## GENERAL INTRODUCTION

## Introduction

Oxygen atom transfer (OAT) catalyzed by transition metal complexes has received extensive attention from inorganic and bioinorganic chemists for decades due to its contribution to biochemistry and industrial applications. ${ }^{1-3}$ Molybdenum(IV/VI) and tungsten(IV/VI) complexes have been widely explored because of their important roles in oxo-transferases. ${ }^{2,4-6}$ To the contrary, rhenium(V/VII), as a neighbor, only has been explored only to a limited extent. ${ }^{7}$

A rhenium(V) dimer, $\{\mathrm{MeReO}(\mathrm{mtp})\}_{2}$, a model of a proposed intermediate for sulfur transfer reaction, was synthesized from methyltrioxorhenium(VII), abbreviated MTO, and mtpH $\mathrm{H}_{2}, 2$-(mercaptomethyl) thiophenol ( $o-\mathrm{HSC}_{6} \mathrm{H}_{4} \mathrm{CH}_{2} \mathrm{SH}$ ). ${ }^{8}$ Lewis bases, pyridines and phosphanes, were found to monomerize $\{\mathrm{MeReO}(\mathrm{mtp})\}_{2}$, giving rise to $\mathrm{MeReO}(\mathrm{mtp}) \mathrm{L}(\mathrm{L}=$ Lewis base). ${ }^{9-11}$ All of these rhenium(V) complexes are able to catalyze OAT reactions, especially $\mathrm{MeReO}(\mathrm{mtp}) \mathrm{PPh}_{3}$, showing remarkable reactivity for reaction between pyridine N -oxides and phsophanes in eq $1 .{ }^{12-14}$

$$
\begin{equation*}
\mathrm{PyO}+\mathrm{PZ}_{3} \rightarrow \mathrm{Py}+\mathrm{OPZ}_{3} \tag{1}
\end{equation*}
$$

A notable feature of these rhenium(V) complexes is the five-coordinate distorted square pyramidal structure in chart 1 . The rhenium atom is surrounded by the terminal oxo group at the axial position and a basal plane defined by a methyl, two thiolate and one thioether sulfur atom for the dimer, or a Lewis base for monomers. There is vacant position trans to the terminal oxo group, from which substrates access rhenium as well as the departure of the products.

## Chart 1

(MeReO(mtp) $\}_{2} \quad$ MeReO(mtp)L

Aside from studies on OAT, in Chapter 1 , we described an unique methyl transfer from rhenium to thiolate sulfur, which occurs during the oxidation of MeReO(edt) $\mathrm{PPh}_{3}$ with sulfoxides and the reaction of MTO with 1,2 -ethanedithiol as well. Only a few precedents exist for this type of methyl transfer. An example is the conversion of D,L-homocystein, $\mathrm{HS}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{CHNH}_{2} \mathrm{CO}_{2} \mathrm{H}$, to L-methionine, $\mathrm{MeS}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{CHNH}_{2} \mathrm{CO}_{2} \mathrm{H}$ with methylcobalamin and methylcobinamide, which is catalyzed by Vitamin $\mathrm{B}_{12}$, modeled by methylbis(dimethylglyoximato)cobalt(III) and related complexes which are able to convert thiols to thioethers. The new reactions of rhenium complexes, reported in Chapter I, give sound evidence for the analogous conversion, which affords further mechanistic understanding of methyl transfer. Although the structure of $\operatorname{ReO}\left(\kappa^{2}\right.$-edt) $\left(\kappa^{2}\right.$-edtMe) was unsolved, evidence from NMR, UV spectra for oxidation products by $\mathrm{H}_{2} \mathrm{O}_{2}$ and structure of further ligand displacement product of $\operatorname{ReO}\left(\kappa^{2}-e d t\right)\left(\kappa^{1}-e d t M e\right) T P A$ all proved that the methyl group, originally on rhenium in MeReO (edt) $\mathrm{PPh}_{3}$ or MTO, transfers to thiolate sulfur. On the basis of kinetic information and a literature study, a reductive methyl transfer mechanism was proposed.

Often a monoanionic bidentate ligand is employed for the study of the coordination chemistry of rhenium for the radiotherapeutic applications of the $\beta$-emitting isotopes ${ }^{186} \mathrm{Re}$
and ${ }^{188} \mathrm{Re}$, containing a $\left\{\mathrm{Re}^{\vee} \mathrm{O}\right\}$ core without methyl group. Typical donor atom pairs are $\mathrm{P}, \mathrm{O}$ ( $\mathrm{HPO}=$ phosphinocarboxylic acid); $\mathrm{N}, \mathrm{O}$ ( $\mathrm{HNO}=$ e.g., picolinic acid or 8 -hydroxyquinoline); and $\mathrm{N}, \mathrm{S}$ (HNS = 2-mercaptoquinoline). In Chapter II, we described syntheses and characterization of four methyloxorhenium(V) complexes: $\operatorname{MeReO}(\mathrm{PA})_{2}, \mathrm{MeReO}(\mathrm{HQ})_{2}$, $\mathrm{MeReO}(\mathrm{MQ})_{2}$, and $\mathrm{MeReO}(\mathrm{DPPB})_{2}$ (in which $\mathrm{PAH}=2$-picolinic acid, $\mathrm{HQH}=8$ hydroxyquinoline, $\mathrm{MQH}=8$-mercaptoquinoline, and DPPBH $=$ diphenylphosphinobenzoic acid). These compounds catalyze the sulfoxidation of thioethers by pyridine $N$-oxides and sulfoxides. Here we report kinetic and mechanistic studies of the latter reaction. The trapping of a transient dioxorhenium(VII) species was performed.

To extend our exploration of rhenium catalysts, in Chapter IIII we describe the formation and characterization of three methyl(oxo)rhenium(V) complexes; two contain the anion $\mathrm{MeReO}(\mathrm{edt})(\mathrm{SPh})^{-}$with the cations 2-picolinium and 2,6-lutidinium, and the third is a neutral rhenium compound, $\mathrm{MeReO}(e d t)(\operatorname{tmtu})$, where edt stands for 1,2-ethanedithiolate and tmtu for 1,1,3,3-tetramethylthiourea. To understand the OAT process catalyzed by $\mathrm{MeReO}(\mathrm{mtp}) \mathrm{PPh}_{3}$, which is described early, it is important to investigate the steps of OAT from pyridine N -oxides to rhenium catalyst separately, including a study of the intermediates $\mathrm{MeReO}(\mathrm{edt}) \mathrm{PyO}$ from ligand displacement and $\mathrm{MeReO}_{2}$ (edt)PyO from oxidation. An especially the striking feature is that nucleophiles assist oxidation by incorporation of a second molecule of pyridine N -oxide in the transition state. The ionic compound was found to be suitable for this purpose because formation of both intermediates can be clearly separated and kinetically investigated. To extend an understanding of ligand displacement, the non-oxidizing ligands pyridines and $\mathrm{PPh}_{3}$ were employed as well. An unanticipated assistance of ligand displacement of ionic compound by Brønsted bases was discovered and studied.

As an essential step in OAT and an important part of rhenium chemistry, ligand displacement has attracted our attention. In Chapters IV and $V$, kinetic and equilibrium studies of ligand displacements of MeReO(dithiolato)Py and $\operatorname{ReO}\left(\kappa^{2}\right.$-edt) $\left(\kappa^{2}\right.$-edtMe) were performed. In Chapter IV, equilibrium and rate constants have been determined for this family of ligand displacement reactions of previously-prepared five-coordinate, squarepyramidal rhenium(V) complexes:

$$
\begin{equation*}
\mathrm{MeReO}(\mathrm{dt}) \mathrm{Py}+\mathrm{PZ}_{3}=\mathrm{MeReO}(\mathrm{dtt})\left(\mathrm{PZ}_{3}\right)+\mathrm{Py} \tag{2}
\end{equation*}
$$

In this equation, $\mathrm{PZ}_{3}$ denotes a generalized phosphane $\left(\mathrm{Z}=\right.$ aryl, alkyl), often $\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{4}-4-\mathrm{Y}\right)_{3}$ with subsituent $\mathrm{Y}, \mathrm{Py}$ is a generalized pyridine, $4-\mathrm{X}-\mathrm{C}_{5} \mathrm{H}_{4} \mathrm{~N}$ with subsituent X and dt represents either 1,2-ethanedithiolate or 1,3-propanedithiolate. We have evaluated equilibrium constants for reaction 2 , and correlated them by a two-variable linear free-energy relationship. The rate constants for eq 2 were also evaluated, but their interpretation was less straightforward. A multiple-substituent correlation analysis, authenticated for certain organic reactions, was not particularly satisfactory. The answer lies in a multiple step mechanism, in which the rate controlling step may vary with the influence of the substituent on the entering ligand.

In Chapter V, we report the kinetics and mechanism of ligand (phosphane) displacement (eq 3 ) of the thioether sulfur to generate a phosphane-rhenium $(V)$ compound.

$$
\begin{equation*}
\mathrm{ReO}\left(\kappa^{2}-\mathrm{edt}\right)\left(\kappa^{2} \text {-edtMe }\right)+\mathrm{PZ} Z_{3}=\operatorname{ReO}\left(\kappa^{2} \text {-edt }\right)\left(\kappa^{1} \text {-edtMe }\right)\left(\mathrm{PZ}_{3}\right) \tag{3}
\end{equation*}
$$

Hammett analysis for both equilibrium and rate constants revealed that an early transition state was involved in the reaction. Also, sulfur inversion of the thioether ligand has been observed as a line-broadening effect of proton residual of the methyl on thiolate sulfur. A planar intermediate was proposed for sulfur inversion, derived from the comparison of activation energy parameters of ligand displacement and sulfur inversion.

The study of OAT catalyzed by rhenium(V) complexes revealed that the oxidation of rhenium(V) complexes to rhenium(VII) is an essential step in the catalytic cycle. Steric demand is always an important issue for such catalysts. Different ligands for rhenium(V) complexes have been employed, especially those with " $3+1$ ", " $3+2$ " and " $3+1+1$ " coordination shells, where " 3 ", " 2 ", " 1 " represent tri-, bi-, and mono-dentate ligands. They differ in geometry as well as coordination number. In Chapter VI, we describe the syntheses and characterization of four new rhenium(V) compounds with tridentate chelating ligands: 2mercaptoethyl thioether, 2-mercaptoethyl ether, thioldiglycolic acid and 2(salicylideneamino)benzoic acid, abbreviated as HSSSH, HSOSH, HOSOH and HONOH respectively. Compounds $\mathrm{MeReO}(\mathrm{SSS})$ and $\mathrm{MeReO}(S O S)$ have a five-coordinate distorted pentagonal pyramidal geometry about rhenium. To the contrary, $\mathrm{MeReO}(\mathrm{OSO})\left(\mathrm{PZ}_{3}\right)$ and $\mathrm{MeReO}(\mathrm{ONO})\left(\mathrm{PPh}_{3}\right)$ are six-coordinate compounds with distorted octahedral structures. The
oxidation of three of these compounds was investigated and followed different rate laws. These mechanistic differences have been interpreted as reflecting the different steric demands of five- and six-coordination shells.

During the period 1998-2003, around two dozen rhenium complexes were synthesized and characterized in our group. In Chapter VII, we summarized the syntheses of rhenium complexes including some unpublished results. The criteria for syntheses were discussed as well, which lie in two issues. First, rhenium(VII) in MTO needs to be reduced to rhenium(V). Usually thiols, phosphanes and even sulfides were employed as reducing reagent. Second, suitable ligands must be used to stabilize rhenium(V). As is well known, methyldioxorhenium(V) does not persist in solution, but it can be readily oxidized by oxidants such as dioxygen, pyridine N -oxides, sulfoxides, nitrate and even perchlorate etc. ${ }^{15,16}$ Without an oxidant, a black precipitate was observed as the product of polymerization of methyldioxorhenium(V). ${ }^{17}$

## Dissertation Organization

This dissertation consists of seven Chapters. Chapter I has been published in Angewandte Chemie International Edition. Chapter II has been published in Inorganic Chemistry. Chapter III has been submitted to Inorganic Chemistry. Chapter IV has been submitted to Dalton transactions. Chapter V has been published in Organometallics. Chapter VI has been published in Inorganic Chemistry. Chapter VII contains part of a manuscript submitted to Inorganic Synthesis. Each Chapter is self-contained with its own equations, figures, tables, references, and supporting information. Following the last Chapter are general conclusions. Except for the X-ray structural analysis and several synthetic procedures in Chapter VII, all the work in this dissertation was performed by the author of this thesis, Xiaopeng Shan.

## CHAPTER I. METHYL TRANSFER FROM RHENIUM TO COORDINATED THIOLATE GROUPS

A communication published in Angewandte Chemie International Edition Xiaopeng Shan, Arkady Ellern and James H. Espenson

A prominent reaction of Vitamin $\mathrm{B}_{12}$ is the conversion of D,L-homocystein, $\mathrm{HS}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{CHNH}_{2} \mathrm{CO}_{2} \mathrm{H}$, to L-methionine, $\mathrm{MeS}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{CHNH}_{2} \mathrm{CO}_{2} \mathrm{H}$ with methylcobalamin and methylcobinamide. ${ }^{1-4}$ Methyl-bis(dimethylglyoximato)cobalt(III) and related complexes also convert thiols to thioethers. ${ }^{5}$

$$
\begin{equation*}
\mathrm{Co}^{\mathrm{III}}-\mathrm{CH}_{3}+\mathrm{RSH} \rightarrow\left[\mathrm{Co}^{\mathrm{l}}\right]^{-}+\mathrm{RSCH}_{3}+\mathrm{H}^{+} \tag{1}
\end{equation*}
$$

There are, however, a lack of precedents in the literature that do not involve organocobalt complexes. In this work, new reactions of rhenium complexes have been examined, and sound evidence for the analogous conversion has now been obtained.

## Chart 1

1

5

3

6

7
$\mathrm{MeReO}_{3}$ (MTO, 2) ${ }^{6}$ reacts with the readily-oxidized $\mathrm{mtpH}_{2}$, 2-(mercaptomethyl)thiophenol $\left(\mathrm{mtpH}_{2}\right)$, to yield a disulfide (eq. 2 ):

$$
\begin{equation*}
2 \mathrm{MeReO}_{3}+4 \mathrm{mtpH}_{2} \rightarrow 4+2(6)+4 \mathrm{H}_{2} \mathrm{O} \tag{2}
\end{equation*}
$$

With 1,2-ethanedithiol, however, a quite different result was obtained. As $\mathrm{Re}^{\mathrm{VII}}$ was reduced to $\mathrm{Re}^{\mathrm{V}}$, one edtH $\mathrm{H}_{2}$ molecule was transformed to $\mathrm{HS}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{SMe}$, which remains coordinated to rhenium(V) through both sulfur atoms in a $K^{2}$ fashion (eq. 3):

$$
\begin{equation*}
\mathrm{MeReO}_{3}+2 \mathrm{edtH}_{2} \rightarrow 1+2 \mathrm{H}_{2} \mathrm{O} \tag{3}
\end{equation*}
$$

Details of the synthesis and characterization of the dark red compound 1 are given in the Experimental Section. A similar reaction starting with [MeReO(edt) $\left(\mathrm{PPh}_{3}\right)$ ], $3,{ }^{7}$ gave the same product in lower yield. Crystals of 1 suitable for x -ray diffraction could not be obtained. We have formulated composition of 1 as $\operatorname{ReO}\left(\kappa^{2}-e d t\right)\left(\kappa^{2}-e d t M e\right)$ on the basis of the elemental analysis and spectroscopic data. An alternative formulation as an organorhenium(VII) compound, MeReO (edt) $)_{2}$, could not be ruled out by these data, although there was faint evidence in favor of structure 1 , in that the $\mathrm{CH}_{3}$ resonance appeared at $\delta 1.90$ ppm , which is further downfield than would be expected for a methyl group coordinated to a $\mathrm{Re}^{\mathrm{VII}}$ center. Indeed, the proposed mechanism suggests that $\mathrm{MeReO}(\mathrm{edt})_{2}$ lies on the pathway to 1.

Chemical methods were therefore used to obtain information about the molecular structure of 1 , particularly with respect to whether the Me-Re interaction present in the starting materials is retained. Its reaction of 1 with $\mathrm{H}_{2} \mathrm{O}_{2}$ in wet acetonitrile gave $\mathrm{ReO}_{4}{ }^{-}$ions, which are easily recognized from its characteristic UV spectrum. The same product was obtained from 5, another compound that lacks a Me-Re bond. In contrast, several compounds that do contain a Me-Re group (2, 3 and 4) clearly reacted with hydrogen peroxide to form $\left[\mathrm{MeReO}\left(\kappa^{2}-\mathrm{O}_{2}\right)_{2}\left(\mathrm{OH}_{2}\right)\right]$, with a characteristic absorption maximum at $360 \mathrm{~nm}(\varepsilon=1200)$. Thus, these results suggest that no Me-Re bond exists in $1 .{ }^{8}$

Figure 1. The molecular structure of $\left[\operatorname{ReO}\left(\kappa^{2}-\mathrm{edt}\right)\left(\kappa^{1}-\mathrm{edtMe}\right)(\mathrm{PTA})\right]$. The methyl group at $S_{4}$ was disordered; the structure was refined at $50 \%$ occupancy of the two sites. Selected bond lengths (pm) and angles ( ${ }^{\circ}$ ) are: Re-O, 170.05(5); $\mathrm{Re}-\mathrm{S}(3)$, 230.54(17); Re-P, $242.25(18) ; \mathrm{S}(4)-\mathrm{C}(10), 181.0(9) ; \mathrm{S}(4)-\mathrm{C} 11 \mathrm{~A}, 175.6(17) ; \mathrm{S}(4)-\mathrm{C}(11 \mathrm{~B}), 184.0(4) . \mathrm{O}-\mathrm{Re}-$ $\mathrm{S}(3), 110.68(19) ; \mathrm{O}-\mathrm{Re}-\mathrm{P}, 97.3(2) ; \mathrm{S}(2)-\mathrm{Re}-\mathrm{P}, 153.94(6) ; \mathrm{S}(1)-\operatorname{Re}-\mathrm{S}(3), 133.58(7) ; \mathrm{C}(10)-$ $\mathrm{S}(4)-\mathrm{C}(11 \mathrm{~A}), 102.7(7) ; \mathrm{C}(10)-\mathrm{S}(4)-\mathrm{C}(11 \mathrm{~B}), 104.3(17) ; \mathrm{C}(11 \mathrm{~A})-\mathrm{S}(4)-\mathrm{C}(11 \mathrm{~B}), 133.1(14)$. The structure was drawn with the program CrystalMaker. ${ }^{[14]}$

The reaction of compound 1 with phosphanes $\left(\mathrm{PZ}_{3}\right.$, in general) yields a new series of compounds, $\left[\operatorname{ReO}\left(\kappa^{2}-\mathrm{edt}\right)\left(\kappa^{1}-\mathrm{edtMe}\right)\left(\mathrm{PZ}_{3}\right)\right]$ (7) in which the thioether arm has been displaced. One such compound, where $\mathrm{PZ}_{3}=1,3,5$-triaza-phosphaadmantane (PTA), ${ }^{9}$ has been characterized crystallographically; the molecular structure is displayed in Figure 1. Phosphanes are generally much stronger Lewis bases than thiocthers and will, to a great extent, displace RSR' group. In keeping with this fact, the equilibrium constant for $\mathrm{PPh}_{3}\left(\mathrm{~K}_{4}\right.$,
eq. 4) is $6 \times 10^{5}\left(\mathrm{C}_{6} \mathrm{H}_{6}, 25{ }^{\circ} \mathrm{C}\right),{ }^{10}$ whereas that for eq. 5 is 8.0 under the same conditions. The large difference in theses values arises from the chelate effect, and illustrates its very substantial importance in this case.

$$
\begin{align*}
& \mathrm{MeReO}(e d t)\left(\mathrm{Me}_{2} \mathrm{~S}\right)+\mathrm{PPh}_{3} \rightarrow \mathrm{MeReO}(\mathrm{edt}) \mathrm{PPh}_{3}+\mathrm{Me}_{2} \mathrm{~S}  \tag{4}\\
& 1+\mathrm{PPh}_{3}=\operatorname{ReO}\left(\kappa^{2}-\mathrm{edt}\right)\left(\kappa^{1} \text {-edtMe }\right)\left(\mathrm{PPh}_{3}\right) \tag{5}
\end{align*}
$$

The formation of 1 , as shown in reaction (3), follows the net $1: 2$ stoichiometry given. It is a sequential process that obeys the rate law (eq. 6):

$$
\begin{equation*}
\mathrm{d}[1] / \mathrm{dt}=\mathrm{k} \times[2] \times\left[\mathrm{edtH}_{2}\right] \tag{6}
\end{equation*}
$$

with $\mathrm{k}=7.3 \times 10^{-2} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}\left(\mathrm{Me}_{2} \mathrm{SO}, 25^{\circ} \mathrm{C}\right)$. Clearly the first condensation step is rate determining, as the methylation step occurs more rapidly and is not manifest in the kinetics. The sequential mechanism proposed is given in Scheme 1. The final step appears to involve nucleophilic attack of the coordinated thiolate sulfur on the methyl group of the intermediate. Precedents for this mechanism, aside from those found in organocobalt systems, are rare. While the transfer of a phenyl group to an oxo group of an intermediate species ( $\left[\mathrm{TpRe}(\mathrm{O})_{2} \mathrm{Ph}\right]^{+}, \mathrm{Tp}=$ hydrotris(1-pyrazoly)borate) represents a distantly related example; ${ }^{[1]}$ a more relevant case is the thermal decomposition of $\left[\mathrm{MeReO}\left(\mathrm{K}^{2}-\mathrm{O}_{2}\right)_{2}\left(\mathrm{OH}_{2}\right)\right]$, which yields MeOOH and $\mathrm{HReO}_{4}{ }^{12}$

Scheme 1. Proposed mechanism for the formation of 1 (RDS = rate-determining step)

In summary, a novel transformation of $\operatorname{MeRe}(e d t)$ complex to give a $\operatorname{Re}($ thiolatemethylthioether) complex (1) has been discovered and established. This transformation is without precedent, aside from the homocystein-to-methionine transformation found for Vitamin $B_{12}$ and its mimics. Furthermore, the thioether group can be replaced by a phosphane; the derivative with PTA was characterized crystallographically. All of these reactions proceed to equilibrium, but owing to the chelate effect, the equilibrium constants are smaller by a factor of $10^{5}$ than the analogous values of K for the displacement of a nonchelated RSR' group.

## Experimental Section

Synthesis of $\left[\operatorname{ReO}\left(\kappa^{2}\right.\right.$-edt) $\left(\kappa^{2}\right.$-edtMe $\left.)\right], 1$. Dimethylsulfoxide ( 0.2 mmol$)$ was added to 5 mL of toluene containing 0.5 mmol of 2. 1,2-Ethane dithiol ( 0.5 mmol ) was added, whereupon the mixed solution turned red. After $4 \mathrm{~h}, 10 \mathrm{~mL}$ of hexanes was layered on top resulting in a deep red solid ( $87 \%$ yield) which was purified by recrystallization from methylene chloridehexanes. Elemental analysis, $\mathrm{C}_{5} \mathrm{H}_{11} \mathrm{OReS}_{4}$. Found $\mathrm{C}: 15.16$ (14.95 calcd.), $\mathrm{H}: 2.82$ (2.76); S: 32.09 (31.94). ${ }^{1} \mathrm{H}$ NMR: ( $400 \mathrm{MHz},\left[\mathrm{D}_{6}\right]$ benzene, $25^{\circ} \mathrm{C}$ ): $\delta=3.55\left(\mathrm{~m}, 1 \mathrm{H} ; \mathrm{CH}_{2}\right), 3.36(\mathrm{~m}, 1 \mathrm{H}$; $\mathrm{CH}), 2.70\left(\mathrm{~m}, 1 \mathrm{H} ; \mathrm{CH}_{2}\right), 2.51\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{2}\right), 2.11\left(\mathrm{~m}, 1 \mathrm{H} ; \mathrm{CH}_{2}\right), 1.92\left(\mathrm{~m}, 1 \mathrm{H} ; \mathrm{CH}_{2}\right), 1.90(\mathrm{~s}, 3 \mathrm{H}$, $\left.\mathrm{CH}_{3}\right), 0.84\left(\mathrm{~m}, 1 \mathrm{H} ; \mathrm{CH}_{2}\right) ;{ }^{13} \mathrm{C} \operatorname{NMR}\left(400 \mathrm{MHz},\left[\mathrm{D}_{6}\right]\right.$ benzene, $\left.25^{\circ} \mathrm{C}\right): \delta=45.6,45.0,43.5,36.2$, 22.3; UV/Vis (benzene): $\lambda_{\text {max }}(\varepsilon)=510 \mathrm{~nm}(1 \sigma \tilde{)}$ ), 389 nm (3400).

Synthesis of $\left[\operatorname{ReO}\left(\kappa^{2}-e d t\right)\left(\kappa^{1}\right.\right.$-edtMe)(PTA)]. A 1:1 reaction between 1 and PTA in toluene gave dark, shiny single crystals after recrystallization from toluene-hexanes. Elemental Analysis: $\mathrm{C}_{11} \mathrm{H}_{23} \mathrm{ON}_{3} \mathrm{PReS}_{4} . \mathrm{C}: 23.57$ (23.65 calcd), H: 4.12 (4.15), N: 7.55 (7.52), S: 23.25 (22.96), P: 5.61 (5.54). ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz},\left[\mathrm{D}_{6}\right]$ benzene, $25^{\circ} \mathrm{C}$ ), $\delta=4.34\left(\mathrm{~m}, 1 \mathrm{H} ; \mathrm{CH}_{2}\right)$, $4.21\left(\mathrm{~m}, 7 \mathrm{H} ; \mathrm{CH}_{2}\right), 3.86\left(\mathrm{~m}, 6 \mathrm{H} ; \mathrm{CH}_{2}\right) ; 3.43\left(\mathrm{~m}, 1 \mathrm{H} ; \mathrm{CH}_{2}\right), 3.34\left(\mathrm{~m}, 1 \mathrm{H} ; \mathrm{CH}_{2}\right), 3.20(\mathrm{~m}, 1 \mathrm{H} ;$ $\left.\mathrm{CH}_{2}\right), 2.97\left(\mathrm{~m}, 1 \mathrm{H} ; \mathrm{CH}_{2}\right), 2.41\left(\mathrm{~m}, 2 \mathrm{H} ; \mathrm{CH}_{2}\right), 1.98\left(\mathrm{~s}, 3 \mathrm{H} ; \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C} \mathrm{NMR}(400 \mathrm{MHz}$, $\left[\mathrm{D}_{6}\right]$ benzene, $\left.25^{\circ} \mathrm{C}\right): \delta=72.5(\mathrm{~d}, \mathrm{~J}(\mathrm{C}, \mathrm{P})=7 \mathrm{~Hz}), 51.9(\mathrm{~d}, \mathrm{~J}(\mathrm{C}, \mathrm{P})=16 \mathrm{~Hz}), 43.6(\mathrm{~d}, \mathrm{~J}(\mathrm{C}, \mathrm{P})=8$ $\mathrm{Hz}), 42.0(\mathrm{~s}), 37.2(\mathrm{~s}), 35.5(\mathrm{~d}, \mathrm{~J}(\mathrm{C}, \mathrm{P})=9 \mathrm{~Hz}), 15.3(\mathrm{~s}) ;{ }^{31} \mathrm{P} \operatorname{NMR}\left(400 \mathrm{MHz},\left[\mathrm{D}_{6}\right]\right.$ benzene, 25 ${ }^{\circ} \mathrm{C}$ ): $\delta=-74.0$; UV/Vis (benzene) $\lambda_{\text {max }}(\varepsilon)=386 \mathrm{~nm}(1900), 318 \mathrm{~nm}(1600 ; \mathrm{sh}), 262 \mathrm{~nm}(3 \tilde{8})$.

# CHAPTER II. METHYLOXORHENIUM(V) COMPLEXES WITH TWO BIDENTATE LIGANDS: SYNTHESES AND REACTIVITY STUDIES 

A manuscript published in Inorganic Chemistry

Xiaopeng Shan, Arkady Ellern, James H. Espenson

#### Abstract

Four new methyloxorhenium(V) complexes were synthesized: $\operatorname{MeReO}(\mathrm{PA})_{2}$ (1), $\mathrm{MeReO}(\mathrm{HQ})_{2}$ (2), $\mathrm{MeReO}(\mathrm{MQ})_{2}$ (3), and MeReO (diphenylphosphinobenzoate) ${ }_{2}$ (4) (in which $\mathrm{PAH}=$ 2-picolinic acid, $\mathrm{HQH}=8$-hydroxyquinoline and $\mathrm{MQH}=8$ mercaptoquinoline). Although only one geometric structure has been identified crystallographically for 1,2 and 3 , two isomers of 3 and 4 in solution were detected by NMR spectroscopy. These compounds catalyze the sulfoxidation of thioethers by pyridine N oxides and sulfoxides. The rate law for the reaction between pyridine N -oxides and thioethers, catalyzed by 1 , shows a first-order dependence on the concentrations of pyridine N -oxide and 1. The second order rate constants of series of para substituted pyridine N -oxides fall in the range of $0.27-7.5 \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$. Correlation of these rate constants by the Hammett LFER method gave a large negative reaction constant, $\rho=-5.2$. The next and rapid step does not influence the kinetics, but it could be explored with competition experiments carried out with a pair of methyl aryl sulfides, $\mathrm{MeSC}_{6} \mathrm{H}_{4}-p-\mathrm{Y}$. The value of each rate was expressed relative to the reference compound that has $Y=H$. A Hammett analysis of $k_{Y} / \mathrm{k}_{\mathrm{H}}$ gave $\rho=-1.9$. Oxygen-18 labeled 1 was used in a single turnover experiment for 4-picoline N -oxide and dimethyl sulfide. $\mathrm{No}^{18} \mathrm{O}$ labeled DMSO was found. We suggest that the reaction proceeds by way of two intermediates that were not observed during the reaction. The first intermediate contains an opened PA-chelate ring; this allows the pyridine N -oxide to access the primary coordination sphere of rhenium. The second intermediate is a cis-dioxorhenium(VII) species, which the thioether then attacks. Oxygen-18 experiments were used to show that the two oxygens of this intermediate are not equivalent; only the "new" oxygen is attacked by, and transferred to, $\mathrm{SR}_{2}$. Water inhibits the reaction because it hydrolyzes the rhenium(VII) intermediate.

## Introduction

Certain aspects of the coordination chemistry of rhenium have been widely developed because of the radiotherapeutic applications of the $\beta$-emitting isotopes ${ }^{186} \mathrm{Re}$ and ${ }^{188} \mathrm{Re}$. ${ }^{1-3}$ Most of these rhenium complexes contain a $\left\{\mathrm{Re}^{\mathrm{V}} \mathrm{O}\right\}$ core. ${ }^{4-7}$ Often a monoanionic bidentate ligand is present. Typical donor atom pairs such as $\mathrm{P}, \mathrm{O}$ ( $\mathrm{HPO}=$ phosphinocarboxylic acid), ${ }^{8,9}$ $\mathrm{N}, \mathrm{O}$ ( $\mathrm{HNO}=$ e.g., picolinic acid or 8 -hydroxyquinoline), ${ }^{10-13}$ and $\mathrm{N}, \mathrm{S}$ (HNS $=2$ mercaptoquinoline). ${ }^{12}$ Molybdenum complexes have been extensively investigated owing to interest in their oxotransferase activity, ${ }^{14-18}$ In comparison, only a few rhenium complexes have been investigated. ${ }^{19-23}$ This research focuses on compounds containing a methyl(oxo)rhenium(V) core, $\left\{\mathrm{MeRe}^{\mathrm{V}} \mathrm{O}\right\}{ }^{24-27}$

We have now extended our exploration of rhenium catalysts ${ }^{28-33}$ by the preparation and characterization of four new $[2+2]$ methyl-oxorhenium compounds, Chart 1 . These reactions are catalyzed by them:

$$
\begin{align*}
& \mathrm{RSR}^{\prime}+\mathrm{XC}_{5} \mathrm{H}_{4} \mathrm{NO} \stackrel{[\mathrm{Re}]}{\longrightarrow} \mathrm{RS}(\mathrm{O}) \mathrm{R}^{\prime}+\mathrm{C}_{5} \mathrm{H}_{4} \mathrm{~N}  \tag{1}\\
& \mathrm{R}_{2} \mathrm{~S}+\mathrm{R}_{2} \mathrm{SO}^{2} \stackrel{[\mathrm{Re}]}{\rightleftarrows} \mathrm{R}_{2} \mathrm{~S}(\mathrm{O})+\mathrm{R}_{2}^{\prime} \mathrm{S}
\end{align*}
$$

Chart 1. Structural Formulas of [2+2] Methyloxorhenium(V) Compounds

$\mathrm{MeReO}(\mathrm{PA})_{2} 1$

$\mathrm{MeReO}(\mathrm{MQ})_{2} \mathbf{3 a}$

$\mathrm{MeReO}(\mathrm{MQ})_{2} \mathbf{3 b}$

$\mathrm{MeReO}(\mathrm{HQ})_{2} 2$

MeReO(diphenylphosphinobenzoate) ${ }_{2} 4 \mathrm{a}$

MeReO(diphenyiphosphinobenzoate) ${ }_{2} \mathbf{4 b}$

Kinetic studies were carried out with 1, the most effective catalyst. Our goal has been to identify the steps in the mechanism, including the formulation of chemically-reasonable reaction intermediates. This includes the trapping of a transient dioxorhenium(VII) species.

## Experimental Section

Reagents and Instrumentation. Methyltrioxorhenium(VII), $\mathrm{CH}_{3} \mathrm{ReO}_{3}$ or MTO, was prepared from sodium perrhenate, tetramethyl tin and chlorotrimethylsilane. ${ }^{34}$ The chelating
ligands were purchased from commercial sources and used as received. Anhydrous methylene chloride was the solvent for UV/Visible spectrophotometry. $\mathrm{D}_{1}$-chloroform for NMR studies was dried over 4A molecular sieves (Fisher) for 24 h at $200^{\circ} \mathrm{C}$.

UV/Vis data were obtained with a Shimadzu Model 2501 spectrophotometer. Leastsquares kinetic fits were carried out with KaleidaGraph software. Bruker DRX-400 MHz and AC200 spectrometers were used to record ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{31} \mathrm{P}$ NMR spectra. The chemical shift for ${ }^{1} \mathrm{H}$ was defined relative to that of the residual $\mathrm{CHCl}_{3}$ in the solvent, 87.27 pprn . Infrared spectra were recorded by a Nicolet-500 spectrometer. GC-MS spectra were recorded by Finnegan MAT MAGNUM mass spectrometer. Elemental analysis was performed by Desert Analytics Laboratory.

Syntheses. Compounds $\mathbf{1 - 3}$ were prepared from MTO ( $50 \mathrm{mg}, 0.2 \mathrm{mmol}$ ), the bidentate ligand ( 0.4 mmol ), and the reducing agent triphenylphosphine ( $53 \mathrm{mg}, 0.2 \mathrm{mmol}$ ) in 20 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. After stirring the mixture for $12 \mathrm{~h}, 20 \mathrm{~mL}$ of hexanes was layered the top of the resulting solution and the mixture placed in a freezer at ca. $-12^{\circ} \mathrm{C}$. After 24 h a black powder had deposited; it was filtered and rinsed with hexanes. A crystal suitable for x-ray diffraction analysis was obtained by recrystallization from methylene chloride-hexanes. Dimethyl sulfide ( $19 \mathrm{mg}, 0.3 \mathrm{mmol}$ ) could also be used as the reducing agent for the preparation of 1 provided anhydrous sodium sulfate was added as a drying agent to complete the reaction. If the acidic form of the monoanionic ligand is written as $H(X, Y)$, where $X$ and $Y$ are the donor atoms, the chemical equation for the syntheses is

$$
\begin{equation*}
\mathrm{MeReO}_{3}+2 \mathrm{H}(\mathrm{X}, \mathrm{Y})+\mathrm{PPh}_{3} / \mathrm{Me}_{2} \mathrm{~S} \rightarrow \mathrm{MeRe}(\mathrm{O})(\mathrm{X}, \mathrm{Y})_{2}+\mathrm{H}_{2} \mathrm{O}+\mathrm{Ph}_{3} \mathrm{PO} / \mathrm{Me}_{2} \mathrm{SO} \tag{3}
\end{equation*}
$$

1 was obtained in $83 \%$ yield from triphenylphosphine, $53 \%$ from dimethyl sulfide. NMR ${ }^{1} \mathrm{H}: \delta 8.84(\mathrm{~d}, 1 \mathrm{H}), 8.52(\mathrm{~d}, 1 \mathrm{H}), 8.44(\mathrm{~m}, 1 \mathrm{H}), 8.29(\mathrm{~m}, 1 \mathrm{H}), 8.19(\mathrm{~d}, 1 \mathrm{H}), 7.77(\mathrm{~m}, 3 \mathrm{H}), 4.43$ $(\mathrm{s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}: 180,163,153,150,148,146,143,130,126,125,53,29,11$. IR $\left(\mathrm{CHCl}_{3}\right): 1003$ $\mathrm{cm}^{-1}$ and, for the ${ }^{18} \mathrm{O}$-labeled compound, $951 \mathrm{~cm}^{-1}$. The two agree precisely with the predicted $(18 / 16)^{1 / 2}$ ratio. UV-Vis $\left(\mathrm{CHCl}_{3}\right), \lambda_{\max } / \mathrm{nm}\left(\log \varepsilon / \mathrm{L} \mathrm{mol}^{-1} \mathrm{~cm}^{-1}\right): 568$ (2.3), 396.5 (3.83) and 260 (4.14). Elemental Analysis: $\mathrm{C}_{13} \mathrm{H}_{11} \mathrm{~N}_{2} \mathrm{O}_{5} \mathrm{Re}$, Found (Calcd.) C 33.85 (33.84), H 2.48 (2.40), N 6.06 (6.07).
2 was obtained in $80 \%$ yield. NMR ${ }^{1} \mathrm{H}: 88.56(\mathrm{~d}, 1 \mathrm{H}), 8.36(\mathrm{~m}, 1 \mathrm{H}), 8.21(\mathrm{~m}, 1 \mathrm{H}), 7.66(\mathrm{~m}$, $4 \mathrm{H}), 7.40(\mathrm{~m}, 3 \mathrm{H}), 7.07(\mathrm{~d}, 1 \mathrm{H}) 6.46(\mathrm{~d}, 1 \mathrm{H}), 4.53(\mathrm{~s}, 3 \mathrm{H}) .{ }^{13} \mathrm{C}$ : too insoluble. IR $\left(\mathrm{CHCl}_{3}\right)$ :
$980 \mathrm{~cm}^{-1}$. UV-Vis $\left(\mathrm{CHCl}_{3}\right), \lambda_{\text {max }} / \mathrm{nm}\left(\log \varepsilon / \mathrm{L} \mathrm{mol}^{-1} \mathrm{~cm}^{-1}\right.$ ): 470 (sh), 417 (3.70) and 360 (sh).
Elemental Analysis: $\mathrm{C}_{19} \mathrm{H}_{15} \mathrm{~N}_{2} \mathrm{O}_{3} \mathrm{Re}$, Found (Calcd.): C 44.64 (45.14), H 2.92 (2.99), N 5.29 (5.54).

3 was obtained in $50 \%$ yield. Two sets of ${ }^{1} \mathrm{H}$ NMR resonance peaks were found in solution with a ratio $3: 1$. Two geometric isomers were assigned to these peaks according to the x -ray structure and an earlier study of pyridine exchange reactions. ${ }^{35}$ In solution, the major species is 3a, NMR ${ }^{1} \mathrm{H}: ~ \delta 10.88(\mathrm{~d}, 1 \mathrm{H}), 8.39(\mathrm{~d}, 1 \mathrm{H}), 8.34(\mathrm{~d}, 2 \mathrm{H}), 8.06(\mathrm{~d}, 2 \mathrm{H}), 7.80(\mathrm{t}, 1 \mathrm{H}), 7.74(\mathrm{~d}$, $1 \mathrm{H}), 7.58(\mathrm{~m}, 1 \mathrm{H}), 7.74(\mathrm{~d}, 1 \mathrm{H}), 7.41(\mathrm{t}, 1 \mathrm{H}), 6.95(\mathrm{~d}, 1 \mathrm{H}), 6.75(\mathrm{~m}, 1 \mathrm{H}), 4.95(\mathrm{~s}, 3 \mathrm{H})$. The minor solution species is $\mathbf{3 b}$. Only three peaks are available due to broadening and overlap with peaks from 3a. NMR ${ }^{1} \mathrm{H}: \delta 9.40(\mathrm{~s}, 1 \mathrm{H}), 8.65(\mathrm{~s}, 1 \mathrm{H}), 5.14(\mathrm{~s}, 3 \mathrm{H}) \mathrm{ppm} .{ }^{13} \mathrm{C}$ : too insoluble. IR $\left(\mathrm{CHCl}_{3}\right): \mathbf{3 a}, 985.46 \mathrm{~cm}^{-1} ; \mathbf{3 b}, 999 \mathrm{~cm}^{-1}$. UV-Vis $\left(\mathrm{CHCl}_{3}\right), \lambda_{\text {max }} / \mathrm{nm}(\log \varepsilon / \mathrm{L}$ $\mathrm{mol}^{-1} \mathrm{~cm}^{-1}$ ): 699 (2.6), 432 (3.78) and 267.5 (4.43). Elemental Analysis: $\mathrm{C}_{19} \mathrm{H}_{15} \mathrm{~N}_{2} \mathrm{OReS}_{2}$, Found (Calcd.): C 42.16 (42.44), H 2.54 (2.81), N 5.13 (5.21), S 11.37 (11.93).

4 was prepared by adding MTO ( $50 \mathrm{mg}, 0.2 \mathrm{mmol}$ ) into 20 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ containing 2diphenylphosphinobenzoic acid ( $184 \mathrm{mg}, 0.6 \mathrm{mmol}$ ), which served both as the reducing agent and the new ligand. The color of the solution changed to violet. After 12 h stirring the mixture was layered with hexanes and put into the freezer. A dark powder was isolated by filtration 24 h later and rinsed with hexanes. It consisted of two geometric isomers, $\mathbf{4 a} \mathbf{a n d} \mathbf{4 b}$, in a total yield of $65 \%$. The two could not be separated, but their NMR spectra in $\mathrm{CDCl}_{3}$ were resolved and assigned as explained later. $4 \mathbf{a}^{\mathrm{I}} \mathrm{H}$ NMR: $\delta 6.5-8.5(\mathrm{~m}, 14 \mathrm{H}), 3.39(\mathrm{t}, 3 \mathrm{H})$; ${ }^{31}$ P NMR: $-0.34\left(\mathrm{~d}, \mathrm{~J}_{\mathrm{PP}}=9 \mathrm{~Hz}\right),-3.07\left(\mathrm{~d}, \mathrm{~J}_{\mathrm{PP}}=9 \mathrm{~Hz}\right) ; 4 \mathrm{~b}: 6.5-8.5(\mathrm{~m}, 14 \mathrm{H}), 4.12(\mathrm{t}, 3 \mathrm{H}) ;{ }^{31} \mathrm{P}$ NMR: $6.64\left(\mathrm{~d}, \mathrm{~J}_{\mathrm{PP}}=262 \mathrm{~Hz}\right),-5.28\left(\mathrm{~d}, \mathrm{~J}_{\mathrm{PP}}=262 \mathrm{~Hz}\right)$.

X-ray studies. Crystals for 1,2 and 3a were selected under ambient conditions. Each crystal was mounted and centered in the X-ray beam by use of a video camera. The crystal evaluation and data collection were performed on a Bruker CCD-1000 diffractometer with Mo $\mathrm{K}_{\mathrm{\alpha}}(\lambda=0.71073 \AA)$ radiation and a detector-to-crystal distance of 4.98 cm . The initial cell constants were obtained from three series of $\omega$ scans at different starting angles. Each series consisted of 30 frames collected at intervals of $0.3^{\circ}$ in a $10^{\circ}$ range about $\omega$ with the exposure time of 10 s per frame. The reflections were successfully indexed by an automated indexing routine built into the SMART program. The final cell constants were calculated
from a set of strong reflections from the actual data collection. The data were collected using the full sphere routine for high redundancy. The data were corrected for Lorentz and polarization effects. The absorption correction was based on fitting a function to the empirical transmission surface as sampled by multiple equivalent measurements ${ }^{36}$ using SADABS software. ${ }^{37}$
The position of the heavy atom was found by the Patterson method. The remaining atoms were located in an alternating series of least-squares cycles and difference Fourier maps. All non-hydrogen atoms were refined in full-matrix an isotropic approximation. All hydrogen atoms were placed at calculated idealized positions and were allowed to ride on the neighboring atoms with relative isotropic displacement coefficients. The ORTEP diagrams were drawn at $50 \%$ probability level.

Kinetics. Reactions of pyridine N -oxides and dimethyl sulfide were monitored by following the decrease in absorbance from 275 to 310 nm according to which pyridine N oxide was being studied. Owing to the large values of their molar absorptivities, a cell with a path length of 0.05 cm in a cylindrical cell holder thermostated at $25.0 \pm 0.2^{\circ} \mathrm{C}$ was used. Dimethyl sulfide was added in at least ten-fold excess, allowing the absorbance-time data to be fitted to pseudo-first-order kinetics, according to eq 2 .

$$
\begin{equation*}
A \mathrm{Ab}_{\mathrm{t}}=\mathrm{Abs} s_{\infty}+\left(\mathrm{Abs}_{0}-\mathrm{Abs} \infty_{\infty}\right) \times \exp \left(-k_{\mathrm{obs}} t\right) \tag{4}
\end{equation*}
$$

Competition kinetics. A different aspect of the reaction scheme was studied by this method. A pair of methyl aryl sulfides with different para substituents at concentrations ten times higher than that of 4-picoline N -oxide. The concentrations of the two starting sulfides and of the sulfoxides formed were determined by NMR spectroscopy 15 min after the beginning of the reaction. The rate constant ratio for $\mathrm{MeSC}_{6} \mathrm{H}_{4} \mathrm{Y}$ as compared to MeSPh is given simply as the product of two concentration ratios at a given time because the sulfide concentrations are nearly invariant during the initial reaction period.

$$
\begin{align*}
& \frac{\mathrm{ky}_{\mathrm{Y}}}{\mathrm{k}_{\mathrm{H}}}=\frac{\mathrm{d}\left[\mathrm{MeS}(\mathrm{O}) \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Y}\right] / \mathrm{dt}}{\mathrm{~d}[\mathrm{MeS}(\mathrm{O}) \mathrm{Ph}] / \mathrm{dt}}=  \tag{5}\\
& \frac{\left[\mathrm{MeS}(\mathrm{O}) \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Y}\right]_{t}}{[\mathrm{MeS}(\mathrm{O}) \mathrm{Ph}]_{t}} \times \frac{\left[\mathrm{MeSPh}_{0}\right.}{\left[\mathrm{MeSC}_{6} \mathrm{H}_{4} \mathrm{Y}\right]_{0}}
\end{align*}
$$

Oxygen-18 labeling. Equilibration between MTO and 30 times the molar ratio of $\mathrm{H}_{2}{ }^{18} \mathrm{O}$ ( $90 \%$ enrichment) was allowed to proceed for 20 min in anhydrous methylene chloride,
which was sufficient for oxygen exchange between MTO and water. ${ }^{38}$ The resulting solution was vacuum dried. The same procedure was repeated three times, yielding a sample of $\mathrm{MeRe}{ }^{18} \mathrm{O}_{3}$, enriched to ca. $50 \%{ }^{18} \mathrm{O}$ content. It used to prepare 1 by the $\mathrm{PPh}_{3}$ method. The ${ }^{18} \mathrm{O}$ content of 1 was ca. $50 \%$ by IR spectroscopy. A reaction was carried out in anhydrous methylene chloride with 4-picoline N -oxide ( 10 mM ), dimethyl sulfide ( 20 mM ) and 1 ( 10 mM ) to guarantee the formation of enough sulfoxides. The isotopic content of the resulting solution was determined by GC-MS.

${ }^{\text {a }}$ Italicized entries: trans-[Oxo-Re-donor atom] angles

## Results

Structures. Table 1 shows the crystallographic parameters for 1, 2 and 3a, and Figure 1 displays their molecular structures drawn by the program CrystalMaker. ${ }^{39}$ In all three compounds the rhenium $(\mathrm{V})$ atom occupies the center of a distorted octahedron defined by its axial ligands, the terminal oxo group and one donor atom of one bidentate ligand. The three remaining donor atoms and the methyl group occupy the equatorial plane. Table 2 lists the
important bond distances and angles. In all of these compounds the $\mathrm{Re} \equiv \mathrm{O}$ distances are virtually identical at 167 pm , as are the $\mathrm{Re}-\mathrm{C}$ distances at 211 pm . The values of $v(\mathrm{Re}-\mathrm{O})$ from the IR studies fall in the range $985-1003 \mathrm{~cm}^{-1}$ for $1-4$, relatively insensitive to the ligand environment. In every case, the donor atom trans to the terminal oxo group lies at a longer distance than its counterpart in the equatorial plane; this comes as no surprise, reflecting extensive $\pi$ back-bonding from oxo to rhenium(V). In keeping with that, the $\operatorname{trans}\left(\mathrm{O} \equiv \mathrm{Re}\right.$-donor atom) angles lie in the range $162.9-165.5^{\circ}$, notably less than $180^{\circ}$.

All of 1-4 should exist as four geometrical isomers. No evidence for structures of 1 or $\mathbf{2}$, other than the ones characterized, was obtained. Even the solution NMR in deuterated chloroform from the original preparation prior to product isolation showed the single isomer. Two isomers in ca. 3:1 ratio were found for $\mathbf{3}$ in solution, but only the major one, 3a, was isolated. The minor isomer, $\mathbf{3 b}$, is characterized by $\delta(\mathrm{Me}-\mathrm{Re})$ 5.14. The hydrogen signals from the MQ ligand are somewhat broadened, which is not the case for 3a or free MQH. This suggests an internal process, and brings to mind the exchange between $P y$ and fivecoordinate $\mathrm{MeReO}(\mathrm{edt}) \mathrm{Py}$ ( $\mathrm{edtH}_{2}=1,2$-ethane dithiol). For it, the transition state is sixcoordinate and features a turnstile rotation that interchanges the Me group and the two Py ligands. ${ }^{35,40}$ Such an exchange, if it occurs within $\mathbf{3 b}$, could well give rise to signal broadening.

Compound 4 exists as ca. equimolar amounts of two isomers, the structures of which are presented in Chart 1. The basis for these assignments is the widely different coupling constants in the ${ }^{31} \mathrm{P}$ NMR spectra. $\mathrm{J}_{\mathrm{P}-\mathrm{P}}=9 \mathrm{~Hz}$ in $\mathbf{4 a}$ and 262 Hz in $\mathbf{4 b}$. According to the literature ${ }^{41-43}$ the very high coupling constant suggests a structure for $\mathbf{4 b}$ in which the two phosphorus donor atoms lie trans to one another.

The donor atoms are N and O for PA and HQ ; we surmise the heterocyclic nitrogen is the more weakly bound when both are equatorial; consequently 1 and 2 adopt structures with an axial O-donor atom. Whatever atom is trans to the oxo group is the most weakly bound of all, irrespective of the inherent Lewis basicity. The same rule applies to ligand MQ, which gives rise to the minor isomer $\mathbf{3 b}$, because a thiolate sulfur is a better Lewis base than a ring nitrogen. In that sense, 3 a is similar insofar as the MQ ligand that spans an axial and an equatorial position. The two isomers differ only in regards to the orientation of the in-plane
ligand, which may be a factor of less consequence. Again, the two isomers of 4 differ in the same way as do the two isomers of 3 . Both isomers of 4 have an O-donor atom trans to the oxo group; that donor is a weaker Lewis base than a phosphine towards $\operatorname{Re}(\mathrm{V})$. The comparable abundances of $\mathbf{4 a}$ and $\mathbf{4 b}$ may reflect the steric influence of the bulky phosphine ligand.

Oxygen atom transfer: Sulfoxide to sulfide. The following nearly isoenergetic reaction, ${ }^{19}$ occurred when any of the compounds 1-4 was used in catalytic quantity with a 10 -fold excess of dimethyl sulfide:

$$
\begin{equation*}
\mathrm{Ph}_{2} \mathrm{SO}+\mathrm{Me}_{2} \mathrm{~S} \rightarrow \mathrm{Ph}_{2} \mathrm{~S}+\mathrm{Me}_{2} \mathrm{SO} \tag{6}
\end{equation*}
$$

Unlike some oxorhenium(V) compounds that catalyze this reaction efficiently, such as $\left[(\mathrm{hoz})_{2} \operatorname{Re}(\mathrm{O})\left(\mathrm{OH}_{2}\right)\right][\mathrm{OTf}]^{19}$ and $\mathrm{MeReO}($ dithiolatte $) \mathrm{PPh}_{3},{ }^{32,33}$ none of these compounds led to a rapid reaction for reasons that will be presented later. We therefore turned our attention to a catalytic system where efficient reactions could be observed.
Oxygen atom transfer: pyridine $\mathbf{N}$-oxides to thioethers. Kinetic studies of these reactions in anhydrous methylene chloride were carried out:

$$
\begin{equation*}
\mathrm{XC}_{5} \mathrm{H}_{4} \mathrm{NO}+\mathrm{RSR}^{\prime} \rightarrow \mathrm{XC}_{5} \mathrm{H}_{4} \mathrm{~N}+\mathrm{RS}(\mathrm{O}) \mathrm{R}^{\prime} \tag{7}
\end{equation*}
$$

Studies were limited to catalyst 1 because 2 and $\mathbf{3}$ react more slowly and $\mathbf{4}$ is not available as a single compound. A sample repetitive scan spectrum ( $\mathrm{X}=4-\mathrm{Me} ; \mathrm{Me}_{2} \mathrm{~S}$ ) is presented in Figure 2.

Figure 2. Repetitive scans of 10 mM 4 -picoline N -oxide, 100 mM dimethyl sulfide and 2 mM 1 in anhydrous methylene chloride at $25^{\circ} \mathrm{C}$. The inset shows the plot of $\mathrm{k}_{\text {cat }}$ against the concentration of the catalyst.

The absorbance-time decrease, which shows the greatest amplitude at 279 nm , follows firstorder kinetics. The values of $\mathrm{k}_{\text {obs }}$ so obtained are linear functions of the total catalyst concentration, designated as $[1]_{T}$, to reflect the fact that at various points during the cycle 1 exists in different forms present at low concentrations.

$$
\begin{equation*}
-\frac{d\left[\mathrm{XC}_{5} \mathrm{H}_{4} \mathrm{NO}\right]}{\mathrm{dt}}=k_{\text {cat }}\left[\mathrm{XC}_{5} \mathrm{H}_{4} \mathrm{NO}\right]\left[\mathrm{I}_{\mathrm{T}}\right. \tag{8}
\end{equation*}
$$

The kinetic determinations employed a $\geq 0$-fold excess of sulfide over pyridine N -oxide. Varying the sulfide concentration gave the same rate constant, $\mathrm{k}_{\text {cat }}=1.23 \pm 0.01(10 \mathrm{mM}$ $\mathrm{Me}_{2} \mathrm{~S}$ ) and $1.20 \pm 0.05 \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}\left(100 \mathrm{mM} \mathrm{Me}_{2} \mathrm{~S}\right)$. Different thioethers also gave the same value of $\mathrm{k}_{\mathrm{ca}} / \mathrm{L} \mathrm{mol}{ }^{-1} \mathrm{~s}^{-1}: 1.20 \pm 0.05\left(\mathrm{Me}_{2} \mathrm{~S}\right), 1.22 \pm 0.01$ (pentamethylene sulfide) and $1.28 \pm$ 0.07 (tert-butyl methyl sulfide. For a range of pyridine N -oxides, the identity of X exerts a strong influence on the value of $\mathrm{k}_{\text {cat }}$, as can be seen from Table 3 .

${ }^{\text {a }}$ In anhydrous dichloromethane at $25{ }^{\circ} \mathrm{C} ;{ }^{b}$ Conditions: $10 \mathrm{mM} \mathrm{XC} \mathrm{C}_{5} \mathrm{H}_{4} \mathrm{NO}, 100 \mathrm{mM} \mathrm{Me} \mathrm{Me}_{2} \mathrm{~S}$, $2-8 \mathrm{mM} \mathrm{1;}{ }^{c}$ At $25^{\circ} \mathrm{C}$ in $\mathrm{D}_{1}$-chloroform with $10 \mathrm{mM} 4-\mathrm{MeC}_{5} \mathrm{H}_{4} \mathrm{NO}, 2 \mathrm{mM} 1$, and 50 mM each of MeSPh and $\mathrm{MeSC}_{6} \mathrm{H}_{4} \mathrm{Y}$.

Competition experiments. The foregoing reveals that the sulfide enters the catalytic cycle at a stage later than the step(s) that determine the rate and the value of $\mathrm{k}_{\mathrm{cat}}$. That is, RSR' reacts with an active rhenium intermediate in a fast subsequent step. To evaluate the effects of thioethers it was therefore useful to take the thioethers in pairs, for which purpose
$\mathrm{MeSC}_{6} \mathrm{H}_{4} \mathrm{Y}$ and MeSPh were employed. The design of the experiment is presented in this diagram:

The NMR data were analyzed to determine the ratio ${ }^{\mathbf{S}}{ }^{\mathrm{Y}} / \mathrm{K}^{\mathbf{S}} \mathrm{H}$ for the different aryl groups on sulfide according to eq 5. Table 3B presents the results of such determinations. For reasons to be presented later, it was deemed essential to determine the same ratio for two other pyridine N -oxides. These data are also given in Table 3.

Oxygen-18 labeling. Stoichiometric amounts of 1 and 4-picoline N -oxide and twice as much $\mathrm{Me}_{2} \mathrm{~S}$ were employed in the case where $\mathrm{MeRe}^{18} \mathrm{O}(\mathrm{PA})_{2}$ was employed in anhydrous dichloromethane. The solution was analyzed by GC-MS after two h reaction time. Although ample $\mathrm{Me}_{2} \mathrm{~S}^{16} \mathrm{O}$ was detected, $\mathrm{Me}_{2} \mathrm{~S}^{18} \mathrm{O}$ proved absent.

## Discussion

Thermochemical and electronic considerations. Sulfoxide-to-sulfide transfer of an oxygen atom is nearly isoenergetic; $\Delta \mathrm{G}^{\circ}=-2.9 \mathrm{~kJ}$ for reaction 6 between diphenyl sulfoxide and dimethyl sulfide in methylene chloride. ${ }^{19}$ The use of pyridine N -oxides provides a system with a considerably greater driving force. From thermochemical data for $\mathrm{C}_{5} \mathrm{H}_{4} \mathrm{NO}$ and $\mathrm{Me}_{2} \mathrm{~S},{ }^{44-47}$ we estimate $\Delta \mathrm{G}^{\circ} \cong \Delta \mathrm{H}^{\circ}=-63 \mathrm{~kJ} \mathrm{~mol}^{-1}$.

The value of $\mathrm{k}_{\text {cat }}$ depends strongly on the electronic properties of the substituent on the pyridine N -oxide ring. For the five entries in 3 with substituents in the 4 - and 3-positions, an analysis according to Hammett's method gives $\rho_{\text {cat }}=-5.2$ in Figure 3. This is an exceptionally negative value, most reasonably interpreted in terms of two composite effects that enter in the same direction. More will be said about this in what follows.

Figure 3. LFER correlations. (1) of $\mathrm{k}_{\text {cat }}$ values for reactions between $\mathrm{XC}_{5} \mathrm{H}_{4} \mathrm{NO}$ and 100 mM $\mathrm{Me}_{2} \mathrm{~S}$ in presence of $2 \sim 8 \mathrm{mM} 1$ in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at $25^{\circ} \mathrm{C}$; (2) of relative rate constants $\mathrm{k}_{\mathrm{Y}} / \mathrm{k}_{\mathrm{H}}$ determined by competition kinetics for reactions of $\mathrm{MeSC}_{6} \mathrm{H}_{4} \mathrm{Y}$ reactions between 10 mM 4-picoline N -oxide and 50 mM each of $\mathrm{MeSC}_{5} \mathrm{H}_{4} \mathrm{Y}$ and $50 \mathrm{mM}_{6} \mathrm{H}_{5} \mathrm{SCH}_{3}$ in the presence of $2 \mathrm{mM} 1 \mathrm{in} \mathrm{CDCl}_{3}$ at $25^{\circ} \mathrm{C}$.

A similar analysis was carried out on the rate constant ratio $k^{\mathrm{S}} / \mathrm{k}^{\mathrm{S}}{ }_{\mathrm{H}}$. The fact that this quantity is a ratio and not an absolute rate constant does not compromise the answer in the least. From the data in Table 3, we find $\rho_{\mathrm{S}}=-1.9$, as shown in Figure 3.

Substrate binding. It seems self-evident that activation of a pyridine $N$-oxide requires its coordination to rhenium $(\mathrm{V})$ for the catalyst to exert its effect. In systems studied earlier, this has not appeared to pose a significant part of the overall barrier, because five-coordinate catalysts such as MeReO (dithiolate) $\mathrm{PPh}_{3}$ permit its ready entry. For 1 , however, one must propose either that PyO attacks 1 as it is, giving rise to a seven-coordinate intermediate, or that ring-opening of one arm of one PA ligand precedes entry of PyO. We surmise the N donor atom is preferentially released to avoid the presumably unfavorable $[\mathrm{Re}]^{+} \mathrm{O}^{-}$in dichloromethane.

We have argued strongly against any dissociative process for complexes such as MeReO(dithiolate)L. ${ }^{35,40}$ Thus it seems we must also consider direct ligand displacement as the route to 5 . We discount this mechanism, however; because the parent is not a fivecoordinate complex from which ligand dissociation becomes unlikely, but a six-coordinate one in which the weakness of a rhenium-ligand trans to the oxo group has been well established.

By whichever pathway the $\mathbf{1}=5$ reaction occurs, the net process is an equilibrium that can be represented by an equilibrium constant $\mathrm{K}_{15}$, the value of which varies with the X-group of $\mathrm{XC}_{5} \mathrm{H}_{4} \mathrm{NO}$ according to its Lewis basicity. Because this step remains at equilibrium, its mechanism, while of intrinsic interest in its own right, remains immaterial in the kinetic analysis. Stronger Lewis bases are more strongly coordinated in 5 , which provides one factor contributing to the negative reaction constant $\rho_{\mathrm{cat}}$ found for $\mathrm{k}_{\mathrm{cat}}$. That contribution is designated $\rho_{\mathrm{t}}$, and it is one component of $\rho_{\text {cal }}$.

The rate-controlling step (RCS). The rate law indicates that the thioether is not involved in the mechanism until after the RCS, because the rate remains independent of variations in the concentration and identity of RSR'. We therefore conclude that intermediate 5 undergoes unimolecular cleavage of the $\mathrm{N}-\mathrm{O}$ bond of coordinated pyridine N -oxide:

The experimental rate constant $\mathrm{k}_{\mathrm{cat}}$ is therefore a composite: $\mathrm{k}_{\mathrm{cat}}=\mathrm{K}_{15} \times \mathrm{k}_{\mathrm{RCS}}$. The large negative reaction constant $\rho_{\text {cat }}=-5.2$ allows us to argue that the substituent effects on each component must have the same sign, lest cancellation of the effects take place. Because $\mathrm{K}_{15}$ represents a Lewis acid-base equilibrium, $\rho_{15}$ will therefore be negative, as argued previously. The negative reaction constant $\rho_{\mathrm{RCS}}$ indicates that electron flow from the oxygen of the coordinate pyridine N -oxide provides the principal barrier at the transition state:

The thioether step and its oxo-group selectivity. A direct reaction occurs between intermediate 6 and RSR'. Because it occurs rapidly compared to the RCS, kinetic competition
experiments were employed. The rate constants relative to MeSPh are given in Table 3B. The reaction constant is $\rho_{\mathrm{S}}=-1.9$, which indicates nucleophilic attack of the thioether on one oxygen of dioxorhenium(VII) intermediate 6 . This forms the next intermediate, 7 , that might best be viewed as being or becoming a sulfoxide complex of rhenium(V).

What is astonishing, however, is the high selectivity the thioether exhibits as to which of the two oxo groups of 6 it attacks. Data obtained with the catalyst 1 as $\operatorname{MeRe}\left({ }^{18} \mathrm{O}\right)(\mathrm{PA})_{2}$ (oxygen-18 content, $50 \%$ ) gave, in combination with an equimolar quantity of 4 $\mathrm{MeC}_{5} \mathrm{H}_{4} \mathrm{~N}^{16} \mathrm{O}$ and dimethyl sulfide, only $\mathrm{Me}_{2} \mathrm{~S}^{16} \mathrm{O}$. Had the thioether reacted non-selectively, the enrichment level of the sulfoxide would have corresponded to $25 \% \mathrm{Me}_{2} \mathrm{~S}^{18} \mathrm{O}$.

Examination of the plausible structure of 6 is helpful in this regard. As shown in Scheme 1 , intermediate 7a appears to be a dead-end because displacement of sulfoxide by the dangling pyridine arm of PA is impossible. On the other hand, unimolecular displacement within $\mathbf{7 b}$ restores 1 directly and forms $\mathrm{Me}_{2} \mathrm{~S}^{16} \mathrm{O}$ exclusively.

Scheme 1: Oxo-group selectivity at the thioether step

Conclusion. Four new rhenium(V) complexes with monoanionic bidentate ligands, PA, HQ, MQ, and DPPB, were synthesized and characterized. All of them catalyze oxygen atom transfer from milder oxidants, pyridine N -oxides or sulfoxides, to thioethers. Based on
kinetic and mechanistic studies, a multi-step mechanism has been proposed with involvement of several unobserved but plausible intermediates to account for the reaction at each stage.

# CHAPTER III. LIGAND DISPLACEMENT AND OXIDATION REACTIONS OF METHYLOXORHENIUM(V) COMPLEXES <br> A manuscript submitted to Inorganic Chemistry <br> Xiaopeng Shan, Arkady Ellern, Ilia A. Guzei, James H. Espenson 

#### Abstract

Compounds containing the anion $\mathrm{MeReO}(\mathrm{edt})(\mathrm{SPh})^{-}$(3) were prepared with the countercations 2-picolinium ( $\mathbf{P i c H}^{+} \mathbf{3}^{-}$) and 2,6-lutidinium ( $\mathbf{L u t H}^{+} \mathbf{3}^{-}$), where edt is 1,2ethanedithiolate, were synthesized. $\mathrm{PicH}^{+} \mathbf{3}^{-}$and $\mathrm{MeReO}(\mathrm{edt})(\mathrm{tmtu})$ (4) were crystallographically characterized (tmtu is $1,1,3,3$-tetramethylthiourea). The rhenium atom in these compounds exists in a five-coordinate distorted square pyramid. In the solid state, PicH ${ }^{+} 3^{-}$contains an anion with a hydrogen bonded ( $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ ) interaction to the cation. Displacement of PhSH by $\mathrm{PPh}_{3}$ followed second-order kinetics, whereas with pyridines the reaction was second-order with respect to [ Py ] and first-order in $\left[\mathrm{PicH}^{+} 3^{-}\right]$in chloroform. To account for this unusual kinetics, the structure formula of $\mathbf{P i c H}^{+} \mathbf{3}^{-}$in chloroform was proposed to be the molecular species $\mathrm{MeReO}(\operatorname{edtH}) S P h$, which can react with a Brönsted base to accelerate ligand displacement. When $\mathrm{PicH}^{+} 3^{-}$reacts with pyridine N -oxides, a threestage reaction was observed, consistent with ligand replacement of $\mathrm{SPh}^{-}$by $\mathrm{PyO}, \mathrm{N}-\mathrm{O}$ bond cleavage of the PyO assisted by another PyO , and eventual decomposition of $\mathrm{MeReO}_{2}$ (edt)PyO to $\mathrm{MeReO}_{3}$. Each of first two steps showed a large substituent effects, $\rho=$ -5.3 and $\rho=-4.3$.

## Introduction

Our exploration of oxorhenium(V) catalysts ${ }^{1-7}$ for oxygen atom transfer (OAT) reactions has been extended. The stoichiometric reactions and certain mechanistic aspects are analogous to those catalyzed by molybdenum oxotranferases. ${ }^{8-10}$ Three new methyl(oxo)rhenium(V) complexes have been prepared and characterized; two contain the anion $\mathrm{MeReO}(\mathrm{edt})(\mathrm{SPh})^{-}$(3) with the cations 2 -picolinium ( $\mathbf{P i c H}^{+} \mathbf{3}^{-}$) and 2,6-lutidinium ( $\mathrm{LutH}^{+} 3^{-}$), and the third is a neutral rhenium compound, $\mathrm{MeReO}(\mathrm{edt})(\mathrm{tmtu})$ (4), where edt
stands for 1,2-ethanedithiolate and tmtu for 1,1,3,3-tetramethylthiourea. Their structural formulas are shown in Chart 1.

Chart 1. Structural formulas of 1-4

3

2

4

Our goal has been to characterize the steps of OAT from pyridine N -oxides to triphenylphosphine, eq 1 , including a study of the intermediates MeReO (edt)PyO from ligand displacement and $\mathrm{MeReO}_{2}(e d t) \mathrm{PyO}$ from oxidation, especially the striking feature that nucleophiles assist oxidation by incorporation of a second molecule of pyridine N -oxide in the transition state. To extend understanding of ligand displacement, the non-oxidizing ligands pyridines and $\mathrm{PPh}_{3}$ were employed as well. An unanticipated assistance of ligand displacement of $\mathbf{3}$ by Bronsted bases was discovered and studied.

$$
\begin{equation*}
\mathrm{PyO}+\mathrm{PPh}_{3} \rightarrow \mathrm{Py}+\mathrm{Ph}_{3} \mathrm{PO} \tag{1}
\end{equation*}
$$

## Experimental Section

Reagents and instrumentation. $\{\mathrm{MeReO}(\mathrm{edt})\}_{2}$ (2) was synthesized from 1,2ethanedithiol and $\{\operatorname{MeReO}(\text { benzenethiolate })\}_{2}(1),{ }^{11}$ the later prepared according to the literature. ${ }^{12}$ Other chemical reagents were purchased from Aldrich and used as received. Acetonitrile- $d_{3}$, benzene- $d_{6}$ and chloroform- $d_{1}$ were employed as solvents for NMR
spectroscopy. Chloroform from Fisher Scientific was used as solvent for UV/Visible and IR spectrophotometry and for kinetics.

UV/Visible spectra and kinetic data were obtained with Shimadzu Model 3101 and OLIS RSM stopped-flow spectrophotometers. A circulating water thermostatic system controlled the temperature variation to within $\pm 0.2^{\circ} \mathrm{C}$ was used for the stopped-flow instrument and an electronic thermostatic holder that maintained the temperature of the cell to $\pm 0.2^{\circ} \mathrm{C}$ was used for the UV/visible spectrophotometer. $\mathbb{R}$ spectra were collected with a Nicolet-500 spectrometer. A Bruker DRX- 400 MHz spectrophotometer was used to record ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra. The chemical shift for ${ }^{1} \mathrm{H}$ was calculated relative to the residual proton of the solvent, $\delta 1.94$ for acetonenitrile- $d_{3}, 7.16$ for benzene- $d_{6}$, and 7.27 for chloroform- $d_{1}$. Elemental analyses were performed by Desert Analytics Laboratory.

Kinetics. Reactions of 2, $\mathrm{PiCH}^{+} \mathbf{3}^{-}, \mathrm{LutH}^{+} \mathbf{3}^{-}, 4$ with $\mathrm{PPh}_{3}$ and pyridines were followed by the increase in absorbance from 380 to 420 nm from the products MeReO (edt) $\mathrm{PPh}_{3}$ and $\mathrm{MeReO}(\mathrm{edt}) \mathrm{Py}$. The concentrations of the ligands were in at least 10 -fold excess over rhenium. Thus the absorbance-time data could be fitted to pseudo-first-order kinetics,

$$
\begin{equation*}
A b s_{t}=A b s_{\infty}+\left(A b s_{0}-A b s_{\infty}\right) \times \mathrm{e}^{-\mathrm{k} \psi \cdot \mathrm{t}} \tag{2}
\end{equation*}
$$

Reactions of 2,3 and 4 with pyridine N -oxides were monitored by the change in absorbance from 400 to 500 nm according to the identities of pyridine N -oxides and rhenium compounds. In most case, the concentrations of pyridine N -oxides were at least 100 times larger than those of rhenium compounds. Multiple-phase absorbance changes were observed; reactions with 2 and 3 displayed a three-stage absorbance change: a fast rise and fall followed by a slow decrease. Kinetic traces of the first and second phases can be fitted to consecutive pseudo-first-order kinetics,

$$
\begin{equation*}
A b s_{t}=A b s_{\infty}+\alpha \times e^{-k_{\alpha} \cdot t}+\beta \times e^{-k_{\beta} \cdot t} \tag{3}
\end{equation*}
$$

The third phase was too sluggish to be studied. In contrast, reaction with compound 4 was a simplified version of reactions with 2 and 3 ; only two-stage absorbance change was observed: a fast rise and slow decrease, the former can be fitted to eq 5 and the latter, which spans almost same period of time as the third stage of reactions of 2 and 3 , is not suitable for kinetic study.

Preparation of Salts of $\mathbf{M e R e O}$ (edt)(SPh) ${ }^{-}$(3). 1,2-Ethanedithiol ( $18.8 \mathrm{mg}, 16.8 \mu \mathrm{~L}, 0.2$ $\mathrm{mmol})$ was added to a mixture of $1(87 \mathrm{mg}, 0.1 \mathrm{mmol})$ and 2 -picoline for $\mathrm{PicH}^{+} 3^{-}$or 2,6 lutidine for $\mathrm{LutH}^{+} 3^{-}(0.2 \mathrm{mmol})$ in 20 mL of toluene. The resulting solution was stirred for 2 $h$ as a dark red solid deposited. The product was collected by filtration, rinsed by hexanes, and dried under vacuum.
$\mathrm{PiCH}^{+} \mathbf{3}^{-}$was obtained in $97 \%$ yield. A crystal suitable for x -ray diffraction analysis was obtained by recrystallization from methylene chloride-hexanes. NMR (acetonitrile- $d_{3}$ ) ${ }^{1} \mathrm{H}: \delta$ $8.48(\mathrm{~d}, 1 \mathrm{H}), 8.41(\mathrm{~m}, 1 \mathrm{H}), 7.81(\mathrm{~m}, 2 \mathrm{H}), 7.57(\mathrm{~m}, 2 \mathrm{H}), 7.23(\mathrm{t}, 2 \mathrm{H}), 7.10(\mathrm{t}, 1 \mathrm{H}), 2.88(\mathrm{~m}$, $1 \mathrm{H}), 2.73(\mathrm{~s}, 3 \mathrm{H}), 2.67(\mathrm{~m}, 2 \mathrm{H}), 2.49(\mathrm{~m}, 1 \mathrm{H}), 2.18(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}: 150.0,147.0,133.9,128.3$, $127.5,124.8,124.7,43.6,43.4,19.3,7.2$. $\mathbb{R}\left(\mathrm{CHCl}_{3}\right): 1003 \mathrm{~cm}^{-1}$. UV-Vis $\left(\mathrm{CHCl}_{3}\right), \lambda_{\text {max }} / \mathrm{nm}$ ( $\log \varepsilon$ ): $337(\mathrm{sh}), 397(3.48)$. Elemental analysis: $\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{NOReS}_{3}$, Found (Calcd.) C: 35.30 (35.14), H: 4.05 (3.93), N: 2.71 (2.73), S: 19.08 (18.76).
$\mathbf{L u t H}^{+} \mathbf{3}^{-}$was obtained in $90 \%$ yield. NMR (acetonitrile- $d_{3}$ ) ${ }^{1} \mathrm{H}: \delta 8.26(\mathrm{t}, 1 \mathrm{H}), 7.57(\mathrm{~m}$, $4 \mathrm{H}), 7.23(\mathrm{~m}, 2 \mathrm{H}), 7.11(\mathrm{~m}, 1 \mathrm{H}), 2.88(\mathrm{~m}, 1 \mathrm{H}), 2.69(\mathrm{~m}, 2 \mathrm{H}), 2.67(\mathrm{~s}, 6 \mathrm{H}), 2.17(\mathrm{~s}, 3 \mathrm{H}),{ }^{13} \mathrm{C}$ : $146.5,133.9,127.4,125.0,124.7,43.6,43.4,18.8,6.5$ UV-Vis $\left(\mathrm{CHCl}_{3}\right), \lambda_{\max } / \mathrm{nm}(\log \varepsilon):$ 337(sh), 369(3.48).

Preparation of MeReO (edt)(tmtu) (4). Tetramethylthiourea ( $24.6 \mathrm{mg}, 0.2 \mathrm{mmol}$ ) was mixed with $2(61.9 \mathrm{mg}, 0.1 \mathrm{mmol})$ in 20 mL of toluene. After stirring the mixture for 4 h , color of the solution changed from brown to violet and 20 mL of hexanes was layered on the top. After one day, black crystals appeared; they were filtered and rinsed by hexanes. The yield was $76 \%$. Crystal suitable for x-ray diffraction analysis were obtained. NMR (benzene$\left.d_{6}\right)^{\mathrm{h}} \mathrm{H}: \delta 3.58(\mathrm{~m}, 1 \mathrm{H}), 3.25(\mathrm{~s}, 3 \mathrm{H}), 3.13(\mathrm{~m}, 1 \mathrm{H}), 3.04(\mathrm{~m}, 1 \mathrm{H}), 2.69(\mathrm{~m}, 1 \mathrm{H}), 2.38(\mathrm{sb}$, $12 \mathrm{H}) ;{ }^{13} \mathrm{C}: 46.2,43.2,6.8 . \operatorname{IR}\left(\mathrm{CHCl}_{3}\right): 976 \mathrm{~cm}^{-1} . \mathrm{UV}-\mathrm{Vis}\left(\mathrm{CHCl}_{3}\right), \lambda_{\max } / \mathrm{nm}\left(\log \varepsilon / \mathrm{L} \mathrm{mol}{ }^{-1}\right.$ $\mathrm{cm}^{-1}$ ): $300(\mathrm{sh})$. Elemental analysis: $\mathrm{C}_{7} \mathrm{H}_{19} \mathrm{~N}_{2} \mathrm{OReS}_{3}$, Found (Calcd.) C: 21.71 (21.76), H: 4.12 (4.34), $\mathrm{N}: 6.34$ (6.34), S: 21.80 (21.78).

X-ray Crystallography. Crystals of $\mathrm{PicH}^{+} 3^{-}$and 4, selected under ambient conditions, were mounted and centered in the X-ray beam by using a video camera. The crystal evaluation and data collection were performed on a Bruker CCD-1000 diffractometer with Mo $\mathrm{K}_{\alpha}(\lambda=0.71073 \AA)$ radiation and the detector to crystal distance of 4.90 cm . The cell constants were calculated from a set of certain amount of strong reflections from the actual
data collection. The data were collected by using the full sphere routine. This data set was corrected for Lorentz and polarization effects. The absorption correction was based on fitting a function to the empirical transmission surface as sampled by multiple equivalent measurements ${ }^{13}$ using SADABS software. ${ }^{14}$

The position of the Re atom was found by the Patterson method. The remaining atoms were located in an alternating series of least-squares cycles and difference Fourier maps. All non-hydrogen atoms were refined in full-matrix anisotropic approximation. All hydrogen atoms were placed in the structure factor calculation at idealized positions and were allowed to ride on the neighboring atoms with relative isotropic displacement coefficients.

## Results

Structures. Table 1 shows the crystallographic parameters for $\mathrm{PicH}^{+} 3^{-}$and 4 and Figure 1 depicts their molecular structures. In both compounds, the rhenium(V) atom lies in the center of a distorted square pyramid defined by the apical terminal oxo group and a basal plane occupied by a methyl group and three sulfur atoms from edt and SPh or tmtu. Important bond lengths and angles are summarized in Table 2. Irrespective of the negative charge on $\mathrm{PiCH}^{+} \mathbf{3}^{-}$, the $\mathrm{Re}=\mathrm{O}$ distances are identical at 169 pm for $\mathrm{PicH}^{+} \mathbf{3}^{-}$and $\mathbf{4}$, as are the values of $v(\mathrm{Re}-\mathrm{O})$ from the $\mathbb{R}$ studies, which fall in the narrow range of $976-1003 \mathrm{~cm}^{-1}$, indicating that the ionic charge does not influence the $\mathrm{Re}=\mathrm{O}$ bond. Re-C distances differ slightly, 215 pm in $\mathbf{P i c H}^{+} \mathbf{3}^{-}$and 213 pm in 4. Also, the chemical shifts of ${ }^{13} \mathrm{C}^{\text {for }} \mathrm{CH}_{3}, \delta 7.2$ for $\mathbf{P i c H}^{+} \mathbf{3}^{-}, 6.8$ for $\mathbf{4}$; the $\mathrm{CH}_{3}{ }^{\prime} \mathrm{H}$ resonance is more sensitive to the ligand environment, being $\delta 2.38$ for $\mathrm{PicH}^{+} 3^{-}$and 3.25 for 4 .

It is worth noting that $\mathbf{P i c H}^{+} \mathbf{3}^{-}$is a salt in the solid state. The 2 pm elongations of $\mathrm{Re}-$ $\mathrm{S}(2)$ and $\mathrm{Re}-\mathrm{S}(3)$ can be attributed to the negative charge on $\mathrm{PicH}^{+} 3^{-}$. Based on the
orientation of $\mathrm{N}-\mathrm{H}$ and the $\mathrm{N} \cdots \mathrm{S}(2)$ nonbonded distance, 319 pm , we assume a hydrogen bond ( $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ ) interaction between N and $\mathrm{S}(2)$. Raper and co-workers discovered a such interaction between a bridging thionate sulfur and a thioamide nitrogen in a copper complex with a $N \cdots S$ distance of $349 \mathrm{pm} .{ }^{15}$ Francois and co-workers found two types of $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ hydrogen bonds in $(\mathrm{TACN})_{2} \mathrm{Fe}_{2} \mathrm{~S}_{6}$ : a "strong" interaction with $d_{\mathrm{SH}}=231 \mathrm{pm}$ and a "weak" interaction with $d_{\mathrm{SH}}=265 \mathrm{pm} .{ }^{16}$ In our case, the calculated position of H gives an angle of $170.3^{\circ}$ for $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}(2)$ and $d_{\mathrm{SH}}=232 \mathrm{pm}$. Compared with the literature values, we conclude that a "strong" hydrogen bond interaction exists in $\mathrm{PicH}^{+} 3^{-}$.

Reactions with $\mathbf{P P h}_{3} . \mathrm{PPh}_{3}$ reacts with $\mathbf{P i c H}^{+} \mathbf{3}^{-}$and 4 to yield MeReO (edt) $\mathrm{PPh}_{3}$, eq 4-5. The product was identified by ${ }^{1} \mathrm{H} \mathrm{NMR} .{ }^{17}$ The reaction of $\mathrm{PicH}^{+} 3^{-}$gave rise to benzenethiol and 2-picoline (2-Pic) according to the (aqueous) acidity of PhSH and 2-picolinium (2$\left.\mathrm{PicH}^{+}\right): \mathrm{pK}_{\mathrm{a}}=6.62$ for PhSH and $\mathrm{pK}_{\mathrm{a}}=6.00$ for $2-\mathrm{PicH}^{+}$; the reaction of 4 generates free tmatu (eq 5).

$$
\begin{gather*}
\mathrm{PicH}^{+} 3^{-}+\mathrm{PPh}_{3} \rightarrow \mathrm{MeReO}(\text { edt }) \mathrm{PPh}_{3}+\mathrm{PhSH}+2-\mathrm{Pic}  \tag{4}\\
4+\mathrm{PPh}_{3} \rightarrow \mathrm{MeReO}(\mathrm{edt}) \mathrm{PPh}_{3}+\mathrm{tmtu} \tag{5}
\end{gather*}
$$

Both reactions are first-order with respect to the concentrations of rhenium complexes and $\mathrm{PPh}_{3}$. The second-order rate constants are $2.57 \pm 0.02 \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ for $\mathrm{PicH}^{+} 3^{-}$and $(8.20 \pm$ 0.06 ) $\times 10^{-2} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ for 4 (Figure 2) in chloroform at $25.0^{\circ} \mathrm{C}$. The thirty-fold slower reaction of 4 can be attributed to the steric hindrance of tmtu. Both rate constants are relatively small compared with the reaction of $\mathrm{MeReO}(e d t) P y$ with $\mathrm{PPh}_{3}$, with $\mathrm{k}=127 \mathrm{~L}$ $\mathrm{mol}^{-1} \mathrm{~s}^{-1}$ in $\mathrm{C}_{6} \mathrm{H}_{6} .{ }^{18}$

Figure 2. Plots of the pseudo-first-order rate constants in $\mathrm{CHCl}_{3}$ at $25^{\circ} \mathrm{C}$ for the reactions of $\mathrm{PicH}^{+} 3^{-}$against the concentrations of ligands; (a) $\mathrm{PPh}_{3}, 2,2{ }^{\prime}$-bpy, and $1,10-\mathrm{Phen}$; and (b) 4$\mathrm{Me}_{2} \mathrm{~N}-\mathrm{Py}, 4-\mathrm{Ph}-\mathrm{Py}$, and 4,4'-bpy.

Reactions with Pyridines. The reactions of $\mathrm{PicH}^{+} \mathbf{3}^{-}$and 4 with pyridines produce $\mathrm{MeReO}($ edt $) \mathrm{Py}$, eq 6-7. The reactions of $\mathrm{PicH}^{+} 3^{-}$show a second-order dependence on the concentration of pyridines (Figure 2 b ). Two pyridines, $4-\mathrm{Me}_{2} \mathrm{~N}-\mathrm{Py}$ and 4-Ph-Py, gave thirdorder rate constants, $1.02(2) \times 10^{6}$ and $7.4(1) \times 10^{3} \mathrm{~L}^{2} \mathrm{~mol}^{-2} \mathrm{~s}^{-1}$ respectively. The two order of magnitude difference between these rate constants indicates a substantial electronic effect from the substituents on pyridine. The electronic effect is cumulative because two molecules of pyridine are involved in the third-order reactions. No reaction has been observed with the less basic pyridine, 4-cyano pyridine (4-NC-Py), or with the sterically hindered pyridine, 2-Me-Py. Unlike the case of $\mathbf{P i c H}^{+} \mathbf{3}^{-}$, first-order kinetics was observed when 4 reacts with excess $4-\mathrm{Me}_{2} \mathrm{~N}$-Py, giving $\mathrm{k}=20.1(2) \mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$. To rule out the involvement of the dimer, an experiment with $\{\mathrm{MeReO}(e d t)\}_{2}$ (2) and 4-Ph-Py was carried out; the reaction shows a second-order dependence on [Py], with $k=2.76(3) \times 10^{4} \mathrm{~L}^{2} \mathrm{~mol}^{-2} \mathrm{~s}^{-1}$, which is four times bigger than the rate constant for $\mathbf{P i c H}^{+} \mathbf{3}^{-}$.

$$
\begin{gather*}
\mathrm{PicH}^{+} 3^{-}+\mathrm{Py} \rightarrow \mathrm{MeReO}(\mathrm{edt}) \mathrm{Py}+\mathrm{PhSH}+2-\mathrm{Pic}  \tag{6}\\
4+\mathrm{Py} \tag{7}
\end{gather*} \mathrm{MeReO}^{(\mathrm{edt}) \mathrm{Py}+\mathrm{tmtu}} \text {. }
$$

Reactions with Bidentate Ligands. The chelating ligands, 2,2'-bpy and 1,10-phen react with $\mathrm{PicH}^{+} 3^{-}$to produce six-coordinate complexes with first-order dependences on the concentrations of $\mathrm{PiCH}^{+} 3^{-}$and the ligand (Figure 2a). Second-order rate are $\mathrm{k}=0.84(2) \mathrm{L}$ $\mathrm{mol}^{-1} \mathrm{~s}^{-1}$ for 2,2'-bpy and $3.14(3) \mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$ for 1,10 -phen. Reaction of $\mathbf{P i c H}^{+} \mathbf{3}^{-}$with the nonchelating ligand $4,4^{\prime}$-bipyridine follows second-order kinetics with respect to ligand concentration, Figure $2 b$, with $\mathrm{k}=1.53(2) \times 10^{3} \mathrm{~L}^{2} \mathrm{~mol}^{-2} \mathrm{~s}^{-1}$.

Base Assistance in Ligand Displacement. Although the Brønsted bases (B) 4-NC-Py and 2-Pic do not react with $\mathbf{P i c H} \mathbf{3}^{+}$, they do accelerate the reaction of $\mathbf{P i c H}^{+} \mathbf{3}^{-}$with $\mathrm{PPh}_{3}$. It is important to point out that $\mathrm{MeReO}(e d t) B$ was not observed. When $\left[\mathrm{PPh}_{3}\right]$ was kept constant at 10 mM , the pseudo-first order rate constant rises with $[\mathbf{B}]$ and saturates at the high concentration, Figure 3. The data, including that of the reactions without Brønsted bases, were fitted to eq 8 by using the computer program Scientist, ${ }^{19}$ affording $\mathrm{K}=240(40), \mathrm{k}_{2}=$ 3.1(1) $\mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$ for 4-NC-Py, and $\mathrm{K}=23(8), \mathrm{k}_{2}=1.7(9) \mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$ for 2-Pic, and $\mathrm{k}_{1}=$ $2.58(5) \mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$, the same for both. The latter agrees with the directly-determined value, $2.57(2) \mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$.

$$
\begin{equation*}
\mathrm{k}_{\psi}=\mathrm{k}_{1}\left[\mathrm{PPh}_{3}\right]+\frac{\mathrm{k}_{2} \mathrm{~K}[\mathrm{~B}]}{1+\mathrm{K}[\mathrm{~B}]}\left[\mathrm{PPh}_{3}\right] \tag{8}
\end{equation*}
$$

Figure 3. Plots of the pseudo-first-order rate constants for reactions of $\mathbf{P i c H}^{+} \mathbf{3}^{-}$with $\mathrm{PPh}_{3}$ in the presence of the added Bronsted bases 4-NC-Py and 2-Me-Pic against [B] in $\mathrm{CHCl}_{3}$ at 25 ${ }^{\circ} \mathrm{C}$.

Similarly, $4-\mathrm{NC}-\mathrm{Py}$ and 2 -Pic accelerated the reaction of $\mathrm{PicH}^{+} \mathbf{3}^{-}$with $4-\mathrm{Me}_{2} \mathrm{~N}-\mathrm{Py}$, but without rate saturation was even at high [B]. The rate is given by

$$
\begin{equation*}
\mathrm{v}=\mathrm{k}_{\mathrm{m}} \cdot[3-\mathrm{Pic}] \cdot\left[\mathrm{Me}_{2} \mathrm{NPy}\right] \cdot[\mathbf{B}] \tag{9}
\end{equation*}
$$

with $\mathrm{k}_{\mathrm{m}}=5.8(1) \times 10^{4}(4-\mathrm{NC}-\mathrm{Py})$ and $88(18) \mathrm{L}^{2} \mathrm{~mol}^{-2} \mathrm{~s}^{-1}(2-\mathrm{Me}-\mathrm{Py})$.
Brønsted bases like 4-Ph-Py, that react with $\mathbf{P i c H}^{+} 3^{-}$with $\mathrm{k}=7.37(5) \times 10^{3} \mathrm{~L}^{2} \mathrm{~mol}^{-2} \mathrm{~s}^{-1}$, show an additional effect when added to the $\mathrm{PPh}_{3}$ reaction, where biphasic kinetics was observed. The intermediate $\mathrm{MeReO}(\mathrm{edt})(4-\mathrm{Ph}-\mathrm{Py})$ formed and vanished during the course of the reaction. With excess 4-Ph-Py and $\mathrm{PPh}_{3}$, the two-phase absorbance change could be fitted to eq 3, giving pseudo-first -order rate constants, $k_{\alpha}$ for the formation of MeReO (edt)(4- Ph -

Py) and $k_{\beta}$ for its disappearance. Keeping $\left[\mathrm{PPh}_{3}\right]$ constant ( $10 \mathrm{mmol} / \mathrm{L}$ ) during the course of the reaction, $k_{\alpha}$ shows a second-order dependence on [4-Ph-Py], giving $k_{l}=6.8(1) \times 10^{3} \mathrm{~L}^{2}$ $\mathrm{mol}^{-2} \mathrm{~s}^{-1}$; similarly, with [4-Ph-Py] $=30 \mathrm{mM}, k_{\beta}$ depends linearly on $\left[\mathrm{PPh}_{3}\right]$, giving $k_{2}=98(1)$ $\mathrm{L} \mathrm{mol}{ }^{-1} \mathrm{~s}^{-1}$. Both rate constants agree with the independent values from the direct study of the two steps, $\mathrm{k}_{\alpha}=7.4(1) \times 10^{3} \mathrm{~L}^{2} \mathrm{~mol}^{-2} \mathrm{~s}^{-1}$ and $\mathrm{k}_{\beta}=96(1) \mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$.

Again, the acceleration was observed when pyridines were introduced into the reaction of 4 with $\mathrm{PPh}_{3}$. When $\left[\mathrm{PPh}_{3}\right]$ was kept constant, the rate varied linear according to [4-NC-Py] and [2-Pic], giving the second-order rate constants $0.095(1)$ and $0.0103(3) \mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$ for 4-NC-Py and 2-Pic respectively. With the most basic pyridine, $4-\mathrm{Me}_{2} \mathrm{~N}$-Py, biphasic kinetics was observed and intermediate MeReO (edt)(4-Me $\mathrm{e}_{2} \mathrm{~N}$-Py) formed and disappeared during the course of the reaction. The rate constants for the two phases were obtained by fitting the kinetic trace to eq 3 , giving $k_{\alpha}$ and $k_{\beta}$, which are linearly dependent on [4- $\mathrm{Me}_{2} \mathrm{~N}-\mathrm{Py}$ ] and [ $\left.\mathrm{PPh}_{3}\right]$ respectively, $k_{\alpha}=k_{1}\left[4-\mathrm{Me}_{2} \mathrm{~N}-\mathrm{Py}\right]$ and $k_{\beta}=k_{2}\left[\mathrm{PPh}_{3}\right]$, with $k_{1}=19.2(3)$ and $k_{2}=33(1) \mathrm{L}$ $\mathrm{mol}^{-1} \mathrm{~s}^{-1}$. The consistency of these rate constants is acceptable, compared with the independent values, $20.1(2) \mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$ and $28.0(5) \mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$.

Influence of the Cation. This factor was investigated by using $\mathrm{LutH}^{+} \mathbf{3}^{-}$in reactions with $\mathrm{Ph}_{3} \mathrm{P}$ and 4- $\mathrm{Ph}-\mathrm{Py}$. The results are identical with those for $\mathrm{PicH}^{+} 3^{-}$, with $\mathrm{k}=2.53$ (3) $\mathrm{L} \mathrm{mol}{ }^{-1}$ $\mathrm{s}^{-1}$ and $7.14(9) \times 10^{3} \mathrm{~L}^{2} \mathrm{~mol}^{-2} \mathrm{~s}^{-1}$ for $\mathrm{LutH}^{+} 3^{-}$, as compared with $2.57(2)$ and $7.37(5) \times 10^{3}$ for $\mathbf{P i c H}^{+} \mathbf{3}^{-}$. An excess of pyridinium ions was added to the reaction system and it had no effect on the kinetics. This clearly indicates that the counter-cation is not involved.

The reactions and rate constants are summarized in Table 4.

Reactions with Pyridine N -oxides. When $\mathrm{PicH}^{+} \mathbf{3}^{-}$reacts with pyridine N -oxides, a threestage absorbance change was observed. Those changes are consistent with the scheme: (1) the first pyridine N -oxide replaces the $\mathrm{SPh}^{-}$ligand to form MeReO(edt)OPy; (2) a second pyridine N -oxide coordinates to rhenium trans to the oxo group, where it assists the cleavage of the $\mathrm{N}-\mathrm{O}$ bond of the first pyridine N -oxide to yield a $\operatorname{Re}(\mathrm{VII})$ intermediate, $\operatorname{MeRe}(\mathrm{O})_{2}$ (edt) OPy ; (3) the slow decomposition of that intermediate completes the sequence. The UV/Vis spectra of these species are given in Figure 4.

Figure 4. Spectra of $\mathrm{PicH}^{+} \mathbf{3}^{-}$and the intermediates $\mathrm{MeReO}(\mathrm{edt})(\mathrm{OPic})$ and $\mathrm{MeRe}(\mathrm{O})_{2}$ (edt), and the product from the reaction of the latter with $\mathrm{PPh}_{3}, \mathrm{MeReO}(\mathrm{edt})(\mathrm{OPic})\left(\mathrm{OPPh}_{3}\right)$.

The last stage of decomposition was too sluggish for kinetic study. The first two stages of absorbance change were fitted to eq 3, giving two pseudo-first-order rate constants, designated $\mathrm{k}_{\alpha}$ and $k_{\beta}\left(k_{\alpha}>k_{\beta}\right)$. Figure 5 depicts the plots of the pseudo-first-order rate constants for oxidation of $\mathbf{P i c H}^{+} \mathbf{3}^{-}$against concentrations of pyridine N -oxides.

Figure 5. Plots of (a) $k_{\alpha}$, (b) $k_{\beta}$ against [ PyO ] for the reaction between $\mathrm{PicH}^{+} 3^{-}$and pyridine N -oxides in $\mathrm{CHCl}_{3}$ at $25^{\circ} \mathrm{C}$.

Both rate constants vary linearly with [ PyO ]. Rate constants of oxidation of $\mathrm{PicH}^{+} \mathbf{3}^{-}$by pyridine N -oxides are summarized in Table 5 . The rate constants of the first stage span a range of $2.3 \times 10^{3}-1.2 \times 10^{5} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$; those of the second stage lie in the range of $3 \times 10^{2}$ $-8 \times 10^{3} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$. The Hammett analysis for $\mathrm{PicH}^{+} \mathbf{3}^{-}$shows large reaction constants, $\rho_{1}=$ -5.3 and $\rho_{2}=-4.3$, as illustrated in Figure 6.

Table 5. Rate constants for the oxidation of $\mathrm{PiCH}^{+} \mathbf{3}^{-}$and 4 by pyridine N -oxides.

Figure 6. Analysis of the kinetic effects of pyridine N -oxide substituents on the rate constants for oxidation of $\mathrm{PicH}^{+} 3^{-}$by the Hammett equation.

To identify the rate constant for the first two steps, 2 was used to react with $4-\mathrm{MeO}-\mathrm{PyO}$ and 4-Ph-PyO. Three-stage absorbance changes were observed, like those for $\mathbf{P i c H}^{+} \mathbf{3}^{-}$. The first two stages were fitted to eq 3 , affording $k_{\alpha}$ and $k_{\beta}$. Varying the concentrations of two $\mathrm{PyO}, k_{\alpha}$ shows mixed first-order and second-order dependences on $[\mathrm{PyO}], k_{\alpha}=k_{\mathrm{la}}[\mathrm{PyO}]+$ $k_{\mathrm{lb}}[\mathrm{PyO}]^{2}$, affording $k_{\mathrm{la}}=1.27(8) \times 10^{4} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ and $k_{\mathrm{la}}=8(6) \times 10^{4} \mathrm{~L}^{2} \mathrm{~mol}^{-2} \mathrm{~s}^{-1}$ for 4-MeO-PyO and $k_{1 \mathrm{a}}=6.5(3) \times 10^{3} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ and $k_{\mathrm{la}}=1.4(2) \times 10^{5} \mathrm{~L}^{2} \mathrm{~mol}^{-2} \mathrm{~s}^{-1}$ for 4-Ph-PyO. Unlike $k_{\alpha}, k_{\beta}$ varies linearly with [PyO], giving second-order rate constants, $1.70(3) \times 10^{4} \mathrm{~L}$ $\mathrm{mol}^{-1} \mathrm{~s}^{-1}$ for $4-\mathrm{MeO}-\mathrm{PyO}$ and $1.32(1) \times 10^{3}$ for $4-\mathrm{Ph}-\mathrm{PyO}$. The monomerization of 2 follows mixed first-order and second-order kinetics. ${ }^{11,20}$ Although the complexity of the reaction of 2 with pyridine N -oxides causes the difference between the second-order rate constants from $k_{\beta}$ and that of 3 , we can assign $k_{\alpha}$ to ligand displacement and $k_{\beta}$ to oxidation.

The reaction of 4 with PyO is much slower than that of $\mathrm{PicH}^{+} 3^{-}$; the absorbance change occurs in two stages, the second corresponds to the third stage of the $\mathbf{P i c H}^{+} \mathbf{3}^{-}$reaction, namely the decomposition of $\operatorname{MeRe}(\mathrm{O})_{2}(\mathrm{edt}) \mathrm{OPy}$. The first stage shows a first-order dependence on [PyO], affording second-order rate constants in the range of $0.8-23 \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-}$ ${ }^{1}$, as listed in Table 4. A Hammett analysis gave $\rho=-4.7 \pm 0.7$, indicative of an unusually large substituent effect.

Although the decomposition of $\operatorname{MeRe}(\mathrm{O})_{2}(\mathrm{edt}) \mathrm{OPy}$ is too sluggish for kinetics, the relative rate can be estimated by the time for complete reaction. The rate did not depend on [PyO], but did depend on the identity of pyridine N -oxides. The rate for $4-\mathrm{Ph}-\mathrm{PyO}$ is about two times slower than that for $4-\mathrm{PicO}$. When $\mathrm{PPh}_{3}$ was added to the solution of $\mathrm{MeReO}_{2}$ (edt)OPy, the absorbance changed instantaneously, as the catalytic cycle transfers an oxygen atom from PyO to $\mathrm{PPh}_{3}$ according to the stoichiometric reaction of eq 1. Figure 4 depicts the spectrum of $\mathrm{MeReO}(\mathrm{edt})(4-\mathrm{OPic})\left(\mathrm{OPPh}_{3}\right)$, the product from this reaction. The weak ligand $\mathrm{Ph}_{3} \mathrm{PO}$ can be readily replaced by PyO in the system. Although this metastable species was not structurally characterized, certain comparison compounds has been found in the literature, involving $\mathrm{Re}-\mathrm{OPPh}_{3}$ interaction.. ${ }^{21-24} \operatorname{Re}(\mathrm{O}) \mathrm{Cl}_{3}\left(\mathrm{OPPh}_{3}\right)\left(\mathrm{Me}_{2} \mathrm{~S}\right)$ was used as a catalyst for oxygenation of thiols. ${ }^{21}\left[\left(\mathrm{HCpz}_{3}\right) \mathrm{ReCl}_{2}\left(\mathrm{OPPh}_{3}\right)\right] \mathrm{Cl}$ and $(\mathrm{HBpz} 3) \mathrm{ReCl} 2\left(\mathrm{OPPh}_{3}\right)$ was formed from the oxygen abstraction of $\mathrm{PPh}_{3}$ from corresponding rhenium(V) complexes, $\left(\mathrm{HCpz}_{3}\right) \mathrm{ReOCl}_{2}$ and $\left(\mathrm{HBpz}_{3}\right) \mathrm{ReOCl}_{2} .{ }^{24}$ Analogous Mo and W compounds were also found
and structurally characterized, such as $\left[\mathrm{LMo}^{\mathrm{IV}}\left(\mathrm{OPR}_{3}\right)\left(\mathrm{p}-\mathrm{OC}_{6} \mathrm{H}_{4}-\mathrm{OC}_{2} \mathrm{H}_{5}\right)_{2}\right]^{+}$and anti$\mathrm{Cl}_{2} \mathrm{O}\left(\mathrm{Ph}_{3} \mathrm{PO}\right) \mathrm{W}(\mu-\mathrm{S}-i-\mathrm{Bu})_{2} \mathrm{~W}\left(\mathrm{Ph}_{3} \mathrm{PO}\right) \mathrm{Cl}_{2} \mathrm{O} .{ }^{22,23}$ The reaction of $\mathrm{MeRe}(\mathrm{O})_{2}($ edt $) \mathrm{OPy}$ with $\mathrm{PPh}_{3}$ is too fast for stopped-flow kinetics, giving a conservative limit on the second-order rate constant $k>6 \times 10^{5} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$.

## Discussion

The $\mathbf{N}-\mathbf{H} \cdots \mathbf{S}$ Hydrogen Bond. This interaction has been recognized in metalloproteins, electron-transfer iron-sulfur proteins, ${ }^{25-29}$ and cytochrome P 450 compounds containing thiolate-metal coordination. ${ }^{30-32}$ This weak interaction plays an important role in maintaining structures and modulating redox potentials of metal centers. Model compounds containing $\mathrm{Fe}, \mathrm{Co}$, Mo were synthesized and a variety of $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ hydrogen bonds were discovered and characterized. ${ }^{33-37}$ Most of them contain a bent hydrogen bond with an $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ angle $<180^{\circ} .{ }^{33-36}$ In only a few cases has an angle close to $180^{\circ}$ been observed. ${ }^{37}$ To our knowledge, the $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ hydrogen bond in $\mathrm{PicH}^{+} \mathbf{3}^{-}$is the first case of this interaction in a rhenium complex. Another point of significance can be seen from the crystal structure of $\mathrm{PicH}^{+} \mathbf{3}^{\mathbf{*}}$ : the $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ hydrogen bond could arise from the reaction of partially protonated edtH${ }^{-}$with the Bronsted base 2-Pic. This reaction enters into the interpretation of the Bronsted base-assisted ligand displacement.

Ligand Displacement. First-order kinetics with respect to the concentration of entering ligand is a common feature of well-known ligand displacement reactions of methyl(oxo)rhenium(V) complexes. ${ }^{38-40}$ The reaction of $\mathrm{PicH}^{+} 3^{-}$with $\mathrm{PPh}_{3}$ and the reactions of 4 with $\mathrm{PPh}_{3}$ and pyridines exactly follow this behavior. Strikingly, the reactions of $\mathbf{P i c H}^{+} 3^{-}$with pyridines displayed second-order dependences on [Py]. Noting that the monomerization of dimeric methyl(oxo)rhenium(V) complexes with pyridine also shows a second-order dependence on [Py] owing to their two metal centers, ${ }^{11,20}$ we presumed that $\mathbf{P i c H}^{+} \mathbf{3}^{-}$in solution has two reaction centers. One can be attacked by $\mathrm{PPh}_{3}$ and Py , another can be attacked only by the Brønsted base, Py. This proposal was confirmed by the finding that the added Bransted bases, 4-NC-Py and 2-Pic, which themselves are not able to replace the $\mathrm{SPh}^{-}$ligand, accelerate the reactions of $\mathrm{PicH}^{+} 3^{-}$with $\mathrm{PPh}_{3}$ and Py . Again, the first-order kinetic dependence on the entering ligand for $\mathbf{P i c H}^{+} \mathbf{3}^{-}$with the chelating bidentate ligands

2,2 'bpy and 1,10 -phen confirms the existence of two reaction centers and further indicates that those two centers are relatively rigid and close to one another, because the reaction with $4,4^{\prime}$-bpy, which does not have two N atoms close to one another, is second-order with respect to [4,4'-bpy].

Thus, we presume that the resulting species that exists in chloroform is $\mathrm{MeReO}(e d t H) \mathrm{SPh}$, 5 , with the structural formula

5
This is a neutral complex that contains two reaction centers: a rhenium atom that can be attacked by a Lewis base, $\mathrm{PPh}_{3}$ and Py , and a proton attached to sulfur that can be abstracted by a Bronsted base. This proposal was also based on the fact that the same rate constants were obtained for $\mathbf{P i c H}^{+} \mathbf{3}^{-}, \mathrm{LutH}^{+} \mathbf{3}^{-}$, and $\mathbf{P i c H}^{+} \mathbf{3}^{-}+\mathrm{PyH}^{+}$.

The Lewis base $\mathrm{PPh}_{3}$ can attack only the rhenium atom of $\mathbf{P i c H}^{+} \mathbf{3}^{-}$to yield $\mathrm{MeReO}(e d t) \mathrm{PPh}_{3}$. This reaction is first-order with respect to $\left[\mathrm{PPh}_{3}\right]$. This mechanism was displayed in Scheme 1, pathway a. In the presence of a Brønsted base B, $=4-\mathrm{NC}-\mathrm{Py}$ or $2-$ $\mathrm{Me}-\mathrm{Py}$, the reaction was accelerated to a saturation level in [B], clearly indicating that a prior equilibrium between $\mathrm{PicH}^{+} \mathbf{3}^{-1}$ and pyridine was established before the replacement of $\mathrm{SPh}^{-}$ with $\mathrm{PPh}_{3}$ (pathway b). An intermediate with the same structure, containing an $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ hydrogen bond, was proposed in accord with the kinetic observations.

Scheme 1. Alternative pathways a-c for displacement of $\mathrm{SPh}^{-}$by $\mathrm{PPh}_{3}$, assisted by Py

Given that Py can react with $\mathrm{PicH}^{+} 3^{-}$to form $\mathrm{MeReO}(\mathrm{edt}) \mathrm{Py}$, it seems plausible that there will be yet another possible pathway (c) by which 4-NC-Py and 2-Pic might assist ligand displacement from $\mathbf{P i c H}^{+} 3^{-}$with $\mathrm{PPh}_{3}$. It is through an intermediate, MeReO (edt) Py , which might be formed from more basic and less sterically hindered pyridines. But in the cases of 4-NC-Py and 2-Pic, there is no direct reaction between these pyridines and $\mathbf{P i c H}^{+} \mathbf{3}^{-}$; one can presume that the equilibrium between $\mathrm{PicH}^{+} \mathbf{3}^{-}$and MeReO (edt) Py is unfavorable with $\mathrm{K} \ll 1$. This is totally opposite to the data obtained from the kinetic study, $\mathrm{K}=240 \pm 40$ for 4 -NC-Py and $\mathrm{K}=23 \pm 8$ for 2 -Me-Py. For 4-Ph-Py, however, which is capable of replacing $\mathrm{SPh}^{-}$, pathway c becomes available, especially at a high ( 30 mM ) concentration of $4-\mathrm{Ph}-\mathrm{Py}$; indeed, MeReO (edt)(4-Ph-Py) was detected spectrophotometrically and the rate constants for the biphasic kinetics were obtained. These values were in good agreement with those from the independently-studied reactions between $\mathrm{PicH}^{+} 3^{-}$with 4- $\mathrm{Ph}-\mathrm{Py}$ and $\mathrm{MeReO}(\mathrm{edt})(4-\mathrm{Ph}-$ Py) with $\mathrm{PPh}_{3}$.

As was already mentioned, pyridine, both a Brønsted and a Lewis base, can attack both reaction sites in $\mathrm{PicH}^{+} 3^{-}$, affording the second-order kinetics with respect to [Py]. The two pathways in Scheme 2 are potentially consistent with the kinetic data. In pathway d, a prior equilibrium was proposed as in $\mathbf{b}$, followed by an attack of second Py on rhenium from the position trans to oxo group. In e, Py approaches rhenium from the lower empty position and
equilibrates quickly; then second Py attacks the proton on sulfur, followed by a fast step to yield the final product MeReO (edt)Py.

Pathway $\mathbf{d}$ can be ruled out by the following analysis. Since the prior equilibrium in $\mathbf{d}$ is as same as that in scheme 1 pathway $b$, the same rate saturation should be observed as that in the Py assisted reaction of $\mathrm{PicH}^{+} \mathbf{3}^{-}$with $\mathrm{PPh}_{3}$. But in experiments no saturation was ever observed with single or mixed pyridines. To the contrary, for $\mathbf{e}$, the prior equilibrium for formation of six-coordinate rhenium species is unfavorable. Indeed, no $\mathrm{MeReO}(\mathrm{edt}) \mathrm{L}_{2}$, where $L$ is a monodentate ligand, has ever been observed. The clear implication is that the equilibrium constant is small and can not lead to saturation. On the other hand, it is reasonable to postulate the formation of intermediate six-coordinate rhenium species because they are known with chelating ligands. ${ }^{39}$ The reason for requirement of the second Py possibly lies on that the abstraction of proton from sulfur increases the electron density on sulfur, and further on rhenium; the scission of $\mathrm{Re}-\mathrm{S}$ bond requires the shift of electron from Re to $S$.

Scheme 2. Alternative pathways d-e for the two-stage displacement of $\mathrm{SPh}^{-}$by Py

In contrast to 3,4 only has one reaction site, the rhenium atom. Displacement of tomtu in $\mathbf{4}$ by Py and $\mathrm{PPh}_{3}$ is a simplified version of the reactions of 3 . Since there is no proton on the sulfur atom of 4 , pathway $\mathbf{b}, \mathbf{d}$ and $\mathbf{e}$ are not suitable for the reactions of 4 any more. But pathways a and $\mathbf{c}$ are adaptable. Scheme 3 depicts two pathways for the reactions of 4 which can account for of the kinetic data. Pathway $f$ stands for a common ligand displacement mechanism, affording a second-order kinetics, first-order dependence on both rhenium
complex and the entering ligand. Pathway $g$ is a two-step scheme. For $4-\mathrm{Me}_{2} \mathrm{~N}-\mathrm{Py}$, the reaction stops at the first step. For the Py assisted reaction of 4 with $\mathrm{PPh}_{3}$, the reaction goes through two steps, the formation of intermediate $\mathrm{MeReO}(\mathrm{edt}) \mathrm{Py}$ and the generation of final product $\mathrm{MeReO}(\mathrm{edt}) \mathrm{PPh}_{3}$. For the case of $4-\mathrm{Me}_{2} \mathrm{~N}-\mathrm{Py}$, the formation and disappearance of $\mathrm{MeReO}(e d t)\left(4-\mathrm{Me}_{2} \mathrm{~N}-\mathrm{Py}\right)$ was observed and the kinetic curve was fitted to the biphasic kinetics. When 4-NC-Py and 2-Pic were used, the first step becomes very slow compared the rate of the second step. Thus the biphasic kinetics changes to a single-phase kinetics. That is, the first step becomes the rate-controlling step, which is first-order dependence on [4-NC-Py] and [2-Pic].

Scheme 3. Alternative pathways $\mathbf{f}, \mathbf{g}$ for displacement of tmtu by $\mathrm{PPh}_{3}$, assisted by Py

g

Oxidation of Rhenium Complexes. The nucleophilic assistance on the severing of the $\mathrm{O}-\mathrm{Py}$ bond was first discovered in the reduction of pyridine N -oxides with the catalyst $\mathrm{MeReO}(\mathrm{mtp}) \mathrm{PPh}_{3} .{ }^{6,7}$ In the case of oxidation of $\mathrm{PicH}^{+} 3^{-}$, the three-stage absorbance change corresponded to the mechanism proposed in Scheme 4. The first stage is a common ligand displacement since pyridine N -oxide acts well as Lewis base, ${ }^{41-44}$ showed first-order dependence on [PyO]. By using series of substituted pyridine N -oxides, a large substituent effect, $\rho=-5.3$, was found, which is possibly caused by the change of the charge on rhenium during the first step.

## Scheme 4. Oxidation of $\mathrm{PiCH}^{+} 3^{-}$

The scission of the $\mathrm{O}-\mathrm{N}$ bond of PyO coordinated to rhenium occurs in the second step with the assistance of a second PyO. Two reasonable species can be assigned as the transient oxidation product, $\operatorname{MeRe}(\mathrm{O})_{2}(\mathrm{edt})$ and $\operatorname{MeRe}(\mathrm{O})_{2}(\mathrm{edt}) \mathrm{OPy}$. The former is a five coordinated rhenium(VII) complex with two terminal oxo groups. An analogous compound, $\left\{\mathrm{MeRe}(\mathrm{O})_{2}\right\}_{2}\left\{\mathrm{SCH}_{2} \mathrm{CH}(\mathrm{O}) \mathrm{CH}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{~S}\right\}$, was discovered with a distorted trigonal bipyramidal structure that contained two identical oxo groups. ${ }^{11}$ The reaction of $\operatorname{MeRe}(\mathrm{O})_{2}\left(\mathrm{OCH}_{2} \mathrm{CH}_{2} \mathrm{~S}\right)$ with $\mathrm{PPh}_{3}$ occurs at relatively slow rate. ${ }^{1}$ Similar to these renium compounds, five-coordinate $\mathrm{Mo}(\mathrm{VI})$ complexes with two terminal oxo groups were recognized as key models for sulfite oxidase, which has been widely studied and characterized. ${ }^{45-49}$ The later species is a six-coordinate rhenium complex containing one PyO trans to one of the oxo groups. With 8-hydroxyqulinoline as ligand, a six-coordinate dirhenium complex was synthesized from the condensation of methyltrioxorhenium(VII) with free ligands. ${ }^{50}$ Similarly, the condensation of methyltrioxorhenium(VII) with diols and diamines affords dioxorhenium(VII) complexes with an extra Lewis base as the sixth ligand. ${ }^{12,51,52}$ Both of these compounds have two oxo groups cis to each other. In the catalytic OAT reaction, six-coordinate dioxorhenium species were proposed as the immediate oxidation product. ${ }^{4,53}$ The dependence on the identity of PyO of the decomposition of this species indicates that PyO is coordinated. Thus $\operatorname{MeRe}(\mathrm{O})_{2}(\mathrm{edt}) \mathrm{OPy}$ is the product from the scission of the $\mathrm{O}-\mathrm{N}$ bond.

As to why nucleophilic assistance is necessary, we note that the scission of O-N bond requires electron transfer from O to N . With coordination of another PyO , the electron density on rhenium is enriched; as is it on the $O$ atom. Another possibility is that the coordinated PyO stabilizes the oxidation product, dioxorhenium(VII), which would direct the
reaction through a nucleophile-assisted pathway. Electron-rich ligands are known to stabilize and lower the reactivity of $\mathrm{Re}=\mathrm{O}$ bond. ${ }^{54}$

The first step of the oxidation of 4 by pyridine N -oxides is much slower than the second, which is as same as the second step of oxidation of $\mathrm{PicH}^{+} 3^{-}$. So the reactions simplify into two stages, ligand displacement and decomposition of $\mathrm{MeRe}(\mathrm{O})_{2}$ (edt) OPy .

## Conclusion

Two ionic and one neutral methyl(oxo)rhenium(V) compounds were synthesized and structurally characterized. They were compared in reactivity towards the ligands triphenylphosphane, pyridines, pyridine N -oxides. Assistance from Brønsted bases was found on ligand displacement of ionic rhenium compounds as well as nucleophile assistance on oxidation of all of compounds. From the kinetic data, crystal structures, and an analysis of the intermediates, a structural formula of $\mathrm{PicH}^{+} \mathbf{3}^{-}$and mechanisms of ligand displacement and oxidation were proposed.

S-7. Crystal data of Compound 4.
A. Crystal data and structure refinement for 4.
Identification code4
Empirical formula $\mathrm{C}_{8} \mathrm{H}_{19} \mathrm{~N}_{2} \mathrm{OReS}_{3}$
Formula weight ..... 441.63
Temperature ..... 293(2) K
Wavelength ..... $0.71073 \AA$
Crystal system Monoclinic
Space group
P2(1)
Unit cell dimensions
$\mathrm{a}=8.7615(12) \AA$

$$
\alpha=90^{\circ} .
$$

$$
b=16.426(3) \AA \quad \beta=93.768(4)^{\circ}
$$

$$
\mathrm{c}=10.0210(15) \AA \quad \gamma=90^{\circ} .
$$

Volume1439.1(4) $\AA^{3}$
Z ..... 4
Density (calculated) $2.038 \mathrm{Mg} / \mathrm{m}^{3}$
Absorption coefficient $8.859 \mathrm{~mm}^{-1}$
F(000) ..... 848
Crystal size $0.22 \times 0.18 \times 0.08 \mathrm{~mm}^{3}$
Theta range for data collection 2.04 to $24.72^{\circ}$.
Index ranges
$-10 \leq h \leq 3,-18 \leq k \leq 15,-8 \leq 1 \leq 11$
Reflections collected4488
Independent reflections$3787[\mathrm{R}(\mathrm{int})=0.0233]$
Completeness to theta $=24.72^{\circ}$ ..... 89.4 \%
Absorption correction Empirical
Max. and min. transmission
0.68 and 0.26

| Refinement method | Full-matrix least-squares on $\mathrm{F}^{2}$ |

D. Anisotropic displacement parameters $\left(\AA^{2} \times 10^{3}\right)$ for 4 . The anisotropic displacement factor exponent takes the form: $-2 \pi^{2}\left[h^{2} a^{*} U_{11}+\ldots+2 h k a^{*} b^{*} U_{12}\right]$
