ABSTRACT

This is the third semi-annual Technical Progress Report for DOE Grant No. DE-FG-26-00BC15192 entitled *“Assessment of Hydrocarbon Seepage on Lands Belonging to Ft. Peck Tribes: Soil Geochemistry Application on Aeromagnetic, Landsat Lineament, and 3D Seismic Anomalies”*. In the third, six month time period, the principle contractor for the project, the Assiniboine and Sioux Tribes, performed the following work: 1) Collected reconnaissance micro-magnetic data and background field data for Area 1, 2) Identified and collected soil sample data in three anomalous regions of Area 1, 3) Sampled soils in Northwest Poplar Oil Field, 4) Graphed, mapped, and interpreted all data areas listed above, 5) Registered for the AAPG Penrose Conference on Hydrocarbon Seepage Mechanisms and Migration (postponed from 9/16/01 until 4/7/02 in Vancouver, B.C. Results include the identification and confirmation of an oil and gas prospect in the northwest part of Area 1 and the verification of a potential shallow gas prospect in the West Poplar Area. Correlation of hydrocarbon micro-seepage to TM tonal anomalies needs further data analysis.

Part 1

PHASE II INTERIM REPORT
Fort Peck Reservation Assessment
Semi-Annual Progress Report #3

By Lawrence M. Monson

INTRODUCTION

Satellite image tonal anomalies mapped above the Smoke Creek Aeromagnetic Anomaly may represent vegetative and soil geochemical changes caused by the micro-seepage of hydrocarbons. Phase I of the DOE Grant #DE-FG26-00BC15192, "Assessment of Hydrocarbon Seepage on Fort Peck: A Comparison of Surface Exploration Techniques" sampled soils above a known oil field and a 3D seismic anomaly. [See semi-annual reports 15192R1 (Monson, 2000) and 15192R2 (Monson, 2001)]. Selected methods from Phase I were applied to the Smoke Creek Area after a reconnaissance micro-magnetic survey identified anomalous sites. Further statistical and geographic correlation is needed to determine whether the tonal anomalies are caused by hydrocarbon seepage. The micro-magnetic survey did locate a hydrocarbon prospect, which was confirmed by the selected surface exploration methods. These methods also confirmed the presence of Methane above a shallow gas prospect. The report that follows primarily presents data acquired during the past field season. Initial observations and comparisons are made. Final interpretations will be made in future reports.

EXECUTIVE SUMMARY

Phase II of the Fort Peck Tribes project to “Assess Hydrocarbon Seepage on the Reservation utilizing surface exploration techniques” applied the methods, which best correlated to the areas sampled in Phase I. The Head Gas method correlated well to production in the Palomino Oil Field (Area 6) and to 3D seismic anomalies in the Wicape Prospect (Area 7). Because the Tribes acquired Soil Gas chromatograph equipment, this method was also continued. The Non-gas, indirect hydrocarbon detection methods retained, were Microbial and Iodine. The Head Gas lab also provides Eh, pH, and K data at little extra charge.

Phase II fieldwork covered the principle reason for this entire study. In 1993 the author published a paper with George Shurr, which focused on the overwhelming set of surface and sub-surface geologic evidence that the Smoke Creek Aeromag Anomaly mapped a subsurface body of tremendous significance. Fold axes, stratigraphic deposition, regional dip, salt dissolution, topographic relief, drainage, soils, satellite lineament/fault blocks, and finally, curved tonal anomalies, all concentrate or hinge on what is buried beneath the eastern plains of the Fort Peck Reservation. A logical explanation of the curvilinears is that they represent hydrocarbon micro-seepage chimneys (Land, 1991).

See Figures 2-15 for background maps summarizing these observations.

Because of the size of Area 1 (9 townships) and because of the chimney model, Mr. Land was contracted to conduct a micro-magnetic survey using a Magnetic Susceptibility (MS) meter. His interpretations are not yet available and will follow in the next semi-annual report. MS profiles and maps reveal a complicated data distribution that cannot be correlated to Landsat curvilinears at the scale presented. Three anomalous areas were found, two, which are outside the SC Mag Anomaly. One proved to also have high “background” gas values, which were confirmed by denser Sampling. Site 26, as it is named, is a valid oil prospect although may be structurally low. It does point to hydrocarbons in the area of a 3D defined structure. See Figures 7, 73, and 82 for Site 26 maps.

Hydrocarbons were not confirmed in the other two anomalous MS areas. This report compares the two methods to the other non-gas methods employed. Microbial and Iodine techniques continue to have merit although not always directly or consistently with the Head Gas method.

Phase II also detected Methane near a proposed shallow gas project. Results were inconclusive and Methane’s utility, as a surface hydrocarbon technique, remains unsubstantiated.

TECHNICAL DESCRIPTION OF WORK

EXPERIMENTAL PROCEDURES

The Phase I Report 15192RO1.pdf (Monson, 2000) includes an explanation and summary tables for the various methods of surface hydrocarbon exploration utilized in this study. The methods retained for Phase II include: 1) Head Gas, 2) Soil Gas, 3) Microbial (method 2), 4) Iodine and 5) Other indirect measurements provided by the Head Gas Analysis package of services (Eh, pH, and Conductivity). Magnetic Susceptibility measurements were also taken on the soil samples sent for Acid Extract analysis. The methodology, theoretical basic, and procedural observations of each technique appear in that Phase I Preliminary Report.

New to Phase II is the utilization of reconnaissance micro-magnetic exploration techniques as the initial investigation tool. The most extensive sampling to date occurred in the Smoke Creek Area with 1185 Magnetic Susceptibility measurements taken. This study, and this author, benefited greatly from the guidance of John Land. His participation in this project was both fortuitous and appropriate for two reasons: 1) Mr. Land has conducted micro-magnetic surveys for more than 47 years, and thus brought valuable experience and interpretation skills 2) The hydrocarbon seepage model cited in the author's previous work was published by Mr. Land and appears in Figure 12 of this report as well.

To conduct the Magnetic Susceptibility Survey, Mr. Land used an Exploranium KT-9 Kappameter. (See Map Figure 17). The procedure was simply to record at least three soil contact readings, which were then averaged by the meter. Bare soil was usually prepared by scraping the surface with the heel of a shoe in cultivated or sparsely vegetated soil. Where more dense and undisturbed prairie grasses grew, a small spade was used to open a test hole.

The theory behind using Magnetic Susceptibility measurements as a hydrocarbon exploration tool is that the meter measures how easily the near surface soil is magnetized. Electric currents sent into the soil create a magnetic field that is adsorbed by ferrous minerals in the soil. The indirect inference is that these alteration minerals are more likely formed in a reducing chemical environment caused by the presence of natural gases in the soil. The tool is primarily a relative indicator (as most surface techniques are) of higher gas levels relative to background levels along the day's profile or profiles.

On the last three magnetic survey profiles, paths were chosen that best crossed the Smoke Creek Aeromag Anomaly. On these traverses, field magnetic measurements were made with a Geometrics Model G-856 Magnetometer (Figure 18). For each day a similar unit was also set up as a base station to measure the diurnal magnetic variations of the earth in this area (Map Fig. 21). Field measurements were subtracted from the base station readings by synchronizing each unit's time clock and processing the data utilizing post acquisition software. Map Figure 19 shows the author and Mr. Land in action with the

two magnetic instruments described above. The magnetometer was used to measure local variations in the earth's magnetic field. Although the survey apparently confirmed the overwhelming signature of the Smoke Creek Aeromag Anomaly, subsequent high frequency preservation may provide valuable hydrocarbon traces that could relate to the satellite tonal anomalies (curvilinears). This process will be summarized in the next semi-annual report.

In all of the magnetic profiles the following sampling distances were employed: 1) Inside the Aeromag Closure - .2 mile (.32 km), 2) within 3 miles (4.8 km) - .3 mile (.48 km), 3) 3-6 miles (4.8 - 9.6 km) - .5 miles (.81 km). The Aeromag Closure is approximately 6 miles (9.6 km) in diameter. Thus each traverse was approximately 18 miles (29 km). Sampling profiles followed existing roads and trails wherever possible with only a couple short traverses on foot. As with all earlier sampling, GPS locations were mapped and data entered into a laptop computer.

RESULTS AND DISCUSSION

Background

Public domain aeromagnetic data was one of the primary data sets acquired by the Fort Peck Tribes in 1990 for their Minerals Assessment Study, funded by the Bureau of Indian Affairs, Energy and Minerals Division. Map Figure 2 displays two significant aeromag "structures" on the Fort Peck Reservation. The first is a narrow linear trend in the western part of the Reservation. Pertinent to this entire DOE funded project is the circular, "bull's eye" anomaly, which dominates the northeastern part of the Reservation. When this study began, GCRL, the Tribes IMDA partner and technical matching fund participant of the grant, was more than passively interested in the Smoke Creek Aeromag Anomaly (SC Mag). GCRL's parent company, Gulf Canada, fully appreciated the economic significance of what one explanation for SC Mag could be: an astrobleme. Gulf operates the prolific Steen River Oil Field in Northern Alberta, thought to produce from fractured reservoirs draping a buried meteorite. Other astrobleme fields occur in the Williston Basin, such as Red Wing Field in North Dakota.

At first the author, from geophysical and petrological training, assumed that SC Mag represented an ultramafic intrusive, perhaps a lopolith formed near the margins of a pre-Paleozoic tectonic suture zone. (Shurr & Monson, 1991, 1993, 1995). These papers document considerable evidence for SC Mag to be more than just an ultramafic intrusion. The historical case began long before when the author was shown Ft. Peck's NW/SE drainage pattern in an undergraduate Geomorphology course (See Map Figure 3). Note the east-west deflection of Smoke Creek in the northeast part of the Reservation, exactly where SC Mag is located. Taught as a classic example of structurally controlled drainage, within the Williston Basin tectonic framework, Ft. Peck's stream patterns encouraged the author and George Shurr to map satellite lineaments and propose tectonic blocks. (Map Figures 4, 6-10). SC Mag lies at the intersection of the Poplar and Big Muddy Lineament Blocks (Map Figure 6). It was proposed by Shurr that these lineament zone boundaries represent surface expressions on deep-seated, reactivated faults, which

enhance structural drape traps as well as encourage reservoir deposition over tectonic highs. Map Figure 7 details the SC Mag Aeromag anomaly (from a commercial data acquisition) and became the focus for Shurr and Monson (1993) and this study. That earlier paper documented numerous other anomalies above SC Mag:

- 1) Map Figure 8; deflection of structural folds, and seismic time and isochron contours.
- 2) Map Figure 9; Lineament Zone Intersection
- 3) Map Figure 10; Other Anomalies – radial drainage, radial soil map pattern, thicker till soils characterized by unusual colors, more resistant soils characterized by a flattening in the Smoke Creek stream profile (clockwise maps from top left).
- 4) Map Figure 11; satellite tonal anomalies (curvilinears) with contoured abundance over SC Mag.
- 5) Map Figure 12; Curvilinears (bubbles) concentrated at lineament intersections and associated with other interpreted aeromag structural “fault” lines (Geoterrex, 1990).

All of this evidence led Shurr and Monson to propose that the SC Mag curvilinears could be hydrocarbon micro-seepage chimneys as described by Land, 1991 (see Map Figure 13).

Maps Pages 14 and 15 complete the Fort Peck structural picture by displaying a seismic profile and fold and fault axes which place the SC Mag feature in the Williston Basin tectonic regime adjacent to the Prairie Salt Edge and coincident Smoke Creek Syncline. This project’s Summary Poster brings all this background together in Map Figure 16.

PHASE II FIELD WORK

The surface hydrocarbon exploration methods employed in Phase II of this project are explained in the Experimental Procedures section of this and earlier reports. The instruments employed in the two new techniques added to Phase II, are pictured in Map Figures 17 (Magnetic Susceptibility) and 18 (Magnetometer). Field pictures of a relatively docile Smoke Creek (20), and the east/west portion of the Smoke Creek Valley (21) characterize the terrain traversed. The reddish colored rocks in the second photo bear further investigation. In no other location were these outcrops that color.

MAGNETIC SURVEY

Magnetic Susceptibility

Although background Soil Gas and Head Gas samples were taken in June, 2001 around the SC Mag, the data was not evaluated until the fall of 2001. Thus we will first examine the results of the Magnetic Susceptibility (MS) reconnaissance, which followed established roads and trails outlined by the sample sites plotted on Map Figure 23. The

next 25 Map Figures plot the MS data profiles, which are shown in order of start (left) to finish (right). Compass directions reverse according to the day's direction of travel. Line labels correspond to the Roosevelt County Road numbers: N-S roads begin with a "2", and display in the last two digits, the distance from North Dakota, while E-W roads begin with a "1", and record the distance from Canada, in the last two digits. As mentioned in the Experimental Procedures, MS values have relative, and not, absolute significance. Table 1a in Appendix 1 lists all the sample locations while Table 1b, Appendix 2, lists all the MS and magnetic readings. Each profile has an index map.

First, specific observations on the MS Profiles (all locations in reference to nine township study area enclosing the SC Mag Anomaly Core):

- Line 133 (Fig. 28) – Noticeable MS increase in, and along, NW perimeter of SC Mag.
- Line 134 (Fig. 28) – Same increase noted.
- Line 139 (Fig. 33) – MS increase in west core area.
- Line 113 (Fig. 35) – 4 high MS areas and 3 low MS areas on west edge of survey area outside SC Mag core. Considerable "background" area variation noted.
- Line 230 (Fig. 37) – Strong MS peak in Northwest, high at NW perimeter of SC Mag.
- Line 235 (Fig. 38) – Peaks NW & NE of SC Mag, and within core area.
- Line 236 (Fig. 39) – MS peak east of SC Mag
- Line 237 (Fig. 41) – Higher MS values near east perimeter of SC Mag.
- Line 238 (Fig. 42) – Similar to Line 237.
- Line 241 (Fig. 46) – MS lows near SW perimeter, but highs across south central core.

In general there appears to be relatively higher MS values on the northeast and east perimeter of the SC Mag core. The southwest part of the core also had areas of higher MS values. The most significant increases in MS values, however, were found in the northwest part of the study area, outside the SC Mag anomaly.

The last three survey lines recorded noticeably lower MS values (Lines 134, 236, 240). This was caused by the loss of the protective rubber tip on the MS probe. Map Figure 50 graphs the tie point values of the earlier surveys above the "tip-less" probe values. The ratio of the two profiles is also plotted. The tip-less probe values were multiplied by the ratios, which served as correction factors.

Map Figure 51 is a contour map of all MS values. The core area has lower values with the hint of higher values near the perimeter. The complexity of the contour pattern warrants further investigation to determine whether MS values correspond to the tonal anomalies (curvilinear "bubbles"). Two significant "highs" plot in the northwest and east, with one minor "high" in the south central core. The two outside anomalous areas are well displayed in Map Figure 52, which plots MS values as a ratio to a defined anomaly value of 1.5 times the mean.

Field Magnetics

Field magnetic readings for Lines 134, 236, and 240 were collected to record local variations in the magnetic field, which might be attributed to hydrocarbon modified soil mineralization. Map Figures 29, 40, and 45, respectively, plot these profiles. Map Figure 53 combines all three and displays a glaring calculated residual difference for Line 236. By examining the Line 236 tie points with Line 134, a corrected profile comparison was made in Map Figure 54. The sharp peaks of Line 134 and 236 confirm the Smoke Creek Aeromag Anomaly. Line 240 crosses only the southern part of the anomaly and is relatively flatter and undulating. A contour map of the field data is plotted in Map Figure 55 and enforces this observation.

Further utility of both the air mag and field mag data lies in reprocessing the data so as to extract the high frequency data, which is normally removed for basement tectonic interpretations. The high frequency “noise” is in fact most desirable information for a micro-seepage hydrocarbon exploration tool. This line of investigation will hopefully be explored in the next part of the project.

Background Gas Samples

Prior to the MS reconnaissance survey, 36 sites, in eight locations, were sampled around the perimeter of SC Mag in order to establish background data quantities of both Soil Gases and Head Gases. Sampling began in the southwest and proceeded counter clockwise. Because Area 1 encompasses nine townships (324 sq. miles – 843 sq. km, 207,360 acres!) it was beyond the budget of this project to sample the entire area at a meaningful grid spacing. A decision was made to conduct the MS survey as an initial reconnaissance in order to compare the results to the gas background samples and to identify potential anomalies for further soil sampling utilizing the most favorable techniques determined in Phase I.

The Background sample locations are listed in Table 1c (Fig. 56). Soil Gas data is presented in Table 1d (Fig. 57). Unusually high values can surprisingly be seen in Table 1d. This is confirmed by Map Figure 58, which plots C1-C3 Soil Gases. A Methane peak occurs in the southwest, but most noticeable is the strong Soil Gas anomaly in all three gases at Site 26. For a change, the Soil Gas data validity appears quite good, as seen by the linear relationship between Ethane and Propane in this data set.

The Head Gas analyses in Table 1e (Fig. 60) mirror the Soil Gas values. Oddly, some samples returned no Head Gas values from the lab, however the southwest “Background” and again, the northwest (Site 26), display anomalies. In addition, the west Background sites had higher Head Gas levels than expected. See Map Figure 61 for a graphical display of these observations. Data validity is excellent for the Head Gas analyses as seen in the linear relationship plotted in Map Figure 62.

A comparison of Soil Gas and Head Gas values for Methane, Ethane, Propane, and Butane is plotted in shaded area charts for the “Background” sites (Map Figures 63-67).

The best correlation occurs at Site 26. As in Phase I, the Head Gas values are 5-10 times greater than the more direct Soil Gas analyses. A notable exception is Propane and Butane Soil Gas at Site 26. This is the only instance to date where Soil Gases were observed to be greater than Head Gases.

The other indirect indicators, Eh, pH and K are plotted against Head Gas Propane in Map Figures 67-69 respectively. When Eh is lower the Propane is greater, except in sites 30-32. Eh values were divided by 10 to facilitate similar graph scales. PH also appears lower over sites with higher Propane. Again, the western sites do not follow this pattern. Subtracting 7 and multiplying by 20, again for display purposes, enhanced PH variation. K, conductivity, appeared to increase where Propane was higher. The Background sites were too widely spaced to draw any more specific conclusions. K values were modified by a factor of 200 for better display units. These modifications of the indirect indicators, $Eh/10$, $(pH-7) \times 20$, and $K/200$ will be used throughout the remaining Phase II data interpretations.

SITE 26

One of the areas of higher Magnetic Susceptibility in DOE Area 1, Smoke Creek sample site SC-26. Map Figure 72 contours this anomaly in the northwest corner of section 15. Map Figure 73 is a time structure map from the Smoke Creek 3D survey. Site 26 lies at the southeast end on a structural nose that has closure in section 8, 1.5 miles (2.4 km) northwest. A cross-section profile of the data as seen in Map Figure 74 also displays this MS anomaly. Recall that the "Background" Soil and Head Gas data also had sharply higher values here. Entirely by coincidence, and outside the primary area of focus (SC Mag Anomaly), independent sampling identified a potential hydrocarbon seepage prospect. Tables 2a, 2b, 2c (Map Figures 75-77) list the sample locations, gas data, and non-gas data, respectively. Soil and Head Gas analyses are graphed in Map Figures 78-79. Among the highest Soil Gas Propane and Butane are found here. The Head Gas Methane values were so large that a log scale had to be used. The first map for Soil Gas Methane (Fig. 80) plots the sample grid for Site 26. In the NW/4 samples were collected on offsetting 330 ft, (101 m) spacing. This is the densest grid employed to date in the project. Map Figures 80-84 plot Soil Gases while Map Figures 85-89 display Head Gases. All show elevated light hydrocarbon gases. The Soil Gas anomalies stretch in a bimodal closure across the north half of Section 15 while the Head Gas closures trend more to the west. No data was collected within the northeast quarter of Section 16 so contour shading there is extrapolated from the section lines.

The Non-Gas techniques applied to Site 26 include: Eh, pH, K, Microbial, and Iodine. The following relationships were observed:

- 1) Eh was not depressed over the gas anomalies, but was low in the southwest of Sec. 15.
- 2) PH contours crudely rim the gas anomalies but not enough background data was present to determine whether the anomaly core was also higher in pH.

- 3) The color scheme on the Conductivity Map is confusing. Higher k values do surround the gas anomaly area (NW/4) thus creating a halo as required by the theoretical basis model.
- 4) Microbial “highs” correlate well to the Head Gas “highs”. There is also an apparent halo around the NW/4.
- 5) Iodine anomalies are present both over and south of the NW/4.

For comparison purposes, the commercial vendor’s color fill maps are included for Methane, pH, and K (Figs. 95-97). The Soil Gas validity checks out well in 1a Map Figure 98 and the Head Gas data validity is excellent, as graphed in Map Figure 99. Soil Gas and Head Gas Propane values for Site 26 are graphed in Map Figure 100. As noted in the Background data section, the highs and lows approximate each other, but there is sometimes an offset of one sample site. Three, scale exaggerated N/S profiles for Propane, are found in Map Figures 101-103. The apparent data shift is obvious and cannot be explained at this time. Both detection methods found relatively higher gas concentrations in the soil, but not necessarily at the same locations. Profile 1 sites were also plotted as comparisons between Head Gas Propane (C₃) and Eh (Fig. 104), pH (Fig. 105), K (Fig. 106), Microbial Values (Fig. 107), and Iodine (Fig. 108). Note that the Head Gas peak is over site #25, not 26. Eh does not correlate as well as it did in the Phase I study areas (6 & 7). PH appears to border the C₃ peak in Fig. 105. As observed on the maps, conductivity best correlates to C₃ in Fig. 106. It should be a halo relationship. Microbial values appear antithetic to C₃ values in the profile on Map Figure 108. They are thus effectively halo patterns, something not observed in Phase I data sets. Iodine values only partially correlate to C₃ in the entire Site 26 data set. (Fig. 109). There is no correlation between Iodine and C₃ in the N/S Profile 1 (Fig. 110).

SC Core

In the south central part of the SC Mag core area, a small Magnetic Susceptibility anomaly was detected (See Map Figures 54 and 55). Because this area contained a high concentration of curvilinear “bubbles”, it was selected for a soil sampling profile, and named SC Core. Tables 3a (GPS locations, Fig. 111), Tables 3b (Gas data, Fig. 112), and Table 3c (Non-gas data, Fig. 113) list the SC Core data. Head Gas values are noticeably lower when compared to the Soil Gas values in this area. This is not the normal relationship. Map Figure 114 indicates that the Soil Gas data is suspect. In fact, several sites were re-sampled at a later date in order to check the data validity. As usual, the Head Gas data validity is excellent (Fig. 115). Head Gas Propane does increase in three parts of the 3-mile (4.8 km) traverse (see Fig. 116). Soil Gas Propane does not correlate very well with the Head Gas values. Map Figure 117 displays poor gas correlation to the Magnetic Susceptibility data, which of course, prompted the selection of this prospect area in the first place. The only exception is sample site SC-625.

In the western part of the SC core profile (right side of Map Figure 118) Iodine values trace MS values nicely, but Microbial values appear to be antithetic. Because of the data validity question regarding the Soil Gas data, only Head Gas Propane was plotted vs. the three non-gas techniques: Mag-Sus, Microbes, and Iodine. Eh, pH, and K had no

apparent utility in this profile. The MS correlation to Head Gas C₃ is only good at SC-625 as already mentioned (see also Fig. 119). Microbial values generally track similar to Propane in Map Figure 120, except at SC-625. Iodine only sometimes correlates to Propane in the graph on Map Figure 121. No maps were made due to insufficient data points.

LOBO WEST

The strongest MS anomaly mapped in the Smoke Creek, DOE Area 1, was found in the northeast, and outside SC Mag. Because this area lies 1-3 miles (1.6 – 4.8 km) west of the abandoned Lobo Oil Field, it was named the Lobo West Prospect Area. An east to west sample traverse was conducted to sample soils for the same methods employed at Site 26 and SC Core. GPS data collection is listed on Table 4a (Fig. 122). Head Gas and Soil Gas data are presented in Table 4b (Fig. 123), while non-gas data can be found on Table 4c (Fig. 124). Unlike the SC Core profile, samples for Lobo West were collected at a closer spacing. Therefore the data points do not exactly correspond to those for the MS survey.

In a disturbing reoccurrence, the Soil Gas Data validity was again poor here (Fig. 125). However Head Gas data remains valid (Fig. 126). The Propane comparison on Map Figure 127 is probably meaningless when the previous two sentences are considered. Head Gas values are disappointingly low in the Lobo West profile. When compared to the “Bugs” in Map Figure 128 an inverse relationship is once again observed. Whether this is significant in an area of such low gas values is debatable. Iodine appears to track the Propane data quite well (see Fig. 129).

Two profiles were constructed in order to compare Head Gas Propane values to Magnetic Susceptibility. The first, Map Figure 130, approximates an overlap of the two data sets sample sites. There is good correlation along Profile 1 for Propane and MS. Even better correlation is displayed in Profile 2 (Fig. 131), which attempted to match which MS survey points were located next to which Head Gas sample sites.

Again, as with the SC Core area, not enough samples were collected to warrant any maps for Lobo West.

POPLAR WEST

With no other identified leads in the Smoke Creek Area, and the field season ending, a decision was made to run a quick reconnaissance survey in the Northwest Poplar Oil Field. The survey was designed to search primarily for Methane gas seepage on Tribal lands above a Cretaceous structural closure, where Judith River sandstone reservoir parameters and gas shows were good. Map Figure 132 contours that closure in the Eagle Formation, which is also a shallow gas target. Both the Judith River and Eagle formations produce significant amounts of gas in north-central and southeastern Montana. Williston Basin wells, and exploration plays, have almost completely ignored shallow gas in search of deeper Paleozoic oil. Since 1985, the Fort Peck Tribes have

encouraged shallow gas exploration is their KGAS Project. Eight unsuccessful tests were drilled in the mid-90's, and the play awaits new partners. Seismic acquisition is too expensive in a shallow gas play, so any surface exploration technique that could detect Methane seepage, would be extremely valuable to the Tribes.

The Judith River Net Sandstone thickness is mapped on Map Figure 133. Note that both a structural high, and a sandstone reservoir buildup, occur in the west central part of the township where the Tribes also own mineral rights. The structural closure is significant because it is peculiar to the higher Cretaceous time and not found in the Mississippian rocks, which produce the Poplar Dome oil. Excellent Judith River tests discovered gas in the adjacent township to the east, over the prolific East Poplar Oil Field.

Two data collection profiles were done in this area, named Poplar West. Map Figure 134 plots the 22 locations, while Tables a-c list the GPS data (Fig. 135), Gas analyses (Fig. 136), and Non-Gas analyses (Fig. 137). Not enough of a grid was sampled to construct valid contour maps, but all the data for each method is displayed by graduated color symbols according to the relative value. See Map Figures 138-142 for Soil Gas, 143-147 for Head Gas, 148 – Eh, 149-pH, 150-K, 151 – stacked parameters. High Soil Gas Methane values were found in the west and south parts of Poplar West. From the previous mapping, it was thought that the SW/4 of section 20 was the best prospect. The higher Methane values to the west and south may mean the prospect is larger than originally thought. An extremely high Head Gas Methane analysis was recorded in the SW/4 of sec. 20 however. Variation in other gases in Poplar West may be due to the oil production, which is present in the area, as seen on Map Figure 132. The conductivity halo in Map Figure 150 surrounds the SW/4 of section 20 where the high Head Gas Methane value was found.

The stacked parameters map (Fig. 151) is a standard package display from the vendor combining gas and non-gas parameters. As with most of the Area 1 data, the Soil Gas validity is poor (see Map Figure 152). The east/west profile comparison of the two Methane values has a poor correlation in the west, but is better in the east (Profile 1, Fig. 153). In Profile 2, the north/south comparison (Fig. 154), there is not very good correlation between Soil Gas and Head Gas. No obvious correlation between either Microbes (Fig. #155) or Iodine (Fig. #156) and Head Gas Methane can be established. Map Figures 157 and 158 are a complex comparison of Methane values for the two gas methods vs. Eh, pH, and K along the two profiles. Eh appears to drop when the Methane peaks, which is according to the model.

CONCLUSION

The application of surface hydrocarbon exploration techniques in DOE Area 1 focused on a reconnaissance survey utilizing micro-magnetic methods in, and around, the giant Smoke Creek Aeromagnetic Anomaly (SC Mag). Three positive Magnetic Susceptibility areas were mapped and then sampled in greater detail using the other selected methods. Purely by coincidence, one of the background soil sample areas also had positive gas indicators. This prospect, named Site 26, lies on the flank of a 3D seismic structural nose. Unfortunately, this hydrocarbon seepage area does not lie up structure on top of a closure as did the Phase I, Area 6 prospect. The high Soil Gas Butane and Propane values were unusual and encouraging.

Magnetic Susceptibility values appear to increase near the northeast perimeter of the SC Mag. There are local anomalies in MS data within the SC Mag, but more detailed examination is required to evaluate if they correlate to the curvilinears. Potential exists for the filtering of high frequency magnetic data from both the field survey conducted in this study as well as from the commercial aeromag survey acquired earlier by the Tribes. This will be done in next six months. In addition the author is awaiting Mr. Land's observations and interpretations, which undoubtedly will present better utilization of the micro-magnetic tools.

In general, Soil Gas values do not correlate well with Head Gas values. This was also observed in Phase I for Areas 6 and 7. Soil Gas data checked out as valid in the background samples and in the Site 26 samples, but a scattered plot of Ethane vs. Propane in the SC Core, Lobo West, and Poplar West areas questions the validity of this method. Head Gas data always appears to be statistically valid in all data sets. Methane analyses are an enigma however, randomly appearing as very high values independent of the other light gases. These should be used with caution in shallow gas exploration since there may be other environmental reasons for Methane accumulations.

When compared to Head Gas, Eh usually decreases as the gases increase. PH also follows this trend, but a higher halo was not usually observed as the model predicts. Microbial values rise in areas of higher Head Gas, but more often as halos or increases in adjacent samples. Iodine often correlates well with higher Head Gases, but the relationship is not consistent.

The data collected in the SC Mag south central core area (SC Core) did not confirm hydrocarbon seepage nor correlate to curvilinears. Additional tonal anomalies must be examined to determine whether they are hydrocarbon micro-seepage chimneys. Additional soil sampling may be necessary to statistically populate a meaningful evaluation.

The third area of higher MS values, Lobo West, appears to have little hydrocarbon potential. The reason for the MS anomaly is not apparent.

The Poplar West area displayed some high Methane values, but not necessarily over the mapped structural closure or prime reservoir area. Further sampling on a denser and more expansive grid is necessary to decide whether these techniques can be applied to the Tribes KGAS Project.

Table 6 summarizes the conclusions for Phase II of this project.
Recommendations for the final six months of activity are also listed there.

North Arrow

Scale bar: 0, 660, 1320, 1980, 2640 ft

Map Scale: 1:17020

The map displays several wells (represented by circles with crosshairs) and numerous data points (represented by triangles). Contours of head gas methane concentration are shown as dashed lines with numerical labels: 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 110, 120, 130, 140, 150, 160, 170, 180, 190, 200, 210, 220, 230, 240, 250, 260, 270, 280, 290, 300, 310, 320, 330, 340, 350, 360, 370, 380, 390, 400, 410, 420, 430, 440, 450, 460, 470, 480, 490, 500, 510, 520, 530, 540, 550, 560, 570, 580, 590, 600, 610, 620, 630, 640, 650, 660, 670, 680, 690, 700, 710, 720, 730, 740, 750, 760, 770, 780, 790, 800, 810, 820, 830, 840, 850, 860, 870, 880, 890, 900, 910, 920, 930, 940, 950, 960, 970, 980, 990, 1000.

Methane Gas & Eh, pH, and K Poplar West, S-N Profile

PHASE II CONCLUSIONS & RECOMMENDATIONS

- Magnetic Susceptibility survey of Area 1 found three prospects.
- One already had gas anomalies.
- Site 26 was confirmed as an excellent hydrocarbon prospect.
- SC Mag Core not confirmed.
- SC Mag Core “bubbles” not confirmed.
- Lobo West MS anomaly not confirmed as H/C bearing.
- Poplar West Shallow Gas Prospect inconclusive.
- Await Mr. Land’s Report
- Filter regular mag data for HF.
- Promote Site 26 as an oil prospect and plan for more updip soil sampling to the NW.
- Correlate other MS data to “bubble” geometries.
- Plot all data as ratios to anomaly threshold ($1.5 \times \text{mean}$)
- Locate other 3D prospects for sampling.
- Re-sample on a better grid.
