (1) the container is not disturbed, (2) the area is isolated, and (3) the manager or building emergency director is notified. The manager or Building Emergency Director will contact the Industrial Hygiene organization and the Hanford Fire Department to arrange for proper handling and disposal in accordance with SNF Project implementing procedures.
8.10.5 Material Safety Data Sheets

An MSDS is required for each chemical and product on the hazardous chemical inventory listing. The MSDS provides a standard format for explaining chemical hazard information and is readily accessible to all workers. Each MSDS must provide the following information:

- Physical and chemical characteristics
- Physical hazards
- Health hazards signs and symptoms of exposure, and any medical conditions that are generally recognized to be aggravated by this chemical
- PEL and/or TLV
- Emergency and first aid procedures
- Applicable control measures such as engineering controls, work practices, or personal protective equipment
- Precautions for safe handling and use
- Name, address, and phone number of chemical manufacturer

The SNF Project procurement organization has the responsibility for ensuring that MSDSs are received with each shipment from the chemical manufacturer or supplier and submitted to the MSDS coordinator. Each chemical used in SNF Project facilities has an updated MSDS that is maintained by the MSDS coordinator. Outdated or superseded MSDS files are replaced by hard copies of the new MSDS. The MSDS is included in the work package for activities involving hazardous chemicals, and individuals performing the work are responsible for reviewing each MSDS in the work package before performing the work. The MSDS database available through the Hanford Local Area Network provides an inventory option so that facilities can track their chemical inventories through the MSDS request system. Using this system ensures that facilities are notified of any MSDS updates and/or new formulations.

8.10.6 Information and Training

As required by the OSHA hazard communication standard (29 CFR 1910.1200), workers and contractors are provided information concerning the hazardous substances to which they may be exposed and are made aware of exposure risks, hazards, personal protective equipment requirements, and emergency procedures associated with the hazardous chemical. This training covers an explanation of the SNF Project hazard communication program and how to find information regarding chemical hazards. All workers receive this training during Hanford General Employee Training.
During facility orientation, new workers are provided with facility-specific information regarding the specific hazards of chemicals that may be encountered during routine work. They are also informed of the location of chemicals in their work area, as well as the location and accessibility of the MSDS for any chemical in their work area.

Where work is nonroutine, a JHA is performed to systematically identify the hazards associated with the activities being performed and the areas in which a worker may be exposed to hazardous conditions. The hazard analyses identifies specific effective, safety measures that may be applied to eliminate or control the hazard. Prejob safety meetings are conducted to discuss the hazards with workers who may be exposed to the hazard during the course of their work. The prejob briefings address conditions in the workplace, hold points, and limiting conditions that may void the permits or work plans. The training also identifies engineering, administrative, and personal protective control mechanisms.

The SNF Project hazard communication program requires that facility managers inform Site contractor and subcontractor workers of chemical and physical hazards they may encounter. Contractors and subcontractors have the responsibility to inform facility managers of any chemical hazards and/or physical agents that they might bring onsite.

8.11 OCCUPATIONAL CHEMICAL EXPOSURES

No routine chemical processes are conducted within the SNF Project facilities. The multi-canister overpack process involves the use of an inert gas. Some chemicals, such as those used for equipment decontamination, may be used occasionally. However, the predicted annual exposures to workers from hazardous materials in SNF Project facilities are expected to be negligible for normal operation.

As discussed in Chapter 9.0, maintenance and monitoring activities may require the use of small amounts of activity-specific products that are not expected to contribute to occupational chemical exposures. However, in the event that additional hazardous materials are introduced into SNF Project facilities, occupational safety and health controls, such as engineered and administrative controls, as well as personal monitoring and sampling, are implemented to ensure that overexposure does not occur.

The Hanford Fire Department is the designated emergency response organization for all hazardous materials emergencies, including medical emergencies. The department's function is to mitigate and stabilize the emergency event. The department also is the designated rescue agency for the Hanford Site, including confined spaces, hazardous areas, cave-ins, trench rescue, building collapse, and high-angle rescues. In accordance with the SNF Project implementing procedures, all SNF Project employees are responsible for promptly notifying the Hanford Fire Department of any hazardous material spill or incident requiring response by the Hanford Fire Department. Hazardous materials response team members include any employee who becomes unexpectedly or extremely ill or injured.

9.0 RADIOACTIVE AND HAZARDOUS WASTE MANAGEMENT

9.1 INTRODUCTION

This chapter describes the essential features of the radioactive and hazardous waste management programs that provide for safe control, collection, and handling of wastes generated during routine operations at Spent Nuclear Fuel (SNF) Project facilities. The overall radioactive and hazardous waste management programs and organization including objectives, plans, procedures, and training, are described. Radioactive and hazardous waste streams and sources are identified in the facility annexes to the SNF Project Final Safety Analysis Report (FSAR).

The SNF Project facility operations are not expected to produce appreciable amounts of hazardous wastes. The SNF Project facilities will produce miscellaneous industrial wastes, radioactive waste, and employee-generated trash. Miscellaneous industrial waste results from maintenance and repair of equipment, such as cranes and heating, ventilation, and air conditioning equipment. The major volumes of radioactive waste will come from K Basins operations and decommissioning. This chapter addresses the processes of packaging and transporting these waste categories.

The SNF Project waste management processes adequately protect the health and safety of the worker, the public, and the environment in a manner that meets as-low-as-reasonably-achievable criteria for radioactive and hazardous waste.

In those cases where policies, programs, and practices important to safe operation are described in detail in other documents, the information is summarized in this chapter and the documents are referenced. The detailed programs and procedures described in referenced documents may be changed without further US Department of Energy (DOE) approval to the extent that the changes do not constitute an unreviewed safety question as defined by DOE Order 5480.21 Unreviewed Safety Question.

9.2 REQUIREMENTS

The requirements that form the basis for the radioactive and hazardous waste management program are found in HNF-SD-SNF-RD-001 Spent Nuclear Fuel Project Standards/Requirements Identification Document. Specific requirements applicable to this chapter include:

- DOE Order 5400.5, Radiation Protection of the Public and the Environment
- DOE/RL-95-07 Hanford Site Air Operating Permit Application
9.3 RADIOACTIVE AND HAZARDOUS WASTE MANAGEMENT PROGRAM AND ORGANIZATION

9.3.1 Program Summary

The SNF Project waste management philosophy revolves around protecting workers, the public, and the environment, ensuring proper management of waste from its point of generation to its final disposition, and ensuring compliance with applicable federal, state, and local laws and regulations. To meet these goals, the SNF Project policy is to conduct operations and activities in a way that minimizes the quantity and toxicity of wastes generated, eliminates or minimizes pollutant releases to the environment, and minimizes the use of toxic substances.

SNF Project policy also requires that radioactive and hazardous material exposure of workers, visitors, the public, and the environment be as low as reasonably achievable. The waste management program is governed by the requirements of Section 16 of the SNF Project standards/requirements identification document (S/RID) (HNF-SD-SNF-RD-001). The following basic elements are included:

- Procedures governing solid waste treatment, segregation, monitoring, characterization, packaging, storage, transportation, and disposal.
- Waste minimization goals and practices that reduce generation of radioactive and hazardous waste, spread of contamination, and generation of nonhazardous refuse.

Hanford Site waste is handled by Waste Management Federal Services of Hanford, Incorporated (WMH), and the waste transportation organizations on a sitewide basis. The responsibilities and authorities of these organizations are presented in WMH-200 Series, Waste Management Operations Administrative Manual Procedures.

SNF Project waste management procedures are developed, prepared, reviewed, approved, issued, and maintained according to SNF Project administrative procedures. Procedures are in place for anticipated operations, maintenance, tests, and abnormal or emergency situations. Chapter 12.0 contains a description of the SNF Project facilities procedure program. At the SNF Project facilities, WMH uses a combination of SNF Project procedures and WMH internal procedures in the fulfillment of its waste management role.

The SNF Project follows the site waste minimization and pollution prevention management plan. Engineers and planners provide a checklist as part of that plan that states how they expect to minimize waste. For solid waste, a predetermination of waste characteristics is conducted to determine characteristics of materials that have been analyzed and to suggest alternatives to the use of hazardous materials. These tools aid in minimizing the generation of hazardous waste. Using these guides, introduction of asbestos or polychlorinated biphenyl-containing materials into the facilities is avoided.

November 1999
9.3.2 Waste Minimization Plan

Waste minimization is the prevention or reduction of waste at the source or reduction of the quantity of pollutants, contaminants, hazardous substances, or waste for treatment, storage, or disposal. Waste minimization is any source reduction or recycling activity that results in (1) reduction of the total volume of waste, (2) reduction of the toxicity of waste, or (3) both (1) and (2), as long as that reduction is consistent with the general goal of minimizing present and future threats to human health and the environment. The hierarchy of waste management practices places highest priority on source reduction followed by recycling, and finally treatment, storage, and disposal, in that order.

Section 16.7 of the SNF Project S/RID (HNF-SD-SNF-RD-001) describe waste reduction efforts that are applied at SNF Project facilities and are in agreement with the objectives described in the previous paragraph. The various levels of the waste minimization and pollution prevention programs are identified below. The Hanford Site waste minimization program is prescribed in HNF-PRO-462, Pollution Prevention, and is overseen by the Pollution Prevention Program Group. A Hanford Site waste minimization and pollution prevention awareness program plan targets all waste types — radioactive, hazardous, mixed, and nonregulated. The plan documents present and future activities that reduce the volume and toxicity of wastes. Waste minimization practices are integrated into operating procedures.

The SNF Project pollution prevention activities are implemented by facility administrative procedures and contain the key elements of source reduction, toxicity reduction, volume reduction, and product substitution. The work planning process evaluates waste generation activities for opportunities of pollution prevention. The program is based on HNF-PRO-462.

9.3.3 Radioactive and Hazardous Waste Management Organization

The SNF Project operations organization outlined in Chapter 17.0 administers the radioactive and hazardous waste management program within the SNF Project facilities. Facility personnel as waste generators, have the responsibility to ensure that all newly generated wastes are handled, stored, and packaged in accordance with requirements contained in Section 16 of the SNF Project S/RID (HNF-SD-SNF-RD-001). The radioactive and hazardous waste management processes are implemented by the SNF Project personnel identified in the following subsections.

9.3.3.1 Facility Manager: The facility manager at each SNF Project facility is responsible for daily functional activities and regulatory compliance associated with those activities (i.e., inspection, sampling, analysis, handling, packaging, storage, shipping, and disposing of wastes), ensuring compliance with employee training programs and approved procedures, ensuring adherence to approved plans, record keeping, reporting, and groundwater monitoring activities; supporting inspections by regulatory agencies responding to regulatory findings; and ensuring permitted activities are performed in compliance with permit requirements.
At the SNF Project facilities, WMH has contracted to provide waste management services including the following:

- Operation and maintenance of satellite accumulation areas, less-than-90-day pads, and low-level waste and transuranic management areas.
- Scheduling and removal of waste materials from satellite accumulation areas, less-than-90-day pads, and low-level waste and transuranic management areas to the appropriate treatment, storage, and disposal facility.
- Development and verification of waste documentation.
- Advice for planning waste generation and waste characterization, segregation, and packaging.

These contracted activities are performed in compliance with SNF Project procedures.

9332 **Environmental Compliance Officer**  An environmental compliance officer is assigned to assist the facility manager on waste management issues. The environmental compliance officer is responsible for regulatory compliance within the SNF Project.

9333 **Environmental Compliance and Support Services**  Environmental Compliance and Support Services performs activities associated with managing and permitting hazardous waste activities at SNF Project facilities, including developing the documentation required for managing treatment, storage, and disposal units and drafting permit applications to support operating activities.

9334 **Pollution Prevention**  The WMH Pollution Prevention Group serves as the lead Hanford Site coordinating group to support development and implementation of waste minimization and pollution prevention programs. This group, as described in HNF-PRO-462, will assist the facility manager in the development of successful programs, in the assessment of program effectiveness, and in preparation of regulatory required reports.

9335 **Hanford Analytical Services Management**  Hanford Analytical Services management provides guidance regarding the number of samples, sample types, sample quantities, and types of analyses required, reviews sample and analysis plans received from the waste owners for consistency with requests for laboratory services and capabilities, and provides data validation verification and coordination of laboratory support.

9336 **Facility Personnel**  Individual workers perform work activities in accordance with the specified work instructions, work procedures, and standard operating procedures. Each employee is responsible for promptly notifying management of events and conditions that could have adverse safety or environmental implications, including releases to the environment.
9.4 RADIOACTIVE AND HAZARDOUS WASTE STREAMS AND SOURCES

The following subsections identify SNF Project radioactive and hazardous waste management and handling processes. Facility-specific waste streams and sources are identified in the facility FSAR Annexes.

9.4.1 Waste Management Process

The goals and policies of the SNF Project hazardous and radiological waste management process are described in the following sections.

9.4.1.1 Solid Waste Management Process

The solid waste management process goals are as follows:

- Collect, store, and dispose of all waste in a safe, economical, and environmentally acceptable manner.
- Segregate, package, and ship nonradioactive wastes to the appropriate disposal or recycling facility.
- Segregate radioactive waste to prevent cross-contamination of radionuclides.

Criteria to ensure that the management process goals are met are specified in SNF Project control manuals and acceptance criteria documents. These internal documents meet the requirements specified in the SNF Project S/RID (HNF-SD-SNF-RD-001), and are in accordance with appropriate DOE orders, Hanford Site requirements, federal, state, and local regulations, and industry standards. Requirements for contact-handled solid wastes comply with the requirements of the appropriate SNF Project S/RID.

9.4.1.2 Air Quality Waste Management Process

Normal operations at the SNF Project facilities are not expected to generate any considerable amounts of air pollutants. Therefore, no air quality waste management process is necessary. The facilities are permitted, however, by the U.S. Environmental Protection Agency and Washington State Department of Health for air emissions.

Criteria for confinement, safe handling, and disposal of liquid and gaseous effluent streams are contained in Section 20 of the SNF Project S/RID (HNF-SD-SNF-RD-001).

9.4.1.3 Water Quality Waste Management Process

No unpermitted discharge of liquid or water pollutants to the environment is expected from the SNF Project facilities. The following normal precautions are necessary and will be followed by the SNF Project to protect the environment:

- Obtain permits and permit modifications for the SNF Project facilities, as applicable.
• Ensure septic systems are located, designed, installed, operated, maintained, and permitted according to WAC 173-272 (Sewage permits are issued by the Washington State Department of Health).

• Maintain facility operations within the authorization envelope.

• Ensure compliance with the requirements of the regulatory codes and applicable permits.

• Provide prompt notifications of failures in the sampling process or of any releases that exceed the requirements defined in applicable waste water permits required by Section 20.2 of the SNF Project S/RID (HNF-SD-SNF-RD-001).

• Ensure (where required for liquid discharges) that a facility effluent monitoring plan is issued and that annual reviews are provided in accordance with WHC-EP-0438, *A Guide for Preparing Hanford Facility Effluent Monitoring Plans*.

• Ensure training is provided for personnel who collect samples, verify and maintain personnel qualification records.

• Ensure proper use of sewage systems through strict adherence to operating procedures.

• Comply with spill prevention and reporting requirements as applicable.

9.4.2 Waste Sources and Characteristics

The following subsections summarize how and where SNF Project waste is generated and how it enters the appropriate waste handling or treatment system. Specific waste sources and characteristics are addressed in the facility FSAR Annexes.

9.4.2.1 Solid Waste Streams and Sources

The operations conducted by the SNF Project either directly or indirectly result in the generation of solid waste to be discarded. Solid waste is solid but may contain liquids or gases. It is sorted into solid waste streams on the basis of characteristics, constituents of interest, regulatory requirements (if applicable), and the waste acceptance criteria for final disposition. The following generally identifies the major sources and corresponding facility FSAR Annex. Criteria for the management of solid waste including its designation is provided in HNF-PRO-455, *Solid Waste Management* and meets the requirements of Section 16 of the SNF Project S/RID (HNF-SD-SNF-RD-001). The S/RID defines the steps in the waste designation process for mixed and hazardous wastes.

9.4.2.1.1 Radioactive Solid Wastes

Continued operations and decontamination and decommissioning of K Basins is expected to generate significant volumes of sludge, spent ion exchange modules, contaminated materials, and equipment. Only small amounts of hazardous or
Radioactive waste are expected to be generated within other SNF Project facilities. Solid waste could include sludge, spent water purification filters and units, contaminated equipment construction waste, compactable and noncompactable containerized waste from radiological control areas, decontamination waste used containers, and miscellaneous waste (i.e., waste generated by off-normal events such as spills or equipment failures and wastes generated during surveillance and monitoring operations). Most of these radioactive wastes will be designated as low-level waste, however, it is anticipated that the K Basins sludge will be remote-handled transuranic waste. Sources of radioactive solid waste include the following:

- **K Basins sludge** from storage of the SNF in the water basins and includes corrosion products from the storage racks and containers, dusts, corroded SNF, and other materials.

- **Water conditioning process components** including spent ion exchange modules and spent water treatment filters.

- **Low-level waste debris.** This waste stream consists of debris that is radiologically contaminated. The activities that produce this waste include the following:
  - Routine surveillance and maintenance activities. Tools and equipment used during routine surveillance and maintenance may create a waste stream.
  - Construction, demolition, and facility upgrades. Maintenance and removal of facility components and equipment generate a variety of low-level waste debris, including tools, wood, concrete, asphalt decontamination materials, and containment materials (e.g., tents and glovebags).
  - High-efficiency particulate air filter replacement (if they contain a sufficient level of activity present on the filters).
  - Decontamination. Fluids (water and nonhazardous decontamination fluid) and other materials are used in decontamination of equipment requiring maintenance and repair. Fluids are normally solidified by absorption in materials designed to meet landfill crush strength requirements.

### 9.4.2.1.2 Hazardous Wastes

Hazardous wastes produced by SNF Project operations consist primarily of maintenance waste (batteries and oily waste) and miscellaneous waste from the use of chemical cleaning agents or pesticides and herbicides. Hazardous waste will be recycled, as appropriate. There is a possibility that oils containing hazardous constituents will be used in the SNF Project facilities, resulting in any waste oil in this category being managed as a hazardous waste.
Oily debris is generated by maintenance and cleanup activities. This debris will be designated as hazardous waste based on the chemical constituents identified on the material safety data sheet or from analytical analysis. The source of this waste can be any of the following activities:

- **Routine operational activities**: Cleaning and degreasing of equipment systems produce oily and greasy rags and absorbents.

- **Routine maintenance activities**: Changing oil in compressor systems, crane hydraulics, and other permanently installed equipment creates a waste stream of hydraulic and engine oils and other lubricating fluids. These oils are absorbed in organic sorbents.

Identified hazardous solid wastes will be packaged and shipped to the appropriate regulated waste storage or disposal facility.

**9 4 2 1 3 Nonregulated Wastes** Nonregulated waste will be recycled as appropriate.

Nonregulated waste streams include the following:

- **Office waste**: This is disposed of by site contractors or through other approved means.

- **Vegetation growth around the facilities and animal carcasses (e.g., snakes, mice, ants, rabbits)**: These are managed and controlled by established site contractors. Removal when necessary is done in accordance with the applicable acceptance criteria for the waste type.

- **Sewage from the facilities**: This is disposed of via septic drain fields or collection tanks that are pumped and moved by established site contractors to approved facilities.

- **High-efficiency particulate air filters that are not classified as radioactive or hazardous waste**: These are disposed of by site contractors or through other approved means.

**9 4 2 2 Liquid Effluents and Sources** Radioactive water in the K Basins is treated to remove radioactive constituents by operation of water purification systems. Following the removal of the fuel from the basins, the water will be treated in site treatment effluent facilities.

Nonradioactive, nonhazardous liquid effluent streams are generated from routine operations such as hydrostatic testing, construction, and maintenance and from storm drains and condensate cooling coils. These streams discharge small amounts of water to the ground. Requirements for this type of effluent are contained in ST 4509, *Washington State Department of Ecology Waste Water Discharge Permit*. See the facility FSAR Annexes for specific effluents and sources.
9.4.2.3 Gaseous Effluents and Sources  Descriptive information for all the existing facility emission points and estimated emission quantities for all known emission points will be summarized in the update to DOE/RL-95-07. Passively ventilated, actively ventilated, and fugitive-type emissions will be addressed.

9.4.3 Waste Handling or Treatment Systems

Treatment methods for K Basins wastes are being evaluated, and treatment systems may be established for the sludge and basin wastes to allow them to be dispositioned. Such systems will be independently reviewed before they are implemented.

Nonregulated waste that can be unconditionally released is accumulated along with nonregulated waste generated outside the facility and stored in containers outside the facility.

Currently, no newly generated waste is treated by SNF Project operations because only existing wastes are being processed. The only "processes" applied to facility wastes are segregating, packaging, and transporting to a waste disposal facility. Details on the handling of each waste stream are contained in Sections 9.4 of the facility FSAR Annexes.

10 0 INITIAL TESTING, IN-SERVICE SURVEILLANCE, AND MAINTENANCE

10 1 INTRODUCTION

Essential features of the initial testing program, the operational readiness review (ORR), the in-service surveillance program, and the maintenance program implemented at Spent Nuclear Fuel (SNF) Project facilities are described in this chapter. This chapter provides the basis for initial testing and maintenance activities through preoperational acceptance testing. This chapter describes the basis for preoperational testing, operational dry runs, the ORR, in-service surveillance, and operational phase maintenance. The initial testing program ensures that, at the time of initial operation, structures, systems, and components (SSCs) function as designed. The ORR verifies that the hardware, programs, and personnel are in place and effective in supporting safe operations of the SNF Project facilities. The in-service surveillance and maintenance programs help ensure that SSCs are available and perform as designed when needed. Discussions in this chapter demonstrate that a well-defined program with a commitment to testing, surveillance, and maintenance is an integral part of the overall safety assurance philosophy at SNF Project facilities.

The intent of this chapter is to accomplish the following objectives:

- Identify the requirements used to develop initial testing, ORR, in-service surveillance and maintenance programs.
- Describe the responsibilities of, and relationships among, the organizations having initial testing, ORR, in-service surveillance, and maintenance responsibilities.
- Present information on Hanford Site organizations that support initial testing, ORRs, in-service surveillance, and maintenance programs.

10 2 REQUIREMENTS

The requirements that form the basis for the initial testing program, the ORR program, the in-service surveillance program, and the maintenance program are found in HNF-SD-SNF-RD-001, Spent Nuclear Fuel Project Standards/Requirements Identification Document. Specific requirements applicable to this chapter include:

- DOE O 425 1, Startup and Restart of Nuclear Facilities
- DOE O 430 1, Life Cycle Asset Management
- DOE Order 4330 4B, Maintenance Management Program
- DOE Order 5480 19, Conduct of Operations Requirements for DOE Facilities
- RLID 425 1, Startup and Restart of Facilities

fsar10 sar 10-1 November 1999
10.3 INITIAL TESTING

The SNF Project initial testing program ensures the operability of equipment and facilities before facility operation. The initial testing program is developed and conducted in accordance with the requirements of DOE O 430 1 and includes testing of all SSCs to ensure compliance with design safety specifications and acceptance criteria.

10.3.1 Testing Program

The initial testing program consists of factory acceptance tests, construction acceptance tests, preoperational acceptance tests (PATs), and operational dry runs. SNF Project administrative procedures provide a planned systematic approach to testing activities and address the duties and responsibilities of participating organizations.

SSC testing requirements are extracted from applicable SNF Project documents, such as functional design criteria, Title II design documents (including architect-engineer generated test specifications), U.S. Department of Energy (DOE) orders and regulations, manufacturer testing and operational instructions, and this safety analysis report. These requirements, including any need for special testing, are compiled on a system by system basis into a system test specification. PATs are scheduled based on test sequence logic that takes into account system boundaries, system testing requirements, testing activity interfaces, and non-testing project activities such as critical path construction turnover and readiness review processes. Continuous online scheduling is used to facilitate response to design change-induced testing requirements and system and equipment availability. A punchlist process is established during startup testing to record and track incomplete work, test exceptions, outstanding approved design modifications, temporary modifications, and other open items on each system. A final punchlist is part of the release-to-operations package providing a comprehensive systems status in support of the ORR.

10.3.1.1 Factory and Construction Acceptance Tests

Factory acceptance tests are those tests performed in the factory that demonstrate compliance with construction and procurement specifications, or those operational tests that are best performed at the factory due to manufacturers' expertise or access restrictions on the field-installed equipment.

Construction acceptance tests are performed in the field by the construction organization to demonstrate compliance with installed requirements and to demonstrate quality of workmanship.

The factory and construction testing activities are monitored by construction management, the startup organization, the design authority, and DOE as required to ensure that the test requirements are met.

10.3.1.2 Preoperational Acceptance Tests

The PAT is a thorough test of the integrated system performance during normal and abnormal operating conditions. The PAT demonstrates that the system meets or exceeds the design requirements. The PAT is reviewed prior to testing by the test review board to ensure the test adequately demonstrates the test requirements. At the
completion of the PAT, a test summary report is developed summarizing the test results, identifying any problems encountered, and documenting the system status prior to turnover to operations. The test summary report and completed PAT are reviewed and approved by the test review board.

10.3.3 Operational Dry Runs  Operational dry run testing is performed to demonstrate the integration of the various SNF subprojects. Systems are brought online and operated under anticipated standard operating conditions using simulated special nuclear material and nonradioactive multi-cask overpacks. Dry run testing is performed by operations personnel with actual plant equipment and operating procedures. This testing demonstrates that operators and procedures are in a final satisfactory state of readiness to safely load and condition SNF, and transport receive, handle, and store multi-cask overpacks.

10.3.2 Test Procedures

Test procedures are developed, reviewed, and approved in accordance with the implementing instructions provided in the SNF Project startup administrative procedures. For PATs, the startup organization identifies test objectives, test methods, test conditions, applicable cautions, test boundaries, and acceptance criteria based on test specifications. The test procedure clearly describes test performance (e.g., initial conditions, sequence of testing, recovery actions, acceptance criteria). Test specifications, test procedures, and test reports are controlled, approved, and released in accordance with the implementing instructions provided in the SNF Project startup administrative procedures.

10.3.3 Review, Evaluation, and Approval of Test Results

Test results are reviewed to confirm that the results and the tests meet established requirements and that sufficient data have been obtained to proceed with further testing. A test review board facilitates technical review of test specifications, test procedures, test procedure changes, and test summary reports (including test results). The test review board consists of representatives from startup, operations, construction, design authority, safety, and quality assurance. Functions and responsibilities assigned to the test review board are defined by SNF Project administrative procedures. This board is responsible to ensure that nuclear and industrial safety considerations are incorporated into test documents and to ensure that critical facility and system characteristics are tested and meet defined acceptance criteria. The test review board recommends acceptance of test program results to SNF Project Operations management with the ultimate approval authority being the SNF Project director.

10.3.4 Test Program Control and Administration

The SNF Project startup administrative procedures provide the directions required to implement an effective test program, including the following:
• Testing control functions — instructions for conduct of testing, test deficiency reporting and resolution, punchlist tracking of open issues, and interfacing with engineering functions (design change initiation and control of modification-induced changes to the test program)

• Custody control functions — instructions for transfer of SSC custody from construction to startup and from startup to operations, and instructions for defining system test boundaries

SNF Project administrative procedures define the organization and responsibilities of the groups involved in the SNF Project facility startups. The SNF Project startup organization is responsible for startup management functions, including test program and sequence planning, test program implementation, punchlist item tracking and closeout, preoperational procedure preparation and review, test results review and approval, test specification development, and test records preparation. PATs are conducted by the SNF Project startup organization. The startup organization reports to the SNF Project operations organization and is independent of design and construction functions. The SNF Project startup organization manager has ultimate responsibility for establishing and implementing controls that ensure safety during execution of the startup program.

Test engineers are selected and trained in accordance with SNF Project startup administrative procedures. Operations and other support personnel are selected and trained in accordance with the program described in Chapter 12.0 of this document.

Records of the test program are kept using the guidance of HNF-PRO-210, *Records Management Program Standards*. These documents are retained as records in accordance with HNF-3552 *Spent Nuclear Fuel Project Execution Plan*.

### 10.3.5 Operational Readiness Reviews

The SNF Project facilities are classified as hazard category 2 facilities. These facilities require an ORR before restart of an existing facility or startup of a new nuclear facility in accordance with the requirements of Sections 1.7 of the standards/requirements identification documents (HNF-SD-SNF-RD-001) and RLID 4251. The purpose of the ORR process is to provide an adequate independent review of readiness to start or restart nuclear facility operations and to ensure that the facility or project can begin operation without undue risk to the public, onsite personnel, operating staff, or the environment.

The SNF Project implements the readiness review process described in RLID 4251 in accordance with the directions contained in SNF Project administrative procedures. Whenever a facility is started or restarted, guidance on approaches and methods approved as acceptable for implementing the requirements of RLID 4251 is provided in DOE-STD-3006-95, *Planning and Conduct of Operational Readiness Reviews (ORR)*. The SNF Project uses this guidance in the planning and implementation of ORRs.
An ORR verifies that the new facilities, facility modifications, new systems, new equipment installations, and associated operations are

- Operated safely
- Operated, maintained, and supported by trained and competent personnel
- Operated in conformance with applicable DOE orders and regulatory requirements
- Operated so that no undue risk to workers, the public, or the environment results
- Documented properly and adequately

The SNF Project facilities ORRs will be performed following a management self-assessment of readiness to start operations performed by the contractor. Responsible line management efforts to achieve readiness are conducted in accordance with the project management plan, startup plan, and other project management documents. The contractor validates readiness to proceed with the ORR. The operating contractor's ORR is followed by a DOE ORR. The Secretary of Energy has approval authority for initiation of radiological operations at the SNF Project facilities and for restart decisions following upgrades.

SNF Project facility ORR activities will be documented in formal ORR reports in accordance with Sections 1.7 of the standards/requirements identification documents (HNF-SD-SNF-RD-001) and with RLID 425.1. When only a small but manageable list of prestart findings remains, the approval authority prepares and forwards a readiness to proceed memorandum to DOE, Richland Operations Office. This action will result in the commencement of the DOE ORR.

10.4 IN-SERVICE SURVEILLANCE PROGRAM

The SNF Project in-service surveillance program is designed to maintain the integrity of facility systems and to ensure that systems perform their function of protecting the health and safety of the public, workers, and facility staff by prevention or mitigation of accident consequences. In-service surveillance of designated facility equipment and systems ensures technical safety requirement (TSR) performance requirements are met, as discussed in Chapters 5.0 of the facility annexes to the SNF Project Final Safety Analysis Report (FSAR). Chapters 5.0 of the facility FSAR Annexes explain how each TSR surveillance (test, calibration, or inspection of plant equipment) demonstrates operability or fulfills limiting condition for operations or limiting control setting. The analyses documented in Chapters 3.0 of the facility FSAR Annexes will define the numeric setpoints and values associated with each TSR.

The surveillance program is conducted in conjunction with the process standards and maintenance programs at the SNF Project facilities. SNF Project administrative procedures and the preface to the process standards describe the process of preparation, review, and implementation of process standards. Surveillance procedures providing in-the-field instructions for systematic inspection, testing, or calibration of plant equipment identified in the process standards are prepared using the guidance contained in SNF Project administrative procedures. Surveillance procedure performance is scheduled and tracked. SNF Project administrative
procedures describe the responsibilities for administering and using the tracking and scheduling process, including forecast reporting, overdue surveillance reporting, work package preparation, and generation of notices of discrepancies. Figure 10-1 is a flowchart illustrating the major steps in the performance of the surveillance testing process.

SNF Project administrative procedures define the actions to be taken when a failure to comply with TSR requirements is identified and pertinent action statements are successfully implemented. Tracking and resolution of this type of occurrence as a nonconformance report is described in HNF-PRO-052, *Corrective Action Management*, and SNF Project administrative procedures. SNF Project administrative procedures also define the actions to be taken when a violation of TSR requirements occurs. Response to this type of occurrence includes performance of the pertinent controls and responses specified in the administrative controls section of the TSR followed by occurrence tracking and resolution as specified in SNF Project administrative procedures.

The following sections describe the in-service surveillance program including provisions for testing and calibrations, control and calibration of measuring and test equipment (M&TE), trending and test result review, programmatic review, and training of surveillance personnel.

**10.4.1 In-Service Surveillance Measuring and Test Equipment**

The maintenance implementation plan for the SNF Project facilities discusses the control and calibration of M&TE for the maintenance program. This discussion also applies to M&TE used for in-service surveillance.

**10.4.2 Review and Trending of Surveillance Test Results**

SNF Project administrative procedures describe the requirement for, and the process used for, trending of surveillance test results. Cognizant engineers are responsible for surveillance test result review. Cognizant engineers use the Job Control System data processing database for the analysis of equipment history and system performance trends.

**10.4.3 Programmatic Review**

Inspections, audits, reviews, investigations, and self-assessments are necessary for an effective surveillance program. Title 10, *Code of Federal Regulations* Part 830, "Nuclear Safety Management," Section 830.120, "Quality Assurance Requirements" (10 CFR 830.120) requires management assessments to identify problems that hinder the organization from achieving its objectives. In addition, DOE Order 4330.4B requires that senior managers periodically review and assess elements of the maintenance program to assist line managers and supervisors in identifying and correcting program deficiencies. SNF Project administrative procedures define the management assessment process for SNF Project facilities. The procedure requires that the
The systematic approach used by the SNF Project to develop the overall maintenance plan includes the following elements:

- The design engineering organization specifically the design authority, prepares performance specifications that identify the need for reliability, availability, and maintainability or failure modes and effects analyses (FMEAs) for a system or component. This information is provided to the architect-engineer.

- The architect-engineer prepares the design addressing all elements/requirements of the performance specification. The result is drawings and procurement specifications.

- The architect-engineer prepares procurement specifications that include requirements for vendor submittals to address maintenance recommendations, spare parts recommendations, special tools or equipment recommendations, or any other required information for servicing, maintaining, or operating the system or component.
The architect-engineer also evaluates the need for reliability, availability, and maintainability analyses (RAMAs) or FMEAs and provides the master equipment list for the facility.

The vendor provides operations and maintenance (O&M) requirements/recommendations (often in the form of O&M manuals).

The design authority with the assistance of the architect-engineer evaluates the adequacy of the vendor's maintenance recommendations utilizing sound engineering judgment and considering the service conditions to be experienced by the equipment. The recommendations are also evaluated in light of the results of any RAMAs or FMEAs performed. The design authority then prepares the design baseline for the system or component, which includes the O&M manual, and provides this document to the operations organization which includes the initial testing function and the operations engineering function.

The design authority causes the O&M manual to be revised based on experience gained during initial testing.

The operation engineering organization specifically the assigned cognizant engineer, evaluates the O&M manual, prepares the maintenance requirements for the components and systems included in the master equipment list, prepares the maintenance procedures, and prepares the approved spare parts list.

The maintenance organization reviews, evaluates, and validates maintenance procedures recommends adjustments to the spare parts list based on maintenance experience and recommends adjustments to the maintenance requirements based on experience.

Facility management approves these plans and procedures.

During the design of the SNF Project subprojects, the architect-engineer uses hazard analysis or other analysis methods such as FMEAs to evaluate the need for features or actions to increase safety and reliability. These analyses identify equipment items that should be included in or removed from the design to simplify the operations or improve reliability. The hazard analysis process also identifies hazards resulting from identified maintenance activities. These hazards, if they result in accidents or contribute to an accident, will result in preventive or mitigative features or features that will decrease the frequency of the initial maintenance problem. In some cases where excess equipment capacity exists for short-term subprojects decisions are made to operate selected equipment to failure. For example, the results of these analyses for the Canister Storage Building did not identify maintenance activities that should have requirements similar to TSRs applied to them. In addition, the only Canister Storage Building TSRs related to maintenance identified in Chapter A5 0 of Annex A, the Canister Storage Building FSAR, and not associated with functional or calibration testing are those regarding changeout of high-efficiency particulate air filters when the filter load reaches a preset value.
A job analysis is performed to identify the scope of a job and associated critical tasks. Based on the results of the job analysis, training is developed as described in Section 12.2. This process, along with the design authority and management input, is the basis for determining specialized maintenance capabilities (e.g., vendor support or in-house journeyman knowledge) required. In addition, the SNF Project analyzes the types and complexity of equipment included in subproject design and, applying past experience with these types of equipment identifies the types and numbers of the various craftsmen needed for SNF Project maintenance support. To date, these analyses have resulted in the decision to initially have maintenance response teams assigned to each shift. The plans are to have the maintenance response teams be composed of a cross-section of craft and technical support including an engineer, a millwright, an electrician, and an instrument technician. This diversified team will have the capabilities to respond to problems identified by the facility operating staff, diagnose the problem, and to accomplish repairs. The remaining maintenance staff levels and levels of vendor support will be further defined based on a management review of the design and the specific maintenance requirements identified. Vendor and maintenance support staff will be available to perform maintenance that is beyond the capabilities of the shift response teams. Calibration and preventive maintenance tasks will be assigned to available qualified personnel, either shift response teams or support maintenance personnel based on work load. No maintenance tasks are planned for performance by operations personnel.

The following sections describe details of maintenance program implementation, including organization, training, facilities and equipment, post-maintenance testing, control and calibration of measuring equipment, trending, and limitations.

10.5.1 Maintenance Organization

DOE Order 4330.4B specifies that the organization and administration of the maintenance function ensure that a high level of performance in maintenance is achieved through effective implementation and control of maintenance activities. These activities include:

- Establishing written policies, procedures, and standards for maintenance
- Periodically observing and assessing performance
- Holding personnel accountable for their performance

Management policies and SNF Project procedures are in place to effectively manage SNF Project facility maintenance activities. SNF Project administrative procedures describe the philosophy, responsibilities, and processes for management of work activities.

The SNF Project organization including the maintenance and work control functions is described in Chapter 17.0. The SNF Project Operations Manager provides the overall management of O&M of each facility and provides consistent management direction for maintaining an effective work management system. The specific Facility Operations Manager is responsible for establishing a safe work environment while maintenance activities are being performed, maintaining consistent prioritization, adhering to an approved work schedule.
maintaining effective coordination among operations maintenance management, and support organization management to ensure full support of the work management systems and ensuring systems and equipment are acceptable after post-maintenance testing.

Managers of SNF Project support organizations or servicing organizations, including maintenance, are responsible for ensuring that the employees assigned to perform work in a facility use approved work documents that employees assigned to work are trained and qualified for the tasks to be performed, that work is only performed by employees when the activity is released by Operations, and for ensuring a safe work environment. The work management process for all categories of maintenance involves work screening, work completion, and retest, and post-work review. Each phase of the work management process considers factors related to health, safety, environment, and maintaining risks at a level as low as reasonably achievable. The process provides priority to work-affecting systems or equipment relied on for safety.

The maintenance work control manager is expected to provide or ensure that sufficient controls, training, and oversight are available to accomplish quality work, minimize rework, and avoid personnel-related problems such as procedure violations or bypassed quality control established hold points.

Procedures using a graded approach are provided for maintenance of equipment depending on the related design safety classification, the complexity of the work, and the potential hazard to personnel or equipment. Procedures for preventive, corrective, and predictive maintenance are prepared based on the guidance provided in SNF Project administrative procedures.

The work control administrative procedure assigns authority and responsibilities and defines the minimum responsibilities, requirements, and procedures used in performing maintenance, modifications, and fabrications. This procedure addresses the following:

- Personnel responsibilities for identifying deficiencies and initiating work requests that adequately describe symptoms or problems
- Supervisory responsibilities for controlling the conduct of maintenance activities and processing work requests
- Description of the process for initiating and processing work requests
- Definition of the priorities used to schedule work
- Determination of the impact of maintenance activities on facility operations
- Work planning and scheduling
- Requirements for personnel and equipment safety and for radiological protection
- Post-maintenance testing
• Collection of maintenance history for trending

The SNF Project facilities use a number of performance indicators to periodically observe and assess performance (e.g., open work packages, corrective maintenance completions, skin contaminations). Performance assessment activities are described in SNF Project administrative procedures.

10.5.2 Training of Maintenance Personnel

The SNF Project maintenance training program ensures that maintenance personnel possess the knowledge and skills necessary to perform their assigned duties in a safe, efficient, and cost-effective manner. The maintenance manager is responsible for determining the training and qualification needs of each individual in the maintenance organization. The maintenance manager and supervisors interface closely with the SNF Project training organization to establish and maintain course content, determine and support training schedules, implement on-the-job training, and provide feedback to adjust course content and emphasis.

Training and qualification of maintenance and work control personnel are defined in SNF Project administrative procedures. See Chapter 12.0 for a description of the training program.

10.5.3 Maintenance Facilities, Equipment, and Tools

DOE Order 4330 4B specifies that maintenance facilities, equipment, and tools should efficiently support facility maintenance and maintenance training. The SNF Project has evaluated the maintenance needs in this area and the necessary office areas, tool and equipment storage, equipment access, and utility services layout (e.g., instrument air, water, electric power) to support safe and effective maintenance are provided at the SNF Project facilities. Satellite work lay down and staging areas are located conveniently near maintenance work locations and take into account industrial safety requirements.

10.5.4 Post-Maintenance Testing

DOE Order 4330 4B specifies that post-maintenance testing requirements should be identified to verify that components will fulfill their functions when returned to service after maintenance. The post-maintenance testing requirements are identified, controlled, documented, reviewed, and accepted via the SNF Project work control process. Post-maintenance testing requirements are specified by the cognizant engineer in engineering-approved work packages and by the person-in-charge or manager as necessary for skill-of-the-craft work. The rigor of post-maintenance testing is applied on a graded approach, which is based on the extent of preventive or corrective maintenance performed and on the importance of the equipment to facility safety and reliability. These requirements are described in SNF Project administrative procedures.
10.5.5 Control and Calibration of Measuring and Test Equipment

DOE Order 4330 4B specifies that a program should be established for control and calibration of M&TE and that this program should ensure the accurate performance of facility instrumentation and equipment for testing, calibration, and repairs. M&TE includes all devices or systems used to inspect, test, calibrate, measure, or troubleshoot an instrument or piece of equipment to verify conformance to specified requirements. The calibration and test program is described in SNF Project administrative procedures and establishes requirements for the evaluation of out-of-calibration conditions identified during the periodic calibration of M&TE.

Each piece of M&TE is identified by a unique, permanently attached identification number. These numbers assist in identifying, tracing, and positively controlling M&TE. A master list of all M&TE provides the following identifying information:

- Generic description of equipment (trade or marketing name, manufacturer, model, and serial number)
- Unique identification number
- Calibration frequency
- Calibration due date
- Calibration procedure reference

Only M&TE that is calibrated to standards that are traceable to the National Bureau of Standards or other nationally recognized standards are authorized for use by SNF Project personnel. Instruments are calibrated at specified intervals, before and after use or just prior to use, as determined by required accuracy, intended use, frequency of use, stability characteristics, and other conditions affecting performance. When repair or calibration of M&TE is necessary, the recalibration must be traced to the National Bureau of Standards or to the standard of record for the M&TE. M&TE is controlled by the recall system of the Hanford Standards Laboratory. New M&TE or M&TE past its calibration date, in need of repair or with suspect calibration, is removed from the M&TE storage area and placed in a locked storage area until it can be sent to the Hanford Standards Laboratory or disposed of. Additional discussion of M&TE is included in Chapter 14.

10.5.6 Maintenance History and Trending

DOE Order 4330 4B specifies that a maintenance history and trending program should be maintained to document data, provide historical information for maintenance planning, and support maintenance and performance trending of facility systems and components. The SNF Project maintenance history and information system provides for this data retention service and allows for rapid retrieval of equipment identity and specification information and is maintained in...
accordance with SNF Project administrative procedures. The system provides a means to retrieve SSC maintenance histories as well as providing on a graded approach for trending types of maintenance performed to support analysis of problems.

10.5.7 Limitations on Maintenance

There are no known limitations at the SNF Project facilities imposed by design and operation on routine maintenance, renewal or repair of SSCs. Equipment in hazardous and radiological areas is designed to be free of maintenance as much as possible and is operated in a run-to-break mode. Accessibility for maintenance and provisions to support effective maintenance were considered in the facility designs.

11 0 OPERATIONAL SAFETY

11 1 INTRODUCTION

Features of the Spent Nuclear Fuel (SNF) Project conduct of operations program and fire protection programs are described in the following sections and in the facility annexes to the SNF Project Final Safety Analysis Report (FSAR). The objective of this chapter is to provide a description of the essential features of the two programs as they relate to facility safety. Elements of other operational safety programs identified in Attachment 1 to DOE Order 5480 23, Nuclear Safety Analysis Reports, are covered elsewhere in this safety analysis report (e.g., fuel storage and criticality safety are addressed in Chapters 3 0 and 6 0, radiological protection is addressed in Chapter 7 0, hazardous material protection is addressed in Chapter 8 0, waste management is addressed in Chapter 9 0, and procedures and training are addressed in Chapter 12 0). The names and structures throughout the Hanford Site change frequently. Generic names (e.g., operations, engineering, facility management) are used in this chapter to demonstrate compliance with applicable requirements. See Chapter 17 0 for descriptions of organizations and institutional safety provisions.

11 2 REQUIREMENTS

The requirements that form the basis for conduct of operations and general aspects of operational safety are found in HNF-SD-SNF-RD-001, Spent Nuclear Fuel Project Standards/Requirements Identification Document, and the approved Conduct of Operations Graded Approach Applicability Matrix. Specific requirements applicable to this chapter include:

- DOE Order 5480 4, Environmental Protection Safety and Health Protection Standards
- DOE Order 5480 7A, Fire Protection
- DOE Order 5480 19, Conduct of Operations Requirements for DOE Facilities
- DOE Order 5480 20A, Personnel Selection Qualification and Training Requirements for DOE Nuclear Facilities
- Uniform Building Code (ICBO 1994)
11.3 CONDUCT OF OPERATIONS

"Conduct of operations" is a set of principles that establishes an overall philosophy for achieving excellence in the operation of the SNF Project facilities. The Project Hanford conduct of operations policy, which meets the applicable elements of DOE Order 5480 19, is documented in HNF-PRO-696, Conduct of Operations Policy. The degree to which each principle is applied is determined by the magnitude of the hazards and the complexity of the activities being performed by the facility staff.

Elements of the conduct of operations principles that are major contributors to safety performance at the SNF Project facilities are summarized in the following subsections or elsewhere in this safety analysis report (e.g., control of procedures and training is addressed in Chapter 12, and the operating contractor's process for handling events is discussed in Chapter 17.0). SNF Project administrative procedures implement the applicable guidance of DOE Order 5480 19. The approved conduct of operations graded approach applicability matrix for each SNF Project facility indicates the aspects of each principle that apply and the corresponding operating or administrative procedure that implements the principle.

11.3.1 Operations Organization and Administration

Excellence in operations is accomplished by establishing high standards by management, communicating operations standards (including worker safety standards) to the workers providing sufficient resources to the operations department, ensuring workers are well trained, monitoring operating performance, and holding workers and their managers accountable for their performance in conducting activities. SNF Project administrative procedures and HNF-3552, Spent Nuclear Fuel Project Execution Plan, outline the actions and responsibilities needed to implement a strong operations program. The organizational structure, responsibilities, and interfaces for the SNF Project are summarized in Chapter 17.0.

The facility operations manager is responsible for establishing specific goals and objectives for the operations organization and assigning responsibility for achieving these objectives. Performance measures are identified to assist in the measurement of success in meeting organizational objectives. Operating personnel are informed of the organizational objectives and their individual responsibility, authority, and accountability relative to these objectives. SNF Project administrative procedures describe the SNF Project goals identification process and address the issues of operational staff responsibilities, authorities, and accountability.

The operations personnel training requirements of DOE Order 5480 20A and DOE Order 5480 19 are implemented within the SNF Project facilities as described in...
SNF Project administrative procedures The shift manager certification program includes supervisor and management training in subjects such as leadership, interpersonal communications, motivation of personnel, and problem analysis and decision making.

Inspections, audits, reviews, investigations, and self-assessments are a part of the checks and balances needed in a successful operating program. Management performs routine observations of personnel performing operating activities. Deficiencies identified are documented, analyzed, trended, and corrected. In addition, other groups such as quality assurance also periodically review and assess operational performance. Programs to monitor personnel performing operating activities are described in SNF Project administrative procedures. Problem tracking, trending, and closure activities are implemented in compliance with SNF Project administrative procedures. Safety analysis report commitments are compiled in a commitment tracking log to facilitate report compliance.

11.3.2 Shift Routines and Operating Practices

SNF Project procedures define standards for professional conduct that ensure operator performance meets U.S. Department of Energy (DOE) and facility management expectations. The following subsections summarize the aspects of routine SNF Project shift activities and watch-standing practices that are important to safety. Chapter 17.0 discusses the integrated safety management system that denotes the philosophies, principles, and requirements of the Project Hanford Management Contractor's formal safety process.

11.3.2.1 Status Practices The operations staff manages, operates, and maintains the SNF Project facilities in a safe and efficient manner. Adherence to operating procedures and technical safety requirements helps to ensure that this objective is accomplished. Workers and their supervisors are held accountable for operating performance. Operators and operations shift management are notified promptly of all changes in facility status, operational abnormalities, or any difficulties operators encounter while performing assigned tasks.

11.3.2.2 Safety Practices As part of the conduct of operations program, operators must follow the requirements of the operating contractor's industrial safety program as described in the industrial health and safety manuals. The SNF Project hazardous materials program as described in Chapter 8.0 ensures that radiological, chemical, toxic material, and other exposure hazards are maintained as low as reasonably achievable. Strict adherence to procedures and posted personnel protection requirements ensure (1) appropriate use of monitoring instruments, (2) cognizance of permissible exposure levels, (3) proper use of and adherence to radiological work permits, and (4) effective and accurate deficiency reporting practices. Appropriate hearing, eye, head, foot, and respiratory protection is worn in designated areas to reduce the potential for illness and injury. Similarly, operators working at the facility exercise appropriate precautions when working with or around potential hazardous objects (e.g., ladders, electrical equipment, machines) or hazardous materials (e.g., chemicals, toxic materials) to reduce personal injury. Occupational injuries and illnesses are promptly reported. Radiological protection safety practices are addressed in Chapter 7.0. Personnel protective actions implement the requirements of the...
applicable standards designated in Section 19 of the facility standards/requirements identification document (S/RID) (HNF-SD-SNF-RD-001)

11 3 2 3 Operator Inspection Tours  Operators conduct periodic inspection tours of their areas of responsibility to ensure that the status of equipment is known. During a tour, equipment is inspected to ensure that it is operating properly or, in the case of standby equipment, that it is fully operable. The tour activities include, but are not limited to, inspection, troubleshooting, responding to alarms, housekeeping, logkeeping, and reporting deficiencies. SNF Project administrative procedures provide detailed direction to operations personnel on proper conduct of operator tours.

11 3 2 4 Tour Inspection Sheets  Tour inspection sheets (roundsheets and logs) are a means to uniformly record the status and condition of equipment and work areas. Use of operator roundsheets and logs is an effective method of providing operators with guidance on the extent to which equipment and areas are inspected. The sheets are also an effective place to record events and status of the areas and equipment inspected. Limits on the sheets remind operators of important control parameters for safe operation. The operator records notes on the sheets as a reminder of abnormalities and other items that should be reported to other operators or shift management. The roundsheets and logs are monitored periodically by shift management as part of normal shift routine to ensure that inspection tours are being conducted as required and that out-of-limit parameters are promptly corrected. SNF Project administrative procedures provide direction to operations personnel on the proper use of roundsheets and logs.

11 3 2 5 Response to Indications  Instrument readings are considered accurate and are responded to accordingly until inaccuracy is proven. Operators are trained to check other indications, if possible, when unexpected readings are observed. SNF Project administrative procedures provide direction to operations personnel on proper response to indications.

11 3 2 6 Resetting Protective Devices  When protective devices (e.g., circuit breakers, fuses) trip, an attempt is made to understand the cause of the trip before resetting. Before action is taken an evaluation will be performed to ensure that no unsafe or abnormal conditions exist that would preclude reset. SNF Project administrative procedures provide direction to operations personnel on proper precautions to be taken prior to resetting protective devices.

11 3 3 Control Area Activities

Control area activities are conducted in a manner that ensures safe and reliable facility operations. Operators are trained to be alert and attentive to indications and alarms. Indicators are monitored frequently and responses to alarms are swift, resulting in timely actions to correct alarm conditions. All reasonable actions are taken to clear alarming conditions. Distractions or ancillary duties that compromise an operator's primary responsibilities are minimized so that they do not interfere with the operator's ability to monitor and respond to facility parameters changes. Professional behavior is required at all times in designated control areas.
Control area conduct of operations principles will be applied in the SNF Project control rooms. Administrative procedures address the application of conduct of operations principles to the control areas.

### 11.3.4 Communications

Various communication devices are provided for transmission of information within the SNF Project (e.g., telephones, paging equipment, horns, bells, sirens, two-way radios). These devices are controlled to ensure that they do not detract from normal operations and are available in an emergency. The operating base for each shift position is equipped with adequate communication equipment to ensure proper performance of assigned duties. SNF Project administrative procedures delineate management expectations relative to formal, accurate, reliable and uniform face-to-face and remote communications during normal and emergency situations. Use of the public address system is administratively controlled to avoid excessive paging and unnecessary announcements.

Facilities and areas of the SNF Project are provided with systems (e.g., horns, bells, sirens) for communicating facility emergencies. If areas are identified where emergency systems cannot be heard, these areas are provided with alternative methods for alerting personnel including flashing lights, personal pagers that vibrate, or persons dedicated to make notifications. Emergency communication systems are tested periodically as part of a system surveillance procedure to ensure that they are functional.

### 11.3.5 Control of On-Shift Training

Operations training is controlled, and personnel being trained are carefully supervised to use the trainee's time effectively, to avoid mistakes during training operations, and to ensure that the trainee receives training within the job environment with as much hands-on experience as possible. SNF Project administrative procedures describe the on-the-job training program and controls. Operations personnel training has well-defined knowledge requirements and objectives for the trainee and is conducted under the direct supervision and observation of a qualified operator or instructor. The operator qualification program is based on small group instruction on the equipment being operated and on documentation of the training. Training is immediately suspended during unanticipated or abnormal events, accident conditions, or whenever the instructor believes suspension is necessary to ensure safe and reliable facility operation. The training program is described in Chapter 12.0.

### 11.3.6 Investigation of Abnormal Events

Chapter 17.0 describes the event investigation and lessons-learned programs used at the SNF Project facilities. These programs address the DOE Order 5480.19 guidance on investigating abnormal events including near miss situations.
11.3.7 Notifications

Chapter 15 describes the event notification program for the SNF Project facilities. This program addresses the DOE Order 5480 guidance on event notification to appropriate outside agencies. Instructions on internal notifications within the SNF Project are described in SNF Project administrative procedures.

11.3.8 Control of Equipment and System Status

Equipment and facility configuration is maintained within the design requirements through disciplined operation. Operations personnel are knowledgeable of operational limits and their responsibilities for actions that ensure compliance with these limits. Operators know the status of the equipment and operate systems using approved procedures. Direction on the use of procedures by facility personnel is addressed in SNF Project administrative procedures. Operations shift management is responsible for maintaining proper configuration and for authorizing status changes to major equipment and systems, which include all of the structures, systems, and components required to maintain the safety envelope as described in Chapters 40 of the facility FSAR Annexes. Shift management also ensures that operators of SNF Project equipment possess the necessary procedures, training, and qualifications. Nonroutine operations do not occur without specific approval by shift management. Operators are trained in accordance with approved procedures to take specific actions during emergencies to ensure the safety of personnel, the facility, and the environment without obtaining prior approval, however, the appropriate managers are promptly informed of these actions. Operators are trained that worker and facility safety should be achieved over facility production. Before first placing equipment or a system into operation, the individual components are checked for proper alignment and readiness for operation.

Equipment deficiency identification and documentation (e.g., tags, logs, and status boards) provide the necessary communication for removing equipment from active service until it is repaired, tested, and returned to service. The status of control panel and local panel alarms is readily available to operating personnel. Administrative controls include instructions for operators during installation of temporary equipment and when equipment is upgraded. These various forms of communication and administrative controls ensure that operators have the latest information to enable safe operation of the facilities.

11.3.9 Lockouts and Tagouts

The lockout/tagout program at the SNF Project facilities is established in accordance with DOE-RL-SOD-INST-L-T-001, Hanford Site Lockout Tagout Program. The lockout/tagout program is used to prevent personnel injury or equipment damage due to inadvertent activation during equipment operation, servicing, maintenance, or modification activities. SNF Project administrative procedures provide direction for SNF Project implementation of the lock and tag program requirements of the operating contractor's industrial safety procedures as required by...
29 CFR 1910, Section 1910.147, "The Control of Hazardous Energy" All SNF Project facility personnel receive fundamental lock and tag training. In addition, all authorized workers and all controlling organization-qualified workers receive detailed lock and tag training applicable to the functions that they perform.

11.3.10 Independent Verification

Independent verification is the act of (1) checking that a given operation conforms to established operational criteria, and (2) checking equipment component position independent of activities related to establishing the component's position. Operators are trained to perform independent verifications of component positions and to regularly consult the procedures and other reference materials that provide instructions on independent verification techniques. All components in systems that have safety-related functions are evaluated for the application of independent verification. Guidance on independent verification application is provided in administrative procedures, and each evolution requiring the application of independent verification is identified in the applicable operating procedure. At the SNF Project facilities, independent verification is applied to the lock and tag process. Double verification, as defined in Chapters 50 of the facility FSAR Annexes, is required for certain technical safety requirements.

11.3.11 Logkeeping

Narrative logs are established and maintained to provide an accurate history of SNF Project facility activities and to provide tools for reconstructing off-normal events. Logs are established for key operations shift positions in accordance with SNF Project administrative procedures. The log sheets provide accessible information and data associated with normal operation, testing, and off-normal activities for review by facility personnel.

11.3.12 Operations Turnover

Turnover guidelines are established and proceduralized to ensure that information required to adequately perform shift operations is documented by the shift going off and reviewed by the shift coming on. Hence, operations personnel will have an accurate picture of overall facility status. Personnel coming on shift review documentation such as daily operating roundsheets, logs, and checklists before assuming responsibility for their shift position. Shift management and operators going off shift are responsible for documenting equipment status, making entries on the roundsheets and logs, and apprising oncoming personnel of equipment status. SNF Project administrative procedures provide detailed direction on implementation of proper shift turnover practices and establish a turnover checklist to aid in effective communication of facility status at the time of turnover. Shift turnover practices at the SNF Project facilities include walkdowns of control panels by the appropriate operator and/or by shift management, and a shift briefing conducted by shift management coming on shift following turnover from the personnel going off.
The shift briefing ensures that operations and support personnel understand shift priorities and objectives.

**11.3.13 Operations Aspects of Facility Chemistry and Unique Processes**

Unique processes associated with evolutions at SNF Project facilities include hydrogen generation and maintenance of inerted atmospheres to prevent hydrogen fires. The hydrogen generation hazards are controlled via plans and procedures issued within the SNF Project. Administrative procedures provide guidance to operations personnel for control of unique processes. The procedures ensure that engineering (1) collects and evaluates data prior to a unique process operation and (2) establishes criteria that ensure operators are aware of parameter controls and recovery actions. Operators are qualified to survey and trend the required parameters, to recognize adverse conditions, to take appropriate action to provide timely reports of the condition to management, and to record required information.

**11.3.14 Required Reading**

The required reading program provides one method for disseminating various types of information applicable to SNF Project facilities to pertinent personnel. SNF Project administrative procedures provide direction for implementing this program. Types of documents applicable for required reading include selected procedure changes, selected occurrence reports, process standards and technical safety requirements, and selected training material. The SNF Project functional managers determine the appropriate material for the required reading list for their staff. The required reading program includes appropriate controls, including an acknowledgment sheet for the reader to indicate that the reading has been completed, and record retention measures.

**11.3.15 Timely Orders to Operators**

Timely orders allow management to rapidly disseminate essential daily or long-term directions and instructions to operating personnel to support operational activities. The timely orders contain concise information that is dated, prominently posted, and segregated into daily and long-term orders. A timely order is not used to change facility operating procedures but is incorporated into the appropriate procedure when the information is essential to facility operations. SNF Project administrative procedures provide direction for implementation of timely orders.
11.3.16 Operations Procedures

Chapter 12 describes the operations procedures program used by the SNF Project facilities. Chapter 12 describes the development process, content requirements, review and approval process, and requirements for the use of operations procedures. The process for procedure control of changes and revision is also described in that chapter.

11.3.17 Operator Aid Postings

An operator aid is a posting, diagram, sample schematic, or similar instruction intended to assist operators in performing their duties. A posting is an aid and therefore controlled by the process described in SNF Project administrative procedures if the following conditions apply:

- It is used by operators to perform their duties
- Changes to the information would affect the quality of the operator's work
- Postings are not controlled or required by other programs or information is taken from or referenced in an operations procedure

Operator aids are formal tools used to provide information to operators (but do not establish the facility operations baseline) and are, therefore, posted close to the area of expected use. Operator aids are approved by SNF Project management, are controlled in an operator aid log, and are periodically reviewed to ensure they are correct and necessary. Outdated aids are removed.

11.3.18 Equipment and Piping Labels

A standardized equipment labeling program at SNF Project facilities ensures that facility personnel are able to positively identify specific pieces of facility equipment. Label information meets regulatory requirements (e.g., Occupational Safety and Health Administration requirements) and is consistent with equipment descriptions used in facility procedures. All facility personnel are responsible for monitoring for missing or incorrect labels during performance of their normal functions or during assignment to housekeeping or facility condition inspections. SNF Project administrative procedures describe the labeling program, including specific direction on label information requirements, acceptable label material, proper label placement, and the categories of equipment that require labels.
11.4 FIRE PROTECTION

The SNF Project facilities' fire protection programs are implemented by SNF Project administrative procedures, which were developed in accordance with the criteria specified in Section 12.0 of the facility S/RID (HNF-SD-SNF-RD-001). SNF Project facility-specific elements of the fire protection programs are addressed in the facility FSAR Annexes.

Fire hazard analyses were prepared for all SNF Project facilities to meet the requirements of DOE Order 5480.7A. As required, these analyses addressed the following elements. Future changes to the fire hazard analysis will be screened to these elements to ensure that no unreviewed safety question is created.

- Description of construction
- Protection of essential safety-class equipment
- Fire protection features
- Description of fire hazards
- Life safety considerations
- Critical process equipment
- High value property
- Damage potential, maximum credible fire loss and maximum possible fire loss
- Fire department or brigade response
- Recovery potential
- Potential for toxic, biological, and/or radiological incident due to a fire
- Emergency planning
- Security considerations related to fire protection
- Natural hazards (earthquake, flood, wind) impact on fire safety
- Exposure fire potential, including the potential for fire spread between fire areas

11.4.1 Fire Hazards

Fire hazard analyses have been developed for the SNF Project facilities as required by Section 12.4.6 of the facility S/RID (HNF-SD-SNF-RD-001) and is implemented using HNF-PRO-340, *Fire Protection Program Overview*. A fire hazard analysis comprehensively assesses the risk from fire at the facilities to determine (1) whether the potential for the occurrence of fire is minimized, (2) that fire does not cause an onsite or offsite release of radioactive or other hazardous materials that will threaten the public health and safety or the environment, (3) whether requirements that will provide an acceptable degree of life safety to SNF Project personnel are in place and there are no undue hazards to the public from fire and its effects in SNF Project facilities, and (4) that safety systems are not damaged by fire.
11.4.2 Fire Protection Program and Organization

The fire protection program for the SNF Project facilities meets the requirements of Section 12.2 in the facility S/RID (HNF-SD-SNF-RD-001) and is structured and implemented in accordance with the operating contractor's safety management policies, philosophies and the criteria identified in SNF Project administrative procedures. The S/RID requires an administrative program that provides a level of fire protection that fulfills the requirements for the best protected class of industrial risks. The program is to be characterized by the inclusion of a continuing, sincere interest on the part of management and employees in minimizing losses from fire and related perils and the inclusion of preventive features necessary to ensure the satisfaction of objectives related to safety. Basic elements of the program must include the following:

- A reliable water supply for fire suppression
- Noncombustible facility construction
- A well-trained and equipped response force
- A means of notification of an existing fire
- Other protective measures identified in the hazard analysis

The SNF Project fire protection program (SNF Project administrative procedures) includes the following, as required by Chapter 12.0 of the facility S/RID (HNF-SD-SNF-RD-001):

- Minimize the potential for the occurrence of a fire or related peril by implementing industry standards and reduced risk criteria relative to fire protection and prevention (including National Fire Protection Association requirements)

- Ensure that fire does not cause an unacceptable onsite or offsite release of radioactive and other hazardous material that would threaten the public health and safety, worker safety, or the environment

- Establish requirements to provide an acceptable degree of life safety to SNF Project and subcontractor personnel and to ensure the public will not be exposed to undue hazards associated with fire and its effects in SNF Project facilities

- Ensure that process controls and safety systems are not damaged by fire or related perils

- Ensure that the SNF Project facilities will not suffer unacceptable delays as a result of fire and its effects

- Ensure that property damage from fire and related perils does not exceed an acceptable level

This policy applies to all operating contractor subcontractors and managed facilities, programs, projects, and activities.
Different aspects of the fire protection program are administered or addressed by various Project Hanford Management Contractor groups as follows:

- Fluor Daniel Hanford, Incorporated, Industrial Safety and Fire Protection, is responsible for policy development, program requirements, subcontractor overview, interpretations, and interfacing with DOE, Richland Operations Office.

- Hanford Fire Department (HFD) is responsible for maintaining a fully staffed, trained, and equipped response force for fire suppression, fire system inspection, testing, maintenance, and repair activities (except where interface agreements with other organizations exist), hazardous material, emergency rescue, and medical response for the Hanford Site, and administering the fire prevention program.

- Project Hanford Management Contractor Subcontractor's Fire Protection Engineers are responsible for program development, providing fire protection document reviews, providing technical assistance to the projects and facilities for implementing the fire protection program, performing fire protection facility assessments and fire hazard analyses. The Project Hanford Management Contract subcontractor is also responsible for establishing administrative programs that include fire prevention measures such as housekeeping practices, control of hot work activities, and storage of flammable materials, and employee training on fire prevention.

**11 4 2 1 Fire Protection Features** Facility-specific fire protection features are described in the facility FSAR Annexes.

**11 4 2 2 Spent Nuclear Project Fuel Fire Protection Program** The SNF Project fire protection program is managed by the SNF Project engineering organization. A full-time, qualified fire protection engineer is maintained on staff. The fire protection engineer is responsible for developing the fire protection program in accordance with DOE Order 5480.7A and Section 12 2.1 of the facility S/RID (HNF-SD-SNF-RD-001). The applicable requirements are implemented through SNF Project administrative procedures. A written agreement is maintained with the HFD Fire Maintenance Group for testing, inspection, and repair services. The HFD is responsible for fire suppression, emergency rescue, and medical response. The SNF Project fire protection engineer is responsible for performing fire protection document reviews, providing technical assistance to the SNF Project-related projects and facilities for fire protection program implementation, and performing fire protection facility assessments and fire hazard analyses.

Consistent with the facility S/RID (HNF-SD-SNF-RD-001), fire-related issues identified during the fire hazard analysis process (i.e., preliminary through final fire hazard analysis) were documented in an "open items" section of the preliminary fire hazard analysis.
11.4.3 Combustible Loading Control

Controls on flammable and combustible materials for all SNF Project facilities are implemented as described in HNF-PRO-359, *Control of Combustibles*, and SNF Project administrative procedures. These controls prevent or minimize the accumulation of flammable, combustible, and reactive materials. The essential requirements include housekeeping, control of hot work, control of flammable or combustible liquids, control of transient combustibles, control of construction sites, control of oxidizing and pyrophoric materials, proper storage of hazardous material, and disposal of waste absorbent material. See the facility FSAR Annexes for facility-specific combustible loading information. HNF-PRO-359 and HNF-PRO-076, *Safety Inspections*, describe the frequency and scope of housekeeping and safety inspections.

11.4.4 Fire Fighting Capabilities

The HFD maintains a training program for fire fighting, fire testing, and fire inspection. These training programs have been designed to meet National Fire Protection Association and DOE Order 5480-series criteria.

11.4.4.1 Fire Response Procedures The facility FSAR Annexes contain discussions of facility-specific fire response procedures.

11.4.4.2 Basic Training and Personnel Qualifications for Fire Fighters The HFD is responsible for training its employees, including response personnel, test and services fire fighters, and system maintenance craft personnel. The HFD also provides hands-on fire extinguisher use training for Hanford Site workers. Training records that record the levels achieved by individual HFD members using the National Fire Protection Association professional qualification standards are maintained. HFD members are trained to respond to events that occur in radiological and hazardous material environments.

11.4.4.3 Fire Fighting in Radiological and Hazardous Materials Environments

Radiological Environments WHC-IP-0939, *Hanford Fire Department Implementing Procedure*, establishes requirements and responsibilities for fire fighting and other emergency activities in radiological zones. The policy applies to all members of the HFD and addresses emergency operations and training. The policy identifies personnel responsibilities, precautions for wild land fires involving radiological zones, and requirements for protective equipment, dosimetry, and emergency dose limits.

Hazardous Material Environments A hazardous materials emergency response plan and a hazardous materials operations plan are maintained by the HFD. The emergency response plan is a general outline for all hazardous material responses designed to meet the requirements of NFP A 472, *Standard for Professional Competence of Responders to Hazardous Materials Incidents*. The operations plan is a detailed step-by-step guideline that includes specific actions to be taken during an incident.
11 4 5 Fire Fighting Readiness Assurance

11 4 5 1 Fire Prevention The Hanford Site fire marshall is responsible for preparing and managing a fire prevention program in accordance with the requirements of NFPA 101, *Life Safety Code*. The Hanford Site fire prevention program includes annual facility employee training on recognizing and controlling fire hazards, on response and notifications in the event of fire, and on use of portable fire extinguishers. This program also includes a requirement for annual facility inspections, performed by the HFD, to identify potential fire hazards, to verify reliability of fire protection systems, and to verify emergency access for response personnel. Written inspection findings are provided to the facility manager, who is assigned responsibility for identifying and implementing corrective actions.

11 4 5 2 Types and Frequencies of Fire Safety Drills and Exercises In association with the Hanford Site emergency preparedness organization, the HFD participates in site emergency exercises. These exercises are managed by the site emergency preparedness organization and are scheduled on a monthly basis. Field exercises requiring full HFD participation are typically conducted on a quarterly basis. Desktop exercises requiring HFD participation in the form of representation (typically by an incident commander) are generally conducted on an annual basis. The HFD may be requested by the SNF Project facility manager to participate in facility fire drills. Facility fire drills are scheduled and conducted by the emergency preparedness organization as part of the annual drill schedule. Drills are performed to satisfy the requirements of DOE O 151 1, *Comprehensive Emergency Management System*, which requires the facility to conduct a range of drills that represent credible events that can occur at the facility. The goal of the fire drill program is to involve each shift in at least one fire drill per year.

11 4 5 3 Fire Protection Record Keeping The Hanford Site fire marshall maintains records on the following items:

- General examinations and approvals conducted by the Hanford Site fire marshall
- Fire prevention inspections and findings
- "Permitted areas or operations"
- Fire investigations
- Fires
- Hanford Site project reviews in support of the Site Selection Review Board

Records of all fire protection system acceptance testing are maintained by the HFD manager, Fire Protection Systems Administration and Testing. Other fire protection records (i.e., fire extinguisher inspections, fire barrier inspections) are maintained by facility management.

12.0 PROCEDURES AND TRAINING

12.1 INTRODUCTION

This chapter describes the essential features of the Spent Nuclear Fuel (SNF) Project procedures and training programs. These programs are designed to ensure that personnel are well qualified and prepared to perform their duties in a safe, effective, efficient and environmentally sound manner. SNF Project management recognizes the importance of effective procedures and personnel training in achieving the highest level of safety in facilities operation and maintenance. Line managers are responsible for staffing levels that support completion of required training.

Safety management policies used as a basis for the procedures and training programs are contained in HNF-3552 *Spent Nuclear Fuel Project Execution Plan*. Processes used to meet technical procedures and training program safety requirements are documented in SNF Project administrative procedures.

A structured process for developing, maintaining, and delivering procedures and training ensures that the safety hazard and accident analyses summarized in Chapters 3.0 of the facility annexes to the SNF Project Final Safety Analysis Report (FSAR) form the basis of the technical content of operating procedures and training for normal, abnormal, and emergency conditions. This process also ensures that specific procedures and training, as described in other chapters of this document, are systematically developed and maintained to meet the regulatory requirements for each safety-related topic.

- Prevention of inadvertent criticality (Chapter 6.0)
- Radiation protection (Chapter 7.0)
- Hazardous material protection (Chapter 8.0)
- Radioactive and hazardous waste management (Chapter 9.0)
- Initial testing, operational readiness reviews, in-service surveillance and maintenance (Chapter 10.0)
- Conduct of operations and fire protection (Chapter 11.0)
- Quality assurance (Chapter 14.0)
- Emergency preparedness (Chapter 15.0)
12.2 REQUIREMENTS

The requirements that form the basis for the procedures and training programs are found in HNF-SD-SNF-RD-001, *Spent Nuclear Fuel Project Standards/Requirements Identification Document*. The specific requirements applicable to this chapter include:

- DOE Order 5480 19, *Conduct of Operations Requirements for DOE Facilities*
- DOE Order 5480 20A, *Personnel Selection Qualification Training and Staffing Requirements at DOE Reactor and Non-Reactor Facilities*

12.3 PROCEDURE PROGRAM

SNF Project activities are conducted in accordance with written procedures. SNF Project Training and Support Services specifically the procedures organization, develops, maintains, and controls procedures in conformance with applicable federal and state regulations U S Department of Energy (DOE) orders, and industry standards and codes. HNF-PRO-552, *Project Controls*, provides guidance on the responsibilities, requirements, and approaches for controlling administration, baseline, design, construction, reporting, and closeout activities for Hanford Site projects. It references additional Site manuals that provide specific requirements and approaches applicable to a project including quality assurance program requirements. Existing Site procedures used as applicable, on all Hanford Site projects represent the procedure program for SNF Project design, construction, and procurement activities. The SNF Project quality assurance program plan and implementing procedures control SNF Project work processes.

Technical procedure development and control processes are based on the guidance of HNF-PRO-229, *Technical Procedure Standard*, which defines minimum requirements for facility and organization technical procedure development and use. HNF-PRO-229 establishes processes for the identification of need, preparation, review, approval, change, revision, and periodic review of procedures for production, testing, operations surveillance, and maintenance activities.

Procedure users use and comply with approved technical procedures as required by an assigned classification code (except when an employee received direct management or supervisory approval during emergency or off-normal conditions). SNF Project administrative procedure instructions for using and complying with procedures are different depending on the classification code. Classification descriptions for technical procedures include:

- Step by step — the nature of the task requires this type of rigor because (1) potential difficulties are present either through the complexity of the procedure, the nature of the work or the task affecting other components within a more sensitive system or (2) a safety problem or damage to the equipment could occur if this procedure is not followed correctly.
General intent — those procedures where the task can be accomplished using the skill of the user, indicates that the task is performed routinely and indicates there is little to no liability to personal safety, economic value, the environment, or equipment failure if performed out of sequence.

HNF-PRO-589, *Processing Project Hanford Procedures*, states that all managers are responsible for work performed in their divisions and for ensuring the work is accomplished in accordance with established procedures. Specific responsibilities and requirements associated with procedure use and compliance are established in SNF Project administrative procedures. The SNF Project procedures organization is responsible for promptly providing operations with the most recent version of all applicable procedures. It is the managers' responsibility to supply controlled copies of procedures and instructions at work locations. The procedure user has the responsibility to ensure that the procedure to be used is the most current by verifying the hard copy against the electronic copy or index on the controlled file server, or, if the electronic version is unavailable, by checking it against the backup hard copy or by contacting the procedures organization.

### 12.3.1 Development of Procedures

Section 1.2 of the standards/requirements identification document (S/RID) (HNF-SD-SNF-RD-001) requires that procedures be developed for all anticipated operations, evaluations, tests, and abnormal or emergency situations. The extent of detail in a procedure depends on the complexity of the task, the experience and training of the user(s), the frequency of performance, and the significance of the consequences of error. Section 1.2 of the S/RID further requires that the methods for developing procedures are clearly defined, including descriptions of procedure formats. SNF Project administrative documents provide guidance for standards and requirements identification document requirements, personnel responsibilities, procedure development, procedure change, and procedure use and compliance. All technical procedures are prepared and revised in accordance with applicable SNF Project administrative procedures. SNF Project administrative procedures delineate the process and requirements for the preparation or modification of administrative procedures.

The SNF Project technical procedures program is controlled and applied using SNF Project administrative procedures. These controlling procedures meet the applicable requirements of DOE Order 5480 19. Startup administrative procedures and startup technical procedures are prepared and revised in accordance with applicable SNF Project administrative procedures.

Primary steps in the technical procedure development process are illustrated in Figure 12-1 and are described in the following subsections.

#### 12.3.1.1 Identify the Need

Technical procedures are developed for anticipated operations: transients, evolutions, surveillances, maintenance, and abnormal or emergency situations.
A new or revised procedure may be identified when modifications in the conduct of an operation are implemented, when equipment or systems are modified, when a procedure is deemed inadequate during task performance, or as a result of a periodic review of technical procedures.

12.3.1.2 Develop the Technical Basis  During the technical draft development phase, a subject matter expert gathers information that will lead to identifying the sequence of steps that should be performed in a particular process (i.e., the technical basis for the procedure). A Technical Basis for Procedure Development form documents the technical basis. Source documents used in developing the technical basis for a procedure include, but are not limited to, the following:

- Safety analysis report
- Technical safety requirements
- Safety evaluation report
- Standards and requirements identification documents
- Process standards
- System design descriptions
- Facility configuration
- Vendor information
- Operational lessons learned
- Functions and requirements documents

12.3.1.3 Prepare and Review the Draft  Draft procedures are prepared consistent with administrative procedure requirements. A writer's guide is used to ensure the format and content of each procedure is consistent, the procedure steps are written to effectively communicate the required operator actions, and the procedure incorporates human factors that lead to effective procedure use.

Technical review and verification ensures the technical accuracy of a procedure, ensures the procedure incorporates human factors principles, and compares the procedure against the appropriate source document requirements (e.g., system design descriptions, functions and requirements documents, DOE orders, technical requirements, regulatory requirements).

Technical procedure validation is a review of a procedure performed by the end user to ensure its usability and correctness. This validates that the procedure provides sufficient and understandable guidance and direction to the user and that the procedure is compatible with the equipment or system being maintained.

12.3.1.4 Review and Approve the Procedure  New procedures, procedure revisions, and technical changes to procedures are reviewed and approved according to approval designator requirements contained in SNF Project administrative procedures. Approval designators verify that environmental, safety, health, and quality assurance requirements have been properly addressed. Document approval is indicated by a signature from the functional reviewer.
12.3.1.5 Release and Use the Procedure  All SNF Project administrative and technical procedures are assigned a procedure and revision number. A record copy is placed into the procedure master file, and working and controlled copies of the procedures are made available through electronic media.

12.3.2 Maintenance of Procedures

The safety of SNF Project facilities and personnel depends on the availability of operating, maintenance, and alarm response procedures that correspond to the current plant configuration. To ensure that personnel use only the most current procedures, the SNF Project has implemented a process that provides timely review, approval, change, revision, and control of procedures consistent with the requirements contained in Section 1 2 3 of the S/RID (HNF-SD-SNF-RD-001).

This process for technical procedure maintenance and review is documented in SNF Project administrative procedures. Training needs related to procedure revisions is determined by the line manager who is responsible for the procedure being revised. This determination is based upon the significance of the change. For changes that require new skills or knowledge, the line organization would request the training department to assist in determining a training need. For changes that do not involve new skills or knowledge but need to be communicated, the line organization would use the required reading process. Employees are required to read revisions that apply to their duties prior to implementation of the revisions and are required to document this training per SNF Project administrative procedures. For changes that are not deemed significant or are editorial, the line organization would denote no action.

12.3.2.1 Procedure Change  Section 1 2 of the S/RID (HNF-SD-SNF-RD-001) requires that procedures be technically and administratively accurate and that they incorporate appropriate facility design, safety analysis, and vendor technical information. To satisfy these requirements, technical and administrative procedure changes are made in accordance with the guidance of HNF-PRO-229 and SNF Project administrative procedures. Changes to Project Hanford Procedures are controlled by the process described in HNF-PRO-589, which requires a review and screening of the changes, including a screening for facility impact, by appropriate Project Hanford Management Contract contractor personnel.

The procedure change process is used to proceduralize modifications to essential equipment, processes or requirements, and to correct procedural errors and ambiguities and/or human factor deficiencies that could result in operator error or unsafe job performance. Procedure modifications also result from issues identified during training activities and from efforts to resolve operating occurrences. SNF Project administrative procedures require that procedure users stop work if the work cannot be accomplished as described in the procedure or if accomplishment of the work would result in an undesirable situation. Under these circumstances, the procedure user is required, by procedure, to notify supervision of the problems.
The level of review and approval for procedure changes depends on the scope of the recommended change, and the approval process is addressed in SNF Project administrative procedures.

12 3 2 2 Periodic Review of Procedures Section 1 2 2 of the S/RID (HNF-SD-SNF-RD-001) requires that procedures be reviewed at periodic intervals to ensure that information and instructions are technically accurate and that appropriate human-factor considerations have been included. SNF Project administrative procedures implement a periodic review process that ensures the technical accuracy and the proper consideration of human factor issues in procedures that implement the safety basis. This process specifies that procedures affecting the safety-class and safety-significant systems are reviewed at least every two years. Administrative procedures that implement the requirements identified in technical safety requirement administrative controls are also reviewed at least every three years.

The due date for a periodic review is defined as two years (one year for emergency response procedures) after the previous revision issue date. The procedures program organization maintains a recall system that will initiate the periodic review process by notifying the designated technical authority of the due date for a review. The technical authority is responsible for ensuring that the procedure is technically adequate, accurate, meets current facility design, and meets SNF Project content and format requirements. The technical authority also identifies other reviewers who should participate in the review process for the particular procedure undergoing periodic review. All reviewers are required by procedure to be trained to perform their assigned review assignments. The SNF Project administrative procedure addressing the periodic review process includes a table of positions that are designated as reviewers or approvers of the various types of Project procedures.

12 4 TRAINING PROGRAM

Section 4 1 1 of the S/RID (HNF-SD-SNF-RD-001) requires that a nuclear facility operating organization have an initial and continuing training program to ensure that operating organization personnel are qualified to perform job requirements. This program is to be achieved by using a systematic approach to training. The training program for the SNF Project operating organization is consistent with these requirements.

The objective of the personnel training program is to provide and maintain a qualified work force for safe and efficient facility operations. Training is one element of an employee's qualification which typically includes a combination of education, experience, and job-specific training. Managers identify training and qualification requirements for their personnel from federal and state regulations, DOE orders, industry standards, company manuals, and personnel performance. Individual training must be current before performance of tasks requiring training.
Selection and qualification requirements are established for operators, training instructors, and maintenance staff and technical staff positions. Operations organization management is responsible for establishing selection and qualification requirements. Nuclear chemical operator and shift manager positions require certification as described in DOE Order 5480.20A.

The SNF Project procedures and training organization develops classroom, self-study, and on-the-job training programs consistent with the requirements contained in DOE Order 5480.20A. The sitewide training organization offers courses that meet general training requirements in the program areas of general employee orientation, health, safety, and environmental and occupational radiation protection. SNF Project Training and Support Services, specifically the Training organization, provides training support to ensure that facility- and job-specific training requirements are satisfied.

12.4.1 Development of Training

Section 4.1.1 of the S/RID (HNF-SD-SNF-RD-001) requires that training design, development, and implementation be based on learning objectives. The S/RID also requires that material, such as lesson plans and on-the-job training guides, training aids, and student materials, are developed to conduct training. A graded approach is allowed to be used to develop training material. Trainers are required by Section 4.2.1 of the S/RID to be qualified both in the subject being presented and in instructional skills.

The SNF Project training program is developed and implemented through a joint effort between the SNF Project Training and Support Services organization and line organizations (i.e., Operations, Maintenance, Radiological Control). SNF Project management maintains full responsibility for ensuring that plant training needs are satisfied. All formal qualification training is provided by qualified instructors or experienced vendors.

The training program applies performance-based training to specific job requirements including factors such as the following:

- Plant operations and design
- Instrumentation and control
- Methods of dealing with process malfunctions
- Emergency procedures
- Radiological control
- Hazard communication
- Hazardous material recognition
- Criticality

SNF Project Training and Support Services, specifically the Training organization, applies a graded systematic approach to training development, as indicated in Section 4.2 of the S/RID.
(HNF-SD-SNF-RD-001) This systematic approach, as it is applied within the SNF Project, is developed and documented in SNF Project administrative procedures. This performance-based approach to training comprises five phases: analysis, design, development, implementation, and evaluation.

12.4.2 Maintenance of Training

The SNF Project recognizes that training programs will only be effective if they reflect current operating practices, conditions, and procedures. To ensure that training properly reflects operating practices and procedures, SNF Project administrative procedures implement a training materials maintenance process that is used to track items that may affect the content of SNF Project training programs and materials. This process is accomplished in conjunction with the configuration management process and permits the training organization to respond to requirements for changes resulting from revised regulatory requirements, safety analyses, technical safety requirements, procedural changes, changes in the facility equipment configuration, feedback from course evaluations, feedback from operating experience, and resolution of audit findings. The training materials maintenance system is used to document the origin of the change request, the evaluation and disposition of the change request, and the recommended changes in program materials. Training content and materials are revised using the same process that is used to develop new training materials.

The effectiveness of the training program is maintained through feedback mechanisms such as course evaluations and training program evaluations. Competency of the instructional staff who deliver the facility training is maintained through compliance with initial and continuing instructor qualification requirements contained in SNF Project administrative procedures.

SNF Project training records are managed in accordance with SNF Project administrative procedures. Official training records are maintained in the central Training Services organization in accordance with the requirements of DOE Order 5480.20A. Courses completed, applicable training expiration dates, and summary reports are available electronically to managers and designated individuals.

12.4.3 Modification of Training Materials

The need to modify training materials may be identified through the configuration management system as a training deficiency identified by students, instructors, operations or maintenance staff, or management. In addition, training packages will be reviewed after any significant program change and will be updated in accordance with the requirements of DOE Order 5480.20A to ensure that information in the training package is current with plant operations. Per SNF Project administrative procedures, all changes to training program content, together with the reason for the changes.

13 0 HUMAN FACTORS

13 1 INTRODUCTION

Human factors engineering (HFE) is important in assuring the safe operation of the Spent Nuclear Fuel (SNF) Project facilities. This chapter identifies appropriate HFE requirements and describes the process to incorporate HFE into SNF Project facilities. The facility annexes to the SNF Project Final Safety Analysis Report (FSAR) contain an HFE review of the significant facility structures, systems, and components (SSCs) that include human–machine interfaces (HMIs), a review of abnormal sequences involving human operators, and a discussion of how the SNF Project human factors program will be used for design modifications and operation of SNF Project facilities.

HFE considerations are commensurate with the following:

- Planned SNF Project mission
- Hazard category 2 classification of SNF Project facilities
- Level of complexity of the SNF Project operations
- Phase of the system life cycle for which U S Department of Energy (DOE) approval is sought
- Potential consequences of a human error and the likelihood of error occurrence
- Type of the human operations with the SSCs and the SNF Project processes

HFE is the application of knowledge about human performance capabilities and behavioral principles to the design, operation, and maintenance of human–machine systems so that personnel can function at their optimum level of performance.

The incorporation of HFE considerations into the SNF Project facilities designs and operational processes ensures that human contributions to operational success are enhanced while abnormal situations resulting from human error are reduced. Facility design and operations that include insights from a human factors perspective help to ensure that facility and equipment design, staff capabilities and operational procedures all combine to enhance human performance while protecting against susceptibility to human error.

Staffing and qualifications of personnel, personnel training and written procedures to guide operations and maintenance are covered primarily in Chapters 10 0, 12 0, and 17 0. Allocation of human–machine functions were considered by the design team using structured and systematic methods. A design goal was to reduce human operation to a reasonable degree and move systems into a more automatic function. Human involvement in this case is delegated to routine.

November 1999
maintenance of these automatic systems, and thus reduces both the complexity and interaction of human to system. An example of allocation function is the design team looking at the weights and materials and determining that machinery is needed for handling large weight equipment that utilizes handling devices like the receiving crane. Human–machine allocations were also appropriately considered during the design of the multi-camister overpack handling machine. Additional human factors concerns are addressed as described in this chapter.

The specific facility FSAR Annexes discuss the HFE design process as implemented in the facility.

See Figure 13-1 for inclusion of the overall method for human factors into the design of the system.

13.2 REQUIREMENTS

According to DOE Order 5480 23, Nuclear Safety Analysis Reports, Attachment 1, Section 3 c (1)(b), human factors safety includes allocation of control functions to humans and machines, staffing and qualifications of personnel, personnel training, written procedures to guide operations and maintenance, and design of HMI’s. Human factors design activities focusing on each of these areas responding to governing DOE orders and standards, and non-DOE referenced standards, commensurate with classification of the SNF Project facilities as category 2 nonreactor nuclear facilities. Specific requirements applicable to this chapter include:

- DOE Order 5480 19, Conduct of Operations Requirements for DOE Facilities
- DOE Order 5480 20A, Personnel Selection Qualification and Training Requirements for DOE Nuclear Facilities
- DOE Order 5480 23, Nuclear Safety Analysis Reports
- DOE Order 6430 1A, General Design Criteria, Section 1300-12
IEEE 1023-88, Guide for the Application of Human Factors Engineering to Systems Equipment and Facilities of Nuclear Generating Stations

HNF-SD-SNF-RD-001, Spent Nuclear Fuel Project Standards/Requirements Identification Document

Each of the above listed documents were used to create the checklists cited for use in evaluating the implemented systems. These requirements were also used in evaluating the systems still being designed.

Table 13-1 lists the DOE orders and standards that apply to the design and operation of facilities. Through checklists, these orders and standards have been used to evaluate the current designs and to provide human factors design considerations into the design modification process.

13.3 HUMAN FACTORS PROCESS

The SNF Project recognizes the need for the inclusion of human factors principles in the design, operation, and maintenance of SNF Project facilities. The SNF Project is committed to including human factors principles through a process of expert review of the information requirements, job task knowledge, skills, and abilities, and control layouts, display relationships, gauging, instrumentation, physical access, and other HFE issues associated with the operation and maintenance of the SNF Project facilities.

The SNF Project's human factors process meets the requirements of DOE Order 6430 1A and implements it for SNF Project facilities. This process will ensure appropriate consideration of the HFE aspects involved with constructing, operating, and maintaining the facilities. This process utilizes existing procedures for ensuring that HFE issues are captured, tracked, and implemented with sufficient organizational control and adequate configuration management priority. The SNF Project human factors process is currently being updated and will adequately address the requirements of DOE Order 6430 1A.

HNF-PRO-229, Technical Procedure Standard, states that human factors are considered during procedure preparation to minimize risk to personnel and equipment, and procedures are written to the degree of detail necessary to safely perform the activity. HNF-PRO-704, Hazard and Accident Analysis Process, provides a process to systematically identify the hazards associated with a given operation and determine the engineered and administrative features taken to eliminate, control, or mitigate the identified hazards and evaluate their adequacy. Human–machine design considerations include communication, and operational aids, layout of controls and instrumentation and labeling, work environment factors such as heat, light, noise, physical access, protective clothing and breathing apparatus and demonstrated ability of personnel to accomplish their responsibilities under normal, abnormal, and accident conditions.

HFE = human factors engineering

NA = not applicable
SNF-4399, Spent Nuclear Fuel Project Human Engineering Program Plan (HEPP), addresses the human factors and ergonomics processes in detail. SNF-4399 meets the requirements of DOE Order 6430 1A, Section 1300, as applicable. The human factors process applied to the SNF Project facilities is described in the following sections.

13.3.1 Systematic Inquiry

DOE Order 5480 23 and DOE-STD-3009-94, Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports, require a systematic inquiry into the HMI's pertinent to safety, especially focusing on those systems that are defined as safety SSCs. Those systems were evaluated using HFE checklists especially designed for HFE evaluations (INEL-95/0117). The checklists are designed to evaluate the HMI of safety-related systems according to criteria established by DOE, the U.S. Nuclear Regulatory Commission, and the HFE professional community. The checklists can be applied to both existing equipment and designs. The checklists result in one of four responses: (1) compliant with the criterion, (2) not compliant with the criterion, (3) the criterion is not applicable, and (4) to-be-determined as the design evolves. Once the HMI's are completed, the issues that resulted in to-be-determined responses are resolved so that the checklist items can classified as compliant, not compliant, or not applicable. For SNF Project facility design and construction, the noncompliance responses were grouped into either "to be resolved" or "not appropriate to the design being contemplated." The facility FSAR Annexes contain results of implementation inquiries. The INEL-95/0117 Human Factors Engineering Checklists for Application in the SAR Process, checklists are maintained in the SNF project files.

13.3.2 Lessons-Learned Applications

The HFE process begins by collecting "lessons learned" from experience in the commercial industry, DOE facilities, and relevant events in other technical domains. As discussed in Chapter 3.0, the dockets for Title 10, Code of Federal Regulations, Part 72, "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel and High-Level Radioactive Waste" (10 CFR 72), were reviewed, including notices of violations issued and reported under 10 CFR 72 75, "Reporting Requirements for Specific Events and Conditions." Events at DOE facilities similar to the SNF Project facilities also were reviewed. These reviews were conducted to ensure that any specific failure in the human–machine interaction that may be applicable to the design of SNF Project facilities were addressed. This also allowed the design teams to glean valuable lessons learned from the experience of others. SNF Project design engineers ensured that lessons learned applicable to maintenance and operation of the SNF Project facilities were discussed with the vendors.

Figure 1 of DOE-STD-1029-92 illustrates a facility safety envelope and shows how lessons learned contribute to human performance. Lessons learned flow into (i.e., are an input to) DOE safety policy, facility safety policy, bases for facility operations, and facility operations (technical safety requirements, training and qualifications and operations, maintenance, and surveillance).
procedures), which all contribute to human performance. Therefore, lessons learned are incorporated into all aspects of the design—from the regulatory requirements and design requirements to operating procedures and training requirements.

As discussed in Chapter 17, the SNF Project maintains a lessons-learned program that includes the identification, documentation, and dissemination of lessons learned. Each facility has a point of contact who is responsible for the distribution of lessons learned to the appropriate organizations or individuals within the facility. The sources of lessons-learned occurrences and conditions include U.S. Nuclear Regulatory Commission documents, Hanford Site internal lessons learned, Occupational Safety and Health Administration safety bulletins, operational readiness review final reports, and Operating Experience Weekly summaries. If applicable, procedures are modified, training is upgraded, and/or maintenance practices are revised to incorporate lessons learned and thereby avoid a recurrence of an adverse work practice or operating experience. The overall lessons-learned process for the SNF Project is described in SNF Project administrative procedures.

13.3.3 Engineering Design and Analysis

Engineering design encompasses design process and analysis in support of original design and design change activities. Designs are prepared in accordance with criteria established in DOE Order 6430.1A, Section 1300-12, in which human factors are considered through the system development process (planning, requirements analysis, system design, and system testing and evaluation). Pursuant to DOE Order 6430.1A, Section 1300-12.4, the design, operation, and maintenance of SNF Project facilities considers appropriate human factors technology to improve human performance through enhancements in the work environment and HMIs. HFE design is applied at a level commensurate with the safety importance, complexity, and degree of HMI of the SSC.

The design and design specifications for SSCs were reviewed according to the DOE orders listed in Section 13.2.

HFE aspects have been included within the design requirements at each step. A separate HFE program has not been developed because it has been determined that, for the purposes of developing requirements and ensuring their appropriate inclusions, the project engineers responsible for the design should have responsibility for the applicable HFE requirements. This process of placing HFE responsibility on the design engineers is similar to promoting accountability downward and reaping the benefits of concurrent HFE in the design phases. In addition, all human factors requirements were made part of the SNF Project procurement for SSCs. Using this approach, SNF Project personnel are aware of applicable HFE criteria, and their design reports and activities make reference to HFE considerations. See Figure 13-1 for a diagram of the process for incorporation of HFE concepts into the SNF Project designs. See the facility FSAR Annexes for results of facility-specific HFE analyses.
Testing and evaluation is considered during verification and validation of systems. Human factors considerations were addressed during testing. See the facility FSAR Annexes for specific human factors interactions.

13.3.4 Designing for Abnormal Operations

An assessment team conducted a hazard analysis at each SNF Project facility to identify potential hazards to the facility worker, collocated workers, the public, and the environment. Potential events considered ranged from normal operation through beyond design basis accidents. The design basis accidents were considered to the extent described in Chapters 3.0 of the facility FSAR Annexes. The hazard analysis process includes identification and analysis of the various operational steps to be conducted within the SNF Project facilities. Human interactions with machines are considered in the analyses. The hazard analysis identifies both engineered and administrative safety features. Engineered safety features are design features that prevent or mitigate a potential accident and may require HMIs. Administrative safety features are procedures and programs designed to ensure that engineered safety features continue to be available for accident prevention or mitigation. Administrative safety features also include programs that implement a particular set of safety practices. The hazard analysis methodology and results are described in more detail in Chapters 3.0 of the facility FSAR Annexes.

The HMIs for engineering safety features were analyzed according to the criteria established in Section 13.2. The analysis results are summarized in the facility FSAR Annexes.

13.4 IDENTIFICATION OF HUMAN–MACHINE INTERFACES

Summaries of safety-class and safety-significant SSCs and the associated HMIs are provided in the facility FSAR Annexes.

13.5 OPTIMIZATION OF HUMAN–MACHINE INTERFACES

Discussions of the optimization of HMIs are provided in the facility FSAR Annexes. The following subsections discuss how the various aspects of HFE are implemented in the SNF Project to assure successful operations.

13.5.1 Human Factors Engineering Analysis of Human-Machine Interfaces

In addition to the HFE review of SNF Project facility systems and the general physical and organizational environment, normal operations were reviewed for the potential for human error and for the programmatic issues related to training, staffing, technical procedure development, and maintenance activities. This review process is depicted in Figure 13-2.
Tabletop task analyses, systems reviews, direct interviews with design authorities and cognizant engineers, and reviews of applicable design documentation were conducted to evaluate whether the design and procurement meet the established HFE guidelines and standards. The results of the task analyses, interviews, and design documentation reviews were analyzed using INEL-95/0117. These checklists are used to determine whether designs meet applicable HFE requirements, whether the design specifications account for the HFE requirements, or whether the HFE requirement is to be considered in the design modification process. Finally, the facility hazard analyses were reviewed to determine whether human operator actions involve using equipment or taking action that must be further analyzed. The checklists (designed per INEL-95/0117) are maintained in the SNF project files.

13.5.2 Staffing

13.5.2.1 Operator Capabilities  Skills and standards that must be attained for a particular job are defined to ensure that personnel have the appropriate knowledge, skills, and abilities to perform the required activities in a safe and reliable manner. As stated in Chapter 12.0, minimum education and experience requirements for management and technical personnel meet the requirements of the SNF Project facility standards/requirements identification document (S/RID) (HNF-SD-SNF-RD-001). Qualification criteria are established to define the experience, education, and training required to perform a designated job. Chapter 5.0 also provides a discussion of the minimum staffing requirements.

A facility-specific training program is developed and maintained as a performance-based training program. Several positions require certification in accordance with the SNF Project facility S/RID (HNF-SD-SNF-RD-001) as fissionable material handlers. These positions are identified in the project training implementation matrix.

Operator capabilities are verified throughout testing and review programs and walkthroughs. Specifically, the operational readiness reviews will include dry run demonstrations that operators and procedures are in a satisfactory state of readiness to safely and efficiently perform the required operations. The dry run demonstrations validate both procedures and the operations staff by confirming that personnel have the appropriate knowledge and capabilities to perform their tasks. Therefore, the SNF Project training plan is considered adequate with respect to the inclusion of human factors concerns.

The FSAR process for selecting safety-class and safety-significant SSCs and technical safety requirements also serves as a systematic inquiry into the ability of facility staff to accomplish their responsibilities and duties during normal and abnormal operations. Input is provided from various disciplines (including operations) in the development of the hazard analysis. For each analyzed accident scenario, operators and engineers are involved in the FSAR process for selecting safety-class and safety-significant SSCs and technical safety requirements for facility operation.
13 5 2 2 Staffing Plan  A current staffing plan through 2002 exists for the SNF Project. A review of this plan concluded that appropriate consideration has been given to the following:

- Learning curves
- Loss of trainees through the process
- Appropriate job titles and functions for operations personnel

Facility-specific staffing levels are addressed in the facility FSAR Annexes.

13 5 3 Procedures

The SNF Project is committed to the inclusion of human factors principles in the development of technical procedures. SNF Project personnel have developed standards and attended training to ensure that technical procedures will follow human factors principles in their content, layout, and format.

The SNF Project has complied with DOE Order 5480 19, DOE-STD-1029-92, HNF-PRO-229, and Fluor Daniel Hanford, Incorporated, contractual obligations. Acceptable compliance is demonstrated by a writer’s guide meeting at least the requirements in DOE Order 5480 19 and DOE-STD-1029-92. A review of TP-DI-001, SNF Project Technical Procedures Writer’s Guide demonstrates that the SNF Project meets the technical procedure writing requirements of DOE Order 5480 19 and DOE-STD-1029-92. TP-DI-001 was developed at the Hanford Site for technical procedure writers. TP-DI-001 includes the technical procedure writing requirements of DOE-STD-1029-92. The Human Factors Area Council created DOE-STD-1029-92 to ensure writers of technical documents will follow basic human factors principles in their content, layout, and format of written technical procedures. DOE-STD-1029-92 complies with accepted human factors principles. Inclusion of the Standard demonstrates that human factors considerations are included in the technical writers’ work.

DOE-STD-1029-92 is used in its entirety to provide guidance to technical procedure writers.

SNF Project technical procedure writers have attended training provided by several offsite experts in technical procedure writing. Subject matters covered by these experts included grammar, layout, format, and human error reduction. Training records exist for SNF Project procedure writer’s completion of these courses. A training matrix that specifies when retraining is necessary is maintained for each procedure writer.

Each technical procedure being developed for startup and operation of all SNF Project facilities is being written to the TP-DI-001 and by writers that have been appropriately trained in the inclusion of human factors considerations, as described in DOE-STD-1029-92. Procedures play a key role in ensuring safe, deliberate, and controlled operations. The intent of DOE-STD-1029-92 is to provide a knowledgeable and reasonable approach to all aspects of procedure management that will ensure the availability and use of sound procedures at DOE facilities.

DOE-STD-1029-92 provides a method for writers to ensure key questions are
addressed and that procedures contribute to maintaining safe operations. For example, key human factors questions that procedure writers are trained to answer include:

- Who is the user and what is the user’s level of experience and training?
- How does this document relate to other procedures for the equipment and facility?
- What materials, equipment, and facilities are to be used?
- What tasks are to be accomplished?
- Why, when, where, and how are the tasks to be accomplished?

Procedure writers learn that the operators are an important source of information when developing procedures. Personnel from the operating organization should be involved in the process from the initial decision to write a procedure through the review, verification, and validation of the procedure.

Facility operators can provide valuable insight into the job being performed, information about past operating experience, and data for developing the basis of the procedure. Their involvement in the process can include participating in walkthroughs and identifying behavioral obstacles, cautions, and valuable nonstandard source documentation beyond safety analysis reports, probabilistic risk assessments, technical safety requirements, vendor manuals, and old procedures.

The procedure has to be constructed and written to communicate to the procedure user all information needed to successfully operate the system within its design environment. Human factors considerations would include such things as using simple and concise language, using action statements, maintaining consistency in language and format among instrument labeling, procedures, and training, and avoiding ambiguity. Limiting use of abbreviations and acronyms, and adhering to grammatical conventions and syntax of standard American English.

The procedure is verified and validated during the test and evaluation of the system. Therefore, the inclusion of human factors principles is occurring and will continue to occur throughout the technical procedure writing process. These actions are considered adequate for compliance to human factors requirements.

In addition to training or day-to-day supervision, providing sound procedures and requiring workers to use them are among the most formal, direct, and effective methods available to facility managers to ensure that operations meet DOE’s objectives. Procedures provide managers with a critical tool to communicate detailed expectations for how individual workers are to perform specific tasks. In other words, the facility’s operating procedures provide the mechanisms for ensuring that facility operation is maintained within the safety basis.

All facility activities are governed by established procedures that specify specific sequences of steps that must be performed to accomplish a desired task. As described in Chapter 12.0, the technical basis for procedures is determined by performing a task analysis on each step in the process. Furthermore, the procedure system requires end-user (operator) participation in both the procedure writing and the review processes. This participation permits the inclusion of...
operational experience and human factors considerations into procedures and ensures that human needs and limitations are carefully considered and incorporated.

Chapter 12 describes the validation portion of the review process for draft procedures, during which the procedure is tested for usability, correctness, compatibility with the system equipment, and human factors considerations incorporation. Validation includes determining whether the user can perform each step correctly and ensuring the units used in the procedure are consistent with the facility instrumentation and possess the required precision for operation. Validation ensures that the sequence of steps is logical and can actually be performed, all documentation (e.g., labels, equipment representations, and diagrams) contained in the procedure is accurate, and tasks required by the procedure are within the operator's capabilities. Each step in each procedure will be checked against the actual equipment and controls to ensure the step is technically accurate. Human factors concerns will also be incorporated from feedback from the operators about the procedures and by observing the operators' interactions with the actual equipment. The goal is to ensure that the procedure can be effectively used by operations personnel during normal, abnormal, and emergency conditions. Alarm response procedures are developed on the basis of the monitoring and control functions of the system or component providing the alarm output. All operating procedures are required to be validated prior to use.

As discussed in Chapter 12, procedures will be periodically reviewed. This periodic review process ensures the technical accuracy and the proper consideration of human factors issues in procedures. Operating procedures, alarm response procedures, and surveillance and test procedures are included in the review process. The process involves verification of the technical basis and procedural steps, validation of the usability of the procedure by operations personnel, and verification of human factors elements that may impact the effectiveness of the procedure.

SNF-4399 addresses the human factors and ergonomics process in detail, including HFE and ergonomics testing and validation. SNF-4399 meets the requirements of DOE Order 6430 1A, Section 1300, as applicable.

13.5.4 Training

Training ensures that all staff have the knowledge, skills, and abilities required to safely operate and maintain the facilities and processes. As discussed in Chapter 12, the SNF Project training organization applies performance-based training to specific job requirements. This training will be implemented using a systematic approach to training development that is in compliance with the requirements of the SNF Project facility S/RID, Chapter 4 (HNF-SD-SNF-RD-001).

Operators receive on-the-job training that consists of learning to operate the specific components and systems. It is anticipated that the majority of the on-the-job training package development and operator evaluations will be performed during preoperational testing. As previously stated, preoperational testing includes dry runs using mockups and in situ equipment and systems to provide verification of the operators' knowledge of facility procedures.
readiness of tools, equipment, and instrumentation, and off-normal and emergency operations.

The major focus is the incorporation of job and task analysis information into the on-the-job training material and ensuring that operators are trained and evaluated on this material.

For some tasks, the job analysis or task analysis will identify the need for continuing training. Schedules, materials, and evaluations for continuing training will be developed. This may include (1) training on selected fundamentals, systems, administrative controls and emergency response and (2) on-the-job training for normal and abnormal operation. Job and task analysis also assists in defining those tasks that require continuing training. To ensure that training properly reflects the current operating practices, conditions, and procedures, a training materials maintenance system is used to track items that may affect the content of training programs. Chapter 120 provides additional details on the maintenance of training programs and the use of a training materials maintenance system.

Operational drills and exercises are an integral part of the facility training program. Drills are an effective means of providing training in the handling of abnormal conditions and situations. Drills also provide management with an assessment tool to help evaluate the staff's ability to respond to off-normal events and conditions. Drills and exercises provide the means for testing crew proficiency and validating procedures. At the completion of operational testing, personnel will have the appropriate training that includes human factors considerations.

13 5 5 Maintenance

Vendor contracts include development of appropriate maintenance manuals and listings of common maintenance to be performed on the systems. Normal maintenance, including preventive maintenance, will be accomplished by SNF Project staff. Operations planning accounted for personnel and equipment necessary to perform maintenance activities. Maintenance activities include ensuring that appropriate diagnostic equipment and maintenance tools are available and the staff has adequate skills and training to accomplish the necessary activities. The above actions are considered acceptable by the human factors professional.

13 5 6 Abnormal Operations

Scenarios for abnormal operations involving human recovery initiator or mitigator actions are addressed in Chapters 30 of the facility FSAR Annexes. Recovery actions that require human intervention initiator or mitigator responses involve the equipment analyzed in Sections 13 5 of the facility FSAR Annexes. Human factors considerations for abnormal operations are covered in Sections 13 5 3 of the facility FSAR Annexes.

14 0 QUALITY ASSURANCE

14 1 INTRODUCTION

The Spent Nuclear Fuel (SNF) Project quality assurance program provides assurance that the design, procurement, construction, SNF characterization and conditioning, testing, inspection, operation, maintenance, packaging, handling, transportation, and interim storage activities conducted at the SNF Project facilities conform to regulatory and contractual requirements. This chapter summarizes the SNF Project quality assurance program for activities conducted at the SNF Project Facilities. It also provides references to documents containing additional details of the SNF Project quality program.

The SNF Project shall execute the applicable quality program requirements in a graded approach to an extent that is commensurate with the importance to safety of the item or related activity. Specific safety structures, systems, and components (SSCs) along with related activity classifications are presented in either the safety equipment list or the SNF Project 'Q' list (HNF-SD-SNF-RPT-007) as described in HNF-SD-SNF-RD-001, Spent Nuclear Fuel Project Standards/Requirements Identification Document. The SNF Project SSCs and related activities are described by three different safety classifications: safety class, safety significant, and general service. Quality-affecting activities performed by any organization that provides equipment, services, or support to the SNF Project facilities also are described in this chapter.

Adherence to the quality assurance program ensures that:

- U.S. Department of Energy (DOE) missions and objectives are effectively accomplished.
- Products and services are safe, reliable, and meet or exceed the requirements and expectations of the user.
- Any hazards to the public, to Hanford Site and facility workers, and to the environment are minimized.

14 2 REQUIREMENTS

Quality assurance requirements based on Title 10, Code of Federal Regulations, Part 830 120, "Quality Assurance Requirements" (10 CFR 830 120), and DOE O 414 1, Quality Assurance, define the quality implementing requirements for the SNF Project SSCs and activities. In addition, DOE-directed compliance with DOE/RW-0333P, Quality Assurance Requirements and Description (QARD), quality program requirements are applicable, as appropriate to certain SNF Project items and activities.
The Office of Civilian Radioactive Waste Management requirements in DOE/RW-0333P, as a minimum, apply to the following SNF Project activities, as they relate to disposal in the repository:

- Characterization or data collection for input or use
- Conditioning into final form
- Handling, packaging, and transportation

Requirements invoked by the standards/requirements identification document (S/RID) comprise the total list of environment, safety, health, and quality requirements to be implemented by a site, facility, or activity. These requirements are appropriate to the life cycle phase to achieve an adequate level of protection for worker and public health and safety and the environment during design, construction, operation, decontamination and decommissioning, and environmental restoration. S/RIDs encompass quality, health, safety, environmental and 'safety-related' safeguards, and security standards/requirements.

The Fluor Daniel Hanford, Incorporated contract S/RID contains standards and requirements, applicable to Fluor Daniel Hanford and its subcontractors necessary for safe operation of Project Hanford Management Contract facilities. Facility S/RIDs contain standards/requirements applicable to a specific facility that are the direct responsibility of the facility manager. Specific S/RID requirements are presented in HNF-SD-SNF-RD-001, *Spent Nuclear Fuel Project Standards/Requirements Identification Document*.

DOE has established a regulatory policy (Grumbly 1995) that SNF Project facilities achieve nuclear safety equivalency to comparable U.S. Nuclear Regulatory Commission (NRC)-licensed facilities. This is to be applied to matters of nuclear safety (including radiological control issues) for new SNF Project facilities. The NRC's guidance for the use of 10 CFR 72, "Licensing Requirements for the Independent Storage of Spent Nuclear Fuel and High-Level Radioactive Waste," is presented in NUREG-1567, *Standard Review Plan for Spent Fuel Dry Storage Facilities*, which states that SSCs are to be placed into two categories according to their function. They are classified as important to safety, or not important to safety. NUREG-1567 references NUREG/CR-6407, *Classification of Transportation Packaging and Dry Spent Fuel Storage Systems Components in Accordance with Importance to Safety*. NUREG/CR-6407 contains a graded approach for determining the classification of SSCs according to important to safety considerations:

- **Category A - Critical to Safe Operation**: SSCs in this category include those whose failure or malfunction could directly result in a condition adverse to public health and safety.
- **Category B - Major Impact on Safety**: SSCs in this category include those whose failure or malfunction could directly result in a condition adversely affecting public health and safety. The failure of a Category B item in conjunction with the failure of an additional item, could result in an unsafe condition.
• Category C - Minor Impact on Safety  SSCs whose failure or malfunction would not significantly reduce the packaging effectiveness and would not be likely to create a situation adversely affecting public health and safety.

• Safety Class - SSCs needed for public protection

• Safety Significant - SSCs of particular importance to defense-in-depth or worker safety

• General service or non-safety class - Little or no impact on worker or public safety

The quality assurance program requirements to be implemented for new SNF Project facilities will be determined by using a merged classification system of the DOE and NRC safety classification systems. The merged quality assurance requirements are as follows:

• For Category A important-to-safety SSCs, the DOE quality assurance program used for safety class SSCs will be implemented using 10 CFR 830.120, "Quality Assurance Requirements," HNF-MP-599, Project Hanford Quality Assurance Program Description, and DOE Order 6430.1A, General Design Requirements. Implementation of NRC equivalence (10 CFR 72, Appendix F, "General Design Requirements") is achieved in accordance with WHC-SD-SNF-DB-002 and HNF-SD-SNF-DB-003.

• For Category B important-to-safety SSCs, the DOE quality assurance program used for safety-significant SSCs will be implemented using a graded approach, in accordance with 10 CFR 830.120 and HNF-MP-599, which uses national and commercial procurement specifications for the implementation of the design. The SNF Project implements the safety-significant classification as defined in HNF-PRO-704, Hazard and Accident Analysis Process.

• For Category C important-to-safety SSCs, the DOE quality assurance program used for general service SSCs will be implemented using good engineering practices and national and commercial standards to control design and procurement.

An evaluation, documented in WHC-SD-SNF-DB-002, Spent Nuclear Fuel Project Path Forward, Nuclear Safety Equivalency to Comparable NRC-Licensed Facilities, identifies requirements to establish nuclear safety equivalency that are to be met in addition to existing and applicable DOE requirements. These requirements, except those related to the design basis earthquake, are contained in HNF-SD-SNF-DB-003, Spent Nuclear Fuel Project Path Forward.

The integrated quality assurance requirements for the SNF Project are summarized in Figure 14-1, which depicts the SNF Project quality assurance program document hierarchy.

The specific regulatory requirements applicable to this chapter include:

- **DOE O 414 1, Quality Assurance**
- **DOE/RW-0333P, Quality Assurance Requirements and Description**

Applicable facility design codes, standards, statutes, rules, regulations, and DOE Orders are summarized in the following technical documents:

- **HNF-MP-003, Integrated Environment Safety and Health Management System Plan**
- **HNF-SD-GN-TI-502, Project Hanford Nuclear Facilities List and Authorization Basis Information**
- **HNF-SD-SNF-DB-003, Spent Nuclear Fuel Project Path Forward Additional NRC Requirements**
- **HNF-SD-SNF-DB-005, Spent Nuclear Fuel Project Multi-Canister Overpack Additional NRC Requirements**
- **HNF-SD-SNF-RPT-007, Application of the Office of Civilian Radioactive Waste Management Quality Assurance Requirements to the Hanford Spent Nuclear Fuel Project**
- **WHC-SD-SNF-DB-002, Spent Nuclear Fuel Project Path Forward Nuclear Safety Equivalency to Comparable NRC-Licensed Facilities**
Additional requirements applicable to specific SNF Project facilities are presented in the facility annexes to the SNF Project Final Safety Analysis Report (FSAR). These documents provide the quality assurance requirements for federal repository acceptance of SNF and satisfy U S Nuclear Regulatory Commission equivalency requirements.

Quality assurance program plans (QAPPs) identify or reference the management processes, functional responsibilities, interfaces, and procedures for implementing HNF-MP-599, *Project Hanford Quality Assurance Program Description*, and project-specific quality assurance requirements.

14.3 QUALITY ASSURANCE PROGRAM ORGANIZATION

14.3.1 Program

The Project Hanford quality assurance program is composed of the Fluor Daniel Hanford quality assurance policy, HNF-MP-599, the quality assurance program implementation plan for nuclear facilities, Project Hanford SNF QAPPs, subcontractor QAPPs, and Fluor Daniel Hanford and subcontractor implementing procedures and work control documents. Figure 14-1 depicts the Project Hanford quality assurance program document hierarchy. The QAPPs, as shown in Figure 14-1, describe the respective quality assurance programs, which present criteria, requirements, responsibilities, interface relationships, and implementation documents for the SNF Project, including facilities and activities.

The QAPPs are maintained to ensure compliance with requirements specified in 10 CFR 830 120, DOE O 414 1, DOE/RW-0333P, 10 CFR 71, Subpart H, and 10 CFR 72, Subpart G, as implemented in HNF-MP-599.

The SNF Project organization that will be implementing the quality assurance program is described in Chapter 17.0, which includes a description of the organizational structures, responsibilities, authorities, and interfaces that meet the requirements of Section 1 of DOE/RW-0333P 10 CFR 72 142, and 10 CFR 830 120.

The SNF Project QAPP quality assurance policy statement includes the following:

- Compliance with the provisions of the QAPP is mandatory.
The SNF Project has committed to implement an effective quality assurance program that is in compliance with the applicable DOE and federal regulatory requirements as presented in Section 14.2.

- Quality assurance controls are written into SNF Project implementing procedures that are used to control work processes.
- Personnel shall be appropriately trained to the procedures they will use prior to the start of the work.
- No work subject to the requirements of the governing documents shall be started prior to the development, review, approval, and issuance of the appropriate work documents or procedures.
- Achievement of quality is a line responsibility, where each performer is accountable for the quality of the work assigned. Line organizations and line management are responsible for the effectiveness of the quality program for SNF Project facilities.

The QAPP establishes prime responsibility for the implementation of the quality program to the SNF Project management and the managers of those organizations that support the SNF Project facilities.

The degree of control over activities affecting the quality of items and services is commensurate with the importance to safety and, as necessary, to ensure conformance to the approved SNF Project facility design. SNF Project personnel have the authority to stop work in accordance with approved procedures for unsafe situations and to control further operation until the conditions that created the unsafe conditions are corrected. Stop work actions are immediately communicated to project management.

Suppliers and subcontractors providing services for the SNF Project are required to implement a quality assurance program consistent with the requirements specified in the SNF Project procurement documents. Quality assurance programs used by subcontractors providing safety-related supplies and services are submitted to the SNF Project for review and approval.

Operational readiness reviews are performed in accordance with approved procedures for determining compliance of the SNF Project facilities and activities with applicable requirements prior to startup or restart of the facility or process.

Compliance with the QAPP is achieved by implementing written procedures that are identified in the QAPP within a baseline requirements matrix, supplemental baseline implementation matrix, and/or quality assurance program index. The QAPP presents the overall structure of the documents hierarchy to meet the quality program requirements.
Application of project activity procedures is described in the QAPP. Procedures identified in a baseline implementation matrix are applied to all SNF Project elements unless exceptions are justified. A supplemental baseline implementation matrix identifies additional procedures to implement SNF subproject-specific requirements. Requirements have been identified that shall be applied to SSCs in specific SNF Project facilities that must also comply with DOE/RW-0333P, 10 CFR 71, Subpart H, and/or 10 CFR 72, Subpart G. Implementing procedures for these requirements are presented in a quality assurance program index. These procedures are used in addition to those identified in a baseline implementation matrix and the applicable procedures identified in a supplemental baseline requirements matrix for the particular SNF Project facility.

The SNF Project will ensure that the quality assurance program requirements will remain in effect during the lifetime of the SNF Project facilities through maintenance of the QAPP and implementing procedures.

14.3.2 Personnel Training and Qualification

Personnel performing activities affecting quality are trained and qualified to perform assigned tasks. This includes knowledge of the work processes, tools, equipment, and requirements. The training and qualification program provides for the development of personnel proficiency commensurate with the scope, complexity, and nature of an assigned activity. Training and indoctrination needs are identified and documented by management.

SNF Project management and managers of those organizations that support the SNF Project facilities are responsible for ensuring that their workers are sufficiently trained to perform assigned tasks in a manner that minimizes (1) risk to the worker performing the task, coworkers, and the public, (2) negative impacts to the environment, and (3) risk of damage to the facility and facility equipment. Training and qualifications for specified job functions are based on analysis of the specified duties and tasks associated with the functions. Job functional descriptions are developed that describe minimum requirements for education, experience, and when required, physical condition, and certification. Management is responsible to verify qualification of personnel before assigning them to do work. Inspection and nondestructive examination positions are certified in accordance with written procedures that are based on ASME NQA-1-1994, Quality Assurance Program Requirements for Nuclear Facilities, or other standards applicable to the work performed.

Qualification and training requirements are periodically reviewed to ensure that they continue to reflect the current systems, procedures, and policies applicable to each position. Continuing training is provided to ensure that job proficiency is maintained. Training is provided by instructors having the technical and instructional skills necessary to provide the training in an effective manner. Training program effectiveness and efficiency is determined by training management through feedback from instructors, students, students' managers, and periodic reviews. Improvements are addressed to increase proficiency based on existing or new requirements.
The SNF Project personnel training and qualifications process meets the requirements of Part 2, Section 2, "Personnel Training and Qualifications," of HNF-MP-599. Implementing procedures for personnel selection, indoctrination, training, and qualification are identified in the respective matrix associated with each SNF Project QAPP. Specific training and qualification requirements for personnel who perform or manage Office of Civilian Radioactive Waste Management-related design, scientific investigation, software development activities, and for personnel who verify or manage the verification of design, scientific investigation, software development activities or items, shall meet the requirements specified in DOE/RW-0333P, Section 2.2.12.

### 14.4 QUALITY IMPROVEMENT

The objective of quality improvement is to detect and correct problems adversely impacting quality and to continuously improve the quality of items and work processes. The basis of the approach to quality improvement is that (1) work activities can be planned, performed, assessed, and improved, and (2) lessons learned from this process can be used when planning subsequent activities to preclude recurrence of problems.

Under the quality improvement program, organizations have the authority to identify quality problems and to initiate, recommend, or provide solutions through designated channels. Conditions adverse to quality (e.g., failures, malfunctions, deficiencies, deviations, defective material and equipment, and nonconformances) are promptly identified to the appropriate level(s) of management and corrected. Management systems for quality improvement include problem identification, screening, evaluation, reporting and resolution, nonconformance identification, control and tracking, corrective action process including root cause analysis, trending, and tracking problems to closure.

Item characteristics, process implementation, and other quality-related information are reviewed and data analyzed to identify items, services, and processes needing improvement. This review and analysis includes an assessment of risk. Items, services, and processes that do not meet established quality requirements are identified, controlled, and corrected promptly in accordance with the significance of the problem and work. Verification of corrective action completion is also conducted.

A problem identification process is used to identify problems that are then evaluated for an unreviewed safety question and Price-Anderson Amendments Act of 1988 violation subject to Title 10, Code of Federal Regulations, Part 820, "Procedural Rules for DOE Nuclear Activities" (10 CFR 820). Correction includes identifying the cause of the problem, risk assessment, determining corrective action for the problem, problem closure, and initiating any additional corrective actions to preclude recurrence.

Periodic inspection of SSCs and equipment is performed to determine whether deterioration is taking place and to identify and address obsolescence that threatens personnel safety or facility preservation.
Performance indicators, item characteristics, process implementation, corrective actions assessments, and other quality-related information are reviewed and data analyzed to identify items, services, and processes needing improvement. When appropriate, these improvement evaluations include use of tools such as root cause analysis and lessons learned. Problem identification processes and nonconformances are periodically analyzed to identify quality trends.

The SNF Project quality improvement process meets the requirements of Part 2, Section 3, "Quality Improvement," of HNF-MP-599. Implementing procedures for quality improvement requirements are identified in the respective matrix associated with each SNF Project QAPP.

14.5 DOCUMENTS AND RECORDS

The documents and records program establishes requirements for control of the preparation, review, approval, issuance, use, and revision of documents that prescribe processes, specify requirements, or establish design. Controlled documents are reviewed for adequacy, completeness, and correctness prior to approval for use. Controlled document revisions are reviewed for adequacy, completeness, and correctness before approval by the organization that originally reviewed and approved the document, or by a designated alternate organization with comparable technical competence and capability. After approval, controlled documents are released to specified users to ensure the latest approved revisions are available to personnel for use at the location where the work is being performed. Compliance to these controlled documents is required. Document control is also discussed in Chapter 17.

Records are specified, prepared, reviewed, approved, maintained, and stored in accordance with approved procedures and instructions. Records retention requirements are specified in the procedures that govern generation of the records.

Records are to be legible, identifiable, accurate, complete, protected, and retrievable. Maintenance of records includes provisions for correction, replacement, retention, preservation, traceability, and accountability. Computer hardware and software used to maintain, index, store, or access records are maintained and controlled to ensure accountability, reproducibility, and protection from loss.

The SNF Project documents and records process meets the requirements of Part 2, Section 4, "Documents and Records," of HNF-MP-599. Implementing procedures for document and record requirements are identified in the respective matrix associated with each SNF Project QAPP.

14.6 QUALITY ASSURANCE PERFORMANCE

This section provides an overview of the SNF Project process to ensure that the performed work meets requirements. Work processes, design, procurement, installation and testing processes, handling, packaging, operation, maintenance, and interim storage are covered in Sections 14.6.1 through 14.6.4.
14.6.1 Work Processes

Work processes include, but are not limited to, activities involving design, analysis, fabrication, procurement, construction, handling, shipping, storing, cleaning, assembly, inspection, installation, and testing. Work on the SNF Project facilities is planned, authorized, and performed under controlled conditions in accordance with approved technical standards and administrative controls using approved procedures, instructions, plans, or other control documentation commensurate with the complexity and risk posed by the work to be performed. Such procedures, instructions, plans, or other control documents contain or reference all of the necessary administrative and technical requirements, including the sequence of actions and interactions, as required to ensure that activities are properly performed and meet acceptance criteria or other requirements.

Work process documents are developed, reviewed, and approved by personnel technically knowledgeable of the work. Work process documents are readily accessible to the worker. Supporting documentation for work activities is reviewed to ensure that the desired quality is being maintained and to identify areas for improvement. Use of such controls is to ensure that process parameters are controlled within defined limits and that specified environmental conditions are maintained. Work completion is documented and appropriate records maintained. Special processes (e.g., welding, heat treating, nondestructive testing) are performed by qualified subcontractors. Specific requirements are established in procurement documents.

Identification is maintained on items, or in documents traceable to them, in a manner that ensures identification is established and maintained to ensure control and maintenance of items for manufacture or receipt through delivery, installation, or use. Items may include hardware, samples, or data. This item identification and administrative control is used to prevent the use of incorrect or defective items and to maintain traceability for items, as required by specifications, codes, and standards. Handling, marking, storage, packaging, shipping, cleaning, and preservation of materials and other items is controlled to prevent damage, loss, or deterioration. Marking and labeling of items is maintained throughout the processes of packaging, shipping, handling, and storage. Status indicators will not be detrimental to the item.

Calibration and maintenance of equipment used for process monitoring and data collection are conducted in accordance with approved procedures. Computer software used in applications important to environmental, safety, health, and quality aspects shall be subject to appropriate controls throughout the software's life cycle.

The SNF Project work process meets the requirements of Part 2, Section 5, "Work Processes" of HNF-MP-599. Implementing procedures for the requirements are identified in the respective matrix associated with each SNF Project QAPP.

14.6.2 Design

Sound engineering and scientific principles, codes, standards, and practices for the assurance of technical quality are identified and incorporated into the design of new or
The design, including design changes, incorporates applicable design requirements, including design bases, functional and performance requirements, regulatory requirements, codes, standards, environmental conditions, and interfaces with new or existing items. DOE has established a regulatory policy (Grumbly 1995) that new SNF Project facilities achieve nuclear safety equivalency with U.S. Nuclear Regulatory Commission-licensed facilities.

The SNF Project design process meets the requirements of Part 2 Section 6 "Design," of HNF-MP-599 Implementing procedures for design are presented in the QAPP.

### 14.6.2.1 Design Inputs

Design, including design changes, incorporates design inputs consisting of controlled requirements, customer expectations, design assumptions, applicable design requirements, including design bases, functional and performance requirements, federal codes, DOE orders and standards, conceptual design criteria, national standards, specifications, drawings, environmental conditions, health and safety considerations, expected life cycle, reliability requirements, and interfaces with new or existing items. Design inputs are identified and documented and their selection reviewed and approved by the responsible design organization to ensure that sound engineering and/or scientific principles and appropriate standards are being used.

A design authority will be assigned for each SSC that will establish and document the design baseline(s) for each assigned SSC. The chief engineer will formally approve the assignment of each design authority. A design authority is responsible for:

- Maintaining the design baseline consistent with the physical configuration of the SSC(s) to ensure that the design baseline is technically correct and meets design requirements.
- Approving modifications to an existing design baseline, establishing an existing design baseline, or establishing a new baseline.
- Establishing design requirements and ensuring that design documents accurately reflect the design baseline.
- Informing affected organizations (e.g., Safety, Quality Assurance, Operations) of changes.

The engineering change notice process is described in Section 14.6.2.4 Computer software validation requirements are contained in Section 14.6.2.6.

### 14.6.2.2 Design Process

Appropriate quality standards are identified and documented as design input and their selection reviewed and approved. Design methods, materials, parts, equipment, and processes that are essential to the functions of the items affecting quality are selected and independently reviewed for suitability of application. Identified deviations from quality standards are controlled in accordance with procedures or instructions.
The final design of SNF Project facilities is related to the design bases input by documentation of sufficient detail to permit design verification, and by identification of assemblies or components that are part of the item being designed. Design documents are adequate to support facility design evolution, procurement, construction operation, and deactivation. The documentation references include the applicable codes, standards, and practices in addition to the applicable regulatory safety requirements.

Design interfaces are identified and controlled and design efforts coordinated among the participating organizations. Interface controls are documented and include the assignment of responsibility and the establishment of procedures among participating design organizations for the review, approval, release, distribution, and revision of documents involving design interfaces. Design information transmitted across organizational interfaces is documented and controlled. Transmittals identify the status of the design information or document provided and, where necessary, identify incomplete items that require further evaluation, review, or approval.

Use of commercial-grade items will be accomplished in accordance with documented processes using recognized nuclear industry standards.

14.6.2.3 Design Verification and Validation Design verification or validation of the adequacy of design products is accomplished by technically knowledgeable persons other than those who performed the work.

Design adequacy is verified in accordance with approved procedures by individual or interdisciplinary design reviews, alternate calculations to verify the correctness of the original design calculations, or qualification testing to demonstrate adequacy of performance under conditions that simulate the most adverse design conditions. The extent of verification is based on the complexity, risk, and uniqueness of the design.

Design verification is performed in a timely manner and identified design errors corrected prior to approval and implementation of the design. Design verification for the level of design activity accomplished is performed prior to release for procurement, manufacture, construction, or release to another organization for use in other design activities except in those cases where this timing cannot be met, such as when insufficient data exist. In cases where insufficient data exist, the unverified portion of the design is identified and controlled. In all cases, design verification is completed before relying upon the item to perform its function.

Engineering documents (e.g., drawings, specifications, design analyses, system descriptions, engineering studies, technical reports) are verified in accordance with approved procedures and instructions.

14.6.2.4 Design Changes Design changes, including field changes, modifications to operating facilities, and disposition of nonconforming items as "use-as-is" or "repair" are justified and subject to design control measures commensurate to those applied to the original design. These control measures will include assurance that the design analyses establishing the safety basis for the SSCs are still valid. Verification and review of design changes are performed to the same level as that of the original design. As-built changes are documented and verified. Design of
temporary modifications receives the same level of control as the original design for permanent modifications. The engineering change notice is the vehicle for development, review/approval, release, and incorporation of changes to engineering documents. The engineering change notice applies to all documents released into the Project Hanford Management Contract engineering release system, except vendor information. Engineering change notices are used to:

- Revise a released engineering document
- Document temporary configuration changes
- Void or supersede an approved and released engineering document
- Cancel or supersede an outstanding engineering change notice
- Add or remove a to-be-determined or hold-point item
- Add additional sheets to an existing released drawing or multiple-sheet drawing

14.6.2.5 Design Documentation and Records. The final design is related to the design input by documentation of sufficient detail to permit design verification and by identification of assemblies and/or components that are part of the item being designed. Design documentation is adequate to support facility design, construction, and operation. Design output documents include drawings, specifications, test and inspection plans, and maintenance requirements. As-built drawings and shop drawings are maintained to show actual plant configuration. The administrative process will clearly indicate responsibilities for design output document activities including marking-up and updating during construction and operation of SNF Project activities.

14.6.2.6 Computer Software. Computer programs used for design analysis are verified to show that they produce correct solutions for the encoded mathematical model within defined limits for each parameter employed. Computer programs also are verified to show that the encoded mathematical model produces a valid solution over the range of applications to the physical problem associated with the particular application. Computer programs are controlled to ensure that changes are documented and approved by appropriate personnel. Control requirements include development, acquisition, use, modification, and configuration management of software used in computer systems.

14.6.3 Procurement

Procurement of items and services by the SNF Project or by its subcontractors is documented and controlled to ensure that regulatory requirements, design, and other necessary quality requirements are included or referenced in the documents used for procurement of items and services and that such items and services perform as specified. As stated in Section 14.3.1, suppliers and subcontractors providing services for the SNF Project are required to implement a quality assurance program consistent with the requirements specified in the SNF Project procurement documents. Quality assurance programs are submitted to the SNF Project for review and approval. Procurement documents are controlled to ensure that applicable requirements, design bases, test and inspection requirements, acceptance criteria, and other requirements necessary to ensure adequate quality are included or referenced in documents for procurement of items and services. Critical parameters and requirements are specified including...
submittal, product-related documentation, nonconformance requirements, administrative documentation, personnel or materials qualifications, tests, inspections, and reviews

A graded approach is used when establishing the stringency of procurement requirements to ensure they are commensurate with the importance of the purchased item or service to the facility or process. Applicable quality assurance requirements are applied to suppliers through the procurement documents issued to these suppliers. Changes also are communicated to suppliers in the procurement documentation. Such changes are evaluated in the same manner and use the same criteria as the original documents. The procurement documents also specify the right of access to suppliers' (including sub-tier suppliers') facilities for surveillance of work activities, inspection of facilities and programs, review of plans and program reports, processing of change information, and review of disposition of nonconformances.

Controls are established to ensure that purchased items and services conform to the procurement documents. These controls include provisions for source evaluation and selection, objective evidence of inspection at the contractor or subcontractor source, examination of items or services upon delivery and assessments. Procurement documents will require that deficiencies discovered by suppliers that involve safety-class, safety-significant, or certain general-service items and/or services are reported to the SNF Project Procurement organization. Nonconformance procedures are in place for disposition of items or services that do not meet procurement requirements.

Documentary evidence that an item conforms to code, regulation, or contract procurement requirements is completed before installation or use of the item. Methods established for the acceptance of an item furnished by suppliers may consist of one or more of the following:

- Supplier certification and release (Certificate of Conformance)
- Source verification or inspection
- Receiving inspection
- Acceptance testing
- Post-installation testing

Supplier-generated documents are controlled in accordance with the requirements in Section 14.5.

Commercial-grade items are used when practical. Requirements for commercial-grade items include specification of critical characteristics, acceptance methods specified to satisfy critical characteristics, and procurement documents identifying commercial-grade items that are to be dedicated.

An assessment to determine the effectiveness of the control of quality by the supplier is conducted, evaluated, and documented before selection and periodically during supplier performance at intervals consistent with the importance, complexity, and quantity of the items or
services The evaluation and selection of procurement sources is based on specified criteria. The evaluation will include one or more of the following:

- Evaluation of the supplier's quality history of providing an identical or similar product that performs satisfactorily in actual use.
- Review of the supplier's current qualitative and quantitative information that can be objectively evaluated.
- Direct evaluation of the supplier's facilities, personnel, and quality assurance program implementation to determine the technical and quality capability of that supplier.

Assurance is obtained that approved suppliers can continue to provide acceptable items and services based on a documented evaluation of their past performance. Suppliers are either re-evaluated and retained on the basis of continued satisfactory performance or removed from a list of acceptable suppliers. This performance history evaluation involves the following:

- Evaluations of the supplier's nonconformance report history relative to received items or services.
- Communications with the purchasing organization to determine whether any contractual problems have been encountered.
- Communications with the supplier to determine whether any changes have occurred to their quality assurance program since their initial acceptance.

The SNF Project procurement process meets the requirements of Part 2, Section 7, "Procurement," of HNF-MP-599. Implementing procedures for procurement are identified in the respective matrix associated with each SNF Project QAPP.

14.6.4 Inspection and Acceptance Testing

Inspection and acceptance testing of specified items, services, and processes are performed in accordance with established acceptance and performance criteria. Inspection and acceptance criteria are derived from engineering design documents, supplier information, construction procedures, and maintenance procedures. Inspection, surveillance, and testing of items, services, processes, operation, and interim storage that have the potential to affect quality during procurement, construction, repair, modification, maintenance, and installation are subject to these requirements on a graded approach based on safety classification.

Hold points (e.g., items or activities where inspection is mandatory), witness points, verification points, methods, acceptance criteria, checklists, and other inspection planning documents are established, documented, and implemented to ensure required inspections are performed. Test requirements and acceptance criteria are identified, documented, and approved.
Test results are documented and their conformance with acceptance criteria evaluated by a responsible authority to ensure that test requirements have been satisfied.

The inspection and testing process establishes the system by which the inspection and testing status of items is controlled to ensure that items that have not passed the required inspections and tests are not inadvertently installed, used, or operated. Status of inspection and test activities is identified either on the item by markings such as stamps, tags, labels, or routing cards, or in documents traceable to the items, including heat number, part number, serial number, or other appropriate means throughout fabrication, installation, and use.

Controls provide for the identification of items that have satisfactorily passed required inspections and tests where necessary to preclude inadvertent bypassing of the inspection and testing. Controls also identify the operating status of SSCs, such as tagging valves and switches to prevent inadvertent operation.

Inspections and tests are performed in accordance with approved procedures, instructions, or inspection plans by qualified personnel to demonstrate that the SSCs will perform satisfactorily in service. This documentation contains the following information:

- References to applicable documents such as drawings, specifications, and procedures
- Type of inspection and testing to be performed
- Mandatory hold points, when required
- Characteristics to be inspected and tested
- Qualification of individuals or groups responsible for performing the inspection and testing
- Acceptance and rejection criteria (explicit or by reference) obtained from specifications, drawings, supplier instructions, and standards
- Suitable environmental conditions
- Description of the inspection and testing method and equipment to be used, or reference to an appropriate procedure (including adequate testing instrumentation, equipment, calibration requirements, and environmental conditions)
- Required safety measures
- Frequency of inspection, testing, or sampling plan
- Results of inspections and tests
Inspection and test results are evaluated and verified by authorized personnel to document that all requirements have been satisfied. Records will identify the item examined, date of examination, examiner or data recorder, results, observations, acceptability (ensuring that all prerequisites for the given test are met), and action taken concerning any deviations noted.

Measuring and testing equipment used for inspections and tests is calibrated, maintained, and verified to be of the required precision and accuracy for use by personnel performing inspections and tests. Where possible, instruments will have calibration certifications traceable to nationally recognized standards. Instruments are calibrated at specified intervals, before and after use, or just prior to use, as determined by required accuracy, intended use, frequency of use, stability characteristics, and other conditions affecting performance. Instruments are labeled, tagged, or otherwise controlled to indicate calibration status and to ensure traceability to calibration test data. Instruments found out-of-calibration or out-of-tolerance are tagged or segregated and not used until they are successfully recalibrated. The acceptability of items or processes measured, inspected, or tested with out-of-tolerance instruments is evaluated and measurements and tests repeated as required.

The SNF Project inspection and acceptance testing process meets the requirements of Part 2, Section 8, “Inspection and Acceptance Testing” of HNF-MP-599. Implementing procedures for inspection and acceptance testing are identified in the respective matrix associated with each SNF Project QAPP.

14.6.5 Assessments

This section briefly describes performance of management self-assessments and independent assessments to determine the adequacy of the quality program. The independent assessments are performed by Fluor Daniel Hanford, Incorporated, as described in Chapter 17.

14.6.5.1 Management Assessments

Management assessments are planned, scheduled, and conducted by organization managers to regularly assess how well the organization is meeting its customer’s requirements and expectations.

Management self-assessments also include the following activities:

- Processes including planning, organizational interfaces, use of performance indicators, training and qualifications, supervisory oversight, and support
- Routinely observing personnel performing operating activities and/or interviewing workers, reviewing documentation, and conducting drills or exercises
- Assessing facility performance indicators and other operational information such as reportable occurrences, for trends in improving or deteriorating conditions
- Measuring performance based on objective standards, clearly defined goals, review, and feedback processes
Any barriers that are hindering the accomplishment of management objectives are identified, response actions documented, and corrective actions implemented.

The SNF Project management assessment process meets the requirements of Part 2, Section 9, "Management Assessments," of HNF-MP-599, and SNF Project administrative procedures. Implementing procedures for management assessments are identified in the respective matrix associated with each SNF Project QAPP.

14.6.5.2 Independent Assessments The independent assessment program (1) provides for the measurement of item and service quality, requirements compliance, and work performance and (2) promotes improvement. The assessment process is conducted using written procedures and/or checklists and incorporates a performance-based approach with emphasis on the results of work processes and compliance with requirements. Independent assessments are conducted by Fluor Daniel Hanford, Incorporated, on SNF Project activities that most directly relate to final objectives and emphasize safety, reliability, and product performance.

The type of independent assessment performed and the frequency with which an assessment is performed are based on the status, complexity, and importance of the activity or process being assessed, and the past performance of the activity or process being assessed. Independent assessments may include methods such as inspections, peer and technical reviews, audits, surveillance, and customer interviews. These independent assessments are conducted by technically qualified staff, knowledgeable in the activity or process being assessed, who have sufficient authority and autonomy from the line organizations to carry out their responsibilities. An independent assessment will include:

- Work performance and process effectiveness
- Abnormal performance and potential problems
- Improvement opportunities
- Results documentation
- Satisfactory resolution of reported problems verification

The independent assessment activity verifies by way of checking, assessing, and inspection that activities affecting the functions important to safety have been correctly performed. Persons and organizations performing these quality assurance functions report to a management level high enough to ensure that the required authority and organizational autonomy are provided, including sufficient independence from cost and schedule considerations when cost and schedule may pose conflicts with safety considerations.

Independent assessment strengths and weaknesses are documented and presented to the management of organizations responsible for performance of the subject activities or processes. Areas of weakness are then analyzed to formulate corrective actions to promote improvements. Actions are tracked and the adequacy of corrective actions, including those taken to minimize or prevent recurrence, are verified. Lessons learned are communicated to other organizations with similar activities or concerns. Follow-up action, including a subsequent assessment of the activity or process, is initiated if appropriate to determine effectiveness of the corrective action.
Facility-independent assessments also will be performed by the Facility Evaluation group using the Facility Evaluation Board. Facility Evaluation Board members are not associated with the activity or process being assessed. Responsibilities of the Facility Evaluation Board are as follows:

- Establish, implement, and maintain an effective independent oversight program to assess operations and management effectiveness across the organization in meeting established environment, safety, health, and quality assurance requirements, applicable regulations, and sound management practices.
- Provide facility managers and senior management with clear, objective, and well-documented assessments of strengths and weaknesses that affect performance to approved standards.
- Ensure that independent assessments are conducted in programmatic or functional areas of environment, safety, health, and quality assurance when required by regulation or contract requirements.

The independent assessment process as performed by Fluor Daniel Hanford, Incorporated, for the SNF Project meets the requirements of Part 2, Section 10, "Independent Assessments," of HNF-MP-599. Implementing procedures for the independent assessment process are identified in the respective matrix associated with each SNF Project QAPP.

15.0 EMERGENCY PREPAREDNESS PROGRAM

15.1 INTRODUCTION

This chapter describes the philosophy, objectives, and organization of the Spent Nuclear Fuel (SNF) Project Emergency Preparedness Program (EPP) for response to emergencies at the SNF Project facilities. The SNF Project EPP requires the Hanford Site Emergency Response Organization (ERO) to respond to an emergency in a timely, efficient, and effective manner. The SNF Project EPP implements the requirements listed in Section 15.2 to ensure the safety and health of the workers, the public, and the environment in the event of an emergency. The EPP applies to all operations, facilities, personnel, programs, procedures, and workers associated with the SNF Project.

This chapter contains the following information:

- SNF Project commitments to meet the emergency preparedness requirements of Federal, state, and U.S. Department of Energy (DOE) rules, orders, regulations, standards, and codes listed in Section 15.2.

- Knowledge of the EPP and subsequent preparedness of the SNF Project in the event an incident should occur.

- Confirmation that the emergency preparedness readiness provided by the SNF Project EPP is appropriate and prudent and, through use of a graded approach, ensures overall consistency with the spectrum of hazards, accidents, and consequences addressed in the facility annexes to the SNF Project Final Safety Analysis Report (FSAR). The increased level of response, based on the severity of the events as called out by each of the successively higher emergency classification levels, represents a graded response embodied in the SNF Project emergency planning.

In addition, this chapter describes the integration of the EPP with DOE/RL-94-02, Hanford Emergency Management Plan, that links to the offsite emergency planning efforts. This chapter describes the features of the SNF Project EPP, the SNF Project building emergency plans (BEPs), and DOE/RL-94-02 as they relate to the SNF Project. The development of this chapter has been coordinated with the development of Chapters 10, 20, 30, 120, and 170.

15.2 REQUIREMENTS

The requirements that form the basis for the EPP are found in HNF-SD-SNF-RD-001, Spent Nuclear Fuel Project Standards/Requirements Identification Document. The specific requirements applicable to this chapter include.
15.3 SCOPE OF EMERGENCY PREPAREDNESS

Potential SNF Project emergencies span the spectrum of identified emergencies for SNF Project facilities, from worker injuries to emergencies with potential public impact. Facility events include fires and/or explosions, radioactive material releases, and hazardous material releases. Natural events include seismic events, high winds, range fires, floods, tornadoes, and aircraft crashes. Potential hazardous events that could affect SNF Project facilities are presented in Chapter 30 of the applicable facility FSAR Annex. Security events including bomb and/or explosive device threats, sabotage incidents, and hostage and/or armed intruder situations will be responded to as described in Sections 15.4.1.2 and 15.4.1.2.2.
This chapter applies to all SNF Project operations, facilities, and personnel (including subcontractors, vendors, visitors, and any noncontractor tenants).

The EPP addresses individual and organizational graded responses to the spectrum of potential SNF Project emergencies, including responses to accidents with very low occurrence frequencies. Planned responses documented in the EPP and the BEPs provide the response actions for these emergencies.

This chapter links the SNF Project EPP to DOE/RL-94-02, which provides the link to subsequent Federal, state, and local organization EPPs. Integration of these programs links potential onsite events with onsite and offsite impacts. This integration assists in mitigation and recovery and provides for protection of the health and safety of the workers, the public, and the environment (see Figure 15-1).

### 15.4 EMERGENCY PREPAREDNESS PLANNING

SNF Project emergency preparedness planning includes identification of emergency organizations, assessment actions, emergency classification notification processes, emergency facilities and equipment, protective actions, training, drills, exercises, and recovery actions. As required by Section 5.3 of the standards/requirements identification document (S/RID) (HNF-SD-SNF-RD-001), development and maintenance of emergency plans (i.e., BEPs) and emergency response procedures will be established for emergency preparedness planning.

The SNF Project facility-specific documentation will address the following topics:

1. Preemergency planning and coordination with onsite parties
2. Personnel roles, lines of authority, and communication
3. Emergency recognition and prevention
4. Safety-distances and places of refuge
5. Site security and control
6. Evacuation routes and procedures
7. Decontamination procedures
8. Emergency medical treatment and first aid
9. Emergency alerting and response procedures
10. Critique of response and follow-up
11. Protective equipment and emergency equipment

Section 5.3 of the S/RID also requires emergency response procedures and other information for handling emergency incidents, including the following:

1. Data on site topography, layout, and prevailing weather conditions
2. Procedures for reporting incidents to local, state, and Federal governmental agencies
3 Procedures for cleanup of spills or accidental releases

4 The emergency response plan shall be compatible and integrated with the disaster, fire, and/or emergency response plans of local, state, and Federal agencies

5 The emergency response plan shall be rehearsed regularly as part of the overall training program for site operations

6 The site emergency response plan shall be reviewed periodically and, as necessary, be amended to keep it current with new or changing site conditions or information

7 An employee alarm system shall be installed in accordance with Federal and state alarm requirements to notify employees of an emergency situation to stop work activities if necessary, and to begin emergency procedures

Facility-specific emergency planning requirements are implemented through administration of the SNF Project EPP. The accident categories derived from each of the SNF Project facility emergency planning hazards assessments drive the planning process. Input for the specific facility emergency planning requirements is obtained from Chapter 30 of the applicable facility FSAR Annex. As modifications to SNF Project facilities are planned during design, construction, and operation, the hazards surveys and hazards assessments will be reevaluated to reflect changes. Subsequent changes to the SNF Project EPP may be required.

Hanford Site-specific emergency planning requirements are implemented through DOE/RL-94-02, which applies to all Hanford Site employees and facilities. Hazardous material emergencies are grouped into one of three classes (Alert, Site Area Emergency, or General Emergency) according to magnitude or severity. This method of classification promotes timely and effective response by triggering planned response actions appropriate to all events of a given class. The increased level of response, based on the severity of the event, as called out by each of the successively higher emergency classification levels, constitutes a graded approach.

15.4.1 Emergency Response Organization

The mission of the Hanford Site ERO is to ensure that, in the event of an emergency, actions will be taken to prevent or minimize impacts to workers, the public, facilities, and the environment. As stated in requirements of Sections 5.1 and 5.2 of the S/RID, the Hanford Site ERO is structured and staffed with trained personnel, including designated alternates, to enable the most timely and effective response possible while meeting the requirements set forth in DOE O 151.1, WAC 173-303 and other applicable Federal and state regulations identified in the S/RID, including Hazardous Waste Operations and Emergency Response, Occupational Safety and Health Administration and National Fire Protection Association (NFPA).
15.4.1.1 Organization Structure  Emergency response on the Hanford Site will be performed in accordance with the Incident Command System, which is an integrated emergency management system with clearly defined responsibilities and communication pathways that allows predesignated trained individuals to jointly determine and implement incident mitigation strategies. While the U.S. Department of Energy, Richland Operations Office (RL) maintains the option to assume overall management, direction, and control of any Hanford Site emergency, the Hanford Site ERO has been formed to allow the Hanford Site contractors to continue their management and operational roles in the event of an emergency. Specific DOE Office of River Protection (ORP) responsibilities within the Hanford Site ERO are presently being defined as part of the ongoing RL/ORP interface clarification discussions.

The Hanford Site ERO has two components. The first component, the Incident Command Organization, consists of the SNF Project Facility ERO and Site contractor emergency response personnel (i.e., Hanford Fire Department, Hanford Patrol). The Facility ERO has responsibility for implementing emergency response activities at the SNF Project facility involved in the event. The site contractor emergency personnel have responsibility for on-scene mitigation of the event.

The second component, the DOE Hanford Emergency Operations Center (EOC), has the responsibility to monitor and provide support for onsite response, assist with issue resolution, assess the offsite impacts, and interface with offsite agencies and the public. The Incident Command System at the Hanford Site is shown in Figure 15-2, the emergency communication chain is shown in Figure 15-3.

A graded approach is used to respond to an event depending upon the nature of the facility and/or the severity of the event. There are a number of events to which the SNF Project facilities have to be ready to respond, including hazardous material releases, spills, operational events, fires, natural phenomena, and security events.

15.4.1.2 Incident Command Organization  As stated above, the Incident Command Organization is composed of two main groups: the Facility ERO and Site contractor emergency response personnel (i.e., Hanford Fire Department and Hanford Patrol). The Building Emergency Director (BED) is responsible for implementing facility response procedures (e.g., protective actions, event classification, notification) until arrival of the Hanford Fire Department or Hanford Patrol Incident Commander (IC). The IC is responsible for the health and safety of all personnel at the event scene.

Upon arrival of the Hanford Fire Department or Hanford Patrol IC, the Facility ERO becomes part of a consolidated Incident Command Organization. The senior Hanford Fire Department official becomes the IC unless the event is primarily a security event in which case the Hanford Patrol senior officer becomes the IC. If the BED is not present at the event facility at the start of the event, the IC will perform the duties of the BED in addition to the IC duties pending arrival of the BED. However, in accordance with DOE/RL-94-02, the BED (primary or alternate) will be on the facility premises in control of the work during any work with hazardous operations that could result in generating an Alert or higher emergency. On-call BEDs will be used only for facilities where hazardous materials are in storage and stable and the only work...
being performed is that of surveillance. SNF Project Operations will maintain a listing of on-call BEDs assigned to non-hazardous and hazardous facilities with work and home telephone numbers at the Occurrence Notification Center (ONC).

The BED retains responsibility for direct configuration control over SNF Project facility systems and components, the IC controls the overall management strategy associated with the incident and ensures that all functional areas are staffed and working effectively to mitigate the incident. At the site level, the Hanford Patrol security services provides services such as activation of crash alarm telephone systems and sirens, coordination of the movement of emergency personnel through security gates, evacuation assistance, and barricade establishment where needed. Additional law enforcement is available from federal and local agencies at the request of RL/ORP.

The Incident Command Organization has the authority to commit resources (equipment and personnel) needed to carry out the emergency response and is responsible for being thoroughly familiar with applicable plans and procedures, operations and activities at the facility, location and properties of all wastes handled, location of all records within the facility, and the layout of the facility. The Incident Command Organization will be staffed by pre-appointed and trained personnel. Initial, annual, and refresher training of the Incident Command Organization personnel on their respective roles, responsibilities, and authorities is presented in Section 15.4.7. Table 15-1 provides a summary of all Incident Command Organization functions and the staffing responsibilities for each function.

FDH = Fluor Daniel Hanford  
ICP = Incident Command Post

The Hanford Fire Department senior officer will be the IC for events involving fire, medical, hazardous materials, or rescue and also fill the role of the senior emergency response official. The Incident Command Organization, however, may be staffed entirely with SNF Project personnel for less significant events as determined by the BED. Events that might not require assistance from outside the SNF Project facility would include small releases of known substances when mitigation can be accomplished by trained on-scene personnel, minor first aid cases, non-injury contamination incidents, and non-emergency plant responses. In this instance, the BED coordinates emergency response efforts at the scene including oversight of mitigation efforts, use of appropriate personal protective equipment, facility protective actions, and notifications.

An Incident Command Post (ICP) will be established in a safe location near the event scene where emergency responders from different organizations may collocate to coordinate actions. Organizations supporting the ICP retain responsibility for their technical expertise and provide facility expertise to the ICP.

15 4 1 2 1 Spent Nuclear Fuel Project Emergency Response Organization Initial direction and control of emergency response at an SNF Project facility is the responsibility of the Facility ERO. The BED directs the Facility ERO who will assist in the protection of personnel property, and the environment. SNF Project senior management will designate the BEDs. This organization (Facility ERO) will direct appropriate emergency response actions at the event scene prior to arrival of the IC, including effective coordination with the DOE Hanford EOC.

Collective responsibilities of SNF Project senior management, BED and other Facility ERO members for hazardous facilities include the following, as applicable:

1. Assigning and assuring the training of the Facility ERO (BEDs, personnel accountability aides, staging area managers and other facility personnel as appropriate) to support the Hanford Fire Department as the primary hazardous materials emergency response agency.

2. Maintaining, reviewing, revising, and implementing the BEP and applicable facility-specific emergency response procedures.
Ensuring that facility personnel are aware of hazards in and around the SNF Project

Ensuring that facility personnel are trained to respond to emergencies

Determining when an event has occurred or a condition exists that requires appropriate emergency event classification in accordance with DOE/RL-94-02 and DOE O 232 1A

Assisting in emergency classification and emergency notification of such classification within established regulatory time limits

Contacting the Patrol Operations Center (POC) to implement predetermined onsite protective actions and provide initial emergency and classification information in accordance with established procedures

Reporting events or conditions in accordance with applicable federal and state regulations

Assisting in alerting employees of an emergency situation

Activating internal facility alarms or communications systems, where applicable, to implement actions to protect workers within their respective geographic area of responsibility as defined in the BEP or procedures

Assisting in the safe evacuation of the incident scene hazard area, to include emergency lifesaving rescue if required

Providing immediate first-aid if required

Placing operating systems or controls in a safe configuration

Providing event status information to the DOE Hanford EOC

Providing personnel to staff the DOE Hanford EOC including senior management staff and technical representation

Assessing the potential or actual onsite and offsite consequences of the emergency

Implementing or supporting the implementation of protective actions for the general population to include roadblocks and building sweeps

Providing assistance to the Hanford Fire Department to include meeting and directing responders to the event scene, providing safe routes of travel, and providing immediate and constant interface, coordination, and information as the emergency situation requires
Assisting the IC, as necessary, in the mitigation of emergencies within the assigned building by

- Identifying the character, exact source, amount, and extent of any released materials
- Assessing possible hazards to human health and the environment that may result from a release, fire, or explosion
- Taking reasonable measures (e.g., stopping processes and operations, collecting and containing released waste, removing or isolating containers) necessary to ensure that fires, explosions, and releases do not occur, recur, or spread to other dangerous waste
- Monitoring for leaks, pressure buildup, gas generation, or ruptures in valves, pipes, or other equipment, as appropriate

Ensuring that building occupants take appropriate protective actions in response to events occurring in other onsite geographic areas or adjacent facilities

Establishing an initial ICP and assigning other Incident Command Organization functions in accordance with established procedures to provide effective control at the event scene

Serving as emergency response team members in support of the Hanford Fire Department for entry into the incident scene hazard area for mitigation where personnel protective equipment requirements do not specify Level A or Level B dermal protection

Providing radiological monitoring and assessment for emergency response

Providing support for chemical and/or radiological decontamination

Ensuring proper cleanup, transportation, and storage of hazardous materials generated as a result of the event

Providing funding for performance of emergency response and recovery duties and replacement of supplies used by other contractors for event response

Responsibilities of the Facility ERO for administrative and non-hazardous facilities are contained in Section 2 2 1 1 of DOE/RL-94-02. As required by the S/RID (HNF-SD-SNF-RD-001), the positions and responsibilities of the Facility ERO including alternates, will be contained in the facility-specific BEP.
In addition to the BED, the Facility ERO will consist of trained support staff (e.g., Health Physics). In addition, personnel accountability aides are responsible for facilitating the implementation of protective actions (evacuation or take cover) and for facilitating the accountability of personnel after the protective actions have been implemented. Staging area managers are responsible for coordinating and conducting activities at the staging area. Personnel accountability aides assist the staging area managers by ensuring that personnel and visitors are properly evacuated from designated staging areas to a safe location. The Facility ERO supports actions requested by the IC.

15 4 1 2 2 Site Contractor Emergency Response Personnel

15 4 1 2 2 1 Hanford Fire Department As stated in Section 15 4 1 2, the Hanford Fire Department is the designated hazardous material incident command agency responsible for control of all hazardous material and chemical or biological incidents on the Hanford Site, including fire control, releases of hazardous materials, and personnel rescue response activities associated with the incident. The Hanford Fire Department provides hazardous materials first responders as defined in 29 CFR 1910 120(q)(6)(i)-(v) and NFPA 472, and a qualified Safety Officer for all emergency response activities.

The Hanford Fire Department also monitors facility fire alarm systems and coordinates and provides emergency medical services on the Hanford Site as a 24-hour operational facility and dispatch center.

15 4 1 2 2 2 Hanford Patrol The Hanford Patrol serves as the security agency for the Hanford Site and provides services such as coordinating the movement of emergency responders through security gates, assisting evacuation, and establishing barricades when needed. As stated in Section 15 4 1 2, the Hanford Patrol is the IC for security emergencies.

The POC, a 24-hour operational facility, is responsible for emergency functions such as the following:

- Acting as the single point-of-contact to initiate emergency response by
  - Operating the Site's enhanced 911 system
  - Notifying the BED (when not on the premises)
  - Requesting response from the Hanford Fire Department
  - Contacting Hanford Environmental Health Foundation (HEHF) on-call provider for medical incidents involving radiological or chemical exposures
  - Notifying other appropriate on-call personnel
  - Activating or requesting activation of appropriate alarm signals

November 1999
Providing information of onsite medical emergencies to appropriate contractor organizations

- Activating the ONC conference bridge upon notification of a declared emergency and implementing onsite protective actions by activating or requiring activation of warning sirens and crash alarm telephone systems

- Receiving emergency response telephone calls during offsite shipments of RL/ORP-owned hazardous materials

15 4 1 2 3 Hanford Environmental Health Foundation Services provided by HEHF in an emergency include the following

- Minor emergency medical care and consultation

- Medical support for chemical and radiologically contaminated patients

- Medical staffing and operation of the Emergency Decontamination Facility (EDF) and Health Care Centers

- Hostage negotiation and critical stress debriefing support

- Coordination with and support to community medical services

- Senior management and technical staff support to the DOE Hanford EOC

15 4 1 2 3 Other Emergency Response Support Personnel Some emergency situations may require facility or site support personnel for emergency response at the event scene that are not assigned permanent positions within the Hanford Site ERO These emergency response support personnel — termed either as Skilled Support Personnel or Specialist Employees — are not trained to operate within the Hanford Incident Command System and will be used for specific tasks defined in the following subsections

15 4 1 2 3 1 Skilled Support Personnel Personnel needed to operate specific support equipment, including those within the incident scene hazard area but who are not addressed in specific emergency response procedures, may be designated as Skilled Support Personnel Such personnel receive a briefing prior to commencing any work

15 4 1 2 3 2 Specialist Employees Safety professionals and environmental specialists who provide technical advice within their field of expertise but who are not addressed in specific emergency response procedures, may be designated as Specialist Employees Such personnel provide expertise and advise to the IC when requested, however they may not enter the incident scene hazard area
Department of Energy Hanford Emergency Operations Center

The DOE Hanford EOC is an emergency response facility maintained by RL/ORP for the purpose of providing an area where personnel may convene during emergency conditions to provide essential response functions. These functions include public information, offsite protective action recommendations (PARs), field monitoring and sampling, hazards assessments, oversight of onsite mitigative activities, and oversight of onsite protective actions.

The DOE Hanford EOC is activated upon declaration of an Alert or higher emergency. The DOE Hanford EOC also may be fully or partially activated under the following circumstances:

- As directed by the RL/ORP manager or designee, when an event occurs that is not classified as an Alert or higher emergency but where action to provide monitoring assistance to the event scene or other agencies is requested, such events may include the following:
  - Hanford Site emergency conditions that potentially involve significant onsite or offsite consequences
  - Security events
  - Natural disasters (e.g., earthquake, tornado) that could or do result in significant onsite or offsite public or environmental impact
  - Requests from other government agencies for support of regional emergencies
  - Threats or acts of terrorism, or when a national emergency is declared by the President of the United States or the United States Congress

- As directed by the Radiological Assistance Program team leader to support a Radiological Assistance Program response

- In response to non-DOE emergencies that affect the Hanford Site

- In response to transportation emergency preparedness events involving the offsite shipment of DOE-owned hazardous materials

The DOE Hanford EOC is made up of several organizations that are responsible for implementing defined emergency response tasks. These organizational areas are defined in the following subsections. Detailed procedures for the activation, staffing, and operation of the DOE Hanford EOC are contained in DOE-0223, *U.S. Department of Energy Richland Operations Office Emergency Plan Implementing Procedures*. Any emergency procedures applicable to SNF Project facilities that interface with the DOE Hanford EOC procedures are included in the facility-specific procedure manual.
15 4 1 3 1 Policy Team  The primary functions of the Policy Team are the oversight of onsite activities, approval and communication of offsite PARs, approval of reclassification recommendations, oversight of public information activities, and coordination with offsite agencies. The Policy Team is staffed by the RL/ORP Emergency Manager, Public Information Director, Emergency Preparedness Advisor, Offsite Interface Coordinator, DOE Headquarters Liaison, and the responding state and county representatives.

During security events, RL is responsible for all decisions that address mitigation of the security event. This involves direction and control of Hanford Site security and patrol forces and coordination of facility response. However, the Federal Bureau of Investigation may exercise the option to take command of security events involving the violation of the Atomic Energy Act of 1954 or other federal statutes. Associated response by site contractor personnel for personnel and operational safety rests with the IC and the BED.

The Policy Team performs the following duties:

- Overview of onsite response and mitigation actions and assistance to the SNF Project staff.
- Offsite notifications and PARs to state, local, and Federal agencies and continuous updates to the state and counties about conditions.
- Notification to the DOE-Headquarters (DOE-HQ) if facility operations are shut down as a part of the protective action response.
- Direction and control, as appropriate, during a security incident.
- Reclassification or termination of the emergency.
- Direction of the activities of the Joint Information Center (JIC) in providing timely and accurate release of information to the public and media, including approval of all RL/ORP news releases.
- Requests for additional DOE emergency response assets to the Regional Response Coordinator as needed.
- Liaisons to offsite emergency centers and responding DOE emergency response assets.
- Representative to DOE-HQ if requested.
- Designation of a recovery organization.

15 4 1 3 2 Joint Information Center  The primary function of the JIC is the dissemination of accurate and timely information to the public and employees about RL/ORP activities during declared emergencies. The JIC is staffed by RL/ORP, contractor state and county representatives.
communication professionals responsible for coordinating the release of information to the public and media.

Press releases are reviewed for technical accuracy and security sensitivities prior to approval by the RL Public Information Director. Upon approval, the press releases are sent to the JIC for dissemination.

The JIC provides a single location where RL/ORP and Hanford Site contractors can coordinate the release of information with other federal agencies, state, and local jurisdictions. The JIC operates under the direction of the RL Public Information Director and is staffed by RL/ORP and Site contractor personnel. Provisions will be made at the JIC for representatives from the states of Washington and Oregon, plume emergency planning zone (EPZ) counties, and other federal agencies that may be involved in the emergency response.

The following functions are performed at the JIC:

- Preparing and coordinating information released to the public and media
- Answering questions of the public and media
- Rumor control

**15 4 1 3 3 Site Management Team** The primary functions of the Site Management Team (SMT) are to provide support to the Incident Command Organization by providing additional resources not easily obtained by the IC, tracking the status of onsite protective actions and directing implementation of additional onsite protective actions as required, and providing communications support. The SMT also is responsible for hazards assessments activities, tracking personnel medical issues, developing additional offsite PARs, and record keeping. The SMT is made up of four support organizations that are responsible for implementing defined emergency response tasks. These organizations are defined below:

**15 4 1 3 3 1 Executive Team and Support Staff** The Site Emergency Director (SED) is responsible for the coordination of all SMT activities. In this role, the SED is responsible for the activities of the Event Support Coordinator, EOC Operations Manager, and the Consequence Assessment Director. Because RL has an operational function over Hanford Site security forces, the Security Director is responsible for the activities of the Security Operations Coordinator. The Security Director will receive information from and provide direction to the security forces. The Security Director will communicate planned actions of security forces to the SED and Safety Oversight Director to ensure all safety and security issues are addressed and coordinated. The SED, in conjunction with the Security Director and Safety Oversight Director, is responsible for periodically providing status information to the RL/ORP Emergency Manager and the Policy Team. The contractor representative and SMT Emergency Preparedness Advisor provide support to the SED. In this role, the SED reports to the RL/ORP Emergency Manager.
15 4 1 3 3 2 Security and Event Support  As part of the SMT staff, the Security Operations Coordinator's primary functions are security operations, which include interface with local law enforcement agencies, coordination with the Federal Bureau of Investigation, and oversight of onsite patrol activities. In this role, the Security Operation Coordinator reports directly to the Security Director.

The Event Support Coordinator is responsible for event support activities, which include Hanford Site support services, technical support, communications with the event scene, and coordination with the EDF and other medical assessment activities. In this role, the event support coordinator reports directly to the SED.

15 4 1 3 3 3 Unified Dose Assessment Center  As part of the SMT, the primary Unified Dose Assessment Center (UDAC) functions are monitoring and evaluating existing emergency conditions to develop additional PARs. The UDAC is responsible for field team activities which include plume tracking, monitoring, and sampling.

Representatives from the states of Washington and Oregon participate in the development of recommendations and provide direction for offsite environmental monitoring. The UDAC is operated by Hanford Site contractor personnel with knowledge in the technical areas of meteorology, toxicology, industrial hygiene, and health physics. The Consequence Assessment Director is responsible for all UDAC activities. In this role, the Consequence Assessment Director reports directly to the SED.

Specific UDAC responsibilities include:

- Acquiring necessary data and measurements to evaluate personnel radiation doses and chemical exposures resulting from the event.
- Assessing the potential for onsite and offsite consequences of a release of radioactive or nonradioactive materials based on meteorological conditions, source term, location, and dispersal of the hazardous material.
- Assisting the SNF Project Staff or other Hanford Site contractors in onsite hazards assessments or development of onsite protective actions.
- Analyzing the consequences associated with evacuating versus remaining in a take cover situation for onsite personnel and recommending approved additional protective actions if necessary.
- Developing offsite PARs in coordination with representatives from the states of Washington and Oregon.
- Coordinating and directing emergency environmental monitoring teams that are not assigned to the event facility, this may include state field teams performing offsite monitoring if requested by the states.
15 4 1 3 3 4 Department of Energy Hanford Emergency Operations Center Operations

As part of the SMT, the primary functions of the DOE Hanford EOC Operations team are administration, record keeping, and dissemination of information to offsite agencies (e.g., RL Notification Form, UDAC products). The EOC Operations Manager is responsible for these activities. In this role, the EOC Operations Manager reports directly to the SED.

15 4 1 4 Offsite Emergency Support Resources

RL interfaces with federal, state, tribal, and local organizations responsible for offsite emergency response and protection of the public and environment. These organizations work with RL in developing integrated programs and response plans for emergencies at the Hanford Site. Typical interfaces are with state and local emergency management organizations, local hospitals, law enforcement agencies, emergency medical service providers, and fire departments. Coordination with offsite agencies includes planning for potential offsite protective actions. These actions may include controlling access to State Highway 240 and the portion of the Columbia River adjacent to the Hanford Site, and providing protective action recommendations for the public in other offsite areas that may be impacted by an emergency.

RL Security and Emergency Services and the Hanford Fire Department execute and maintain memoranda of understanding with various offsite entities related to emergency preparedness assistance. Copies of the memoranda of understanding are provided in DOE/RL-94-02, Appendix B.

15 4 2 Assessment Actions

Hazards surveys and hazards assessments will be developed and maintained for emergency planning purposes. This section summarizes the process by which the onset of an emergency is recognized and the methodology used to obtain meteorological information and estimate release rates and source terms. The computer models used in the UDAC are summarized. SNF Project personnel use approved and validated emergency response guides that prescribe personnel actions during a facility emergency.

The hazards surveys will briefly describe the potential impacts of SNF Project facility emergency events or conditions and will summarize the planning and preparedness requirements that will apply. The hazards assessments will include the identification and characterization of hazardous materials (radiological and non-radiological) specific to a SNF Project facility or activity analyses of potential accidents or events, and evaluation of potential consequences.

Initial and continuous consequence assessments will be performed to protect workers, the public, and the environment during a declared emergency (See Section 15 4 2 3). Consequence assessments will evaluate and interpret radiological, other hazardous materials measurements, or other information to provide a basis for decision-making. This planning will include developing and preparing postulated scenarios for onsite and offsite consequence projections for development of PARs and identifying personnel and resources to provide an effective response.
15 4 2 1 Hazards Surveys  DOE O 151 1 requires that emergency management efforts begin with the identification of hazards and that the scope and extent of emergency planning and preparedness be commensurate with these hazards. Hazards surveys will be prepared for each SNF Project facility to identify the conditions to be contained in the comprehensive emergency management program. The hazards surveys will:

- Identify and describe the facility or activity
- Describe potential impacts of events or conditions
- Describe the potential health, safety or environmental impacts related to specific and nearby facilities
- Summarize the planning and preparedness requirements that apply

The hazards surveys will be updated as changes warrant a change but not less than every three years.

15 4 2 2 Hazards Assessments  DOE O 151 1 requires a facility-specific emergency planning hazards assessment for each facility that has the potential to generate an Alert or higher emergency. The hazards assessments are prepared from the facility-specific hazard and safety analyses that are developed and contained in Chapters 3 0 of the facility FSAR Annexes. Hazards assessments are also derived from other pertinent facility documentation (e.g., safety assessment documents, interim safety basis documents, and special nuclear material accountability documents). The hazards assessment provides the technical basis for the emergency management program. The scope and extent of planning and preparedness directly corresponds to the type and scope of hazards present and the potential consequences of events.

The observable methods of detecting or recognizing an emergency will be identified using the accident scenarios and consequences contained in SNF Project facility hazards assessments. Indicators and emergency action levels (EALs) described in Section 15 4 3 5 will be used to determine the emergency class. The emergency class will trigger specified, preplanned responses and protective actions. For each emergency class, predetermined protective actions necessary to protect onsite personnel and recommended actions for protection of offsite personnel will be established.

The hazards assessments characterize the potential consequences on workers, the public, and the environment for each postulated accident and determine the EPZ for each facility as well as the emergency class protective actions, and the observable indications and criteria (EALs) corresponding to the range of identified accidents.
A spectrum of potential accidents ranging from minor to beyond design basis are postulated and realistically analyzed. While not every conceivable situation will be analyzed, the hazards assessments will provide the framework for response to virtually any declared emergency.

Hazards assessments will be reviewed at least annually and updated, as necessary, whenever the facility configuration changes, source terms change, or the operations of the facility are modified, and are maintained in accordance with document control requirements of Section 15.4.2.3.

**15 4 2 3 Consequence Assessments** Section 5.6.1 of the S/RID (HNF-SD-SNF-RD-001) requires consequence assessments to be performed. The accident analysis in the emergency planning hazards assessment provides a starting point for real-time consequence assessments during an SNF Project emergency. These accident scenarios are summarized in DOE-0225 and are intended for use in the DOE Hanford EOC. DOE-0225 includes source terms for each analyzed accident scenario and results for adverse meteorology. The usual sequence of events after DOE Hanford EOC activation is to select a preanalyzed accident scenario that is similar to the actual event. The source term for the scenario is used with real-time meteorology to predict the potential consequences. These consequences and facility conditions form the basis for the PARs. As more information becomes available from the event scene, the source term will be refined using improved knowledge of the actual material at risk, facility damage, and standard references for release fractions.

Consequence assessment activities will:

- Be timely throughout the emergency
- Be integrated with the event classification
- Incorporate monitoring of specific indicators and field measurements
- Be coordinated with offsite agencies

The airborne release pathway typically represents the most time-urgent situation, requiring a rapid, coordinated response.

**15 4 2 3 1 Meteorological Monitoring** The routine collection of meteorological data is currently required to support environmental monitoring activities on the Hanford Site. Characterization of atmospheric transport and diffusion conditions (e.g., wind speed, wind direction, stability) in the vicinity of SNF Project facilities is essential for consequence assessments of airborne releases of hazardous materials. Weather information is updated every 15 minutes.

**15 4 2 3 2 Water/Groundwater Monitoring** As stated above, releases to aquatic and ground pathways may not have the same time-urgency as airborne releases. However, consideration of these pathways is part of the consequence assessment activities for the SNF.
Project  The water and groundwater monitoring and environmental surveillance programs required by DOE Order 5400 1 are used to characterize transport and diffusion of accidental releases of hazardous materials to aquatic pathways in the vicinity of an SNF Project facility.

15 4 2 3 3 Event Scene Consequence Assessments  Assessments will be conducted at the event scene by the Incident Command Organization staff. The Incident Command Organization staff will continuously evaluate the environmental conditions for inhabitants of the ICP and relocate the ICP as necessary.

15 4 2 3 4 Area Consequence Assessments  Consequences of releases of radioactive and non-radioactive materials at locations beyond the immediate vicinity of the event scene (e.g., 100N, 200E, 200W, 300, 400 Area) will be evaluated. These evaluations will determine the ability of operations staff to safely shutdown operational facilities and those that affect the ability of residents to take protective actions. This activity of determining impacts to other Hanford Site populations is typically performed by UDAC as indicated below and in Section 15 4 1 3 3 3.

15 4 2 3 5 Coordination of Consequence Assessment Results  The UDAC has the primary responsibility for overall onsite and offsite consequence assessments for the SNF Project and the Hanford Site. UDAC will calculate the consequences of any release of hazardous materials during an emergency. The results of these calculations will be shared with onsite and offsite emergency responders and appropriate protective action decisions and recommendations will be disseminated to affected individuals. RL will provide for representatives of the states of Washington and Oregon to participate in the consequence assessments, field team coordination and the offsite PAR development process.

15 4 2 3 6 Computer Models Used For Consequence Assessments  Two primary calculation models will be used to calculate SNF Project facility emergency airborne releases for consequence assessments. HUDU (Scherpelz 1991) and EPIcode (Homann 1988) HUDU calculates radiological releases by using a straight-line Gaussian plume and Pasquill-Gifford stability classes. EPIcode calculates hazardous chemical releases by using plume and puff Gaussian dispersion modeling, depending on the duration of the release. Other codes are available in the emergency center for specialized applications or more refined analysis.

Model parameters used in the preanalyzed hazards assessment scenarios include the default facility boundary distance of 100 m from the identified release point. Determination of release information is based on assumptions concerning the source term, release duration, wind direction, and wind speed. For example, in modeling ground-level releases, an F-stability class, 1 m/sec wind speed, a 60-m mixing level height, and a boundary receptor distance of 100 m is assumed. Elevated releases are modeled with a stack height of 61 m in accordance with HNF-IP-1201, Guidance for Conducting Emergency Preparedness Hazards Assessments. Consequence assessments during an event will use actual meteorological conditions.
15 4.3 Event Categorization and Classification

Section 5.5.1 of the S/RID (HNF-SD-SNF-RD-001) presents requirements for event classification and EALs. Five event categories will be used to meet DOE Orders, state and Federal regulators, and mutual agreements between RL and state and county agencies. These include Operational Emergencies, Resource Conservation and Recovery Act of 1976 (RCRA) Emergencies, Abnormal Events, Unusual Occurrences, and Off-Normal Occurrences. Provisions described below will be established and maintained to recognize, categorize, and classify events in order to protect workers, the public, and the environment. The Unusual and Off-normal Occurrence categories are used solely for occurrence reporting purposes.

15 4.3.1 Operational Emergency. Operational Emergencies are unplanned, significant events or conditions that require time-urgent response from outside the immediate or affected facility or area of the incident. Operational Emergencies consist of Base Program Operational Emergencies or Hazardous Material Operational Emergencies. Incidents that do not pose a significant hazard to safety, health, and/or the environment and that do not require a time-urgent response are not Operational Emergencies. Procedures to ensure recognition and appropriate categorization and classification of emergencies will be established and maintained.

15 4.3.1.1 Base Program Operational Emergency. Events may occur that represent a significant degradation in the level of safety at an SNF Project facility and that require time-urgent response efforts from outside the facility but do not involve the release or potential release of significant quantities of radiological or nonradiological materials. Such programmatic emergencies do not require classification (i.e., as Alert, Site Area Emergency, or General Emergency). The designated point-of-contact (e.g., BED, contractor single point-of-contact) with assistance from ONC personnel will assess event information to determine whether the event should be categorized as a Base Program Operational Emergency. The criteria for categorization of a Base Program Operational Emergency are part of the Abnormal Event criteria, which are contained as a single criteria list within Hanford implementing directive DOE/HFID 232 1B Notification Reporting and Processing of Operations Information. The ONC will determine whether the event should be categorized as a Base Program Operational Emergency in accordance with the criteria in DOE 0 232 1A, Occurrence Reporting and Processing of Operations Information. Base Program Operational Emergency notification requirements are provided in Section 15 4.4.1.1.

15 4.3.1.2 Hazardous Material Operational Emergency. If an Operational Emergency represents a specific threat to workers and the public because of the release or potential release of significant quantities of radiological and nonradiological hazardous materials, it will be classified as either an Alert, Site Area Emergency, or General Emergency, in order of increasing severity. See the following sections and Tables 15-2 and 15-3 for specific criteria. Periodically the emergency classification will be reviewed to ensure that the classification is commensurate with response activities. The classification will not be downgraded, however, until termination of the event. Hazardous Material Operational Emergency notification requirements are provided in Section 15 4.4.1.2.
Alert

As stated in DOE/RL-94-02, an Alert will be declared when events are predicted, in progress, or have occurred that involve an actual facility or the potential substantial degradation of the level of control over hazardous material (radiological and nonradiological). An Alert will be declared when the entire Hanford Site ERO is required to provide more than event monitoring or minimal assistance to the facility organization. An Alert will be declared for release of radiological material with a potential dose at the facility boundary greater than or equal to 100 mrem total effective dose equivalent (TEDE). Emergency action levels for hazardous nonradiological material are based on Emergency Response Planning Guidelines (ERPGs) (AIHA 1988). Alert levels for hazardous nonradiological material will be potential exposure to air concentrations of greater than or equal to ERPG-1 but less than ERPG-2 at the facility boundary (See Tables 15-2 and 15-3).

### Table 15-2: Hanford Site Hazardous Material Operational Emergency Classification Criteria

<td>≥1 rem TEDE at facility boundary</td>
<td>≥1 rem TEDE at Hanford Site boundary</td>
</tr>
</tbody>
</table>

Appropriate ERPG values or equivalent as stated in the hazards assessment guidance document. Solubility class D uranium compounds are limited by chemical toxicity.

*Facility boundary is defined as the properly protected area perimeter fence when present or a distance of 200 m from the release location unless otherwise specified in the hazards assessments documentation.

*The TEDE includes the summation of the doses delivered from plume submersion, ground shine, and inhalation from accidental releases.

ERPG = Emergency Response Planning Guidelines
TEDE = total effective dose equivalent
Table 15-3  Summary of Hazardous Material Operational Emergency Classifications

<td>Alert</td>
<td>Actual or potential substantial degradation of level of control over radiological or nonradiological hazardous material. Releases are not expected to exceed applicable PAG or ERPG levels at facility boundary OR Actual or potential substantial degradation in the level of safety or security that could with further degradation produce a Site Area Emergency or General Emergency</td>
<td>Substantial actual or potential degradation of level of protection that could with further degradation, lead to the loss of special nuclear material or a radiological sabotage event</td>
<td>Actual or potential substantial degradation of the safety of the shipment. Exposures in excess of PAG or ERPG levels only expected for personnel engaged in cleanup recovery and investigation</td>
</tr>
<tr>
<td>Site Area Emergency</td>
<td>Actual or potential major failures of functions necessary for the protection of workers or the public. Releases could exceed applicable PAG or ERPG levels onsite but not offsite OR Actual or potential major degradation in the level of safety or security that could with further degradation produce a General Emergency</td>
<td>Actual malevolent acts resulting in loss of special nuclear material or a radiological sabotage event that could have impacts beyond the facility boundary but not offsite</td>
<td>Actual or potential major reduction in safety of a shipment. Release may exceed PAG or ERPG levels beyond the exclusion zone* onsite but not at nearest Site boundary</td>
</tr>
<tr>
<td>General Emergency</td>
<td>Actual or imminent catastrophic reduction of facility safety or security systems with potential for the release of large quantities of radiological or nonradiological materials to the environment. Releases reasonably expected to exceed applicable PAG or ERPG levels offsite</td>
<td>Malevolent action resulting in catastrophic degradation of protection systems that could lead to substantial offsite impacts</td>
<td>Actual or imminent catastrophic reduction in safety of a shipment. Release expected to exceed PAG or ERPG levels offsite</td>
</tr>
</tbody>
</table>

*Exclusion zone — the immediate vicinity of the accident

ERPG = Emergency Response Planning Guidelines
PAG = protective action guides
Emergency responses to doses are based on protective action guides (PAGs) that have been adopted by the states of Washington and Oregon and published in EPA-400, *Manual of Protective Action Guides and Protective Actions for Nuclear Incidents*. These PAGs are intended to apply to projected doses from airborne releases of radioactive materials and subsequent depositions during the early, intermediate, and late phases of an accident. The pathways considered include external gamma and beta dose from direct exposure to airborne materials and from deposited material, and the committed dose to internal organs from inhalation of radioactive material.

The projected dose value for initiating protective actions (evacuation or sheltering) specified by the states of Washington and Oregon is 1 rem TEDE, where the projected dose represents the sum of the effective dose equivalent resulting from exposure to external sources and the committed effective dose equivalent from all significant inhalation pathways during the early phase. The PAG values for committed dose equivalent to the thyroid and skin are 5 and 50 times larger, respectively.

The U.S. Environmental Protection Agency PAGs are stated in terms of committed dose. Dose incurred before initiation of protective actions (and after the early phase of an event) normally are not included when considering whether or not to take protective actions. It is intended that the PAG values be compared to the dose that can be avoided by taking protective actions.

Exposures are based on ERPGs developed and approved by the American Industrial Hygienists Association. The ERPGs are used to determine the appropriate emergency class for exposures to nonradiological releases. The Temporary Emergency Exposure Limit values developed by the Chemical Exposures Working Group of the DOE Subcommittee on Consequence Assessment and Protective Actions are used for chemicals that do not have ERPG values.

Upon declaration of an Alert the Hanford Site ERO will:

- Activate the DOE Hanford EOC and establish communications, consultation, and liaison with offsite agencies.
- Continuously assess pertinent information for RL/ORP decision makers, offsite agencies, the public, and other appropriate entities.
- Conduct appropriate assessments, investigations, or preliminary sampling and monitoring.
- Mitigate the severity of the occurrence or its consequences.
- Prepare for other response actions should the situation become more serious, requiring EROs to mobilize or activate resources.
15 4 3 1 2 2 Site Area Emergency  A Site Area Emergency will be declared when events are predicted, in progress, or have occurred that involve actual or potential major failures of functions needed for protection of workers or the public in accordance with DOE/RL-94-02. A Site Area Emergency will be declared for release of radiological material with a potential dose at the facility boundary greater than or equal to 1 rem TEDE. Site Area Emergency levels for hazardous nonradiological material will be potential exposure to air concentrations greater than or equal to ERPG-2 at the facility boundary but less than ERPG-2 at the Hanford Site boundary (See Tables 15-2 and 15-3).

Upon declaration of a Site Area Emergency, the Hanford Site ERO will perform the same actions as an Alert plus the following:

- Initiation of predetermined protective actions for onsite personnel
- Provision of information to the public and the media
- Implementation of or assistance in any evacuations and sheltering
- Mobilization of appropriate emergency response groups or protective or security forces for immediate dispatch should the situation become more serious

15 4 3 1 2 3 General Emergency  A General Emergency will be declared when events are predicted, in progress, or have occurred that result in the actual or imminent catastrophic reduction of SNF Project facility safety or security systems in accordance with DOE/RL-94-02. A General Emergency will be declared for release of radiological material with a potential dose at the Hanford Site boundary greater than or equal to 1 rem TEDE. General Emergency levels for hazardous nonradiological material will be potential exposure to air concentrations greater than or equal to ERPG-2 at the Hanford Site boundary (See Tables 15-2 and 15-3).

Upon declaration of a General Emergency, the Hanford Site ERO will perform the same actions as a Site Area Emergency plus the following:

- Notification, mobilization, and dispatch of all appropriate emergency response personnel and equipment, including appropriate DOE emergency response assets
- Liaison with offsite agencies for the recommendation of predetermined public protective actions

15 4 3 2 Hanford Transportation Emergency Preparedness Program  Shipments of radiological and nonradiological hazardous material on roadways north of the Wye Barricade are exempt from the Department of Transportation regulations in 49 CFR. Shipments transported south of the Wye Barricade are regulated under 49 CFR unless public access control is extended south of the Wye Barricade (but not beyond the Site boundary) for special case shipments.
The Incident Command System will be used to mitigate transportation incidents that occur on the Hanford Site. Upon notification of the event by POC, the Hanford Fire Department will assume incident command responsibilities. The Emergency Duty Officer (EDO) will have the responsibility for event classification and activation of the Hanford Site ERO.

For transportation incidents involving DOE-owned hazardous materials that occur off the Hanford Site, the POC will provide information to first responders on a 24-hour basis in accordance with 49 CFR requirements. The POC will connect the caller directly with the Transportation On-Call Representative and the EDO, who will provide more detailed information regarding the shipment and follow-on response assistance as appropriate.

**15 4 3 3 Resource Conservation and Recovery Act Emergency** A RCRA emergency is defined as release, fire, or explosion that threatens human health or the environment. The BED/IC, in consultation with an environmental single point-of-contact, will determine whether the incident is a RCRA emergency. The BED/IC will ensure that trained personnel identify the character, source, amount, and extent of the release, fire, or explosion to the extent possible. These activities will be performed with a sense of immediacy and will include all available relevant information.

Hazards posed by the event to human health and the environment will be assessed. The assessments will consider the direct, indirect, immediate, and long-term effects of the incident. Input for the assessments will include sources such as Material Safety Data Sheet toxicity and health information, and results from any personnel monitoring examinations conducted at medical facilities.

If assessment of all available information does not yield a definitive assessment of the danger posed by the incident, a worst-case condition will be presumed and appropriate protective actions and notifications will be initiated. The BED/IC will be responsible to initiate protective actions based on their best judgement of the incident. Environmental notification requirements are provided in Section 15 4 4 2.

**15 4 3 4 Abnormal Event** Events or situations may occur on the Hanford Site that may generate public concern or media interest but not create, or indicate, an emergency condition. RL will work with offsite agencies to maintain criteria that will be used to identify these situations, termed Abnormal Events. Abnormal Event notification requirements are provided in Section 15 4 4 3.

**15 4 3 5 Emergency Action Levels** Using the accident scenarios and consequences identified in the hazards assessments, the observable methods of indicating or recognizing an emergency can be determined using EALs. The EALs are specific, predetermined observable criteria used to detect, recognize, and determine the classification of Hazardous Material Operational Emergencies (see Tables 15-2 and 15-3) identified by the hazards assessments. On determining that an event has occurred or is occurring, the BED/IC will promptly assess the conditions, compare the indications to the facility EALs, and determine the appropriate Hazardous Material Operational Emergency classification.
The level of emergency classification will be used to trigger specific, preplanned, graded responses, such as activation of the Hanford Site ERO and initiation of protective actions and appropriate notifications commensurate with the degree of hazard presented by the event. Actual airborne concentrations are determined by obtaining samples at a specific location using samplers.

15.4.4 Notifications

If an SNF Project-related emergency event were to occur, prompt and accurate emergency notifications would be made to mitigate consequences and to protect the health and safety of workers, the public, and the environment in accordance with Section 5.5.2 of the S/RID (HNF-SD-SNF-RD-001). Notifications will be made in order of urgency with Operational Emergency (Hazardous Material Operational Emergency only) notifications performed first, Environmental notifications performed second, and Abnormal Event (including Base Program Operational Emergency), Unusual Occurrence, and Off-Normal Occurrence notifications performed last.

Procedures will be developed to ensure that notification and reporting requirements are in accordance with DOE O 151.1 and DOE O 232.1A, applicable Federal, state or local requirements, and special agreements with offsite agencies or tribal governments. These procedures will be validated through drills and exercises.

The Unusual and Off-Normal Occurrence categories will be used solely for reporting versus immediate action purposes. Notifications and written reports of incidents meeting occurrence reporting criteria will be made to DOE-HQ and also to offsite entities as requested by RL. Offsite transportation events involving RL/ORP-owned hazardous materials will be reported in accordance with DOE O 151.1 and 49 CFR requirements.

15.4.4.1 Operational Emergency Notification

Prompt and accurate emergency notifications will be made to mitigate consequences and protect the health and safety of workers and the public. The person who witnesses or discovers an abnormal or emergency condition will promptly notify the POC by dialing 911 for fire, medical, and hazardous materials assistance, and the SNF Project facility shift manager/Bed. If the shift manager/Bed is not present, the person will notify the on-call BED. Onsite notifications are required as soon as an event is determined to threaten personnel safety.

The BED/IC ensures activation of appropriate system facility take-cover sirens and direction to the POC to make crash-alarm telephone system notifications. Once the event is classified, the BED/IC will contact the POC and ONC to initiate emergency notifications for onsite and offsite EROs. After being notified of the classification of an emergency event, the ONC duty officer and available staff will make offsite notifications to DOE Headquarters and other potentially affected federal, state, tribal, or local organizations. RL/ORP will oversee the offsite contractor notifications.
The release of public information, which is integrated through the JIC (See Section 15 4 1 3 2), is an integral part of the emergency management program. Offsite agency interfaces and mutual assistance agreements are documented in the memoranda of understanding (DOE/RL-94-02, Appendix B). Information is provided to the public and to employees during the course of an emergency. RL, state governments, and local governments share in this responsibility. Each response organization speaks to its individual area of responsibility.

When operational, the DOE Hanford EOC is responsible for followup notifications when emergencies are reclassified or terminated. If the DOE Hanford EOC is not operational, the followup notifications are made by the IC or SNF Project BED through the POC and ONC.

Procedures will be established and maintained to provide prompt initial notification to workers and emergency response personnel and organizations, including appropriate offsite agencies under the most limiting set of conditions.

Operational Emergencies that also meet RCRA emergency criteria will be categorized in accordance with Section 15 4 3 3 and perform notification in accordance with Section 15 4 4 2.

15 4 4 1 1 Base Program The SNF Project will ensure that the designated point-of-contact (e.g., BED) reports events to the ONC that meet notification criteria based on established procedures. These notifications shall be made as soon as possible (within 30 minutes). The designated point-of-contact, with assistance from ONC personnel, will assess the event information to determine whether the event should be categorized as a Base Program Operational Emergency. If the event meets the Base Program Operational Emergency criteria, the ONC will notify the DOE-HQ EOC within 30 minutes following categorization and the offsite agencies immediately following as part of the Abnormal Event notification (See Section 15 4 4 3).

These notification requirements also apply to offsite transportation events involving DOE-owned hazardous materials.

15 4 4 1 2 Hazardous Material Operational Emergency Notification Hazardous Material Operational Emergency notifications are made to:

- Augment the Site and SNF Project operating staff with personnel in designated response roles to respond to the emergency.
- Activate emergency centers.
- Facilitate public notification by offsite authorities and agencies that have decision-making authority for directing protective actions (e.g., evacuation of local areas).
- Protect site and SNF Project personnel and emergency workers through the provision of information necessary to implement accountability and protective actions such as sheltering, decontamination, and evacuation.

fsar15 sar 15-27 November 1999
15 4 4 1 2 1 Initial Onsite and Offsite Notification  The initial event classification (Alert Site Area Emergency, or General Emergency) will be made by the BED or IC in accordance with established procedures  Immediate notifications will be initiated via the 911 emergency number to request emergency response assistance and to notify onsite personnel via sirens, the onsite crash alarm telephone system, or plant telephone for the purpose of initiating protective actions  The BED/IC will also ensure that a completed copy of the RL Notification Form is transmitted to the ONC in accordance with established procedures  If a facsimile machine is not available, the BED/IC is responsible for ensuring that pertinent information from the RL Notification Form is provided to the ONC

For non-facility events (e.g., onsite transportation incidents, range fires), the EDO is responsible to make the initial event classification, initiating appropriate protective actions, and providing notifications, including information to complete the RL Notification Form, to the ONC  Upon notification from the BED or IC of an emergency event classified Alert, or higher, the ONC will make offsite notifications within 15 minutes to the following

- DOE-HQ EOC
- Benton, Franklin, and Grant Counties, Washington State, and Energy Northwest (WNP-2) via the DOE Crash Alarm Telephone System (hot line)
- Oregon State

The ONC will also initiate the automated Emergency Notification System (ENS) and pager system to activate the DOE Hanford EOC and make onsite notifications, as appropriate to the following

- DOE Hanford senior management on-call
- Emergency Duty Officer (Fluor Daniel Hanford [FDH])
- Pacific Northwest National Laboratory single point-of-contact
- Bechtel Hanford, Inc single point-of-contact
- HEHF single point-of-contact

The ONC will also notify, as applicable to the event, other offsite agencies that may have personnel working in remote locations of the Hanford Site (e.g., personnel at locations without alarm or siren capabilities) within 30 minutes of event declaration  All other notifications will be made as soon as practical  The ONC will maintain a list of agencies to be notified

15 4 4 1 2 2 Reclassification Notification  The BED or IC will reclassify rapidly escalating emergencies until the DOE Hanford EOC is operational  In addition, the BED or IC will provide immediate protective action notification to personnel within their respective geographical area of
responsibility and also provide notification to the POC and ONC via the 911 emergency number regarding the reclassification. The ONC will then notify the offsite EROs of the event reclassification.

When operational, the DOE Hanford EOC will have the responsibility for reclassifying or terminating emergencies, disseminating additional protective action decisions to onsite personnel, and performing offsite notifications that include PARs.

15 4 4 1 2 3 Reports The SNF Project will submit a final report on the emergency to the Occurrence Report Processing System in conjunction with the Final Occurrence Report in accordance with the requirements of DOE O 232 1A following termination of the emergency response.

15 4 4 2 Environmental Notifications Environmental notifications will be made verbally or in writing depending on the type of event. The SNF Project will establish procedures to ensure implementation of environmental notifications in accordance with Federal, state, and local requirements and agreements. The SNF Project will ensure that environmental notification procedures are consistent with the environmental notification process depicted in Figure 5 3 of DOE/RL-94-02.

For incidents involving a spill, release, fire, explosion, or environmental permit exceedence, the SNF Project single point-of-contact will be notified to determine applicability of requirements and perform the necessary environmental notifications including notifying the appropriate Federal, state, and local agencies. The ONC will also be notified for determination if an Abnormal Event notification is also required. The SNF Project will develop any necessary written reports for submittal to RL for review and concurrence.

The FDH environmental single point-of-contact will notify the appropriate Federal, state, and local agencies that the SNF Project facility is in compliance with cleanup activities before operation is resumed.

15 4 4 3 Abnormal Event Notifications The SNF Project will ensure that events meeting the Abnormal Event criteria established by RL are promptly reported to the ONC in accordance with the process in DOE/HFID 232 1B Notification, Reporting and Processing of Operations Information.

15 4 5 Emergency Facilities and Equipment

Emergency facilities provide a location for coordinating emergency response activities. Emergency equipment consists of the materials and tools that may be required to measure, control, or mitigate the consequences of an emergency including equipment required to notify employees of an emergency to facilitate safe evacuation.
15 4 5 1 Spent Nuclear Fuel Project Emergency Facilities  Locations are specified in the SNF Project facility BEPs for establishing an ICP where emergency response personnel may gather to manage onsite emergencies. These locations will be equipped with emergency response materials and equipment that may be used to measure, control, and mitigate the consequences of an emergency.

15 4 5 2 Hanford Site Emergency Facilities  The Hanford Fire Department maintains fully staffed and equipped fire stations in the 100 and 200 East areas. These stations are staffed with personnel and resources for ensuring their ability to respond to a variety of emergencies such as fire, natural disasters, hazardous material releases, and personnel injuries. Hanford Environmental Health Foundation maintains a first aid and medical facility in the 200 East Area. This facility is staffed by trained and qualified medical professionals who are available to provide emergency medical care to injured personnel. Personnel decontamination sites are located in several locations in the 100, 200, 300 and 400 Areas.

The EDF (adjacent to the Kadlec Medical Center, 888 Swift Boulevard, Richland, Washington) contains unique equipment for performing minor medical procedures and decontamination on severely contaminated persons with injuries that are non-life threatening. The locations of emergency facilities are shown in Figure 15-4.

15 4 5 3 U.S. Department of Energy, Richland Operations Office, Emergency Centers Supporting the Spent Nuclear Fuel Project  The DOE Hanford EOC is located in the Federal Building, 825 Jadwin Avenue, Richland, Washington. The DOE Hanford EOC, UDAC, and ONC are dedicated facilities located in the basement of the Federal Building. The JIC is a dedicated facility located on the main floor of the Federal Building in Rooms 157 and 158. Telecommunications equipment, word processing support, and duplicating equipment are provided to support JIC-participating agencies and the media. The JIC also may dedicate the use of the auditorium, portions of the lobby, and other areas in the Federal Building for JIC purposes as needed.

The alternate DOE Hanford EOC would be activated if for any reason the DOE Hanford EOC was not habitable. The alternate DOE Hanford EOC is located in the 2420 Stevens building, rooms 117 and 153.

The POC is located in the 2721E Building in the 200 East Area and acts as a single point of contact for RL/ORP and Hanford Site contractors. The POC monitors the emergency response number (911) and business number (373-3800). The POC provides alarm monitoring, activation of crash alarm telephone systems and sirens, and assisting in dispatch and radio communications for emergency responders. The POC notifies and/or dispatches the following:

- Hanford Fire Department, including ambulance and the Hazardous Material Response Team
- Hanford Patrol
The ONC is a 24-hour operational facility equipped to communicate information regarding occurrences at or affecting the Hanford Site to RL/ORP and Site contractor personnel and to state and local emergency management organizations. The ONC

- Activates the Hanford Site ERO via the automated ENS
- Provides initial notifications via the automated ENS to Grant County residents within the Hanford EPZ
- Provides notifications to the DOE-HQ EOC and state and local emergency management agencies

15 4 5.4 Spent Nuclear Fuel Project Emergency Equipment  Emergency equipment is any equipment or system that may be required as identified by results of the hazards assessments to measure, control, or mitigate the consequences of an emergency or in any way be involved in an emergency response. The SNF Project has fixed emergency systems and equipment and portable emergency equipment, including equipment that is staged or in a designated area for easy retrieval. As required by Section 5.4.2 of the S/RID (HNF-SD-SNF-RD-001), a listing of emergency equipment and locations of emergency equipment are listed in Table 15-4. Detection ranges and types of instruments for radiological and nonradiological hazardous materials will be adequate to cover for emergency conditions as determined in Sections 15 4 2.1 and 15 4 2.2. Hanford Site emergency resources and equipment are listed and described below. Emergency equipment and backup equipment will be inventoried in accordance with approved procedures and inspected in accordance with procedures to ensure that it is available, accessible (away from scene of a potential accident), and operational. The quarterly inventory records will be maintained for one year in accordance with DOE/RL-94-02 requirements.

15 4 5.4.1 Nonradiological Hazardous Emergency Response Equipment  Hazardous material spill kits are used to clean up nonradiological emergency spills.

15 4 5.4.2 Radiological Emergency Response Equipment  Protective clothing and equipment used for response to a radiological emergency is stored in designated storage areas maintained specifically by the SNF Project for emergency events.

*Respirators for emergency use will be thoroughly inspected at least once a month and after each use. Records of inspection dates and findings will be maintained.

15 4 5 4 3 Communications Equipment The commercial telephone system is the primary means of communication during an emergency involving the SNF Project. Cellular telephones and radios (i.e., mobile, hand-held, and base stations) will back up the commercial telephone system. Commercial and cellular phones can be used to contact all emergency personnel and organizations for the Hanford Site. If the telephones fail, radio communications to the DOE Hanford EOC can be relayed through the POC.

15 4 5 4 4 Operations Response Emergency Equipment Operations response emergency equipment is stored in designated SNF Project locations. This equipment is used in all types of emergency events and includes ERO staff identification vests, emergency response procedures, personal protective equipment, spill kits, "DO NOT ENTER" tape, yellow rope, radiation rope, flashlights, and first aid kits.

15 4 5 4 5 Fire Fighting Equipment SNF Project facilities use fixed fire alarm systems and, in the majority of hazardous and nonhazardous facilities, a sprinkler system. SNF Projects also have portable fire extinguishers (A-B-C type), located throughout all buildings, that can be used to extinguish small fires. The fire alarm system is used to notify personnel and the fire department of a potential or actual fire situation. The fire sprinkler systems will be used for fire suppression. Other fire fighting equipment is under the control of the Hanford Fire Department.

15 4 5 4 6 Emergency Lighting Emergency lighting is provided for evacuation of SNF Project buildings. The lighting is not intended for reentry into a facility for response activities.
15.4.5.4.7 Operational Alarms  As required by Section 5.4.3 of the S/RID (HNF-SD-SNF-RD-001), an alarm system is required to alert employees of potential emergencies. SNF Project hazardous facilities are equipped with operational alarms for abnormal and emergency conditions, such as the radiation alarms (located in and near radiation areas) and other alarms that provide event indications of a potential or actual emergency. Testing requirements for operational alarms will be contained in controlled procedures.

15.4.5.4.8 Facilities and Site Area Sirens  The 100 K Area evacuation and take-cover sirens are located throughout the 100 K Area and are activated by the 100 K Area BED for the K Basins and Cold Vacuum Drying Facility. The sirens in the 100 K Area may be activated up to 30 minutes during a real event. The sirens are tested monthly.

The 200 East Area also has evacuation and take-cover sirens that will provide coverage for the Canister Storage Building and Interim Storage Area. Various SNF Project buildings are equipped with internal speakers that relay the sirens and public address system announcements.

The SNF Project facility or building manager ensures that preventive maintenance of facility emergency sirens/alarms is performed by the maintenance organization in accordance with procedures as required by DOE/RL-94-02. The FDH emergency preparedness organization will ensure that preventive maintenance is performed on area and river sirens. In order to meet 29 CFR 1910 requirements, the employee alarm system will do the following:

1. Provide warning for necessary emergency action as called for in the emergency action plan, or for reaction time for safe escape of employees from the workplace or the immediate work area, or both.

2. Be capable of being perceived above ambient noise or light levels by all employees in the affected portions of the workplace. Tactile devices may be used to alert those employees who would not otherwise be able to recognize the audible or visual alarm.

3. Be distinctive and recognizable as a signal to evacuate the work area or to perform actions designated under the emergency action plan.

4. The preferred means of reporting emergencies, such as manual pull box alarms, public address systems, radio, or telephones shall be explained to each employee. Emergency telephone numbers shall be posted near telephones, employee notice boards, and other conspicuous locations when telephones serve as a means of reporting emergencies. Where a communication system also serves as the employee alarm system, all emergency messages shall have priority over all non-emergency messages.

5. Procedures for sounding emergency alarms in the workplace shall be established. For those employers with 10 or fewer employees in a particular workplace, direct voice communication is an acceptable procedure for sounding the alarm provided all employees can hear the alarm. Such workplaces need not have a back-up system.
Protective Actions

Protective actions are those actions taken to preclude or reduce the exposure of individuals or the environment impacted by hazards or unsafe conditions during an emergency event at a SNF Project facility as required by Section 5 6 2 of the S/RID (HNF-SD-SNF-RD-001). Protective actions for the SNF Project will reflect the use of chemical ERPGs identified in Section 15 4 3 1. The ERPGs published in the Emergency Response Planning Guidelines (AIHA 1988) are used during an SNF Project facility emergency response to determine protective actions for unique exposures to chemical releases (see Table 15-5). The PAGs also are used during an SNF Project facility emergency response to determine protective actions for unique exposures to radiological releases (see Table 15-2). Published PAGs adopted by the states of Washington and Oregon (EPA-400) will be used in accordance with DOE/RL-94-02.

<table>
<thead>

</tr>
</tbody>
</table>

*For the purposes of applying the emergency class definitions from DOE O 1511 Comprehensive Emergency Management System the terms ERPG and appropriate ERPG exposure levels shall be interpreted to mean a 15 minute time weighted average concentration of the substance in air that equals or exceeds the published ERPG 2 values or its alternative value for that substance.

ERPG = Emergency Response Planning Guidelines

Emergency response procedures include the following types of procedures:

- Activation of internal facility alarms or communication systems
- Area evacuation
The SNF Project is responsible for ensuring that all personnel and visitors within the facility perimeter fences respond appropriately to alarms. Assigned personnel will be provided with specific training on protective actions. The facility ERO will provide area and building sweeps, as necessary to ensure appropriate action is taken.

The Hanford Site emergency management program uses the EPZ concept to focus emergency planning activities. EPZs are designated areas where protective actions may be required. The size of a zone is determined primarily by the expected dispersion distance of a particular concentration of a substance. The two exposure pathways for both radiological and nonradiological hazardous materials are the plume exposure pathway and the ingestion exposure pathway. Table 15-6 presents the plume exposure EPZs for geographical areas on the Hanford Site with potential offsite consequences. The circles in Figure 15-5 illustrate the Hanford Site plume exposure EPZs.

The plume exposure pathway EPZ is the probable area of exposure to a passing cloud, or plume, of the substance potentially resulting in direct contact with the substance through the exterior of the body or through inhalation. The plume exposure pathway EPZ includes the area where emergency planning is conducted (1) to ensure that prompt and effective actions are taken in the event of an emergency (2) to protect onsite personnel, and (3) to ensure public health and safety.

<td>Radiological</td>
<td>72 km (45 mi)</td>
</tr>
</tbody>
</table>

*For the purposes of EPZ definition the receptor location is defined as the south and/or west shore of the Columbia River.

EPZ = emergency planning zone

The ingestion exposure pathway EPZ is the probable area of exposure to contaminated foodstuffs or water potentially resulting in deposition of the material in various internal organs following ingestion (eating or drinking). The ingestion exposure pathway EPZ for radiological and nonradiological incidents at all Hanford Site facilities corresponds to the 80-km (50-mi) EPZ for Energy Northwest's Nuclear Plant 2. The gray area in Figure 15-6 represents the ingestion exposure EPZ for the Hanford Site.

The protective actions required to minimize the exposure of workers and the public are summarized in the following subsections. Examples of protective actions as a function of accident category and consequences are illustrated in Table 15-7.

Protective actions will be predetermined for onsite personnel and the public and will include the following:

- Methods for controlling, monitoring, and maintaining records of personnel exposures to hazardous materials (radiological and non-radiological)
- Plans for timely sheltering and/or evacuation of workers
- Methods for controlling access to contaminated areas and for decontaminating personnel or equipment exiting the area
- Actions to be taken to increase the effectiveness of protective actions (i.e., heating, ventilation, and air conditioning shutdown during sheltering)

- Methods for providing timely PARs, such as sheltering, evacuation, relocation, and food control, to appropriate offsite agencies

- PAGs and ERPGs, prepared in conformance with DOE-approved guidance applicable to the actual or potential release of hazardous materials to the environment, for use in protective action decision making

- The administration of medications

The specific event will determine the initial protective actions at the facility. Other actions may include emergency rescue, decontamination, fire fighting, and medical response. The BED is responsible for event scene protective actions at the SNF Project facility and for initial area protective actions. Immediate offsite protective action decisions (which may include access control, sheltering, and evacuation) and notifications to populations within the plume EPZ are the responsibility of the counties and are primarily provided using the Emergency Alert System. Protective action decisions for the ingestion exposure EPZ are the responsibility of the state, which coordinates implementation of protective actions with the impacted counties.
15 4 6 1 Emergency Evacuation  Planning for emergency evacuations includes determining evacuation routes, transportation needs, and the estimated time when the evacuation sirens would be activated, as well as the possible relocation of emergency facilities in accordance with DOE/RL-94-02. SNF Project facility preparations include establishing safe transportation and notifying personnel as to what protective actions they need to perform and what actions are required when evacuation sirens are activated.

The emergency evacuation process is described in the individual BEPs. Evacuation procedures include activating evacuation sirens, communicating evacuation routing, transporting personnel, and initiating protective actions for personnel immediately adjacent to the event. All personnel are trained in these evacuation procedures. The SNF Project facilities are also equipped with interior evacuation sirens and crash alarm telephones. Facility evacuation routes are designated by the shift manager (BED) according to the event and meteorological conditions. Evacuation routes for the Hanford Site are specified in Figure 7-3 of DOE/RL-94-02. Once determined, the evacuation routes are communicated to other Hanford Site facilities.

As required by DOE/RL-94-02, personnel accountability is conducted following implementation of protective actions (Section 15 4 6) to assure that employees are properly accounted for and the affected facility has been evacuated as necessary. Accountability will be conducted at the staging area to ensure all employees are properly accounted for.

15 4 6 2 Sheltering (Take Cover)  Depending on factors such as the type of materials released and the facility-specific conditions, sheltering (take cover) may be the preferred protective action when it will provide protection equal to or greater than evacuation.

15 4 6 3 Relocation of Emergency Facilities  Unsafe conditions onsite may cause emergency facilities to relocate to alternate locations.

15 4 6 4 Access Control and Traffic Control  A single point of entry and egress is established to control access to the event scene and the incident control personnel. Roadblocks established in safe locations prevent entry into the event scene and downwind locations.

15 4 6 5 Use of Protective Equipment  Protective clothing and respiratory equipment may be used to provide a protective barrier to minimize exposure to loose surface and airborne contamination during response to emergencies.

15 4 6 6 Food Control  Intervention levels for offsite foodstuffs are based on Food and Drug Administration guidelines as described in the Washington State procedure, Derived Intervention Levels (WASH 1991). The DOE Hanford EOC Policy Team provides recommendations to the offsite agencies as applicable.

15 4 6 7 Personnel Monitoring  Personnel are monitored for radiological contamination at the scene to determine appropriate actions (i.e., segregate them from uncontaminated personnel, secure areas where contamination has been spread, transport contaminated personnel to decontamination facility).
15 4 6 8 Exposure and Contamination Controls  Exposure and contamination controls prevent overexposure of response personnel during the initial response phases and thereafter and reduce or prevent the spread of contamination by responders and/or vehicles.

15 4 6 9 Event Scene Controls  Event scene controls and response actions are established at and controlled from the field operations control area.

15 4 6 10 State Highway 240 Closure  The Washington State Patrol has developed preplanned protective actions to implement closure of State Highway 240 depending on the event classification. If the Washington State Patrol does not have sufficient resources to accomplish this task, the patrol can request assistance to set up road blocks from the Benton County Sheriff’s Office and Hanford Patrol.

15 4 6 11 Emergency Rescue  The Hanford Fire Department, including paramedics, provides emergency rescue services and assists injured or severely ill personnel from work locations in the SNF Project.

15 4 6 12 Decontamination  Uninjured, contaminated personnel are decontaminated in designated Hanford Site decontamination facilities. Patients with injuries that are not life threatening but who are severely contaminated will be cared for in the EDF, which provides for both isolation and decontamination. Severely injured personnel will be taken directly to a local hospital emergency room.

15 4 6 13 Medical Support  The Hanford Site medical contractor provides professional medical help for the entire Hanford Site. Doctors and nurses are available for emergency assistance at all times. The medical staff is trained to work with personnel who have been contaminated by a radioactive source or exposed to a hazardous material. Hospital services are available at Kadlec Medical Center in Richland with backup service at Kennewick General Hospital in Kennewick and Our Lady of Lourdes Health Center in Pasco.

15 4 7 Training and Exercises

Requirements in Section 5.2 of the S/RID (HNF-SD-SNF-RD-001), DOE/RL-94-02, and 29 CFR 1910 require that the emergency organizations are formed, trained, and tested to ensure recognition and classification of emergencies and the implementation of protective actions. The SNF Project Emergency Response Training Program ensures the readiness of the SNF Project emergency preparedness organizations as well as general employee awareness of hazards and response actions (see Table 15-8).

</tr>
</tbody>
</table>

*BED = building emergency director*

*DOE = U.S. Department of Energy*

*EOC = Emergency Operations Center*

*ERO = Emergency Response Organization*

**General Employee training** is provided to employees who may have to take protective actions in the event of an emergency when they are employed when their expected actions change, or when the SNF Project facility emergency plan or response procedures change. This training will also include participation in drills and exercises. Refresher training will be provided on an annual basis to employees likely to witness a hazardous material release and who are required to notify authorities of the event. Site personnel will be provided information on facility-specific emergency response documentation including emergency signals, basic instruction, and emergency response structure.

All visitors, vendors, contractors, and consultants will receive safety and emergency preparedness training as part of visitor orientation to the Hanford Site. This orientation is required before badging and is offered on a drop-in basis. As appropriate, RL offers training.
programs to offsite organizations that perform emergency tasks. Training may include facility-specific orientations, hazards information, and review of emergency response procedures.

15 4 7 1 Spent Nuclear Fuel Project Emergency Response Training Personnel in assigned roles of the Incident Command Organization (Table 15-1) will attend Incident Command and task-specific training on an approved equivalency prior to assignment and annually thereafter. Refresher training will be provided annually to these SNF Project employees. This will include lessons learned from past drills and exercises, changes to plans and procedures, and lessons learned from emergencies at DOE and other industrial facilities.

The training will include:

- Duties contained within DOE-0223, Hanford Emergency Plan Implementing Procedures and supporting facility-specific emergency response procedures.
- An overview of the Hanford Incident Command System including roles and responsibilities.
- An overview of the facility hazards and hazard control measures specified in accident scenarios in authorization basis documentation and supporting emergency response procedures.

The SNF Project Emergency Response Training Program is based on DOE-0223, the SNF Project facility BEPs, and emergency response procedures. SNF Project managers are responsible for ensuring that all of their personnel receive incident command and task-specific training or approved equivalency prior to being assigned to the Incident Command Organization and annually thereafter. Training will include roles, responsibilities, and authorities for the respective position within the Incident Command Organization. Personnel supporting the emergency response at the event scene will have first aid training (including cardiopulmonary resuscitation and bloodborne pathogen training) and self-contained breathing apparatus training.

Personnel directing or supervising response actions will be trained for all tasks they assign to be performed and have the same level of qualification for emergency response as the personnel being directed. Additional training requirements are provided below. Training requirements for administrative facilities, non-hazardous facilities, and hazardous facilities are contained in the respective subsections of Section 12.0 of DOE/RL-94-02.

15 4 7 1 1 Building Emergency Directors Training The BEDs, and alternates, will attend approved emergency response training prior to assignment to an ERO. The BED, or alternates, provides an orientation to the staging area managers. The emergency preparedness training is a mix of classroom instruction, tabletop exercises or walkthroughs, and drills. The training programs are systematic and performance based and developed using performance objectives that place emphasis on team training and facility-specific emergency response scenarios based on the hazards assessments, past events, and the lessons learned from those events, past drills and exercises, and changes to plans and procedures. Training for BEDs includes the shift.

November 1999
manager/operational engineer certification program and SNF Project Emergency Response Training

154712 Staging Area Managers and Personnel Accountability Aides Training

Staging area managers and personnel accountability aides for administrative, nonhazardous, and hazardous facilities receive the SNF Project nonhazardous ERO training prior to assignment and annually thereafter.

15471.3 Other Emergency Response Support Personnel Training

Skilled Support Personnel and Specialist personnel who are not permanent members of the ERO are not required to meet the above ERO training requirements. However, other training is required to ensure that such personnel are protected against hazards that may be present at the event scene.

15471.3.1 Skilled Support Personnel

Personnel who are needed temporarily to perform immediate emergency support will be given an initial briefing prior to their participation in any emergency response. This initial briefing will include instruction in the wearing of appropriate personal protective equipment, what hazards are involved, and what duties are to be performed. Any other safety and health precautions will be used to assure the safety and health of these personnel.

15471.3.2 Specialist Personnel

Personnel who in the course of their regular job duties are trained in the hazards of specific hazardous (radiological and nonradiological) substances and who may be called upon by the BED/IC to provide technical advise or assistance shall receive training or demonstrate competency in the area of their specialization annually.

15472 Spent Nuclear Fuel Project Emergency Drill Program

Emergency drills are conducted to provide training for the emergency staff in the use of emergency facilities equipment, procedures, and communication channels for credible emergencies. These drills are developed and conducted by the SNF Project emergency preparedness personnel. SNF Project administrative procedures provide the process for this training.

Crew drills will be performed as scheduled by the appropriate SNF Project operations organization and the SNF Project emergency planning organization. These drills are performed on-shift by operations personnel for response skill training, evaluation, and improvement purposes. Systems will be in place to track corrective actions as a result of drills. SNF Project administrative procedures provide the process for this training.

Emergency preparedness drills will use the appropriate Emergency Plan Implementing Procedures (DOE-0223) to demonstrate the following:

- Implementation and coordination of facility and/or area (e.g., 100 Area, 200 Area, 300 Area) and protective actions such as take cover or evacuation.
- Event recognition and classification.
Event mitigation

Emergency and environmental notifications and communications

Interface with other Incident Command Organization functions and other affected facilities

Senior SNF Project management will be provided with a predrill and post-drill report for all emergency drills and for corrective actions status. DOE/RL-94-02 requires that operations and/or emergency preparedness drills be conducted with a frequency sufficient to provide proficiency and complete confidence in response capability.

15 4 7 3 Hanford Emergency Exercise Program The Hanford Emergency Exercise Program organization administers the site emergency exercise program. The Hanford Emergency Exercise Program organization develops and maintains a five-year schedule to ensure that each hazardous facility participates in one exercise with the EOC. Offsite agencies, including DOE Headquarters, and appropriate federal, state, tribal, and local organizations, are invited to participate in the annual DOE-RL field exercise and preparatory tabletop exercises to improve integration and coordination of the numerous emergency programs. Systems are in place to track corrective actions as a result of emergency exercises. Additional specifics of the exercise program is provided in Section 13.0 of DOE/RL-94-02.

15 4 7 4 Training Program Evaluation The effectiveness of the training program is evaluated by written examinations, qualification cards (knowledge-performance objectives), and emergency drills and exercises. Drills and exercises for this program will be of sufficient scope and detail to ensure the demonstration of adequate response capability. Drills will emphasize facility-specific emergency events and response activities will minimize generic nonspecific simulations. Such drills will be conducted in accordance with approved procedures. The effectiveness of the emergency preparedness training program will be evaluated during the conduct of drills and exercises.

15 4 8 Reentry and Recovery

Provisions for emergency event termination, facility reentry, transition from an emergency organization to a recovery organization, and recovery provisions are summarized in the following subsections.

15 4 8 1 Emergency Event Termination For an event in which the DOE Hanford EOC has not been activated, an emergency can officially be terminated after applicable criterion has been met, and the BED and the IC agree that termination can be declared. However, in an event where the DOE Hanford EOC has been activated, termination occurs after all applicable criteria have been met, concurrence between the SNF Project staff and RL/ORP has been obtained, and the BED, IC, and SED agree on termination and information is communicated to the RL/ORP Emergency Manager. The RL/ORP Emergency Manager will then coordinate the termination.
recommendation with the state and county representatives and make the official emergency termination declaration

15 4 8 2 Facility Reentry Provisions  Authorization for reentry at any time during the emergency, including cases where immediate action is required for saving a life, minimizing injury, or minimizing damage, is the responsibility of the BED and IC. Authorization for reentry during the recovery phase is the responsibility of the onsite recovery manager.

15 4 8 3 Transition from Emergency Organization to Recovery Organization  A recovery plan will be developed when necessary. A recovery plan will be needed following an event when further risk could be introduced to personnel, the facility, or the environment through recovery action and/or to maximize the preservation of evidence. Depending on the magnitude of the event and the effort required to recover from it, recovery planning may involve personnel from RL/ORP and other contractors. If a recovery plan is required, it will be reviewed by appropriate personnel and approved by the manager of recovery operations. Restart of operations will be performed in accordance with the approved plan. Onsite and offsite emergency organizations will develop recovery staffing plans necessary to return the affected facility and surrounding areas to normal after termination of the event.

When the emergency phase is complete, a special recovery organization may be appointed at the discretion of RL/ORP, in accordance with Section 9.2 of DOE/RL-94-02, to restore conditions to normal. The makeup of this organization depends on the extent of the damage and its effects. The onsite recovery organization is appointed by the SNF Project representative to the SMT.

RL/ORP will determine the type and extent of accident investigations to meet the requirements of DOE O 225 1A, Accident Investigations. In addition, the SNF Project will assist RL/ORP in performing an investigation of the emergency root causes and corrective actions in accordance with DOE requirements to prevent recurrence.

15 4 8 4 Recovery Provisions  The RL/ORP directs the recovery planning for Hanford Site facilities and supports the offsite recovery efforts of federal, state, and local agencies. The recovery support team consists of sufficient staff, including facility staff to perform functions applicable to the situation.

15 5 DOCUMENT CONTROL

As required by DOE/RL-94-02, the BEP and implementing procedures are controlled-distribution documents. The document control system will ensure that controlled copies are up to date and available at locations where needed in an emergency. The implementing procedures will be reviewed annually and revised as necessary.
Emergency procedures will provide for documentation of emergency records that contain information for review and reconstruction of major communications and activities taken during an emergency, including logs and documentation produced by the DOE Hanford ERO

16 0 PROVISIONS FOR DECONTAMINATION AND DECOMMISSIONING

16 1 INTRODUCTION

This chapter describes provisions that facilitate decontamination and decommissioning (D&D) of the Spent Nuclear Fuel (SNF) Project facilities after completion of the fuel retrieval, processing, and storage mission. These provisions include guidance on the description of the conceptual D&D plan for the SNF Project facilities. This chapter includes the following:

- Description of design features incorporated in a facility to facilitate future D&D of the facility
- Description of operational considerations to facilitate future D&D
- Description of the conceptual D&D plan

The Cold Vacuum Drying Facility (CVDF) and Canister Storage Building (CSB) and the major modifications to the K Basins and their associated systems and operations have been designed to minimize the spread of contamination and to facilitate future D&D activities. These design features and operational considerations consist of multiple-confinement layers, compartmentalized process areas and systems, modular equipment, and between-processing decontamination that are intended to minimize final building and equipment decontamination and environmental restoration activities.

The process to develop D&D plans for the SNF Project facilities is discussed in Section 16 3.

16 2 REQUIREMENTS

Specific requirements applicable to this chapter include:

- *Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) of 1980, as amended*
- *National Environmental Policy Act (NEPA) of 1969*
- *DOE Order 5820 2A, Radioactive Waste Management, Chapter V "Decommissioning of Radioactively Contaminated Facilities"*
The following are applicable to the safety basis for the CVDF and CSB only

- **Title 10, Code of Federal Regulations, Part 835, "Occupational Radiation Protection" (10 CFR 835), Section 835 1002(d)**

16.3 DESCRIPTION OF CONCEPTUAL PLANS

This section describes the design features and operational considerations pertinent to SNF Project facilities that will facilitate decontamination and ultimate decommissioning and environmental restoration activities. Design and operating practices that minimize the production of contamination and confine it to designated areas are important for final D&D considerations. Additionally, this section describes the conceptual D&D plan for the SNF Project facilities.

16.3.1 Design Features

SNF Project facilities include design features to facilitate D&D. These design features control the location of the planned contamination and minimize the potential for spread of contamination. Planning and designing for reducing the volume of contaminated areas and precluding inaccessible areas where contamination may reside allows for D&D operations to be conducted with less residual risks and in a more cost effective manner. Typical design features that facilitate D&D include the following:

- Use of modular, separable confinements for radioactive and other hazardous materials to preclude contamination of fixed portions of the structure.

- Use of localized liquid transfer systems that avoid long runs of buried contaminated piping.

- Location of exhaust filtration components of the ventilation systems at or near individual enclosures to minimize long runs of internally contaminated ductwork.

• Equipment that precludes, to the extent practicable, the accumulations of radioactive or other hazardous materials in relatively inaccessible areas including curves and turns in piping and ductwork

• Use of materials that reduce the amount of radioactive and other hazardous materials requiring disposal and that are easily decontaminated

• Designs that ease cut-up, dismantlement, removal, and packaging of contaminated equipment from the facility

• Use of modular radiation shielding

• Use of lifting lugs on large tanks and equipment

• Fully drainable piping systems that carry contaminated or potentially contaminated liquids

• Use of metal liners, as required

• Use of smooth finishes (absence of cracks, crevices, and joints to the extent possible) to prevent contaminated material accumulation in inaccessible areas

• Finishes that enhance decontamination of surfaces

Facility-specific design features are described in the facility annexes to the SNF Project Final Safety Analysis Report (FSAR)

16 3 2 Operational Considerations

During normal operating conditions, operating practices will minimize the production of radiological contamination and confine it to designated areas. During the potential accident scenarios identified in Chapters 3 of the facility FSAR Annexes, controls are in place as described in Chapters 4 of the facility FSAR Annexes that will prevent or mitigate the spread of contamination. The likelihood of uncontrolled contamination being present in the SNF Project facilities or contamination being released to the environment during SNF retrieval, processing, and storage is small, thereby aiding eventual D&D cleanup activities. Operational considerations that facilitate D&D include the following:

• Implementation of the radiation protection program which includes elements such as the as low as reasonably achievable (ALARA) policy and program, radiological monitoring, contamination control, access control, and work planning (described in Chapter 7) to minimize the spread or release of contamination.
Implementation of the radioactive and hazardous management program which includes elements such as solid, liquid, and airborne waste handling, treatment, and disposal, and waste minimization practices that reduce the generation of wastes and minimize the spread or release of contamination (described in Chapter 9).

Facility-specific operational considerations are addressed in the facility FSAR Annexes.

16.3.3 Decommissioning

The SNF Project facility shutdown, deactivation, and eventual decommissioning process described in this section provides conceptual D&D plans for the SNF Project facilities. The SNF Project facilities may be identified for reuse instead of a direct path that culminates in facility decommissioning following the end of their present missions. This case is not discussed in this chapter because reuse would require a similar process like that required for the construction, retrofit, and operations of the SNF Project facilities for their current mission of SNF retrieval, processing, and interim storage of SNF.

When operations cease at the SNF Project facilities, the follow-on activities, whether they are associated with shutdown, deactivation, or decommissioning, will be different than those described and evaluated for normal operations in the facility FSAR Annexes. An assessment of these activities based on an evaluation of the type and magnitude of hazards and complexity of the operations conducted in a facility during a specific life-cycle phase is required as described in documentation such as the shutdown, deactivation, surveillance and maintenance, and decommissioning plans identified below.

When a facility's mission has been completed and there are no other identified missions or programs to support, a facility can be shutdown or placed in a standby condition. A facility status change requires U.S. Department of Energy (DOE), Richland Operations Office concurrence. Several options with varying degrees of plant and equipment layup are described in HNF-PRO-1794, Facility Shutdown, Standby, and Transfer. This procedure provides guidance for the preparation of a facility shutdown or standby plan which provides the overall technical guidance for those activities associated with the shutdown or standby. The plan will address the retention of documentation, continued operations of appropriate safety and fire protection equipment, conduct of radiation surveys, reassignment or disposition of property and other activities associated with facility shutdown. A request to transfer to the surplus facility program may take place at this stage.

A facility will undergo deactivation and prepare a deactivation plan once the facility has been formally declared a surplus facility. The deactivation plan is described in HNF-PRO-443, Facility Deactivation Requirements, and provides guidance for the goals, activities, and organizational responsibilities associated with the transition of the surplus facility to a deactivated status. Work includes the removal of all radioactive and hazardous material to the extent possible and the identification and documentation of the material that cannot be removed at this stage. Contamination is also removed to the extent possible or is identified and appropriate confinement.
controls are established. A turnover package is developed that documents the configuration for transfer to D&D. This package includes all of the necessary approved NEPA documentation, safety analysis documents, and configuration documentation.

The SNF Project is not responsible for decommissioning activities, but decommissioning will take place under the DOE Office of Environmental Management program as implemented by the designated onsite contractor. The general stages of a decommissioning project, as identified in DOE/EM-0246, *U.S. Department of Energy Office of Environmental Management Decommissioning Resource Manual*, include the following:

- **Predecision** – Work includes deactivating the facility and establishing a surveillance and maintenance program for care of the facility until actual decommissioning can be performed. After facility deactivation, a preliminary characterization to obtain the general nature and extent of contamination and a preliminary hazard analysis to determine the specific hazards remaining in the facility are performed to determine the appropriate features of the surveillance and maintenance program.

- **Determination of action** – When the decision to proceed with decommissioning is made and the appropriateness of CERCLA reviewed, the scope of the project is defined and the initial cost, schedule, and technical baselines are established in the decommissioning project plan.

- **Choosing the decommissioning alternative** – Additional information is collected and analysis performed to identify the decommissioning alternatives that are addressed in either the CERCLA or the NEPA process. A preferred decommissioning alternative is selected and documented through this process.

- **Engineering and planning** – Engineering and planning work is performed to prepare a decommissioning plan that can be considered Title II, Detailed Engineering, for the project. The decommissioning plan replaces the decommissioning project plan. A readiness review is performed.

- **Performance of decommissioning operations** – Field work is carried out to achieve the end criteria as stated in the decommissioning plan and final radiological, and chemical surveys are conducted to demonstrate meeting the criteria.

- **Post-decommissioning action** – Follow-up actions may include ongoing remedial action programs. Or, as with the case of the entombment option, long-term surveillance and maintenance may be appropriate.

All efforts to keep contamination contained and localized and to prevent its spread to additional items of equipment and other locations will help to minimize the job of decommissioning. Much of the support equipment, such as air compressors and water supplies, and much of the heating, ventilation, and air conditioning equipment, should remain radiologically clean and be relatively simple to dispose of using routine demolition techniques. After completion...
of fuel removal and cold vacuum drying operations, it is anticipated that the K Basins and CVDF will be shutdown, deactivated, and placed in a surveillance and maintenance mode before final dispositioning. This would include removal of all contaminated liquid effluents and flushing and cleaning of liquid effluent systems (e.g., tanks, piping). All loose contamination would be removed from contaminated air systems (e.g., ducting, filters, filter housings). Loose contamination on structure surfaces (e.g., floors, walls, ceilings) would be decontaminated such that all that remains is fixed contamination. Facility decontamination waste will be disposed of at the appropriate waste disposal facilities.

Administrative areas, such as control rooms, kitchens, change facilities, and other structures and equipment located outside of the contaminated areas should remain radiologically clean and be relatively simple to dispose of using routine demolition techniques. Decommissioning of the remaining facility would involve decontamination of the concrete and structure if required, and/or disposal as low-level waste.

All decommissioning plans will comply with DOE Order 5820 2A, Chapter V, "Decommissioning of Radioactively Contaminated Facilities," DOE/EM-0246, or the latest DOE requirements and guidance in effect. The plan will address the restoration of the area and the reduction of any contamination to the level applicable to the preferred decommissioning alternative.

Operational records (e.g., design drawings and modifications, characterization data on contamination levels, prior decontamination activities, and incident reports required by DOE orders) for the SNF Project facilities and their related process equipment are maintained by SNF Project Operations for use in preparing decommissioning plans.

Final decommissioning plans will include detailed characterization and treatment of waste quantities generated during D&D activities. Based on anticipated contamination levels and cleansing techniques, the risk implication for decontamination is low.

During D&D activities, there will likely be some processing of hazardous or radioactive materials generated by cleanup of the SNF Project facilities. Low-level radioactive waste will probably be shipped to onsite disposal. Transuranic wastes will be packaged and certified for permanent disposal in an approved facility. Hazardous waste will be disposed of at a permitted hazardous waste treatment, storage, and disposal facility. The specific treatment, storage, and disposal facility has not been identified.

17 0 MANAGEMENT, ORGANIZATION, AND INSTITUTIONAL SAFETY PROVISIONS

17 1 INTRODUCTION

The Spent Nuclear Fuel (SNF) Project was formed to address the need to move SNF from the present degraded storage conditions in the 100 K Area K Basins to the Cold Vacuum Drying Facility (CVDF) for conditioning and to the Canister Storage Building (CSB) for safe interim storage until final disposition of the SNF is decided at the national level. In addition, the SNF Project has responsibility for stewardship of SNF from locations on the Hanford Site other than the K Basins. SNF from other locations will be stored at the Interim Storage Area (ISA) adjacent to the CSB.

The organizational structure, responsibilities, and interfaces that support safe design, construction, and operational activities of the SNF Project facilities are identified in this chapter. In addition, safety management policies and programs are discussed in sufficient detail to demonstrate the safety conscious environment of the SNF Project. In those cases where policies, programs, and practices important to safe operation are described in detail in other Hanford Site documents, the information is summarized in this chapter and the documents are referenced. The detailed programs and procedures described in referenced documents may be changed without further U.S. Department of Energy (DOE) approval to the extent that the changes do not constitute an unreviewed safety question (USQ) as defined in DOE Order 5480 21, Unreviewed Safety Questions.

17 2 REQUIREMENTS

The requirements that form the basis for management, organization, and institutional safety are found in HNF-SD-SNF-RD-001, Spent Nuclear Fuel Project Standards/Requirements Identification Document. The specific requirements applicable to this chapter include:

- DOE O 232 1A, Occurrence Reporting and Processing of Operations Information
- DOE O 425 1, Startup and Restart of Nuclear Facilities
- DOE Order 5480 19 Conduct of Operations Requirements for DOE Facilities
- DOE Order 5480 20A, Personnel Selection Qualification and Training Requirements for DOE Nuclear Facilities
- DOE Order 5480 21, Unreviewed Safety Questions
17.3 ORGANIZATIONAL STRUCTURE, RESPONSIBILITIES, AND INTERFACES

In accordance with DOE Order 5480 23, this section presents the organizational structure of the SNF Project responsible for design, construction, and operation. This includes organizational responsibilities and interfaces between internal and external organizations. The responsibilities of interfaces are described to a level of detail sufficient to identify the coordination and communication of safety issue discovery, management, coordination, and resolution.

The SNF Project supports the mission to clean up the Hanford Site by managing and reducing hazards associated with the Hanford Site SNF inventory. The SNF Project facilities consist of the K Basins, CVDF, CSB, and ISA. Design and construction of K Basins modifications and the CVDF will allow commencement of SNF removal from the K Basins and provide cold vacuum drying at the CVDF followed by storage of the dried SNF in the CSB while awaiting final disposition in a federal repository. The CSB will provide safe, economical, and environmentally sound storage for the SNF.

17.3.1 Organizational Structure

Fluor Daniel Hanford, Incorporated (FDH) is responsible to DOE, Richland Operations Office (DOE-RL), for planning, integrating, and managing SNF Project activities, including programs, projects, and operations. FDH is supported by subcontractors collectively referred to as the Project Hanford Management Contract (PHMC) team, and other companies referred to as enterprise companies. In addition, other onsite contractors, (e.g., Pacific Northwest National Laboratory, Hanford Site medical contractor), have existing contracts with DOE-RL for Hanford Site support services. Figure 17-1 depicts the FDH organization, the roles of the DOE-RL, FDH PHMC Team, and enterprise companies are shown in Figure 17-2. As shown in Figures 17-1 and 17-2, the PHMC management and integration roles are divided between FDH, major subcontractors, and the enterprise companies.
As noted in Figure 17-1, the FDH Environment, Safety, and Health (ES&H), and Performance Assurance (Quality Assurance and Facility Evaluation Board) organizations, among others, report directly to the president and chief operating officer of FDH and provide oversight to ensure institutional safety provisions are implemented.

17 3 2 Organizational Responsibilities

A summary of DOE roles and the responsibilities of DOE organizations is presented in Sections 17 3 2 1 and 17 3 2 2. The roles of FDH as the managing contractor, the major subcontractors as operations contractors, and the enterprise companies as support organizations to FDH and other onsite contractors are summarized in Sections 17 3 2 3 through 17 3 2 7. Performance assessments and review organizations are summarized in Section 17 3 2 8.

17 3 2 1 U S Department of Energy, Headquarters The DOE, Headquarters (DOE-HQ) general responsibility is to provide funding and direction as required for the SNF Project. Specific responsibilities are provided in the following subsections.

17 3 2 1 1 U S Department of Energy, Headquarters, Assistant Secretary for Environment, Safety, and Health Assistant Secretary for Environment, Safety and Health responsibilities include the following:

- Provide technical support and independent oversight
- Provide support for the National Environmental Policy Act of 1969 (NEPA) documentation
- Participate in the Regulatory Requirements Team (RRT) for developing the project regulatory strategy and safety analysis report (SAR)
- Provide administrative support to the Independent Review Panel (IRP)

Roles and responsibilities of the RRT and IRP are provided in Section 17 3 2 8 4 and 17 3 2 8 5.

17 3 2 1 2 U S Department of Energy, Headquarters, Assistant Secretary for Environmental Management Assistant Secretary for Environmental Management responsibilities include the following:

- Establish overall mission objectives and top-level functional requirements
- Provide program oversight guidance and coordination with other DOE-HQ organizations
- Provide liaison with the national SNF program
• Provide liaison with the Office of Civilian Radioactive Waste Management program

• Participate as a member of the RRT

173213 U.S. Department of Energy, Headquarters, Office of the Associate Deputy Secretary for Field Management Office of the Associate Deputy Secretary for Field Management responsibilities include the following:

• Conduct independent cost estimates for the SNF Project as appropriate

• Participate in the validation of the SNF Project as part of the funding process

17322 U.S. Department of Energy, Richland Operations Office DOE-RL responsibilities are provided below

173221 U.S. Department of Energy, Spent Nuclear Fuel Project Division
Responsibilities for the management of the SNF Project are assigned through the deputy manager for site transition to the DOE Office of Spent Nuclear Fuels (SFO). The director of the SFO is the project manager and will conduct the project in accordance with DOE Order 4700.1, Project Management System.

The SFO organization is consistent with a projectized organization having approximately two-thirds of the staff matrixed from line organizations. The DOE SFO is responsible for the overall management, administration, performance, and operations and maintenance activities of the SNF Project. The DOE SFO ensures that the required levels of quality, safety, and environmental compliance are achieved within established technical, schedule, and cost baselines. Specific responsibilities and authorities include, but are not limited to, the following activities:

• Provide review and approval of SNF Project baseline documents

• Assume overall responsibility for design, construction, startup, and operation of systems and facilities within the scope of the SNF Project through direction to the contractor participants

• Monitor and maintain overview of project activities, cost and schedule status and technical baseline compliance to ensure project performance expectations, quality, cost, and schedule objectives are met

• Provide DOE interface with the DOE-ID/EM-67 National Spent Nuclear Fuel Program

• Provide and coordinate review and approval of required environmental and safety documentation

• Ensure quality, safety, and environmental requirements are applied
- Review and submit budget documents in accordance with the DOE budget cycle
- Interface with stakeholders
- Interface with the IRP

**17.3.2.2 U.S. Department of Energy, Office of Spent Nuclear Fuels Subproject Manager** The DOE SFO subproject manager is responsible for the management and administration of the SNF subproject activities, as well as for assessment of subproject performance and maintenance of subproject baselines. Specific responsibilities and authorities of the DOE SFO subproject manager include the following:

- Provide review and approval of SNF subproject documents including required environmental and safety documentation
- Approve overall scope, cost, and schedule baselines for the subprojects
- Monitor and maintain overview of subproject activities, cost, schedules, and status to ensure subproject performance, quality, cost, and schedule objectives are met
- Issue project authorizations for expense and capital funding as required by DOE-RL
- Release definitive design for construction and performance specification for design-and-build contracts

**17.3.2.3 Fluor Daniel Hanford, Incorporated** As management contractor, FDH is ultimately responsible for (1) contract performance, which includes protecting the public, workers, and environment from hazards associated with Hanford Site operations; (2) providing a focal point for interaction with DOE and the stakeholders; and (3) ES&H and Performance Assurance oversight. Figures 17-1 and 17-2 identify the organizations and organizational responsibilities within FDH that interface with SNF Project operations.

The FDH organization includes a Vice President and Project Director responsible for integrating the SNF Project into the overall Hanford Site organization. The SNF Project Vice President and Project Director provides leadership, oversight, direction, and control and employs the best commercial practices to the subcontractors in the execution of the SNF Project. The Vice President and Project Director monitors and is accountable for FDH subcontractor performance to ensure technical, cost, and schedule baseline conformance, integrating interfaces, evaluating and forecasting, and reporting performance. The reporting relationship of the SNF Project Vice President to the FDH President and Chief Executive Officer is shown in Figures 17-1, 17-2, and 17-3.

**17.3.2.3.1 Environment, Safety, and Health Organization** The ES&H organization reports to the highest operating levels in FDH to ensure coordinated development, incorporation, and implementation of environmental, safety, and health requirements into sitewide programs.
The environmental, safety, and health requirements are incorporated, as appropriate, into specific environmental, safety, and health programs associated with the SNF Project. The ES&H organization provides support to the SNF Project in the following areas:

- Occupational safety and health
- Emergency preparedness
- Nuclear safety and work controls
- Criticality safety
- Environment protection and regulation
- Radiation protection
- Planning and evaluation

Details of roles and responsibilities are provided in HNF-MP-003, *Integrated Environment Safety and Health Management System Plan*.

**17.3.2.3.2 Performance Assurance Organization** The FDH Performance Assurance organization is in place to develop sitewide quality assurance programs and policies and to communicate those programs and policies to the SNF Project. The Performance Assurance organization also reports to the highest operating levels in FDH. The purpose of FDH quality assurance programs is to establish an integrated approach to quality that ensures performance of all Hanford Site activities meets contract expectations. The quality assurance support function includes the following areas:

- Quality assurance programs
- Quality assurance surveillance
- Acceptance inspection
- Quality assurance technical support
- Performance assurance
- Codes, standards, and corrective action management

Details of roles and responsibilities are provided in HNF-MP-001 *Management and Integration Plan*.

The FDH Facility Evaluation Board and Independent Program Assessment organizations reside in the Performance Assurance organization to provide oversight activities including audits, surveillances, assessments, and appraisals of organizations performing environmental or quality-affecting activities.

**17.3.2.3.3 Training Organization** The training organization establishes the standards for all PHMC Team training to ensure that all training programs meet DOE-RL training requirements and to prepare the workforce to perform work safely and effectively. These standards, in conjunction with implementing procedures and supporting documents that govern training under the PHMC, establish a graded, systematic approach to training that is designed to ensure that the
qualifcation and training program meets DOE and federal requirements. The training organization provides support to the SNF Project in the following areas:

- Training programs/standards
- Training business operations
- Management information systems
- Training integration

Details of roles and responsibilities are provided in HNF-MP-001.

17.3.2.4 Spent Nuclear Fuel Project The SNF Project has responsibility for the design, construction, and operation of the SNF Project facilities. The SNF Project is the design authority and maintenance and operations contractor and has primary responsibility for executing the project mission. This includes defining systems through systems engineering, managing the subprojects and programs, providing technical direction to the design agents (architect-engineers) and the construction managers, reviewing and approving products and activities, and ensuring that requirements are met.

The SNF Project Vice President and Project Director has designed an organization and structure (Figure 17-3) combined of special projects and traditional work functions that provides management and technical support to the tasks of the SNF Project. The combination of FDH, SNF Project, SNF Project facilities, enterprise companies, and other onsite organizations ensures that responsibilities, resources, technical expertise, and management involvement are matched for safe, effective, and efficient accomplishment of the SNF Project mission.

The SNF Project organizations will transition from a design and construction, surveillance and maintenance (safe and stable storage of SNF in the K Basins) organization to a processing organization that will be involved with removing SNF from the K Basins, transporting the SNF for cold vacuum drying in the CVDF, and storing the SNF in the CSB.

The mission of the SNF Project is provided in HNF-3552, *Spent Nuclear Fuel Project Execution Plan*, and summarized below:

- Stewardship of applicable 100 K Area facilities until all of the SNF, debris, and sludge has been removed and turned over to the facility decontamination and decommissioning organization (Bechtel Hanford, Incorporated, currently has responsibility for portions of the K Area [BHI-00888]).
- Characterization of the K Basins SNF and sludge.
- Retrieval of all K Basins SNF for packaging and transportation to interim storage (managed as a subproject of the SNF Project).
- Removal and disposition of K Basins sludge and debris (managed as a subproject of the SNF Project).
- Treatment of the K Basins water until the SNF, debris, and sludge is removed
- Design and construction of the CVDF, including the fuel retrieval system, multi-canister overpack, and K Basin modifications, and of the CSB, including receiving and storage facilities perimeter fence, associated roadways and extension of Site utilities
- Operation of the CSB until all SNF from the K Basins is stored in a dry and stable configuration awaiting final disposition
- Stewardship of SNF from locations on the Hanford Site other than the K Basins that will be stored at the ISA adjacent to the CSB
- Other uses of the CVDF, which could include temporary storage of equipment such as the sludge removal system transport package
- Overall compliance with SNF Project quality assurance requirements and the proper delegation of that responsibility
- Development and maintenance of SNF Project-specific implementing documents that translate requirements into work processes
- Oversight of the implementation of specific safety program responsibilities to clearly demonstrate that safety is the first consideration for every activity, this includes responsibilities for accident investigation and corrective actions, worksite inspections and hazards analysis, conduct of safety meetings and prejob briefings, and employee safety training
- Design, construction, and operation of interim storage and stabilization facilities (near-term, interim, and stabilization) until turnover to an operations organization as described in this section

The SNF Project organizational structure is provided in Figure 17-3. This organization provides support to each of the SNF Project facilities. Responsibilities of the organizations reporting to the SNF Project Vice President and Project Director include, but are not limited to, the following

- Fulfilling the SNF Project mission
- Ensuring that design, construction, and operation meet all applicable Federal, state, and local laws and regulations and company standards and procedures
- Maintaining close liaison with DOE, the Defense Nuclear Facility Safety Board, and other external organizations
Establishing a management assessment process and ensuring management assessments involve senior management in determining the effectiveness of each organization and supporting organization.

- Ensuring the achievement of quality
- Implementing full compliance with the quality assurance program plan (QAPP)
- Ensuring QAPP compliance by outside SNF Project participants

17 3 2 4 1 Spent Nuclear Fuel Project Management SNF Project management is committed to providing for the safety and health of the workers and the public and protecting the environment during design, construction, and operation of each SNF Project facility. The responsibility for safety and health practices rests with the line organization. Responsibilities of the SNF Project primary organizations are presented below, the organizational structure is presented in Figure 17-3. Specifics on the organizational structure for K Basins are presented in Chapter 17 of WHC-SD-WM-SAR-062, K Basins Final Safety Analysis Report.

The SNF Project Vice President and Project Director is responsible for all aspects of project execution including safety, health, and environmental issues. Example responsibilities include the following:

- Operate the SNF Project facilities within the safety authorization basis and ensure safe operation of existing wet storage facilities and cost-effective transfer of SNF to a new dry storage facility by providing overall management direction to personnel performing the following functions: operations, maintenance, engineering, construction, safety and health, environmental protection, quality assurance, radiological controls, planning, contracts, procurement, training, scheduling, occupational safety and industrial hygiene, and others
- Direct the integration of multiple subprojects to successfully achieve project goals within schedule and budget constraints
- Develop and oversee the implementation of corrective measures to resolve complex technical and management issues threatening timely completion of the project
- Provide leadership and guidance for occupational safety and industrial hygiene issues. This includes providing leadership for implementation of the Voluntary Protection Program (VPP) and oversight of project construction activities
- Integrate project activities in the PHMC by facilitating effective communications and resolving issues among projects, ES&H, Performance Assurance, FDH subcontractors, PHMC support organizations, management, and DOE-RL
• Lead the SNF Project-specific execution of life-cycle baseline, multiyear, and current fiscal-year plans, integrate subcontractor activities into the planning process, and ensure project integration of these activities from a scope, schedule, interface, and resource perspective

• Interface with DOE-RL regarding incorporation of regulatory commitments and other requirements

• Use dedicated staff support, matrixed from FDH central support (e.g., ES&H and Performance Assurance) to perform verification activities and to formally assess performance

• Manage the overall execution of the SNF Project

17 3 2 4 2 Operations The SNF Project operations organizations (K East–K West Fuel Removal, SNF Transfer–CVDF, CSB SNF Waste Storage, Sludge Debris, Water Cleanup, and Other Site SNF Disposition shown in Figures 17-3, 17-4 and 17-5) manage and direct SNF Project operational activities in a safe, economic, and environmentally sound manner. All activities, including facility operations and maintenance, new facility startup and testing, handling and storage of SNF, and operational support functions (e.g., training, radiological control), are conducted in compliance with DOE contractual orders and applicable Federal, state, and local laws. Functional responsibilities are provided below:

Operations Operations successfully and cost-effectively executes the review process, start-up and ramp-up activities. Operations ensures that workers' safety and health are maintained at a high level of awareness and performance. Other specific responsibilities include the following:

• Operate the SNF Project facilities within the safety authorization basis

• Provide safe and cost-effective interim storage, conditioning, and relocation of SNF from 105K East and 105K West basins to dry, passive, interim storage within the CSB. Ensure activities are managed in accordance with applicable laws, regulations, and contractual obligations

• Develop and monitor performance to SNF Project goals, objectives, milestones, and assigned company performance agreements. Perform required self-assessment, and complete corrective actions with the goal of continuous improvement

• Ensure the development and preparation of schedules and financial documents containing program plans, budgets, and other accountability factors for the successful conduct of the SNF Project mission

• Provide operational input and review for all operational activities planned for the duration of the SNF Project
Execute effective integration and planning of all work activities of each SNF Project facility

Review facility design for operability, maintainability, and a defined safety basis that can be implemented in the field

Establish and maintain effective working interfaces with supporting organizations and act as liaison for Operations

Develop and coordinate initial staffing for operation of the facility and systems

Review preoperational test procedures

Designate representatives to support the Test Review Board, as required

Participate in the operational readiness review (ORR) process

Manage all basin operational activities to meet requirements on schedule and within budget

Maintain standard of performance for formal conduct of operations in accordance with DOE Order 5480 19 as defined in the conduct of operations applicability matrix

Provide surveillance data for all systems, conduct analysis and limited retention of data, and maintain up-to-date status of all facilities and equipment

Establish and coordinate the priorities for production and maintenance activities

Perform operational waste handling and associated analyses

Provide administrative management of the following programs (1) occurrence reporting, (2) key control, (3) lock and tag, (4) event investigation, (5) lessons learned, and (6) operator aids

Establish and maintain excellence in housekeeping

Startup Integration  Startup within Startup Integration (Figure 17-6) develops coordinates, and implements the SNF Project preoperational test program and supports the operational test program for the SNF Project facilities. This function will be absorbed into Operations when the SNF Project facilities are declared to be operational. Specific responsibilities include the following:

Manage test planning and scheduling, work force allocation, and budgeting activities
- Review and recommend revisions to design and procurement specifications, facility acceptance tests, construction acceptance tests, and contractor submittals as they relate to startup and testing
- Support preoperational test specification preparation
- Prepare preoperational acceptance test procedures in accordance with applicable test specifications
- Establish requirements and implement a system for access and work control during startup testing
- Provide maintenance support for equipment and systems that are turned over to Startup
- Manage organizational interface issues between Startup and other groups
- Review and accept project deliverables, which include hardware, software, certified vendor information, drawings, specifications, as-built information, test and inspection data, operation and maintenance procedures and manuals, and any other documentation related to safe and reliable operation of the systems, structures, and components (SSCs)
- Direct performance of preoperational acceptance testing and facilitate test deficiency resolution
- Assist in field training and operational "dry runs" to ensure that operators, procedures, and equipment are in a final state of readiness
- Coordinate control of test equipment, instrumentation, and other materials required to support testing activities
- Ensure special nuclear material accountability is maintained by establishing and maintaining custodial ownership of the special nuclear material
- Ensure all waste control activities for Operations meets the requirements of DOE orders along with applicable Federal, state, and local laws

**Operational Readiness Review**  The SNF ORR function (Figure 17-6) within Startup Integration directs and coordinates all key activities to successfully complete a management self-assessment for operational readiness, independent ORR, and DOE ORR in accordance with Section 1721 of the S/RID (HNF-SD-SNF-RD-001) and DOE O 425 1 for the SNF Project facilities. This includes overseeing the financial and schedule activities, updating the Startup Notification Report to FDH, and ORR records and consultational reviews related to ORRs. The
ORR function also provides oversight and assistance for SNF Project facility readiness assessments. Specific responsibilities include the following:

- Develop, maintain, and update the management self-assessment plan for operational readiness that will meet the requirements of DOE O 425 1, DOE C 425 1, CRD Startup and Restart of Nuclear Facilities, RLID 425 1, Startup and Restart of Nuclear Facilities, and DOE-STD-3006-95, Planning and Conduct of Operational Readiness Reviews (ORR).

- Develop and issue necessary plans of action to FDH and DOE-RL for all CSB activities as required by DOE O 425 1.

- Develop necessary plans, desk instructions and procedures to define and control project readiness determinations, management self-assessment, and ORR process.

- Provide interface with the senior ORR advisor from the DOE-RL staff (if assigned) the independent ORR chair, and the FDH organization responsible for Site ORR coordination, as well as those responsible for project-specific ORR activities.

- Conduct orientation briefings, with assistance from the SNF Project Training and Support Services personnel for all SNF Project staff associated with the management self-assessment or ORR activities.

- Provide guidance and on-the-job training for line managers performing management self-assessment activities for operational readiness and any management self-assessment validation activities to ensure that consistency and quality management self-assessment reviews for operational readiness take place.

- Provide 100% review of all management self-assessment appraisal forms for operational readiness for accuracy and completeness. This includes field assessment checks of select appraisals.

- Establish metrics from management self-assessment and ORR progress, track on a routine basis for trends that may need corrections, recommend changes based on results.

- Routinely monitor activities necessary to ensure appropriate implementation of the management self-assessment plan for operational readiness.

- Ensure implementation (administratively and through field verifications) of requirements from S/RLD assigned to the ORR group.
Procedures  Procedures development (Figure 17-4) includes startup project procedures, technical procedures, administrative support and S/RID coordination. Specific responsibilities include the following:

- Provide direction and maintain responsibility and control for SNF Project technical and administrative procedures in accordance with Section 10 of the S/RID (HNF-SD-SNF-RD-001), including development, control, and issuance, interact with other SNF Project organizations to ensure procedures comply with applicable standards and requirements.

- Provide procedure writers for the development, implementation and maintenance of the SNF Project technical procedures system (e.g., normal operating procedures, fuel handling procedures).

- Implement conduct of operations guidelines and ensure that activities for the training and procedures group are accomplished in a manner that supports procedure compliance, best management practices, and enhances employees' work environment.

- Ensure training and procedures are in compliance with Project Hanford Management System requirements (i.e., providing identified SNF Project functional area owner and lead reviews correspondent to the functional areas of the Project Hanford Management System), review and update SNF Project administrative and technical procedures to ensure compliance and clear guidance is maintained.

- Maintain SNF Project shared-area file server and electronic notification of changes to server for various SNF Project documentation (i.e., policies, charters, and administrative and technical procedures and documents).

- Maintain S/RIDs self-assessment database, provide data sorts for performance indicator charts and various other tasks as requested.

Training  Training includes operations training, maintenance training, and administrative support. Specific responsibilities include the following:

- Manage and direct activities related to SNF Project administrative and/or technical procedure development and the development of a comprehensive technical training program (see Chapter 12 for additional details on training and procedure development).

- Provide management of a comprehensive technical training program of appropriate formality and rigor to ensure that personnel are properly trained for the safe and efficient operation of all SNF Project activities.

- Provide development and instruction of technical training packages and provide scheduling services for required training for SNF Project personnel.
• Administer a comprehensive training plan for guiding technical procedure
development and field implementation for facility systems, and operating practices
and routines, including a qualification/certification program as described in
Section 4.0 of the S/RID (HNF-SD-SNF-RD-001)

• Provide point-of-contact for SNF Project management for all training needs

17.3.2.4.3 Maintenance  The SNF Project Operations Maintenance organization
(Figure 17-7) manages and directs activities for maintenance of the SNF Project facilities
Specific responsibilities include the following

• Direct all maintenance and work control activities in strict compliance with
DOE Order 4330.4B, Maintenance Management Program, Topical Area,
"Maintenance " Ensure that all corrective and preventative maintenance is performed
supporting operations in a manner that reflects the highest commitment to safety,
total quality, and excellence in a timely and cost-effective manner, and in accordance
with established procedures

• Participate in the overview of labor activities, ensure that assignments are in
accordance with the Hanford Atomic Metal Trades Council agreement and that all
grievances and employee concerns are addressed promptly and adequately

• Provide maintenance resources (allocation and coordination) for general facilities
support functions in the assigned areas  This includes transportation services,
management of contract support efforts, and procurement of maintenance materials

• Ensure maintenance personnel are sufficiently trained to meet the requirements of the
work assigned

• Provide daily direction of maintenance work tasks where needed

• Provide work package planning and final package assembly for all job control system
work packages

• Assemble track status, and close out all job control system work packages ensuring
document retention requirements are followed

• Provide material control of tools, shop stock, staged material, and warehoused
equipment

• Manage and control the use of measuring and test equipment and provide reverse
traceability capabilities
Ensure that prejob briefings are held addressing all safety and radiological issues, setting the high standards and expectations for each individual taking part in the work.

Ensure timely investigations of reported off-normal plant events (e.g., events, unusual occurrences and Occupational Safety and Health Administration recordables) and lost work day injuries.

Establish an integrated approach to manage work activities.

Monitor performance versus the established schedule and budget estimates and take action to maintain schedule and budget commitments.

Identify and resolve barriers to complete work activities.

Identify and implement work planning, scheduling, and implementation process improvements.

17 3 2 4 4 Spent Nuclear Fuel Project Engineering  The SNF Project Engineering Manager and Chief Engineer has overall responsibility for establishing, implementing, and maintaining the engineering technical baseline, authorization basis, and nuclear safety regulatory compliance. As design authority for the SNF Project, the Chief Engineer defines requirements for and ensures the technical adequacy of all SNF Project facilities SSCs. This authority ensures that the initial release and changes to all documentation that affect functions, requirements, architecture, interfaces, operability, maintainability, and safety basis are technically sound and consistent with the approved authorization basis.

Responsibilities of the Manager and Chief Engineer position include the following:

- Perform the Chief Engineer function and provide interpretive authority for the resolution of technical issues.
- Establish and maintain an engineering program infrastructure consistent with the SNF Project mission scope and program logic.
- Direct technical integration and coordination to ensure that key SNF Project engineering goals are achieved.
- Lead and manage interfaces with customers, the public, and stakeholders in technical matters associated with the SNF Project mission.
Functional responsibilities of the Engineering organization are as follows

- Facility engineering
  - Provide day-to-day engineering support for the operations and maintenance of the K Basins, CVDF, CSB, and ISA facilities and systems
  - Configuration control of plant design documentation and engineering infrastructure
  - Provide cognizant facility systems engineers and supporting staff to perform responsibilities
  - Provide engineering expertise for plant walkdowns to ensure safe and effective implementation of maintenance upgrades and plant modifications
  - Develop and maintain in-depth knowledge of system design, performance, and current condition through regular system walkdowns, system performance reviews, and communications with SNF Project facility operations, maintenance, and engineering personnel
  - Provide engineering support for work package preparation, execution, and closeout
  - Design, recommend, select, and specify new plant equipment and modifications to plant equipment and systems to support the SNF Project facilities using engineering change notices
  - Provide the design of systems, components, and equipment required to support fuel removal activities, remove waste streams that could result in a potential insult to the environment, and provide and implement dose reduction for decontamination and decommissioning activities
  - Ensure all provided systems are operable within the existing safety authorization basis and technical safety requirements (TSRs), or support necessary updates to the SNF Project Final Safety Analysis Report (FSAR)
  - Support/maintain corrective and preventive maintenance of SSCs
  - Conduct the fire protection program
  - Resolve operations issues
  - Monitor instrumentation and alarms
• Systems engineering
  – Establish the engineering processes and monitor performance of engineering activities
  – Develop and maintain engineering procedures and maintain the configuration management plan
  – Assess performance of engineering activities relative to the approved procedures, the configuration management plan, and other applicable PHMC requirements

• Nuclear safety
  – Provide overall coordination and integration of the SNF Project regulatory matters, including nuclear safety regulations by interfacing with FDH, DOE, and other stakeholders
  – Prepare all safety analysis documents for the SNF Project facilities and perform independent reviews of activities documented with safety implications
  – Manage USQ process for SNF Project facilities

• Process engineering
  – Define process technical basis
  – Develop technical basis documents
  – Provide process validation and monitoring requirements for fuel storage processes
  – Develop thermal-hydraulic models of the multi-canister overpacks in process and storage that will support completion of the SNF Project FSAR and system designs
  – Produce and maintain process flow diagrams and process technical manuals and integrate cross-cutting calculations for subprojects
  – Manage characterization data

• Process control
  – Monitor the overall engineering process relative to technical basis, safety, and regulatory set points
- Provide answers to operational, safety, and quality assurance inquiries
- Maintain chemical and technology information to address questions during operational processing

• Technical integration
  - Provide design authorities for the SNF Project
  - Design authorities interface with cognizant engineers at each SNF Project facility to ensure a strong technical basis for operation, to maintain the SNF Project facility in conformance with the authorization basis, and to build a culture of excellence in engineering
  - Assess performance of engineering activities relative to the approved procedures, the configuration management plan, and other applicable PHMC requirements
  - Provide other design authority responsibilities

• Technical operations
  - Plan, direct, and complete all work necessary to ensure that SNF Project technical issues are identified and brought to closure such that project objectives are achieved
  - Work with managers throughout the SNF Project to facilitate identification of technical issues
  - Ensure that closure plans appropriate to specific issues are prepared
  - Ensure that closure criteria are developed and consensus on the criteria are achieved
  - Bring together and direct all engineering, subproject, or corporate resources necessary to achieve closure
  - Provide oversight of lower tier issues management
  - Integrate issue resolution into project schedules
  - Track and status progress for issue closure
17.3.2.4.5 Spent Nuclear Fuel Project Quality Assurance  The SNF Project Quality Assurance organization (Figure 17-3) develops and maintains the SNF Project QAPP, and interprets and sets quality assurance criteria for SNF Project organizations. The SNF Project line organizations have the overall responsibility for performing work activities within the established criteria. Specific responsibilities of the SNF Project Quality Assurance organization include the following:

- Interpret and approve quality assurance program requirements
- Identify quality problems, initiate, recommend, or provide solutions to quality problems, and verify those solutions are implemented and effective
- Perform oversight activities on workscope to verify implementation of quality assurance requirements
- Provide overview of project management's implementation of the QAPP and implementing procedures
- Review project documentation such as SARs, S/RIDs, and project management plans
- Prepare and support ORR activities to incorporate quality assurance requirements

17.3.2.4.6 Radiological Controls  The SNF Project Operations Radiological Control group (Figure 17-8) administers an occupational radiation safety program that is in full compliance with Section 110 of the S/RID (HNF-SD-SNF-RD-001) and Title 10, Code of Federal Regulations, Part 835 “Occupational Radiation Protection” (10 CFR 835), and in a manner commensurate with HSRCM-1 Hanford Site Radiological Control Manual, for the SNF Project. Specific responsibilities include the following:

- Manage an occupational radiation safety program that is in full compliance with 10 CFR 835 and in a manner commensurate with HSRCM-1
- Perform radiological surveillance and monitoring as specified by 10 CFR 835, Subpart E, Article 835 401
- Administer ALARA (as low as reasonably achievable) Program as specified by 10 CFR 835, Subpart B, Section 835 101 C and 10 CFR 835 Subpart K, including program implementation, design reviews and work control processes pertaining to radiological work and facilities
- Issue dosimetry in support of 10 CFR Subpart E, Article 835 402. In this context, "field dosimetry" applies to job-specific dosimetry only; it does not apply to dosimeters that are issued by SNF Project dosimetry

November 1999
- Identify the need for, and location of, area monitors and air sampling equipment as specified by 10 CFR 835, Subpart E, Article 835 403. Radiological Control personnel obtain readings from these instruments for the purpose of performing occupational monitoring.

- Perform radioactive contamination monitoring as specified by 10 CFR 835, Subpart E, Article 835 404.

- Provide radiological entry control and enforce SNF Project-specific entry control criteria that are consistent with 10 CFR 835, Subpart F, Articles 835 501 and 835 502.

- Establish SNF Project-specific radiological posting criteria that are consistent with 10 CFR 835, Subpart G.

- Administer processing of legal record documents (generated by Radiological Control personnel) that document radiological monitoring, surveillance, dosimetry issue, and radiological access control activities.

- Ensure that health physics technicians receive sufficient training as defined by 10 CFR 835, Subpart J, Article 835 903.

- Prepare radiation work permits that specify adequate protective measures for radiation workers as defined by DOE/EH-0256T, *U.S. Department of Energy Radiological Control Manual*.

- Perform as the SNF Project interpretive authority for 10 CFR 835 and DOE/EH-0256T.

- Maintain a reporting program that identifies radiological issues and alerts SNF Project line management to compliance issues associated with 10 CFR 835 and/or applicable DOE orders governing radiological safety.

- Provide quick turnaround radiological-count-room services, according to 10 CFR 835, HSRCM-1, DOE Order 5400 5, *Radiation Protection of the Public and the Environment*, and SNF Project quality assurance protocols for (1) radiological control samples (air, smear soil, and miscellaneous items) and (2) radiological release of material and equipment.

**17 3 2 4 7 Spent Nuclear Fuel Project Safety, Health and Emergency Planning**  The SNF Project Safety, Health and Emergency Planning organization (Figure 17-3) manages safety and health, chemical management, and emergency planning. Specific responsibilities include the following:

- Provide leadership and guidance for emergency planning issues.
- Maintain, review, revise, and implement the building emergency plan and applicable facility-specific emergency response procedures

- Provide leadership and guidance for chemical management

- Develop and administer programs to control and minimize health and safety hazards and to promote continuous improvement in safety and health performance

- Provide and manage resources to design and implement occupational safety and health programs

- Ensure that applicable requirements are integrated into the occupational safety and health program and the procedures and standards of other applicable organizations

17.3.2.4.8 Performance Improvement and Regulatory Services  The SNF Project Performance Improvement and Regulatory Services organization (Figure 17-3) manages environmental protection, corrective action program, self-assessment management systems, performance indicators, requirements flowdown and S/RIDs, and regulatory interface and technical support. Specific responsibilities include the following:

- Prepare and ensure timely approval and implementation of environmental permits for the project. Ensure other project and site-side environmental initiatives are implemented and act as point-of-contact for environmental issues.

- Manage the SNF Project corrective action program and interface with the Site corrective action program.

- Ensure problems and issues are evaluated and reported in accordance with the Price Anderson Amendments Act of 1988.

- Provide a management assessment program that meets applicable criteria.

- Assist management with the selection, design, development, and implementation of the performance indicators.

- Monitor and assist management with maintaining an accurate set of requirements with the SNF Project S/RIDs.

17.3.2.5 Other Project Hanford Management Contract Team Companies  The following list includes the major subcontractors and a summary of their roles (HNF-MP-599):

- Numatec Hanford Corporation, which is responsible for engineering and technology support.
B&W Hanford Company, which is responsible for the Facility Stabilization Project and the Advanced Reactors Transition Project

Waste Management Federal Services of Hanford, Incorporated, which is responsible for the Waste Management Project and for environmental management and permitting

Lockheed Martin Hanford Corporation, which is responsible for the Tank Waste Remediation System Project and for providing support to FDH site systems engineering

DynCorp Tri-Cities Services, Incorporated, which is responsible for infrastructure services, including facility maintenance, site services, real estate, and property management and emergency preparedness

17 3 2 6 Enterprise Companies that Interface with the Spent Nuclear Fuel Project - Several enterprise companies provide support to SNF Project organizations as matrixed functions. The interfaces between these support companies and the applicable SNF Project organization are controlled by the SNF Project for matters related to cost, schedule, priorities, and safety management. These enterprise companies include:

- Fluor Daniel Northwest, Incorporated, which provides architect/engineering and construction management to the major subcontractors for project and/or task activities

- Lockheed Martin Services, Incorporated, which provides information resource management services and support, including telecommunications and network engineering, information systems, production computing media services, document control, and records management

- Waste Management Federal Services, Incorporated, Northwest Operations, which provides environmental management technical support to the major subcontractors and other services such as integrated pest management, groundwater well services and sampling, and transportation, packaging, and hazardous shipping certification and training

- COGEMA Engineering Corporation, which provides equipment engineering, process engineering, and professional services

- Protection Technology Hanford, which provides support services for the safeguards and security workscope, including special nuclear material control, accountability, physical security, and information security
17 3 2 6 1 Hanford Fire Department  The Hanford Fire Department's jurisdiction encompasses all of the Hanford Site. The Department is managed by DynCorp Tri-Cities Services. The Hanford Fire Department is responsible for providing the following fire protection response functions:

- Maintain command of emergency response forces to control and terminate fire-related incidents, provide emergency medical patient care, and act as the incident command agency for emergency incidents involving hazardous materials.
- Conduct functional testing and maintenance of fire protection self-contained breathing apparatus at all Hanford Site facilities.
- Maintain an active fire prevention program through facility tours and inspections of all flammable and reactive waste sites.
- Maintain a highly trained emergency response team certified under a three-year, Washington State-approved, fire fighter apprenticeship program.
- Maintain a modern fleet of emergency response vehicles consisting of pumper trucks, aerial ladder units, modular ambulances, command vehicles, wild land brush tankers, hazardous materials response vehicles, and specialized equipment designed to deal with the unique requirements of the Hanford Site.

The Hanford Fire Department works closely with the SNF Project Safety and Health and Quality Assurance organizations to support related inspection compliance, and design-review activities. Chapters 11 0 and 15 0 address the fire protection issues that apply to the safety of SNF Project facility operations.

17 3 2 6 2 Procurement and Materials Management  Procurement and Materials Management within the Business Systems group is managed by FDH with support from Fluor Daniel Northwest, Incorporated. The responsibilities of the Procurement and Materials Management organizations include the following:

- Procuring goods and services that meet established standards and requirements in accordance with approved procedures and processes with graded levels of management controls.
- Evaluating prospective suppliers against specified criteria.
- Ensuring that approved suppliers continue to provide acceptable items and services.
- Coordinating inspection and testing of specified items, services, and processes to ensure that established acceptance and performance criteria are used.
17 3 2 6 3  Transportation and Packaging Services  The transportation and packaging services organization, managed by Waste Management Federal Services of Hanford, provides sitewide policies and procedures governing hazardous materials transportation and packaging, qualification requirements and shipper training, preparation and maintenance of required shipping container safety documentation, hazardous materials packaging, design procurement support, analysis and testing, field support to the DOE-HQ transportation management program, and all other transportation management activities.

17 3 2 7  Other Onsite Contractors  Several other onsite contractors provide support to the SNF Project. The responsibilities of these contractors are discussed in the following subsections.

17 3 2 7 1  Pacific Northwest National Laboratory  The Pacific Northwest National Laboratory has responsibility for providing personnel monitoring which includes personnel dosimetry monitoring, internal dosimetry monitoring, dosimetry record management, and dose evaluation in emergency cases. The laboratory provides support to the DOE-RL and its contractors for the Radiation Instrumentation Monitoring Program. This service includes the evaluation of new instruments, maintenance of emergency response units and instruments, and the routine calibration of radiation survey instruments. The organization also performs extensive Hanford Site characterization work. Pacific Northwest National Laboratory is available to provide additional research and development support as well as review, consultation and report preparation support.

17 3 2 7 2  Site Medical Contractor  In accordance with DOE Order 5480.8A, Contractor Occupational Medical Program, the Hanford Site medical contractor serves two functions for the subprojects: (1) maintaining the medical monitoring programs for employees in compliance with Occupational Safety and Health Administration standards and DOE orders and (2) monitoring staff safety performance through reports of on-the-job injuries. The medical monitoring responsibilities include performing preplacement, periodic, return-to-work, and fitness-for-duty examinations for all workers, performing physical examinations for workers who handle hazardous waste, maintaining medical records, providing management consulting, managing the employee occupational exposure database, and managing the material safety data sheet database.

17 3 2 8  Performance Assessment and Review Organizations  As required by 10 CFR 830.120, the performance assessment and review program provides for the measurement of item and service quality, requirements compliance and work performance and promotes improvement. The assessment process incorporates a performance-based approach with emphasis on the results of work processes and compliance with requirements. (See Chapter 14.0 for additional details on the management and independent assessment program including safety issue discovery, communication management, and resolution of issues.)

Several internal and external organizations provide independent performance-based and compliance-based reviews of the SNF Project to applicable requirements. These organizations are described in the following subsections. In addition, management self-assessments are required by 10 CFR 830.120 and are performed as described in Section 17 4.1. An administrative system for
tracking action items identified as a result of internal and external audits, appraisals, evaluations, self-assessments and project schedules is described in SNF Project implementing procedures.

17.3.2.8.1 Quality Assurance Public safety, onsite worker safety, and protection of the environment are overriding considerations for the SNF Project. The commitment to safety by the SNF Project management dictates management and verification activities to ensure safety and environmental considerations are reflected in the design, procurement, construction, and operation of the project facilities in accordance with 10 CFR 830. For purposes of this document, quality assurance is all of those planned and systematic actions necessary to provide adequate confidence that an SSC will perform satisfactorily in service. Periodic inspection of SSCs in accordance with DOE Order 4330.4B will be performed to determine whether deterioration is taking place and to address technical obsolescence that threatens performance, safety, or facility preservation.

The SNF Project QAPP will meet the applicable requirements identified in Section 14.2. Assessments will be conducted to verify that these quality requirements are being met. The organizations that are responsible for providing quality assurance support are identified in Section 17.3.1. The methodology used to determine the quality assurance requirements and procedural controls selected for specific activities includes the following:

- Identifying items and activities that are candidates for procedural control by the quality assurance program

- Selecting the quality assurance requirements (and their degree of application) that are appropriate for each candidate item, component, system, structure, and activity based on the following considerations:
  - Impact of malfunction or failure on safety, health, and environmental protection
  - Design and fabrication complexity
  - Reliability of process
  - Reproducibility of results
  - Uniqueness of product
  - Degree of functional product demonstration
  - Quality history and degree of standardization
  - Impact on cost and schedule to replace in the event of failure
  - Environmental impacts due to failure
- Degree to which functional compliance can be demonstrated by inspection or test
- Necessity for special controls and surveillance over processes
- Significance to any applicable licensing process

The type of independent assessment performed and the frequency with which an assessment is performed will be based on the status, complexity, and importance of the activity or process being assessed, and the past performance of the activity or process. Independent assessments will be conducted by staff members who are technically qualified and knowledgeable in the activity or process being assessed and who have sufficient authority and freedom from the line organizations to carry out their responsibilities. An independent assessment will identify:

- Work performance and process effectiveness
- Abnormal performance and potential problems
- Improvement opportunities

SNF Project contractor participants, including subcontractors and suppliers, are required to implement quality assurance programs commensurate with the contract document requirements. Work is to be performed by contractors having DOE-approved quality assurance programs. Contractors or suppliers providing services for the SNF Project that do not have a DOE-approved QAPP will develop a QAPP meeting the requirements of the SNF Project specific to their area of responsibility. As an alternative, they may elect to use the SNF Project QAPP. QAPPs developed by contractors or suppliers are submitted to the SNF Project for review and approval.

The architect-engineer, construction management, and construction subcontractor organizations are each required by the QAPPs to identify the quality assurance position within their organizations that is responsible for the establishment and implementation of their QAPP. The following characteristics are required of this position:

- An organizational position at the same or higher organizational level as the highest line manager responsible for performing activities affecting quality
- Knowledge and experience in the areas of quality assurance and management
- Authority and responsibility to verify the adequacy and implementation effectiveness of the QAPP and subtier QAPPs
- No other duties or responsibilities unrelated to quality assurance that could prevent full attention to quality assurance program matters
- Sufficient freedom from cost and schedule considerations when such considerations could impact quality or safety
- Access to senior management and management at the next higher organizational level to identify and obtain resolution of quality concerns

- Ability to review and approve the QAPP and subsequent revisions and interpret quality assurance requirements

17 3 2 8 2 Safety Review Board The primary functional responsibility of the Safety Review Board (SRB) is to provide a formal review and approval process for safety basis documents to ensure adherence to the requirements of DOE orders and standards.

Safety basis documents assure the DOE that a nuclear facility can operate safely and be environmentally compliant. They include, as a minimum, ORRs, Plan of Actions/Memorandums of Agreement, SARs, TSRs, fire hazard analyses, criticality safety evaluation reports, and SARs for packaging.

SRB members are appointed by the SNF Project Director and include individuals who serve a minimum one-year term.

An SRB quorum consists of the chairman or vice chairman and any two members of the SRB. No substitutes are allowed in calculating the quorum (unless formally assigned in writing by the SRB member indicating a permanent alternate). However, managers are encouraged to send a representative as a nonvoting member for discussion purposes if they cannot attend.

All SRB members must be familiar with key authorization basis documents and applicable DOE orders. The SNF Project SRB members shall have broad-based knowledge of SNF Project operations, facility design basis, project schedule, and other requirements to effectively review and approve SNF Project safety basis documents. Each member should be knowledgeable in a technical field and familiar with the current SNF Project baseline and path forward planning.

The cognizant manager of a safety basis document shall advise the committee chairman of the need for a committee review and shall prepare a presentation for the meeting. The SRB will perform a documented review of authorization basis documents and changes. SRB-approved authorization basis documents that require DOE-RL approval are submitted to FDH for submittal to DOE-RL.

17 3 2 8 3 Facility Evaluation Board Facility-independent assessments are performed by the Facility Evaluation Board, which is not associated with the activity or process being assessed. Responsibilities include the following:

- Establish, implement, and maintain an effective independent oversight program to assess operations and management effectiveness in meeting established environmental, safety, health, and quality assurance requirements, applicable regulations, and sound management practices.
- Provide facility managers and senior management of the SNF Project and subprojects with clear, objective, and well-documented assessments of strengths and weaknesses that affect performance to approved standards

- Ensure that independent assessments are conducted of programmatic or functional areas of environment, safety, health, and quality assurance when required by regulation or contract requirements

The scope of the independent assessments includes, but is not limited to, radiological controls, occupational safety and health, quality assurance, environmental programs, engineering, training, configuration management, maintenance, nuclear safety, fire protection, and operations.

17 3 2 8 4 Regulatory Requirements Team  An RRT has been established to review and approve selected regulatory requirements applicable to the new SNF Project facilities and fuel products removed from the K Basins that have an influence on the fuel acceptance criteria. The RRT also supports the safety review and authorization process for SNF Project requirements. The RRT as a body has membership thoroughly familiar with the DOE and U.S. Nuclear Regulatory Commission (NRC) regulatory requirements. The members of the team are selected for their knowledge base and are from the various organizations involved with the SNF Project DOE-RL, DOE-HQ (Office of Assistant Secretary for Environmental Management and Office of Assistant Secretary for Environmental Health) and the operating contractor (FDH). Membership also includes outside consultants selected for their knowledge. The RRT is impaneled to support the SNF Project in its mission and, as such, the RRT advises and reports to the SFO Project Director.

The organizational responsibilities are described in Regulatory Requirements Team (RRT) Charter (Sellers 1997).

17 3 2 8 5 Independent Review Panel  The regulatory policy for the SNF Project as stated in WHC-SD-SNF-SP-002, Spent Nuclear Fuel Project Regulatory Strategy, delineates DOE-RL's policy for achieving nuclear safety equivalence for the design, construction startup, and operation of new facilities, and the new processes for removal, handling, and conditioning of the SNF for transfer to the interim storage facility. An IRP has been established reporting to the Office of the Manager of DOE-RL, to provide advice and high-level oversight of the implementation of the regulatory policy. Detailed organizational responsibilities of the IRP are documented in RL-D96-007, Project Plan/Charter, Spent Fuel Project. To accomplish this function, the IRP will conduct interviews, review documents, and attend presentations conducted by the SNF Project to reach conclusions relative to the adequacy of implementation of the regulatory policy.

Specifically, the IRP will

- Review and comment on the SNF project regulatory strategy
- Evaluate and concur with the regulatory requirements document established by the project
- Evaluate and concur with the SAR and safety evaluation report
- Concur with the safety basis for final approval to operate the SNF Project facilities

The IRP consists of three members from outside the DOE complex, with broad technical background, selected for their stature, technical capability, and experience applicable to the SNF Project. The IRP conducts its oversight activity concurrently with the regulatory process. Periodic meetings of the IRP are conducted to enable the panel to keep abreast of SNF Project subproject activities. From time to time, DOE may identify further activities or areas that the IRP may be requested to review. IRP conclusions with respect to each of the chartered responsibilities are expected to be made within the time allotted by the subproject schedule. In interfacing with a subproject, the IRP's principal point of contact is DOE-RL's SFO director or the senior technical advisor to the assistant manager for waste management.

The SNF Project path forward requires approval of several key documents by DOE-RL before initiating operation of the new facilities referenced in the regulatory policy. Principal documents include the SARs prepared for the SNF Project facilities.

The DOE SFO and the Office of Assistant Manager for Engineering and Standards (AMS) collaborate to support the review and approval of key documents prepared by the contractor that are essential to the SNF Project. In addition to approving the SAR and issuing the safety evaluation reports, the AMS and SFO interact on a regular basis with the IRP to resolve technical issues in the SAR as they pertain to the implementation of the new regulatory policy. The DOE-RL SAR review team and the IRP jointly assess the effectiveness of the SFO in implementing the regulatory policy and the DOE orders that direct quality, safety, and health requirements that will be used for the project. The AMS also provides technical support to the SNF Project RRT. The Regulatory Strategy Document (WHC-SD-SNF-SP-002) contains the schedule for performing the SAR reviews.

1733 Staffing and Qualifications

Safe and effective design, construction, and operation of the SNF Project facilities depends upon a staff of qualified, competent personnel that conduct routine and long-range activities. Minimum education and experience requirements for SNF Project facility managers and technical personnel meet the requirements of DOE Order 5480 20A. Qualifications are met through education and related industry experience and through company-sponsored, job-specific training.

17331 Training and Qualification

Training and qualification requirements for SNF Project personnel are summarized in Chapter 12. Other subject-specific training requirements are
summarized in the applicable chapters of this SAR. In addition to meeting the SNF Project and subject-specific training requirements, each SNF Project employee must also successfully complete the following Hanford Site training programs:

- Hanford general employee training
- New employee safety orientation
- Appropriate facility orientation
- Appropriate facility building emergency plan

17.3.3.2 Minimum Staffing Requirements  DOE Order 5480 23 requires that the number of managers, engineers, operators, and support personnel assigned to a SNF Project facility is adequate to support safe design and construction activities and subsequent operation of the SNF Project facility. Abnormal plant conditions are considered when determining staffing assignments including on-shift or off-shift personnel. Establishment of minimum staffing levels for the various SNF Project facility positions is dependent on a job task analysis performed by management with considerations of normal and abnormal plant conditions, allocations for emergency response, monitoring functions, need for backups, availability of temporary staff from other organizations for peak workload periods, on-shift and off-shift personnel, and other factors. Minimum staffing requirements for safe operation are identified in the final TSRs.

17.3.3.3 Fitness for Duty  Fitness for duty involves an individual's ability to perform assigned tasks free from impairments caused by drug or alcohol abuse, emotional distress, or personal health problems. SNF Project management is committed to providing a work environment free of the negative influences of behaviors that jeopardize the work practices required for safe operations and quality services in support of DOE Order 5480 23. All employees will be fit for duty at their assigned tasks. Use, sale, or possession of illegal drugs or alcohol is prohibited on the Hanford Site. Employees who are found to be sellers, distributors, or repeated users of illegal drugs will be denied access to the facilities. To ensure this commitment is met, the SNF Project has an employee assistance program and has trained managers and supervisors to help them better recognize symptoms affecting fitness for duty.

17.4 SAFETY MANAGEMENT POLICIES AND PROGRAMS

The integrated environment, safety, and health management system (ISMS) (HNF-MP-003) establishes a single, defined safety and environmental management system that integrates ES&H requirements into the work planning and execution processes of the project facility effectively protecting the workers, public, and the environment. The ISMS is primarily based on the philosophies, principles, and requirements of DOE P 450 4, Safety Management System Policy, and the specification and guidance for environmental management systems (ANSI/ISO 14001).

The safety management system policy described in DOE P 450 4 is based on the following principles:

- Line management is responsible for safety.
clear roles and responsibilities are established
- Competence of staff is commensurate with responsibilities
- Priorities are balanced
- Applicable safety standards and requirements are identified and implemented
- Hazard controls are tailored to work being performed
- Operations authorizations

The safety management functions of DOE P 450 4 provide the necessary structure for any SNF Project facility work that could affect the workers, public, or the environment. These functions are:

- Scope of work is defined
- Hazards are analyzed
- Hazard controls are developed and implemented
- Work is performed within established controls
- Feedback and continuous improvement is part of the safety culture

The overall management system of each SNF Project facility includes organizational structure, planning activities, responsibilities, practices, procedures, processes, and resources for developing, implementing, achieving, reviewing, and maintaining the environmental management system consistent with the principles of ANSI/ISO 14001, Environmental Management Systems – Specification with Guidance for Use.

HNF-MP-003 contains a crosswalk so that a correlation can be identified for implementation of the elements of ANSI/ISO 14001 and the principles and functions of the ISMS and stipulates the ES&H requirements that will be met in the SNF Project facilities. The ES&H programs include environmental protection, occupational safety, fire protection, industrial hygiene, radiological control, nuclear safety, emergency preparedness and radioactive and hazardous waste management.

Communication and coordination of ES&H programs, including safety issue discovery, management, and resolution, are described in the following subsections and in various implementing procedures for the SNF Project facilities.

17.4.1 Safety Review and Performance Assessment

Safety performance is reviewed and assessed by independent organizations identified in Section 17.3.2.8. Management assessments are required by 10 CFR 830 120, “Quality Assurance Requirements” and are conducted by an organization manager to regularly assess the adequacy of those portions of the quality assurance program for which that manager is responsible to ensure its effective implementation (see Chapter 14.0). The management assessment process for the SNF Project is contained in SNF Project administrative procedures. A management oversight program has also been implemented to ensure high standards of performance in the areas of
In addition, documentation establishing the regulatory and safety basis for the major activities and facilities of the SNF Project will require review and approval by staff of the SNF Project and DOE. SNF Project administrative procedures define the process for preparation, revision, and distribution of the SAR and implementing TSRs and/or operating safety requirements. A discussion of these documents and the review process is provided in the following subsections.

17 4 1 1 Regulatory Policy DOE-RL has established a special regulatory approach to resolve safety concerns associated with the SNF presently stored in the K Basins and with its movement to the CSB for storage following conditioning in the CVDF. The DOE-RL regulatory policy, as contained in WHC-SD-SNF-SP-002, has been approved and will be applied to matters of nuclear safety (including radiological control issues) for new SNF Project facilities.

It is DOE-RL and DOE-HQ policy (Grumblly 1995) that the design and construction of new SNF Project facilities will achieve nuclear safety and radiation protection equivalence with comparable facilities licensed by the NRC. This will be accomplished by applying technical requirements based on those applied by the NRC to comparable licensed facilities or activities in addition to applicable DOE requirements. If cases arise where DOE requirements are more stringent than NRC requirements, then DOE requirements have been selected and applied. In cases where NRC requirements are more stringent than DOE requirements, NRC requirements have been selected and applied. Exceptions will be documented for approval by DOE and the RRT in accordance with DOE's policy.

The regulatory policy's primary focus is on design and construction issues and preparation for operation. The policy does not apply to environmental, Occupational Safety and Health Administration, chemical accident safety, and other nonnuclear or radiation safety issues, these will be covered elsewhere by DOE orders and statutory requirements. Similarly, life-of-facility oversight (e.g., operator training/performance assessment) applied by the NRC to their licensed facilities is not covered by this policy (WHC-SD-SNF-SP-002).

DOE has established this policy for the following reasons:

- To achieve in the design and construction of the SNF Project facilities a level of nuclear safety and radiation protection comparable to that of NRC-licensed nuclear facilities.
- To enhance public understanding and confidence in the safety of the new SNF Project facilities by following an enhanced regulatory strategy.

17 4 1 2 Industrial Safety and Hazardous Material Control Industrial safety and construction safety requirements are identified in DOE Order 5480 9A, Construction Project Safety and Health Management, DOE Order 5480 10, Contractor Industrial Hygiene Program,

These policies and procedures ensure that SNF Project employees are provided with adequate protection, training, and information about industrial safety, construction safety, hazardous waste, and emergency response actions to conduct SNF Project operations safely. These policies and procedures also apply to activities performed by organizations, contractors, and subcontractors supporting the SNF Project organization.

SNF Project implementing procedures reflect all the elements of the DOE VPP provided in DOE/EH-0433, U.S. Department of Energy Voluntary Protection Program and in HNF-MP-003:

- Management commitment
- Employee involvement
- Hazard prevention and control
- Worksite analysis
- Health and safety training

Safety training of SNF Project management and workers places emphasis on the elements of the VPP and workers are encouraged to actively participate in VPP initiatives.

SNF Project implementing procedures outline the rights and responsibilities of SNF Project management and employees (including managers and supervisors) and building managers and administrators. This procedure also contains the Master Safety Rules, with which all employees must comply, and a Workers Bill of Rights, which contains the rights of all employees pertaining to safety. Each SNF Project manager and supervisor is responsible for maintaining active involvement in safety issues. Responsibilities include the following:

- Incorporate specific safety and health responsibilities and requirements into formal job descriptions, clearly communicate them to the affected employees, and establish accountability through a program of performance measurements
- Hazard evaluation development
- Worksite inspections and assessments
- Safety meetings and committee functions
- Accident and near-miss investigation and corrective action planning
- Prejob briefings
Resolution of safety concerns

Worker representation in all facets of safety program development and review

Each SNF Project employee is responsible for recognizing and promptly notifying management of events and conditions that could have adverse safety or environmental implications. Employees are also responsible for obeying all oral and written instructions and procedures, conscientiously applying all health and safety training in daily activities, and properly using all prescribed personal protective equipment. In addition, SNF Project employees have the following specific responsibilities:

- Observe the Master Safety Rules
- Actively support programs designed to protect employees
- Stop work to prevent or control hazards considered to be an immediate threat
- Work defensively and be vigilant that coworkers do not put themselves at risk
- Submit ideas for safety improvements to management
- Report injuries and medically imposed work restrictions to their immediate managers

Performance requirements for reporting, investigating, and managing events that have safety or health significance and for complying with DOE Order 54841, Environmental Protection Safety and Health Protection Information Reporting Requirements, are presented in HNF-PRO-077, Reporting and Investigating Accidents. The requirements include reporting, investigating, and managing the following events:

- Occupational injuries and illnesses
- Government motor vehicle accidents
- Property damage incidents
- Near-miss incidents and other health and safety related incidents

Training courses on a variety of safety and hygiene topics are designed to provide Hanford Site-specific training for employees. These training courses are designed to fulfill certain initial and recurring training requirements specified in the Occupational Safety and Health topical area of Project Hanford Policies and Procedures. These training requirements are summarized in SNF Project implementing procedures.

17 4 1 3 Technical Reviews. Technical reviews verify that all changes are compatible with the facility design and that the proposed changes will not adversely affect facility safety, reliability, or operation. In addition to the reviews described above, SNF Project Engineering, as the design authority and the organization charged with safety and regulatory integration functions, is responsible for these technical reviews. The responsibilities and processes associated with the design authority function are provided in SNF Project administrative procedures.

17 4 1 4 ALARA Strategy. Minimization of exposure to workers and radiological safety is a fundamental precept of the SNF Project. ALARA planning will drive process and equipment selection to optimize cost-benefit, personnel exposure, and radiological safety. The SNF Project...
ALARA policy and program implements, through documents and administrative procedures, requirements from a number of documents. These requirements documents include:

- 10 CFR 835, "Occupational Radiation Protection"
- NRC Regulatory Guide 8.8, Information Relevant to Ensuring that Occupational Radiation Exposures at Nuclear Power Stations will be as Low as is Reasonably Achievable
- HNF-SD-SNF-DB-003, Spent Nuclear Fuel Project Path Forward Additional NRC Requirements
- G-10 CFR 835/E2-Rev 0, Workplace Air Monitoring
- HSRCM-1 Hanford Site Radiological Control Manual

Additional information on the SNF Project ALARA policy and program is presented in Chapter 7 of HNF-PRO implementing procedures will meet the ALARA requirements of the S/RID.

In addition to radiological application, ALARA principles are applied to exposure of personnel to hazardous materials in the workplace. Details of the ALARA program applicable to hazardous materials are contained in Chapter 8. The ALARA process is provided in SNF Project administrative procedures.

17.4.15 Unreviewed Safety Questions: DOE will define the facility authorization basis at the time of approval of the facility FSAR. The USQ process will be used, following DOE approval of the FSAR for each operational SNF Project facility, for evaluating physical and procedural changes and proposed tests and experiments to determine the existence of a USQ. The USQ process is described in SNF Project administrative procedures. SNF Project implementing procedures will meet the USQ requirements of Section 18.5 in the S/RID (HNF-SD-SNF-RD-001).

The USQ evaluation process allows the SNF Project facility management to make physical and procedural changes and to conduct tests and experiments without prior regulator approval provided that the activity does not involve a change to the TSRs or involve a USQ. A proposed change, test, or experiment involves a USQ (1) if the probability of occurrence or the consequences of an accident or malfunction of equipment important to safety previously evaluated in the SAR may be increased, (2) if a possibility for an accident or malfunction of a different type than any evaluated previously in the SAR may be created, or (3) if the margin of safety as defined in the bases of the TSRs could be reduced.
17 4 1 6 **Topical Plans**  Topical plans are used for activities that apply to the SNF Project. This section describes the topical plans and documents required for the successful execution of the SNF Project. Some of the plans already have been developed, others will be developed before release of the final SAR. All plans will be revised as required. The review and approval authority of these and other SNF Project documents is reflected in the SFO Document Review and Approval Matrix contained in HNF-3552. In each case, the SNF Project will submit to DOE-RL an SNF Project-approved document. The plans include the following:

- **The SNF Project Integrated Safety Management Plan (ISMP)** (Williams 1997) presents a comprehensive safety management plan that ensures protection of the public, workers, and the environment. The safety management approach in this ISMP implements the provisions of HNF-MP-003 and provides for a defense-in-depth safety culture in the context of *Defense Nuclear Facility Safety Board Recommendation 95-2*. The ISMP will be updated to incorporate all elements of the DOE Implementation Plan for Defense Nuclear Facility Safety Board 95-2 (DOE 1996). The updates will address the seven safety management guiding principles and the safety management functions of the FDH sitewide ISMS.

  The ISMP (Williams 1997) implements the SNF Project Regulatory Strategy (WHC-SD-SNF-SP-002) and defines the safety processes, requirements, and responsibilities to be applied to the SNF Project. The ISMP also describes the necessary programs and processes required to maintain the existing K Basins Authorization Basis and to develop the Authorization Basis for new SNF Project processes and facilities that ensures compliance with applicable environmental, safety, and health requirements.

- **The Technical Baseline Document (WHC-SD-SNF-SD-003)** is the foundation for SNF Project functions and requirements. All activities within each SNF Project facility are traceable to the technical baseline.

- **The SNF Systems Engineering Management Plan (WHC-SD-SNF-SEMP-001)** implements the provisions of HNF-MP-007, *Systems Engineering Management Plan*, and describes the process used to ensure that the technical requirements and basic design criteria of project subelements are clearly defined throughout design, acquisition, construction, and operation, including those imposed on all project participants and subcontractors.

- **The SNF Project Systems Configuration Management Plan (HNF-SD-SNF-CM-001)** describes the controls used for technical requirements and basic design criteria of project subelements throughout design, acquisition, construction, and operations. This plan implements the provisions of HNF-MP-013 *Configuration Management Plan*, and also addresses the administrative requirements imposed on SNF Project participants and subcontractors. Included are the systems to ensure that changes to the project baselines are reviewed and approved by appropriate levels of management according to established thresholds.
• The SNF Project Acquisition Plan describes the project's acquisition strategy and provides the policy, guidance, and request for services, facilities, and systems acquired by the SNF Project. The project acquisition plan incorporates all DOE Order 4700.1 requirements for the acquisition plan. This document helps the facilitator reconcile user requirements and funding allocations and prioritize efforts.

• The Public Involvement Plan describes how the SNF Project will address the public coordination and involvement required by NEPA, the Tri-Party Agreement (Ecology 1994), and DOE guidance.

• The SNF Startup Plan (HNF-SD-SNF-SUP-003) ensures that the completed facility and all installed systems meet the established safety basis and functions and requirements. Detailed test plans and/or specifications and procedures are prepared, approved, controlled, and maintained. These test plans or specifications and procedures address testing requirements for all plant systems, subsystems, and individual pieces of equipment. The test planning and scheduling coordinate development testing with design, and plant testing with plans for construction completion, turnover, and plant startup. Training requirements for the above activities also are covered.

• The Permitting Plan identifies all preconstruction, preoperation, and operation regulatory requirements to the extent known. A strategy to obtain all required permits will be developed consistent with SNF Project requirements. The appropriate documentation and schedules to comply with the requirements will be included.

• The SNF Project Interface Control Plan (WHC-SD-SNF-CM-003) addresses the physical interfaces and controls required between project subelements. An important aspect of maintaining configuration is effective interface control. The SNF Project will establish an interface control process coordinated by an interface control working group. The interface control working group will manage all internal interfaces and coordinate with the Site Interface Control Working Group for resolution of external interfaces.

• The Technology Acquisition Plan (WHC-SD-SNF-CM-004) describes how technology acquisition services and technology support services will be managed. Included are designated process technology application and laboratory testing equipment adaptation and verification testing, the waste form qualification model, and data development.

• The SNF Project NEPA Integration Plan includes the impacts and interfaces of NEPA compliance related to all Hanford Site SNF.

• The Integrated ES&H Management System Plan (HNF-MP-003) stipulates the ES&H requirements that will be met in each SNF Project facility. The intent is to
apply the appropriate DOE rules, orders, and/or NRC technical requirements to the
various subprojects. This will be done with DOE's concurrence. In addition, the
project will comply with the Tri-Party Agreement (Ecology 1994). A VPP is being
implemented as a best management practice. These requirements and best
management practices protect workers, the public, and the environment and will be
applied using a graded approach. The SNF Project's environmental and safety and
health programs include environmental protection, occupational safety, fire
protection, industrial hygiene, radiological control, nuclear safety emergency
preparedness, and radioactive and hazardous waste management.

The SNF Project independent oversight organizations monitor compliance with the
requirements during operation of the K Basins and during planning, construction,
startup, and operation of the CVDF, the CSB and other SNF Project facilities or
activities. These oversight organizations, as well as workers in the facilities, are
authorized to stop work if an imminent safety, health, or environmental hazard is
observed.

17417 Lessons Learned In response to the requirements of Section 1.9 in the SRID
(HNF-SD-SNF-RD-001), DOE Order 5480 19, DOE Order 5480 26, and DOE O 232 1A, each
SNF Project facility maintains a lessons-learned program that includes the identification,
documentation, validation, and dissemination of lessons learned from design and construction
activities, from in-house events, and from other DOE or commercial nuclear facilities. The
lessons-learned program information is used to improve the design, construction, and operation of
the facility day-to-day operations, and to identify good practices and potential hazards. For
the Plutonium Reclamation Facility, identifies a number of programmatic deficiencies involving
emergency preparedness and hazardous materials that will be corrected in SNF Project programs.
In-house events are evaluated by the operations organization to determine whether the event or
condition should be included in the training program for operations personnel. Immediate training
is scheduled if necessary.

SNF Project personnel are required to review lessons-learned information contained in
required reading files and to incorporate appropriate practices into their daily work habits. This
information is also used in the development of training curricula and in the modification of
training materials as appropriate. Personnel are encouraged to participate in the process by
providing feedback on information distributed and to identify information for potential inclusion in
the process. The lessons-learned program is the responsibility of all SNF Project managers and is
administered by the lessons-learned point-of-contact. The overall process is described in
SNF Project administrative procedures.

17418 Consultation with Native American Tribes and Nations Consistent with the policy
issued by the Secretary of Energy, the SNF Project is committed to a consultation relationship
with Native Americans having treaty rights on the Hanford Site (WHC-SD-SNF-SP-006). The
nations and/or tribes include the Yakama Indian Nation, the Confederated Tribes of the Umatilla
Nation, and the Nez Perce Tribe. In an attempt to keep Native Americans apprised of all

fsar17 sar 17-39 November 1999
significant actions being undertaken by the SNF Project, briefing meetings are held with representatives from each tribe and/or nation.

Documents and strategies containing key decisional information are submitted to the tribes for review and comment concurrent with the decision making process at DOE-RL. The intent of this activity is to ensure that appropriate dialogue is held with the Native Americans and that their concerns are adequately resolved during the decision making process as the SNF Project proceeds towards its conclusion. WHC-SD-SNF-SP-006, *Tribal and Stakeholder Communication and Participation Strategy for the Spent Nuclear Fuel Project*, provides details of this process.

**17 4 1 9 Compliance with Applicable Federal, State, and Local Environmental Laws and Regulations** The SNF Project complies with a number of federal, state, and local environmental protection laws and regulations. The U.S. Environmental Protection Agency is the lead environmental regulatory agency on the Hanford Site for ensuring compliance with requirements promulgated pursuant to the *Comprehensive Environmental Response Compensation and Liability Act (CERCLA)* of 1980. The Washington State Department of Ecology is the authorized regulatory agency for compliance with the *Resource Conservation and Recovery Act of 1976* and WAC 173-303, "Dangerous Waste Regulations."

The applicable compliance requirements imposed by these agencies are documented as major, interim, and target milestones in the Tri-Party Agreement (Ecology 1994).

The SNF Project also regularly interacts with the Washington State Department of Health. The Department of Health has regulatory authority over radiological air emissions on the Hanford Site and must approve any new construction or operational activities undertaken by the SNF Project that may pose the potential for increasing radiological exposure to workers and the public. In addition, permitting authority for potable water supplies falls within the authority of the Department of Health.

Documentation related to compliance with applicable federal, state, and local environmental laws and regulations is processed in accordance with SNF Project administrative procedures.

SNF Project implementing procedures describe the process for complying with the *Price-Anderson Amendments Act of 1988* at the SNF Project facilities. Minor noncompliances are tracked using SNF Project administrative procedures. SNF Project administrative procedures also describe the process for trending of noncompliances to determine whether they are indicative.
of a programmatic breakdown. All of the above activities serve to enhance and protect the radiological health and safety of the public and workers at the SNF Project facilities.

17.4.2 Spent Nuclear Fuel Project Safety Management System Process

17.4.2.1 Integrated Safety Management  FDH has developed an ISMS plan, HNF-MP-003, which responds to Defense Nuclear Facility Safety Board Recommendation 95-2. This plan addresses implementation of an environmental management system consistent with the principles of ANSI/ISO 14001 and supports the Radiological Control Improvement Plan. The ISMS is based on the philosophies, principles, and requirements identified in DOE P 450.4 and the specification and guidance for environmental management systems (ANSI/ISO 14001). The objective of the ISMS is to provide a formal process to systematically integrate safety into work planning and execution processes to ensure work is performed safely to effectively protect the workers, public, and the environment.

Five essential safety functions or elements require consideration in the ISMS: (1) defining the scope of work, (2) identifying and analyzing hazards, (3) developing and implementing controls, (4) performing work within controls, and (5) providing feedback and continuous improvement. The following sections briefly discuss the management of each of the safety functions to ensure work is performed safely.

17.4.2.1.1 Define the Scope of Work  SNF Project work scope involves a variety of activities. These activities are performed in support of the SNF Project mission. To ensure work is performed safely, each activity is broken down into discrete work packages.

The proposed SNF Project ISMS identifies two work scopes: facility level and activity level. Facility-level work scope is directed and controlled based on the contractual agreement between the SNF Project and FDH. At the Hanford Site level, an integrated Hanford Site baseline is developed by FDH to integrate work scope and contractor interfaces between FDH, its subcontractors, and other Hanford Site contractors. Baseline authorization is the mutual acceptance and approval between FDH and DOE-RL for performing the work described by the integrated site baseline. DOE-RL approves the integrated site baseline and authorizes resources for the execution of work within a specific time period. FDH, in turn, authorizes work by its subcontractors through project authorization documents.

The SNF Project input into the integrated Hanford Site baseline comes in the form of a multi-year work plan that is reviewed by FDH and incorporated, if appropriate, in the final integrated Hanford Site baseline. The SNF Project prioritizes the work identified in the project authorization documents in a final multi-year work plan. The prioritization is based on mission compliance, cost, and risk containment objectives. At all working levels of the SNF Project, a risk-based prioritization process is used to establish a technically defensible logic for work planning and execution. This process is intended to balance priorities by using risk-based planning and resource allocation to meet regulatory requirements and control safety and environmental.

November 1999
hazards during the safe execution of work. Risk-based prioritization of work ensures that the most significant hazards are mitigated in the most cost-effective manner.

Activity-level work scope (e.g., work performed on SSCs within the SNF Project facilities) can be identified during facility walkdowns, during SSC surveillance and corrective and preventive maintenance, through engineered modifications to safety-related equipment, or through component or system failure. Work is prioritized according to the safety classification of the system and critical need to support mission requirements. Work at the SNF Project facilities is categorized into three categories based on the required skill of the worker and the hazards associated with the task to be performed. The three categories are (1) routine, (2) skill-of-the-craft, and (3) planning required.

17.4.2.1.2 Identify and Analyze Hazards Hazards are analyzed before initiating work activities. The hazard analyses are performed to identify conditions that could lead to undesired consequences to the public, the workers, and the environment. The hazards and accident analyses contained in Chapter 30 address the SNF Project facilities and their operations. The analyses contained in Chapter 30 are maintained and updated as part of the facility-level work scope. For new activities, including one-time and long-term activities, hazard analyses are performed based on the scope of the work activity and if appropriate are incorporated in the final SAR as a modification. The hazard analyses are designed to address all the hazards identified during the hazard identification activities including material at risk, energy sources, natural phenomena, external events, and common cause failures. The results of the analyses are used to support the identification of requirements and controls specifically related to the task analyzed (i.e., TSRs), training requirements, and the need for safety support (e.g., radiological, industrial hygiene, and safety fire protection).

17.4.2.1.3 Develop and Implement Controls The controls developed for the safe operation of the SNF Project are graded or tailored based on the results of the hazard and accident analyses described in Chapter 30 and on environmental requirements and analyses. The developed controls include TSRs, institutional controls and safety programs, facility-level operations documents, and environmental regulations. The SNF Project also prepares and maintains environmental documentation based upon the risks and hazards associated with the work being performed.

The TSRs, as discussed in DOE Order 5480.22 and Chapter 5.0, define acceptable conditions, safe boundaries, and administrative controls (or management) to ensure safe operations and reduce the potential risk to the public and onsite workers from uncontrolled releases of radioactive or other hazardous material or from radiation exposures caused by inadvertent criticality. The TSR controls are based on the hazard and accident analyses described in Chapter 30 and are considered necessary and sufficient for public safety, significant defense-in-depth, significant worker safety, and for maintaining potential consequences below risk guidelines. These controls define the safety envelope approved by DOE using safety analyses.

Integral to the implementation of the controls, the SNF Project maintains an auditable safety analysis program to maintain the controls. The auditable safety analysis program maintains...
the existing boundary for safe operation (establishing a safety envelope), as defined in Chapter 3 and the TSRs, and supports the identification, analysis, and control of previously unidentified hazards (e.g., hazards based on new work scope). The safety analysis program is used to ensure that each activity and operation within the facility or project is authorized under an approved authorization basis. An authorization basis is defined in DOE Order 5480.21 as those aspects of the facility design basis and operational requirements relied upon by DOE to authorize operation. The authorization basis management system (see Section 17.4.3.2) provides a process for developing authorization basis documents, evaluating and controlling changes, and implementing the authorization basis. All work, either in the form of proposed activities or new information (also known as a discovery), is screened against the authorization basis to verify that the proposed change or discovery is within the authorization basis.

Applicable standards and requirements are identified and documented in the S/RID (HNF-SD-SNF-RD-001). The S/RID defines the requirements agreed to by the contractor and DOE and is implemented through contractor policies and procedures. The S/RID captures the applicable safety requirements of the Code of Federal Regulations, DOE orders and regulations, Washington Administrative Code, and other requirement source documents (e.g., industry standards) that embody the necessary and sufficient requirements to ensure the safety of the public, the workers, and the environment. The process for identifying the applicable requirements is based on the results of the hazard and accident analyses described in Chapter 3. That is, the identified hazards, assumptions, and controls are compared to the entire list of requirements. Only those requirements applicable to the hazards, assumptions, and controls are listed.

Institutional controls, and safety programs are developed for the SNF Project based on the results of the hazard and accident analyses, the standards and requirements identification process, and the TSRs. These controls and programs, discussed in Chapters 6 through 17, address the prevention of inadvertent criticality, radiation protection, including ALARA, hazardous material protection, radioactive and hazardous waste management, quality assurance, emergency preparedness, initial testing, in-service surveillance, and maintenance, operational safety, procedures and training, human factors, provisions for decontamination and decommissioning, configuration control, and authorization basis management.

17.4.2.1.4 Perform Work Within Controls Safe work is conducted in accordance with the controls, procedures, and commitments developed from and contained in the authorization basis. At the activity level, the formality, degree to which work is proceduralized, and the degree of direct supervision is established based on the type and magnitude of the hazards. The confidence that the hazards are well known, the confidence in the hazard controls that are selected, the complexity of the work, the comprehensiveness of the safety envelope, and worker qualifications. Worker involvement plays an important role throughout the work planning process and the performance of work.
The SNF Project work planning process is used to prepare for work. This process defines work performance from planning to execution and includes confirming readiness, worker involvement, worker training, and worker competence, designating responsibilities and approval authority, and performing the work. During the planning process, workers and support personnel (e.g., radiological control personnel) provide input to work documents, perform site walkdowns, and review completed work documents. Through a combination of training, required reading, prejob planning meetings, and prejob safety briefings, workers are made cognizant of hazards and controls required to perform the work.

The SNF Project uses job hazard analyses to identify specific hazards and develop procedures, safety plans, instructions, or work permits to adequately address safety and health at the activity level. The safety instructions and controls identified following the job hazard analysis are written into the work package. Work packages contain numerous elements that are fundamental to worker safety. Within the work package, the hazards are identified and safety boundaries are established for the work to be performed. The applicable requirements are identified, worker skill needs are identified, and job site prerequisite conditions are identified.

SNF Project workers always have the power to "stop work" if any conditions exist that are felt to be unsafe or hazardous to the environment. Workers will not proceed and will halt work if instructions are unclear or inadequate or the controls are not adequate to control the hazards present.

17 4 2 1 5 Provide Feedback. Self-assessments are performed at SNF Projects to provide measurable feedback and support continuous improvement. The self-assessments are incorporated into work processes through the use of performance indicators, in-process monitoring, occurrence reports, management assessments, worker assessments, self-assessments, independent assessments, and the lessons-learned program.

The performance indicator programs at SNF Projects are generated on the basis of requirements, good management practices, and requests from management with conformance to DOE Order 5480 26.

The SNF Project procedure for occurrence reporting and reporting of operations information (Section 17 4 4) establishes and implements criteria for the identification, categorization, and notification of occurrences.

The management assessment program (Chapter 14 0) at the SNF Project is designed to integrate assessment schedules and use the resulting data for effective trending analysis. Program implementation includes guidance for preparation and performance of assessments. Assessment results are entered into the identified corrective action tracking system.

The SNF Project lessons-learned program (Section 17 4 1 7) encourages improvements in safety and operations by communicating Hanford Site and related industry-wide operating experience. Lessons learned are obtainable from a number of inputs including (1) Occurrence Reporting and Processing System final reports, (2) DOE Operational Experience Weekly,
(3) DOE Lessons Learned Information System, (4) Sitewide Lessons Learned Evaluation Request, 
(5) input from SNF Project personnel, (6) Health Physics Radiological Problem reports, 
(7) facility monitoring program, (8) DOE facility representative, (9) DOE Safety Notices, 
(10) results of assessments, (11) performance indicators and trends (12) post-job reviews, 
(13) Emergency Preparedness Drill program, (14) outage critiques, and (15) ORR Lessons 
Learned reports  Guidance is provided on the preparation and dissemination of lessons-learned 
reports, evaluation of action notices, and performing trend analysis

17 4 2 2 Integrated Environment, Safety, and Health Management System Roles and Responsibilities  FDH is ultimately responsible for protecting the public, environment, and 
workers from hazards associated with Hanford Site operations  To support safe and compliant 
work practices and to ensure an integrated approach to safety, the FDH ES&H and Performance 
Assurance organizations develop and communicate sitewide ES&H and Quality Assurance 
programs and policies to the major subcontractors for incorporation into their projects and 
activities

The SNF Project is responsible for establishing mechanisms that delineate responsibilities, 
establish work priorities, and use risk-informed planning to promote effective use of resources. 
The SNF Project also is responsible for designing and documenting work strategies (including 
stop-work authority) that effectively establish mitigative or preventive controls and consider 
hazard severity, worker qualifications, and operational conditions

The SNF Project has the responsibility to establish and maintain hazard analysis processes 
and capabilities and to use these capabilities to perform hazards analysis at all levels of the 
organization. The SNF Project has the responsibility to identify, establish, and implement hazard 
controls at all levels of its organization. Whether work is performed by the SNF Project or by its 
subcontractors, the SNF Project has the responsibility and accountability to perform work safely. The SNF Project is responsible for ensuring that work is proceeding safely and in concert with 
requirements. This obligation can be fulfilled in several ways but, as a minimum consists of a 
combination of three factors

- An established self-assessment program
- Monitoring against the measures established during the agreement process, including 
data collection and evaluation, reporting, and improvement actions taken
- Conducting assessments, routine observation, and awareness

The SNF Project is responsible for the implementation of ES&H requirements at SNF 
Project facilities and for performing work at the facility and activity levels safely. Line managers 
are responsible for the safety of workers and for the protection of the public and the environment. Line management accountability for planning and implementing ES&H requirements is 
fundamental to the management of the PHMC, and line manager responsibility is the key to the 
successful communication and implementation of an ISMS. Line managers establish the operating
procedures that clearly communicate the ES&H policies and directives, and line managers and supervisors also ensure employee understanding through the involvement of their employees.

At the worker level, employees are encouraged and, in some cases, required to participate in the completion of the enhanced work planning, job walkdowns, and monthly zero-accident council meetings. PHMC management requires that all employees participate in monthly safety meetings, whether it involves a local employee zero-accident council or other organized meeting devoted to a timely safety topic or discussion of the safety issues surrounding work. Employee input is welcomed for the purpose of continually improving the ES&H conditions at every work site.

Although DOE does not actively participate in the activities performed at the SNF Project, DOE is an active member of the ISMS process at the SNF Project through Hanford Site planning and oversight activities. Cognizant DOE employees, including workers, have the authority to stop work when they identify violations that significantly diminish the safety of workers, the public, or the environment. DOE performs the following activities:

- Defining mission and program objectives and providing direction and guidance to contractors
- Establishing contract and other agreements with the contractor that define the scope of the work and providing sufficient resources for the safe conduct of the work
- Establishing agreements with the contractor for safety expectations and standards appropriate for the work based on an understanding of the hazards
- Establishing its expectations for the rigor of the contractor's hazard analyses and establishing its role in review and approval of the hazard analyses and controls (e.g., TSRs for nuclear facilities) that are to be incorporated into the authorization basis
- Retaining sufficient oversight to determine whether applicable regulations for industrial hazards are being followed and, if they are not, what additional DOE action is required (through oversight DOE provides reasonable assurance that established controls conform to applicable regulations)
- Using readiness review, direct observation of contractor operations, and monitoring for significant events, and being aware of and monitoring the conditions under which work is performed
- Evaluating both DOE and PHMC performance using DOE assessments, assessing reported data, and performance measures, occurrence reports, and other data
- Providing feedback to support the continuous improvement process
An integrated management system has been developed and implemented to establish and maintain the SNF Project authorization basis (Section 17.4.3.2). This management system comprises four subsystems that are described in more detail in the following sections.

17.4.3 Configuration Control

In accordance with the requirements of Section 3.0 in the S/RID (HNF-SD-SNF-RD-001) and DOE-STD-1073-93, configuration management activities will establish and maintain consistency among design requirements, physical configuration, and facility documentation based on a graded approach. Types of equipment to be included in the configuration management program is identified based on the function provided by the SSCs and includes SSCs with safety design requirements (those necessary to protect offsite personnel, onsite personnel, and facility workers from nuclear and other hazards), environmental design requirements (those necessary to protect the environment from significant damage or to satisfy environmental requirements or permits), and mission design requirements (those necessary to avoid substantial interruptions of the programmatic mission or severe cost impacts).

The physical configuration conforms to the design requirements, which are established by the design output documents. The facility documentation accurately reflects the physical configuration and the design requirements. The facility documentation that supports facility operations includes the as-built configuration documents and facility procedures for activities. Changes to the facility design requirements are reflected in both the facility physical configuration and facility documentation. Changes to the facility physical configuration or its documentation must be supported by design requirements. The configuration control process is the responsibility of SNF Project engineering. Additional details of the configuration management program are contained in HNF-MP-013, HNF-SD-SNF-CM-001, *Spent Nuclear Fuel Project Configuration Management Plan*, and SNF Project implementing procedures.

In accordance with DOE-STD-1073-93, during planning for the configuration management program, initial assessments will be conducted to determine the strengths and weaknesses of existing programs and procedures with regard to determining where upgrade actions and resource investments are necessary. After the configuration management program upgrades are implemented, a horizontal slice assessment will be performed for each configuration management program element to determine if that element addresses identified weaknesses and is effective in accomplishing the configuration management functions.

Physical configuration assessments, or walkdowns, will be performed for representative sample SSCs to determine the degree of agreement between the physical configuration and the configuration depicted in the facility documentation. Physical walkdowns are included as part of the programmatic assessments conducted during the initial assessments and post-implementation assessments. If substantive discrepancies are discovered, appropriate immediate corrective actions will be developed to establish agreement between the physical configuration and the documentation. The corrective actions will include additional walkdowns to characterize the
problem and determine the extent of the problem. They will also include technical evaluations to
determine whether the physical configuration or the documentation needs to be changed.

SSCs within the configuration management program will be tested periodically to determine
if they are still capable of meeting their design requirements. This monitoring will also address
surveillance actions, periodic in-service inspections and tests, and other monitoring of SSCs to
ensure safe and reliable operation of the facility. Monitoring will also include measurements and
trending of data related to the actual aging degradation of equipment.

SSCs within the configuration management program will be tested after modification (and
before being turned over for service) to determine if it is capable of meeting its design
requirements. If a changed SSC fails to meet its post-implementation acceptance criteria,
turnover for operation will be postponed until either a technical review has been completed and
any follow-up actions are completed or until the SSC is returned to its original condition and
tested satisfactorily.

17 4 3 1 Configuration Control Process The configuration control process contains the
following five elements (DOE-STD-1073-93):

- **Identification** — Potential changes are identified and initiated by any project
  participant who determines that a departure from the existing technical baselines is
  warranted.

- **Evaluation** — After identification, the project participant who identifies the change
  performs an evaluation. This evaluation establishes that the potential change is both
  necessary and desirable. The precise evaluation process is determined by the
  importance of the change.

- **Approval** — Each change must be approved by the approval designator on the
  change documentation before authorization of work. Overall responsibility for
  approval resides with SNF Project facility engineering in the areas of design,
  configuration, and safety.

- **Authorization** — When a change is approved, it is processed through the required
  contract and work authorization cycles.

- **Implementation** — After the change has been approved and authorized, the changes
  are implemented and the required work performed.

Requirements associated with the development, review and approval release and
incorporation of changes to SNF Project engineering documents are implemented through the use
of the Engineering Change Notice as described in SNF Project implementing procedures. In
addition, HNF-SD-SNF-CM-001 states that all SNF Project related documents (functions and
requirements, analysis, design calculations, drawing specifications, procedures, etc.) containing
design-related information shall be developed, reviewed, and released in the document control.
system by use of an Engineering Data Transmittal. DOE-STD-1073-93 requires that only currently-approved revisions of documents under the control of the configuration management program should be used. See Chapter 12 of for further descriptions of the process for identifying the approved, current revision of a procedure.

Revisions to documents within the configuration management program should be completed in a timely manner. For each document within the configuration management program, the following information should be readily available: revision level, current status, document owner, information regarding pending changes, and other data necessary for control and tracking such as storage location and outstanding document change notices. See also Section 14.5 which states that following approval, controlled documents are released to specified users to ensure the latest approved revisions are available to personnel for use at the location where the work is being performed. See also Section 14.6.1.

Information Resource Management develops and maintains the project files and ensures that information is available to support the SNF Project facilities and that the information product is complete and accurate for the staging and interim storage of SNF in accordance with DOE-STD-1073-93. Information resources are managed throughout the information life cycle, including information creation, collection, processing, distribution, management, disposition, and retirement. Management of life cycle activities shall be targeted toward making information useful, available, and effective.

Creation of data files is consistent with the following requirements:

- For electronic information systems that produce, use, or store data files, disposition instruction for the data shall be incorporated into the system design.
- Up-to-date technical documentation is available for each electronic information system that produces, uses, or stores data files.

Permanent records are preserved, but records no longer of current use are promptly disposed of or retired. A records management program will be developed consistent with the requirements of federal law, Code of Federal Regulations, DOE directives, DOE guidelines, and DOE-established or accepted referenced standards. All records management program requirements are kept current and available for review.

Project files are developed and maintained in accordance with HNF-SD-SNF-CM-001, HNF-SD-SNF-MP-001, Spent Nuclear Fuel Project Data Management Plan, and SNF Project implementing procedures.

17 4 3 2 Spent Nuclear Fuel Project Safety Management System

The SNF Project safety management system has been developed and implemented to establish and maintain the SNF Project facility authorization basis. This safety management system comprises four subsystems: the technical baseline management system (Section 17 4 3 2 1), the risk management system (Section 17 4 3 2 2), the authorization basis management system (Section 17 4 3 2 3), and...
the safety management programs system (Section 17 4 3 2 4) These subsystems operate as an integrated package, sharing information and resources

17 4 3 2 1 Technical Baseline Management System A total baseline will be established for all SNF Project facility activities to the completion of the project. The technical baseline, discussed below, is the basis for the schedule and cost baselines that are reflected in HNF-SP-1104, Spent Nuclear Fuel Project Multi-Year Program Plan

In addition to the technical baseline, other baselines include Schedule Baseline Control, Cost Baseline Control, Fuels Management, Project Work Authorization, Project Performance and Control, Project Startup, Management Reporting, and Management Reviews, and Management Planning. Details of these may be found in WHC-SD-W441-PMP-001, Project W-441 Cold Vacuum Drying Project Management Plan, and WHC-SD-W379-PMP-001, Project W-379 Canister Storage Building Project Management Plan

Technical Baseline and Control The technical baseline management system is used for management and maintenance of facility documents related to (1) configuration of SNF Project facility SSCs, (2) facility site description and characteristics, (3) inventory of hazardous materials in the facility, (4) facility requirements, and (5) safety basis documents that support the facility authorization basis (WHC-SD-SNF-SD-005)

The technical basis for the SNF Project facilities is the approved technical baseline. It consists of the following documents

- Project Management Plan (HNF-3552, WHC-SD-W441-PMP-001, and WHC-SD-W379-PMP-001)
- Systems Engineering Baseline Document (WHC-SD-SNF-SEMP-001) for the scope defined in the Project Management Plan
- Process strategy document, a product of system engineering methodology, Independent Technical Assessment Group evaluations, and other studies
- Work Breakdown Structure, Work Breakdown Structure Dictionaries and Index (included in the multi-year program plan [HNF-SP-1104])
- End point criteria, facility-specific agreements between the current caretaker of a facility and the future caretaker of the facility regarding the configuration and condition of the facility at the point of turnover
- Acceptance criteria and memoranda of agreement or understanding, agreements between the SNF Project facility and organizations outside of the SNF Project, regarding the transfer of material from one organization to the other or other agreements or understandings regarding the split of responsibilities
Functions and requirements documentation for the SNF Project facilities

The SNF Project facility is responsible for the overall development, implementation, and maintenance of the baseline documentation. The SNF Project facility ensures that configuration management activities and systems engineering activities are performed, while better defining and controlling the project baseline and associated documentation. These activities are applied to all systems and subsystems necessary to achieve all functional requirements and deliver all products to satisfy the integrated technical baseline and overall project objectives.

At all times during the life of the SNF Project facility, current configuration will be maintained in orderly and auditable project files. These project records and files include, but are not limited to system descriptions, system specifications, conceptual and definitive system designs, system and material inspection reports, test reports, operating and surveillance procedures, and vendor documentation.

Structures, Systems, and Components Management

SSC configuration is defined in terms of engineering documents (e.g., drawings, design analyses, design requirements and criteria, equipment lists, vendor information). The SNF Project facility SSCs management subsystem (1) identifies SSCs important to safety, (2) maintains the documents that describe the SSC configuration, (3) provides information about the status of items under configuration control, and (4) provides a process for evaluating and implementing proposed changes. Information about SSC configuration changes also is incorporated into the following subsystems: risk identification, establish prevention/mitigation, authorization basis control, and site safety management.

Site Description Management

Site description information includes meteorological, seismic, lightning, flood, volcanic, and geophysical data. The site description management subsystem entails a process for identifying data important to the safety management system. The site description management subsystem is used to specify appropriate media for the documentation and retrieval of the data and the processes to control changes to the site description data. Changes in the site description also are incorporated into the following subsystems: risk identification, authorization basis control, and site safety management.

Hazardous Material Inventory Tracking

The hazardous material inventory tracking subsystem entails a process for identifying and documenting important attributes (type, quantity form, process or storage condition, and location) of the hazardous materials associated with the SNF Project facility. This hazardous materials information is used to determine the facility hazard categories and resulting authorization basis documentation requirements. Inventory tracking also ensures that any changes to hazards will be identified and evaluated. Changes in hazardous materials information are incorporated into the risk identification and authorization basis control subsystems.

Requirements Management

The requirements management subsystem entails a documented process for identifying and allocating the requirements and systems engineering functions and requirements important to the SNF Project facility safety management system. Changes in requirements are assessed and incorporated into affected subsystems.
HNF-SD-SNF-RD-001 will be used with the systems engineering functions and requirements for the SNF Project safety management system

17 4 3 2 2 Risk Management System The SNF Project facilities will adopt a methodology to minimize the overall risk through timely, documented and defensible project decisions consistent with HNF-MP-005, Risk Management Plan. All major decisions, as documented in a decision log, will be tied to the project critical path and will include an assessment (qualitative or quantitative) of the project risk associated with each proposed alternative solution. Project risk assessments will consider the cost, schedule, and technology risk associated with the proposed alternative solutions and will require decisions in a timely manner to support the project critical path schedule, thus minimizing the overall risk to downstream project activities.

As a guiding principle, and to minimize overall project risk the SNF Project facilities will favor low-cost, commercially available, or tried and proven design solutions over technically unproven options requiring research and development, specialty design, and fabrication. This is consistent with guidance in WHC-SD-SNF-SD-003, Spent Nuclear Fuel Project Technical Baseline Document.

Risk Identification Risk identification entails identification of accident initiators and establishes the processes for performing hazard and accident analyses to determine the frequency and consequences associated with various postulated events. Actual or proposed changes in hazard identification (e.g., type, quantity, form, process or storage condition and location) are incorporated into the hazardous material inventory tracking system in the site characteristics documentation.

Changes in frequency or consequence are considered when performing the following activities: risk evaluation, establish prevention/mitigation, and authorization basis control. Risks originating outside the scope of the SNF Project facilities that may affect the functioning of facility safety-class or safety-significant SSCs, or that may initiate accidents within an SNF Project facility, will be similarly considered.

Risk Evaluation Risk evaluation includes a process for evaluating identified risks against the authorized safety basis to determine whether any controls are necessary or prudent to reduce the overall risk. Changes in frequency or consequences of the hazard analyses (or accident analyses) or changes in the approved risk guidelines are to be factored in when performing this activity. Changes in the level of risk also are to be factored in when establishing prevention/mitigation and when performing the authorization basis control activities.

Establish Prevention or Mitigation Establishing prevention or mitigation includes a process for determining the appropriate SSCs and administrative controls required to reduce identified risks. This process makes use of the risk guidelines and implements appropriate defense in depth. Changes in the level of risk associated with identified accidents and changes in the SSC administrative controls credited in the analyses are factored in when performing this activity.
Changes in the list of required SSCs and administrative controls are inputs to the SNF Project facility SSC management and the authorization basis control activities

17 4 3 2 3 Authorization Basis Management System The authorization basis management system provides a process for developing authorization basis documents, evaluating and controlling changes, and implementing the authorization basis.

Authorization Basis Document Development The authorization basis document development activities provide a process for developing and revising authorization basis documents and for maintaining a list of authorization basis documents. Changes to the authorization basis documents are factored into the authorization basis control and authorization basis implementation activities.

Authorization Basis Control Authorization basis control activities include a process for screening, evaluating, documenting, tracking, and resolving authorization basis changes. The USQ process is a key component of this activity. Actual and proposed changes in the facility SSCs, site description, facility hazards, facility risks, safety basis documents, authorization basis documents, and operating and maintenance procedures must be considered when performing this activity. Discoveries and occurrences must also be factored into authorization basis control activities. Changes to the authorization basis are considered when performing authorization basis implementation, authorization basis document development, and safety basis document management activities.

Authorization Basis Implementation Authorization basis implementation includes a process for implementing the authorization basis in the appropriate documents and procedures and developing the requisite training. Changes in the authorization basis documents and in the functional classification of SSCs are factored into authorization basis implementation activities. Authorization basis implementation activities include tracking the implementation documents and producing a list of documents of use for authorization basis control and safety basis document management activities.

The process of developing the authorization basis includes the following activities:

- Definition of a Requirements Basis The requirements source documents (e.g., codes and standards) establish the requirements for design, safety analysis, environmental permitting, construction, and operation. The requirements basis for the SNF Project facility is the SNF Project technical baseline WHC-SD-SNF-SD-005, Spent Nuclear Fuel Project Technical Baseline Description, and HNF-SD-SNF-RD-001.

- Establishment of Functions and Requirements Using the requirements bases, systems engineering analyses identify the functions to be performed and the specific requirements to be met.

- Develop Design and Safety Analysis Documents The functions and requirements establish the scope and requirements to be met by the design and safety analysis.
documents. The functions and requirements are typically imposed by the performance specifications. The result of these activities is the creation of the detailed design documentation, SAR, and TSRs (or amendments) that support construction.

- Development of Operations Control Documentation. Authorization of operation is based on a comprehensive review (ORR and readiness assessment, as appropriate) to ensure the documentation, systems, and support functions are in place. Key documents supporting operations are the SAR and TSRs (or amendments as needed), the S/RID (or updates, as necessary), and operating procedures that implement the safety basis. The SAR and TSRs are developed during design. The final S/RID (or updates) are prepared based on all of the above activities. The operating procedures are developed during construction, and personnel training is completed during startup testing. SNF Project facility management is committed to the development and effective implementation of operating, technical, and administrative procedures. The process for developing, maintaining, distributing and training on new and/or modified procedures is described in Chapter 12.

Environmental permits are a portion of the authorization basis and are obtained as necessary to support design, construction, and operation activities in accordance with the ISMP (Williams 1997). The process for securing the necessary environmental permits is described in SNF Project administrative procedures.

Actions to be taken by the SNF Project facility organizations to implement new or revised safety bases documents are provided in SNF Project administrative procedures.

Systems Engineering. The SNF Project has several critical interfaces among its facilities, organizations, and suppliers. To ensure that these interfaces are compatible, the SNF Project implements systems engineering as an extension of good engineering and management practices (WHC-SD-SNF-SEMP-001) and HNF-MP-007. The implementation of systems engineering on the SNF Project is the sole responsibility of the SNF Project. A review will be performed to ensure that overall project objectives of cost, schedule, and technical performance are achieved during design of systems and subsystems.

Implementation of systems engineering on the SNF Project is to achieve:

- Clearly identified systems
- Clearly identified management authority
- Clearly identified design authority
- Clearly identified decision methodology
- Timely decision making
- Documented and maintained baseline
- Demonstration of product performance

Additional detail on the above SNF Project commitments is contained in HNF-3552.
SNF Project requirements are managed as a part of the systems engineering process. Requirements include the following:

- Establish and manage the requirements basis
- Establish the functions to be performed and allocate the requirements associated with those functions
- Develop design and safety analysis for equipment and systems that perform the functions and implement the requirements
- Construct equipment and implementing systems in accordance with the designs and requirements
- Develop or update S/RIDs
- Operate the equipment and systems within design and safety limits and requirements and in accordance with TSR and/or operating safety requirements, in accordance with approved operating procedures

Specific responsibilities related to configuration management of the S/RID program are presented in SNF Project administrative procedures.

17 4 3 2 4 Site Safety Management Programs System Numerous other administrative management programs interface with the safety management system. Examples of these administrative management programs include prevention of inadvertent criticality, radiation protection, hazardous material protection, radioactive and hazardous waste management, quality assurance, emergency preparedness, initial testing, in-service surveillance, and maintenance, operational safety, procedures and training, human factors, provisions for decontamination and decommissioning, and management, organization, and institutional safety provisions. Each program is evaluated to determine its impact on the safety management system and to determine when changes to that program must be factored into the SNF Project facility safety management system.

17 4 4 Occurrence Reporting

Section 1 6 of the S/RID (HNF-SD-SNF-RD-001), and DOE O 232 1A (as supplemented by DOE M 232 1-1A) establish requirements for reporting and processing operations information related to emergencies, unusual occurrences, and off-normal occurrences. This system provides equivalency with the evaluation process and reporting schedule requirements of Title 10, Code of Federal Regulations, Part 50 "Domestic Licensing of Production and Utilization Facilities," Section 50 55(e), "Conditions of Construction Permits" (10 CFR 50), for identification of defects and failure to comply associated with substantial safety hazards. Equivalency with the contractor evaluation and reporting requirements of Title 10, Code of Federal Regulations Part 21.
"Reporting of Defects and Noncompliance" (10 CFR 21), for potential defects and noncompliances also is achieved with the occurrence reporting system. Vendors report defects to the SNF Project for reporting to DOE in a manner equivalent to reporting to the NRC under 10 CFR 21.

The SNF Project facility manager, or a designee, has ultimate responsibility for the requirements of DOE O 232 1A. Once the appropriate response is initiated by personnel to stabilize or return the facility to a safe condition, the event or condition is categorized and the Occurrence Notification Center duty officer for unusual occurrences or emergencies and the DOE-RL facility representative are notified. The duty officer assigns a reportable occurrence number and makes other required notifications. During the entire process of notification and reporting, the facility representative and duty officer use the current management chain established for the line organization in providing program direction to the SNF Project.

SNF Project administrative procedures provide the process associated with the investigation, timely reporting, trending, and processing of occurrence reports concerning events or conditions that could have adverse implications for safety, health, environment, quality assurance, or security in accordance with the requirements of DOE Order 5482 1B, Environment Safety and Health Appraisal Program, and DOE Order 5484 1. SNF Project administrative procedures identify the responsibilities and process for identifying administrative and technical deficiencies. They also identify the process for ensuring deficiencies are identified and disseminated to the appropriate tracking and trending systems as required by 10 CFR 820.

17 4 4 1 Notification Procedures As required by 10 CFR 835, Title 40, Code of Federal Regulations, Part 355, “Emergency Planning and Notification” (40 CFR 355), and DOE O 232 1A, events that require notification of DOE personnel (and state and local officials, when appropriate) require a systematic, controlled method for gathering and transferring information. Procedures have been developed to support the fulfillment of DOE requirements.

Management ensures that all appropriate personnel are notified of emergencies when required. Names of primary and alternate contacts and current phone and pager numbers are readily available to the individual who is assigned to make the notifications. All notifications are documented in the manager's or supervisor's narrative log. The procedures for emergency notifications are discussed in Chapter 15 0.

17 4 4 2 Corrective Action Determination The actual or probable causes of a problem are evaluated by one or more techniques or methodologies to establish a final root cause. As required by DOE Order 4330 4B, an acceptable root cause meets three criteria: (1) its correction will prevent recurrence of the unplanned occurrence, (2) its correction will be feasible, and (3) its correction will not adversely impact safety, reliability, or operational goals.

Appropriate corrective action is established for each event investigation, and specific personnel are assigned responsibilities for the corrective action as specified by DOE Order 5480 19. Corrective action can take the form of procedural changes, training, design, etc.
modifications, or changes to administrative controls. The final approval for corrective action is made by the SNF Project facility manager.

An investigative report is prepared in accordance with DOE Order 5480.19 that contains a description of the event, a discussion of the impact of the event root cause, lessons learned, and the proposed corrective actions. The investigative report is approved by the SNF Project facility manager and reviewed by appropriate supervisors, managers, and the safety review committee.

17 4 4 3 Event Training In accordance with DOE Order 5480.19, in-house events are evaluated to determine whether the event should be included in the training program for appropriate SNF Project personnel. Sometimes, because of the severity or possible safety consequences of some events, immediate training is appropriate.

17 4 4 4 Feedback and Trending As described in the lessons-learned program occurrence reports will be used to feed back relevant operational history into the SAR. Trending of occurrences will result in safety analyses that reflect both current and past operating practices and will be used to verify continuous improvement in SNF Project facility management. Feedback trending, and root cause evaluation as part of the investigation process all serve to minimize recurrence.

Patterns of deficiencies, such as operator errors or inadequate procedures, are trended. A periodic summary report of events, causes, and trends is submitted to appropriate managers. Applicable material is incorporated into training programs.

17 4 4 5 Tracking As required by 10 CFR 820, tracking systems will be established to provide:

- Timely self-identification of nuclear safety deficiencies
- Prompt and complete reporting of such deficiencies to DOE
- Root cause analysis of nuclear safety deficiencies
- Prompt correction of nuclear safety deficiencies in a manner that precludes recurrence
- Identification of modifications in practices or facilities that can improve public or worker radiological health and safety

17 4 5 Operational Readiness Reviews

ORRs are required by Section 17 in the S/RID (HNF-SD-SNF-RD-001). ORRs provide a structured methodology for verifying that a facility is ready to be operated in a safe and controlled manner. The process will be applied to SNF Project facilities on a graded approach which addresses all key elements of the ORR, ranging from short, simple, low-level efforts to
comprehensive efforts covering all hardware, personnel, and procedures depending on the complexity and hazards. The ORR process will include a verification of the level of compliance with ES&H orders and Occupational Safety and Health Administration regulations.

DOE O 425.1 and DOE C 425.1 establish the actions to be taken and assign responsibilities for authorizing the startup of new facilities and restart of nuclear facilities. RLID 425.1 implements the requirements of DOE O 425.1 at the Hanford Site. ORRs will be required for startup or restart of the SNF Project facilities under the following circumstances:

- Initial startup
- Restart after an unplanned shutdown directed by DOE management for safety or other appropriate reasons
- Restart after an extended shutdown of 12 months
- Restart after substantial process, system, or SNF Project facility modifications that require changes in the safety basis previously approved by DOE
- Restart after a shutdown because of operations outside the safety basis
- When deemed necessary by DOE management.

SNF Project implementing procedures, in conjunction with DOE O 425.1, DOE C 425.1, RLID 425.1, and DOE-STD-3006-95 define the process by which operational readiness is determined. This includes the breadth of the ORR development of a plan-of-action, development of implementation plans, tracking and closure of findings, and certification and verification that the facility is ready to start up or restart.

17.4.6 Safety Culture

This section summarizes the policies and programs in place to facilitate evaluation to ensure that (1) safety awareness is a primary concern to management and (2) employees at all levels of the SNF Project are aware they have an obligation to ensure operations are conducted safely.

17.4.6.1 Fluor Daniel Hanford, Incorporated

FDH supports safe and compliant work practices through its integrated Environmental, Safety and Health Program. The heart of the FDH Environmental Safety and Health Program is the firm commitment by all managers, supervisors, and employees to prevent accidents and the conditions that could lead to injuries or endanger the environment. Through this emphasis on safety first, FDH management is improving the Hanford Site safety culture and demonstrating its commitment to affect change in the following key areas: management commitment, employee involvement, environmental safety and health training, worksite analysis, and hazard prevention and control.
17.4.6.2 Spent Nuclear Fuel Project  The fundamental principles at the core of the SNF Project management approach to safety are summarized below. These principles support the FDH safety-first emphasis and are infused throughout all layers of the organization, guiding day-to-day decision making and conduct.

- The development of safety culture is compliant with the VPP elements described in Section 17.4.1.2.

- The authorization basis establishes the bounds within which all operations may be safely conducted. This principle permeates every chapter of the SAR. The SNF Project has demonstrated its commitment to this principle by identifying and documenting the safety basis of every SNF Project-managed facility and activity and by implementing physical and administrative controls appropriate to risk in order to protect the public, the workers, and the environment against identified hazards.

- Management is responsible for providing leadership and support to site workers. This responsibility includes establishing goals and standards for work activities and providing the resources and materials necessary to allow workers to succeed. Management fulfills this responsibility through formal planning, coordinating, reporting, and budgeting processes, and through formal and informal interaction with workers.

- Work is performed in accordance with established controls. This ensures repeatable, predictable operation that complies with regulatory requirements and implements safe work practices. The rigorous approach to procedural development, the performance-based approach to training, and the emphasis on following procedures when conducting operations, demonstrate SNF Project commitment to working in accordance with established controls (see Chapters 11.0 and 12.0).

- Workers are responsible for ensuring excellence and are individually responsible for their own safety and the safety of their coworkers and the facility. As noted in Chapter 12.0, the concept of individual responsibility is exemplified by the fact that every worker has the authority to stop work if a procedural step cannot be implemented safely (see Chapters 7.0, 8.0, and 14.0). Stop-work authority is emphasized in the orientation training provided to all Hanford Site workers. Worker empowerment is further emphasized in SNF Project implementing procedures, which contain guidance that encourages and requires employees to immediately notify their supervisors upon observing any event or condition adverse to safety, health, quality safeguards and security, operations, or the environment. An employee concerns program provides another avenue for identifying problems to SNF Project management if an employee is dissatisfied with resolution through normal channels. Employees may also relay concerns directly to regulatory authorities if other alternatives do not result in correction of the problem.
Safety culture includes characteristics and attitudes in organizations and individuals that establish that, as an overriding priority, safety issues receive the attention warranted by their significance (IAEA 75-INSA-4). In addition to the above, the SNF Project promotes a company-wide safety culture through the following activities:

- Increasing individual awareness of the importance of safety, both on and off the job (i.e., through periodic safety meetings)
- Training personnel in safety skills, such as recognition and reporting of unsafe acts or conditions and conducting operations in a safe manner
- Achieving a safety commitment by all personnel
- Using the checks and balances of audit and review practices for meaningful, high-quality self-appraisals
- Developing systems and corrective measures that result in preventive rather than responsive actions
- Encouraging individual responsibility through formal assignment and description of duties
- Developing a high degree of personal accountability for safety in all employees, and acceptance of the philosophy that all injuries and accidents can and must be prevented

B4 0 SAFETY STRUCTURES, SYSTEMS, AND COMPONENTS

B4 1 INTRODUCTION

This chapter provides details on those structures, systems, and components (SSCs) that are necessary for the facility to meet offsite release limits and to satisfy onsite risk evaluation guidelines, provide significant defense in depth or contribute to worker safety. This chapter meets the requirements of DOE Order 5480.23, Nuclear Safety Analysis Reports, follows the format guidance of DOE-STD-3009-94, Preparation Guide for U.S. Department of Energy Nonreactor Nuclear Facility Safety Analysis Reports, and includes the following information:

- A list of the safety-class SSCs

  Subsections contain details of safety functions, system descriptions, functional requirements, system evaluations, and assumptions requiring technical safety requirements (TSRs) to ensure performance of the safety functions.

- A list of the safety-significant SSCs

  Subsections contain details of safety functions, system descriptions, functional requirements, system evaluations, and assumptions requiring TSRs to ensure performance of the safety functions.

There were no SSCs identified in Chapter B3 0 for defense in depth or worker safety that were upgraded to safety-significant.

In general, safety-class SSCs are those items required for protection of the offsite environment and the public. Safety-class SSCs include those items designated as safety class, in accordance with DOE Order 6430.1A, General Design Criteria. Safety-class SSCs also encompass items that are designated as “important to safety” and have been classified as Category A, as defined in Item 29 of HNF-SD-SNF-DB-003, Spent Nuclear Fuel Project Path Forward Additional NRC Requirements.

Safety-significant items are those SSCs required for the protection of onsite personnel not directly involved in facility operations. Safety-significant SSCs also encompass those items that have been designated important-to-safety Category B, in accordance with Item 29 of HNF-SD-SNF-DB-003. SSCs that would prevent or mitigate an onsite fatality or protect large numbers of facility workers (not industrial safety), or those SSCs that would prevent or mitigate toxic chemical exposures, also are designated safety significant.

All SSCs that are not classified as safety class or safety significant are general-service SSCs. Those SSCs that have been designated as important-to-safety Category C, in accordance with Item 29 of HNF-SD-SNF-DB-003, also are classified as the general-service SSCs. General-service SSCs protect workers from standard industrial hazards or are controlled by site safety programs.
The Cold Vacuum Drying Facility (CVDF) is classified as a hazard category 2 nuclear facility and has the potential for an accident resulting in significant onsite and offsite consequences. The CVDF has associated safety-significant SSCs to provide protection to the onsite workers, and as appropriate safety-class SSCs to provide protection to the offsite public. Because of their public protection function, safety-class SSCs generally require more formality in establishing functional requirements and performance criteria than safety-significant SSCs.

The accident analysis in Chapter B3.0 identifies six design basis accidents (DBAs) whose unmitigated consequences bound the accident sequences and scenarios identified in the hazard analysis process. Of these DBAs, two had safety-class consequences. The thermal runaway accident that could occur after draining has safety-class consequences, and the multi-canister overpack (MCO) overpressurization accident that could breach the MCO and blow down from high pressure also has safety-class consequences.

Safety-class systems and components are designed to prevent these accidents or mitigate the offsite consequences to within applicable limits. For the MCO overpressurization accident, redundant pressure management features discharge in a fashion that facility high-efficiency particulate air (HEPA) filtered ventilation systems mitigate the onsite consequence to within risk evaluation guidelines. Safety-class systems and components are designed to prevent these accidents from occurring during credible conditions. For specific instances when the onsite consequence exceeds the guidelines while the offsite consequence is within limits and the event scenario is not demonstrated incredible, the ventilation systems are credited with safety-significant mitigation of the onsite dose.

The other four DBAs (gaseous release, liquid release, MCO external hydrogen explosion, and MCO internal hydrogen explosion) have safety-significant unmitigated consequences. The gaseous and liquid release scenarios are mitigated by maintaining negative differential pressure within the facility, thereby confining radioactive releases within the facility using HEPA-filtered exhaust ventilation systems that are designated safety-significant. External hydrogen explosion release scenarios are prevented in the exhaust duct by hydrogen mitigation strategies incorporating restrictions in the vent paths and dilution flow from the ventilation system. The internal hydrogen explosion is prevented for credible scenarios by accomplishing MCO hydrogen management strategies using some of the same safety-class systems designed to prevent the thermal runaway and additional components of existing processing systems designated safety-significant. In scenarios where blow-back into the process bay is not incredible, the ventilation systems are credited with safety-significant mitigation of the onsite dose.

Each accident analysis section in Chapter B3.0 concludes with a summary of safety SSCs that provides the basis for this chapter. A summary listing of the accident categories and the designated safety SSCs that prevent these accidents or mitigate their consequences is provided in Table B4.1. Table B4.2 provides a summary list of the safety SSCs identified and provides the level of safety credited for each accident category. Many SSCs provide a safety function for prevention or mitigation of more than one accident. Detailed definitions of safety-class and safety-significant SSCs are provided in Section 3.4.1 of the Spent Nuclear Fuel (SNF) Project Final Safety Analysis Report (FSAR).
