TITLE AGING AREA – DESIGN OF A CONCRETE SLAB FOR STORAGE OF SNF AND HLW CASKS			

1.0 Purpose and Scope

This calculation documents the design of the Spent Nuclear Fuel (SNF) and High-Level Waste (HLW) Cask storage slab for the Aging Area. The design is based on the weights of casks that may be stored on the slab, the weights of vehicles that may be used to move the casks, and the layout shown on the sketch for a 1000 Metric Ton of Heavy Metal (MTHM) storage pad on Attachment 2, Sht.1 of the calculation 170-C0C-C000-00100-000-00A (BSC 2004a). The analytical model used herein is based on the storage area for 8 vertical casks. To simplify the model, the storage area of the horizontal concrete modules and their related shield walls is not included. The heavy weights of the vertical storage casks and the tensile forces due to pullout at the anchorages will produce design moments and shear forces that will envelope those that would occur in the storage area of the horizontal modules. The design loadings will also include snow and live loads. In addition, the design will also reflect pertinent geotechnical data. This calculation will document the preliminary thickness and general reinforcing steel requirements for the slab. This calculation also documents the initial design of the cask anchorage. Other slab details are not developed in this calculation. They will be developed during the final design process. The calculation also does not include the evaluation of the effects of cask drop loads. These will be evaluated in this or another calculation when the exact cask geometry is known.

2.0 Quality Assurance

Table A-2 of the Q-List (BSC 2004b) identifies the Aging Pad as an Important-to-Safety (ITS) system. Consequently, the provisions of the Quality Assurance Requirements and Description (QARD) document (DOE 2004) apply to this calculation. This calculation was developed in accordance with the requirements of procedure AP-3.12Q.

3.0 Design Input

Information on a potential cask transporter is taken from J & R Engineering (2003). The supplemental soil report for the Waste Receiving and Preparation System (BSC 2004f) provides the pertinent geotechnical data. The sketch for a 1000 MHTM storage pad on Attachment 2, Sht.1 of the calculation 170-C0C-C000-00100-000-00A (BSC 2004a) gives the pad layout (reproduced on pg. A).

4.0 Assumptions

1. The transporter is assumed to be unloaded during seismic events. The rationale for this assumption is that for the limited time the transporter is used on the pad, the probability that it would be on the pad and loaded during a seismic event is very low.
2. The design storage cask is assumed to be similar to a HI-STORM 100SA cask only with a maximum weight of 200 tons (vs 180 tons for the HI-STORM 100SA(HOLTEC 2002)), a maximum height of 245 in., a height to the CG of 120 in, and a diameter of 11'-01/2". The rationale for this assumption is to base the pad design on the largest vertical storage cask that might be stored on it (see HOLTEC 2002), with an additional margin on its potential weight.
3. The cask pad is assumed to be founded on alluvium. The rationale for this assumption is that the latest soils report (BSC 2004f) indicates varying soil properties for the different types of soil the pad may be supported by . A soil type should be chosen to permit using appropriate soil properties. Given the

TITLE AGING AREA – DESIGN OF A CONCRETE SLAB FOR STORAGE OF SNF AND HLW CASKS			

large thicknesses of the pad – up to 7 feet – it is reasonable to assume alluvium as the foundation soil. This will be confirmed in final design.

6.0 Design Methodology

The slab is designed as a soil supported two-way slab. Internal moments and shear forces are determined by appropriate analyses using the structural analysis program GT-STRUDL V26 (STN: 10829-26-00), BSC 2003a. The concrete slab is modeled as a large flat plate using plate finite elements. The supporting soil is modeled as a series of non-linear springs. Spring properties are based on data from the Soils Report

CALCULATION SHEET

JOB NO. 24540	CALC. NO. 170-00C-HAP0-00100-000	REV. NO. 00B	SHEET NO. 6
TITLE AGING AREA – DESIGN OF A CONCRETE SLAB FOR STORAGE OF SNF AND HLW CASKS			

(BSC 2004f) to model the stiffness of the supporting soil. Reactions from the stored casks are modeled as nodal point loads acting on the elements corresponding to the storage locations. The wheel loads from the transporter are also modeled as point loads at appropriate nodes of the slab model. Dead loads will include the self-weight of the slab. Earthquake loads will include inertial forces acting on the pad and the casks, based on equivalent static acceleration factors to model the effects of earthquakes.

The design calculations also include the evaluation of overturning and sliding.

Reactions from seismic, wind, and tornado forces acting on the storage casks are used to design an anchorage system for the casks. Standard structural analysis techniques are used to develop the reactions acting on the various components of the anchorage system.

6.1 Acceptance Criteria

Section 4.2.2.4.11 of the Project Design Criteria (PDC) (BSC 2004c) requires foundation designs to meet the requirements of Standard Review Plan (SRP) 3.8.5 of NUREG-0800 (NRC 1987). Subsection II. 3. of SRP 3.8.5 states that loads and load combinations used in the design are acceptable if the requirements of SRP 3.8.4 are satisfied. General structural acceptance criteria are provided in Section II. 5 of SRP 3.8.4.

The ultimate capacities of the concrete components, including embedded components of the anchorage system, are based on the provisions of the ACI-349 code (ACI 2001a). The allowable stresses for the un-embedded steel components of the anchorage system are based on the provisions of the AISC N690 code (ANSI/AISC 1994).

Allowable soil bearing stresses are taken from the soils report (BSC 2004f), and are provided below in subsection 6.4, "Material Properties."

6.2 Loads

The following loads are considered in the design of the slab:

Dead Load (D):

Dead loads are the weights of the permanently attached structures and equipment and include the self-weight of the slab. Since the casks will reside on the aging pad for considerable lengths of time, they will be treated as dead loads. The pad design will be based on storing a number of casks similar to the HI-STORM 100SA (232) (HOLTEC 2002) as modified by Assumption 2. In this design, a fully loaded cask weight of 200 tons is used.

Snow Loads (S):

Per section 6.1.1.1 of the PDC (BSC 2004c), the slab will be designed for a maximum snow depth of 4". The snow load magnitude, based on the provisions of ASCE 7-02, is determined in Section A1.2.

Live Loads (L & Lr):

Live loads are those produced by the use of the facilities. The live loads also include the track loads from the cask transporter. The information in J & R Engineering (2003) gives the total loaded weight of the

CALCULATION SHEET

JOB NO. 24540	CALC. NO. 170-00C-HAP0-00100-000	REV. NO. 00B	SHEET NO. 7
TITLE AGING AREA – DESIGN OF A CONCRETE SLAB FOR STORAGE OF SNF AND HLW CASKS			

transporter as 135000 lbs. Wheel loads for input into the GT-STRUDL model based on these weights are determined in Attachment A. The analysis includes two positions for an unloaded transporter and three positions for a loaded transporter. Live loads also include a uniform load of 150 psf. This represents a conservative estimate of loads due to activities on the slab.

Wind and Tornado Loads (W & Wt)

Per PDC (BSC 2004c) 4.2.2.3.6, wind loads shall be based on an extreme wind velocity of 90 mph., also, per PDC (BSC 2004c) 4.2.2.3.7, tornado loads shall be based on a maximum wind velocity of 189 mph.

Earthquake, or Seismic, Loads (E'):

Paragraph II.B.1.b of Standard Review Plan (SRP) 3.7.2 of NUREG-0800 (NRC 1987) requires a 1.5 factor be applied to the peak acceleration of the applicable floor response spectrum unless a lower value can be justified to model the potential effects of higher modes. For seismic forces acting on the casks, a equivalent static force of 1.5 times the acceleration at 7% damping for its fundamental frequency is used. For the slab, the Zero Period Acceleration (ZPA) represents the peak acceleration and an amplification factor of 1.0 is justified since a slab on grade essentially becomes part of the earth and will not be subjected to the effects of higher modes. Table 6.1.3-1 of the PDC (BSC 2004c) identifies DTN: MO0411SDSTMHIS.006 as the appropriate response spectra for a point located on the soil surface (pt. D in Figure 6.1.3.1 of the PDC), however data from DTN: [MO0402SDSTMHIS.004](#) has been used in this calculation. This is acceptable since the results for 7% damping from the latter DTN envelope those from DTN: MO0411SDSTMHIS.006. DTN MO0402SDSTMHIS.004 provides the horizontal and vertical response spectra accelerations used in this calculation (see sht. A14 of attachment A).

6.3 Load Combinations

Since soil bearing pressures are verified based on unfactored loads, the following unfactored and factored load combinations are considered in the analysis of the slab; these are based on those given in Section 4.2.2.4.5 of the PDC:

<u>Load Combination</u>	<u>Limit</u>
1. D + S + L	Soil ⁽¹⁾
2. D + S + L + W	Soil
3. D + W	Soil
4. 1.4D + 1.7S + 1.7L	U ⁽²⁾
5. 1.4D + 1.7S + 1.7L + 1.7W	U
6. D + L + Wt	U, Soil
7. D + Wt	U, Soil
8. D + L + E'	U, Soil
9. 0.9D + E'	U, Soil

Notes: (1) Soil – allowable soil bearing strength and/or structure stability; see Section 6.4 below.

(2) U – required section strength based on Ultimate Strength Design (USD) using the provisions of ACI 349 (ACI 2001a).

6.5 Computer Software Documentation

The originator used the following computer programs to prepare this calculation; all the software used resides on a Personal Computer:

<u>Program</u> ³	<u>Version</u>	<u>Use</u>	<u>Software Tracking Number</u>
Word ²	97 SR-2	Word Processing	N/A – Commercial Off-the-Shelf Software
Mathcad ²	11.2a	Calculations	N/A – Commercial Off-the-Shelf Software
GT-STRUDL ¹	26	Finite Element Analysis	10829-26-00

Notes:

- DOE 2003, and its associated verification test report, document the validation of version 26 of GT-STRUDL. The validation included finite element (use of plate elements) and static non-linear analysis (nonlinear springs) problems applicable to the analysis documented in this calculation. Thus, version 26 is valid, qualified software for the performance of this analysis.
- Microsoft Word, Mathcad are exempted from the qualification and documentation requirements of LP-SI.11Q-BSC, Software Management.
-
- The software is operated on a PC system using the Windows 2000 operating system.

7.0 Design Calculations

Slab Design for Flexure and Shear:

Design the slab based on the reactions from the GT-STRUDL analysis. The following design values are obtained from the analysis (see Section A3.1 of Attachment A). They are enveloped reactions from Load Combinations 4 through 9 given in Section 6.3 of this calculation:

SNF Cask Storage Area:

M_{xx+} , Positive Design Moment (tension in the bottom of the slab; "max" moments from the model) = 1845 ft-kip/ft

M_{xx-} , Negative Design Moment (tension in the top of the slab; "min" (or negative) moments from the model)
= -78 ft-kip/ft (since the resulting negative moments on pg. A40 have similar magnitudes and signs as the positive design moments, when they should have negative signs and different magnitudes, indicates that there is little tension in the top of the slab; for design (of the reinforcing in the top of the slab), however use the same value as used for the minimum M_{yy} moment as the moments can be dependent on the position of the transporter.)

M_{yy+} , Positive Design Moment = 400 ft-kip/ft

M_{yy-} , Negative Design Moment = -78 ft-kip/ft (see note above for M_{xx-})

V_{xx} , Design Shear (can be based on the + or - shear) = 56 kip/ft

V_{yy} , Design Shear (can be based on the + or - shear) = 54 kip/ft

Inner Apron Area at the sides of the SNF Cask Storage Areas:

M_{xx+} , Positive Design Moment = 1600 ft-kip/ft

M_{xx-} , Negative Design Moment = -50 ft-kip/ft

M_{yy+} , Positive Design Moment = 360 ft-kip/ft

M_{yy-} , Negative Design Moment = -50 ft-kip/ft (use the same value as M_{xx-})

V_{xx} , Design Shear (can be based on the + or - shear) = 64 kip/ft

V_{yy} , Design Shear (can be based on the + or - shear) = 45 kip/ft

AGING AREA - DESIGN OF A CONCRETE
SLAB FOR STORAGE OF SNF AND HLW
CASKS

REV. NO. 00B
SHT NO. //

Outer (Sides and Top) Areas:

M_{xx+} , Positive Design Moment = 600 ft-kip/ft

M_{xx-} , Negative Design Moment = -50 ft-kip/ft (see above note for M_{xx+} for the SNF Cask storage area)

M_{yy+} , Positive Design Moment = 160 ft-kip/ft

M_{yy-} , Negative Design Moment = -60 ft-kip/ft (see above note for M_{xx+} for the SNF Cask storage area)

V_{xx} , Design Shear (can be based on the + or - shear) = 32 kip/ft

V_{yy} , Design Shear (can be based on the + or - shear) = 30 kip/ft

SNF Cask Storage Area:

Design the slab starting with a seven feet thick slab as analyzed in the GT-STRUDL model, thus:

$$h := 7.0 \cdot \text{ft} \qquad b := 12 \cdot \frac{\text{in}}{\text{ft}} \quad (\text{unit width of slab})$$

$$d_{7\text{top}} := h - \left(2.0 \cdot \text{in} + \frac{0.87500 \cdot \text{in}}{2} \right) \quad d_{7\text{top}} = 6.797 \text{ ft} \quad \text{based on one layer of \#7 bars}$$

$$d_{7\text{bot}} := h - \left(3.0 \cdot \text{in} + \frac{1.410 \cdot \text{in}}{2} \right) \quad d_{7\text{bot}} = 6.691 \text{ ft} \quad \text{based on one layer of \#11 bars}$$

$$d := \min(d_{7\text{bot}}, d_{7\text{top}}) \quad d = 6.691 \text{ ft}$$

$$h_3 := 3.0 \cdot \text{ft} \quad d_{3\text{top}} := h_3 - \left(2.0 \cdot \text{in} + \frac{0.87500 \cdot \text{in}}{2} \right) \quad d_{3\text{top}} = 33.563 \text{ in} \quad \text{based on one layer of \#7 bars}$$

$$d_{3\text{bot}} := h_3 - \left(3 \cdot \text{in} + \frac{1.27 \cdot \text{in}}{2} \right) \quad d_{3\text{bot}} = 32.365 \text{ in} \quad \text{based on one layer of \#10 bars}$$

$$d_3 := \min(d_{3\text{bot}}, d_{3\text{top}}) \quad d_3 = 2.697 \text{ ft}$$

Determine the minimum amount of reinforcing required by shrinkage and temperature forces.

Use the subgrade drag equation as given in section 6.3 of ACI 360 (ACI 2001b).

$F := 0.55$ Use coefficient of interface reaction as given in section 6.4 of this calculation.

$L := 52 \cdot \text{ft}$ Length between expansion joints; use the length of a storage area for 8 casks.

$w := w_c \cdot h$ $w = 1.05 \times 10^3 \text{ psf}$ Weight per area of slab.

$w_3 := w_c \cdot h_3$ $w_3 = 450 \text{ psf}$

$f_y := 60000 \cdot \text{psi}$ Yield strength of reinforcing steel per section 6.4 of this calculation.

$$f_s := \left(\frac{2}{3}\right) \cdot f_y \quad f_s = 40000 \text{ psi} \quad \text{Estimated actual stress in the reinforcing steel; see section 6.3 of ACI 360 (ACI 2001b).}$$

$$A_s := \frac{(F \cdot L \cdot w)}{2 \cdot f_s} \quad A_s = 0.375 \frac{\text{in}^2}{\text{ft}} \quad \text{Required area of reinforcing steel per formula 6.3 of ACI 360 (ACI 2001b)}$$

$$A_{s3} := \frac{(F \cdot L \cdot w_3)}{2 \cdot f_s} \quad A_{s3} = 0.161 \frac{\text{in}^2}{\text{ft}}$$

Use #6 @ 12 in. oc to provide $0.44 \text{ in}^2 \times (12 \text{ in}/\text{ft}/12 \text{ in}) = 0.44 \text{ in}^2/\text{ft}$ for the 7 ft. thick areas and #4 bars at 12 in oc to provide $0.20 \text{ in}^2/\text{ft}$ for the 3 ft. slabs (see Table A-1, Appendix A of MacGregor (MacGregor 1997) for the area of a bar). Based on this, $\rho_{\min}$ is calculated as:

$$\rho_{\min 7a} := \frac{(0.44 \cdot \text{in}^2) \cdot \frac{12 \cdot \frac{\text{in}}{\text{ft}}}{12 \cdot \text{in}}}{b \cdot d} \quad \rho_{\min 7a} = 0.000457$$

$$\rho_{\min 3a} := \frac{(0.20 \cdot \text{in}^2) \cdot \frac{12 \cdot \frac{\text{in}}{\text{ft}}}{12 \cdot \text{in}}}{b \cdot d_3} \quad \rho_{\min 3a} = 0.000515$$

Evaluate Minimum Reinforcement Requirements per the ACI 349 Code:

Evaluate minimum reinforcement requirements per sections 7.12.2, 7.12.3, and 7.12.5 of ACI 349 (ACI 2001a); concrete cover requirements are taken from Section 7.7.1 of ACI 349; reinforcing steel bar areas and diameters are taken from Table A-1, Appendix A of MacGregor (MacGregor 1997):

7 feet thick SNF Storage Pad Area and Inner Apron Area:

Check top reinforcement - #6 @ 12" (min. bar required per 7.12.3 is #6):

$$f_{tc} := 7.5 \sqrt{f_c \cdot \text{psi}^{-1}} \cdot \text{psi} \quad f_{tc} = 530.33 \text{ psi} \quad \text{Tensile strength of concrete; use modulus of rupture as computed by formula 9-9 of ACI 349 (ACI 2001a).}$$

$$f_s := 0.60 \cdot f_y \quad f_s = 36000 \text{ psi} \quad \text{Stress in reinforcement; take as 60% of the yield strength per Section 7.12.3 of ACI 349 (ACI 2001a).}$$

$$c := 2.00 \cdot \text{in} \quad \text{Concrete cover for concrete exposed to weather per Section 7.7.1 of ACI 349 (ACI 2001a) (used minimum required cover for a #6 bar):}$$

$s := 12 \cdot \text{in}$ Spacing of bars.

$$A := 2 \cdot \left[c + \frac{(0.75 \cdot \text{in})}{2} \right] \cdot s \quad A = 57 \text{ in}^2$$

Effective tensile area of concrete associated with the bars; see definition in Section 7.0 of ACI 349 (ACI 2001a) (based on a #6 bar with 2" cover).

$$\text{use: } A_{smin} := \min \left[\left[\frac{(f_{tc} \cdot A)}{f_s} \right], \frac{A}{100} \right] \quad A_{smin} = 0.57 \text{ in}^2 \quad \text{See Section 7.12.3 of ACI 349 (ACI 2001a)}$$

$$A_{sprov} := 0.44 \cdot \text{in}^2 < A_{smin} = 0.57 \text{ in}^2 \quad \text{NG}$$

Try #7@12" oc:

$$A_{sprov} := 0.60 \cdot \text{in}^2 \quad (\text{bar area provided within a concrete tensile area that is based on a 12" spacing of the bars})$$

OK; this also satisfies the requirement for at least #6 bars as the minimum bar size for concrete sections in Section 7.12.3 of ACI 349 (ACI 2001a).

Check bottom reinforcement (tensile face) - #10@10" oc

$$\rho_{min} := 0.0018 \quad \text{Min. ratio per Section 7.12.5, ACI 349 (ACI 2001a).}$$

$$d_{10bot} := 7 \cdot \text{ft} - \left[3 \cdot \text{in} + \left(\frac{1.27 \cdot \text{in}}{2} \right) \right] \quad d_{10bot} = 80.365 \text{ in}$$

$$\rho_{prov} := \frac{1.27 \cdot \text{in}^2 \cdot 12 \cdot \frac{\text{in}}{\text{ft}}}{10 \cdot \text{in} \cdot b \cdot d_{10bot}} \quad \rho_{prov} = 0.00158 < \rho_{min} = 0.0018 \quad \text{NG}$$

Try #10@8" oc.

$$\rho_{prov} := \frac{1.27 \cdot \text{in}^2 \cdot 12 \cdot \frac{\text{in}}{\text{ft}}}{8 \cdot \text{in} \cdot b \cdot d_{10bot}} \quad \rho_{prov} = 0.001975 > \rho_{min} = 0.0018 \quad \text{OK, Governs}$$

Summary for Flexure and Shear:

All areas meet shear and flexure requirements. As documented in the preceding calculations, the reinforcing scheme depends on the area of the Aging Pad. The figure below presents a summary of this scheme.

Soil Bearing Stresses and Stability:

Soil bearing is investigated by dividing the maximum spring reactions in the y direction by the plate element area associated with that spring type as used in Section A1.1 in developing the spring stiffness curves. This is performed below:

Service Loads:

$$R_{bs} := 27.36 \cdot \text{kip}$$

Spring Element 11347, load combination COMBS10 - D + Sn + L(loaded 1) + Wx, from pg. A47 Section A3.0 of this calculation.

$$B := \sqrt{\frac{(B_{2a} \cdot B_{2b})}{200}}$$

Spring Element 11347 is at the lower edge of the inner apron area, as determined on pg. A10 of Section A1.1 of this calculation.

$$B = 4.015 \text{ ft}$$

$$A_s := \frac{B^2}{2} \quad A_s = 8.06 \text{ ft}^2 \quad 1/2 \text{ the area used since element 11347 is at the lower edge.}$$

$$f_{bs} := \frac{R_{bs}}{A_s} \quad f_{bs} = 3.395 \text{ ksf} < f_{ball} := 7.9 \cdot \text{ksf} \quad \text{OK, allowable bearing pressure from Section 6.4 of this calculation.}$$

Extreme, or ultimate, load cases:

$$R_{bu} := 37.48 \cdot \text{kip}$$

Spring Element 11347, Load COMBU13 - D + L(loaded 2) + 0.4EQX + EQY(down) + 0.4EQZ, from pg. A48 of Section A3.0 of this calculation.

$$f_{bu} := \frac{R_{bu}}{A_s} \quad f_{bu} = 4.65 \text{ ksf} < f_{ballu} := 7.9 \cdot \text{ksi}$$

OK, allowable bearing pressure from Section 6.4 of this calculation.

Sliding:

The factor of safety for sliding is determined by first multiplying the total reaction due to the dead weight, minus the upward seismic force, by the coefficient of soil friction, μ , (the max lateral resistance of the soil) and dividing this by the applied lateral load. This is compared to the allowable values given in Section II.5 of SRP 3.8.5 of NUREG 0800. These are 1.5 for Service Loads and 1.1 for Extreme Loads. Looking at the results for the summation of reactions on pgs. A48 of Section A3.0 of this calculation shows the extreme load cases govern, thus only they are evaluated below. The results for the extreme cases show that cases COMBU20, 0.9D + EQX + 0.4EQY(up) + 0.4EQZ, COMBU21, 0.9D + 0.4EQX + 0.4EQY(up) + EQZ, and COMBU22, 0.9D + 0.4EQX + EQY(up) + 0.4EQZ are critical. These are evaluated below:

COMBU20:

$\mu := 0.81$ Coefficient of soil friction; see Section 6.4 of this calculation.

$$FS := \frac{\mu \cdot 7047}{\sqrt{(7115^2 + 3030^2)}} \quad FS = 0.738 < FS_{all} := 1.1$$

COMBU21:

$$FS := \frac{\mu \cdot 6713}{\sqrt{(2846^2 + 7576^2)}} \quad FS = 0.672 < FS_{all} := 1.1$$

The lateral forces for these load combinations may violate the stability requirements (these calculations are very conservative as they do not include the effects of passive soil pressures action on the sides of the pad are ignored). To confirm stability, therefore, evaluate the potential sliding displacements. See the discussion below.

COMBU22:

$$FS := \frac{\mu \cdot 3879}{\sqrt{(2846^2 + 3030^2)}} \quad FS = 0.756 < FS_{all} := 1.1$$

Evaluate Potential Sliding Utilizing the Rigid Body Approach:

Utilize the procedures for analysis of the sliding of rigid bodies in Appendix B of the Seismic Analysis and Design Approach Document (BSC 2004d) to determine the potential sliding displacements.

$$\mu_e := \mu \cdot (1 - 0.4 \cdot \alpha_V) \quad \mu_e = 0.577 \quad \text{Effective coefficient of friction per Eq. B.2-1 of BSC 2004d}$$

$$c_s := 2 \cdot \mu_e \cdot g \quad c_s = 37.111 \frac{\text{ft}}{\text{sec}^2} \quad \text{Sliding coefficient per Eq. B.2-4 of BSC 2004d}$$

$$SA_{VH} = (1.16 \cdot SA_H^2)^{0.5} \quad SA_{VH} = 1.077 \cdot SA_H$$

$$SA_{VH} = c_s$$

Determination of the vectral horizontal spectral acceleration from Eq. B2.8 of BSC 2004b when both horizontal 7% damped spectral accelerations, SA_H , are the same.

$$\text{Therefore, } SA_H := \frac{c_s}{1.077} \quad SA_H = 34.458 \frac{\text{ft}}{\text{sec}^2} \quad SA_H = 1.071 g$$

Extrapolating in the table for the Horizontal Spectra in MO0402SDSTMHIS.004 gives the following period:

CALC. NO.
170-00C-HAP0-00100-000
AGING AREA - DESIGN OF A CONCRETE
SLAB FOR STORAGE OF SNF AND HLW
CASKS

REV. NO. 00B
SHT NO. 23

$$T := 0.050 \text{ sec} + \left(\frac{1.0710 - 1.0399}{1.0854 - 1.0399} \right) \cdot 0.01 \cdot \text{sec} \quad T = 0.0568 \text{ sec}$$

$$f_{es} := \frac{1}{T} \quad f_{es} = 17.595 \text{ Hz}$$

Per Appendix B2 of BSC 2004d, f_{es} is the effective frequency of the equivalent sliding system of the rigid body; it is equal to the lowest natural frequency at which the 7% damped vector spectral acceleration SA_{VH} equals c_s .

$$\text{Therefore, } \delta_s := \frac{c_s}{(2 \cdot \pi \cdot f_{es})^2} \quad \delta_s = 0.036 \text{ in}$$

See Eq. B2-7 of BSC 2004d. **This is a very low displacement. The slab will be stable with respect to sliding.**

Overturning:

The pad is stable with respect to overturning because the resulting soil pressures are so low, and these are based on a model that includes the overturning moments.

8.0 Conclusions

Summary for Flexure and Shear:

All areas meet the design shear and flexure requirements. The design and analytical results are reasonable for their intended use considering the high loads the slab is designed to. They are suitable for their intended use, namely the design of a large slab on grade for use as a storage area for SNF and HLW storage casks. Reinforcing bar spacings and sizes will be optimized during final design to facilitate construction. As documented in the calculations, the reinforcing scheme depends on the different regions of the Aging Pad. The figure below presents a summary of this scheme.

PAD REINFORCING LAYOUT

CALCULATION SHEET

JOB NO. 24540	CALC. NO. 170-00C-HAP0-00100-000	REV. NO. 00B	SHEET NO. 25
TITLE AGING AREA – DESIGN OF A CONCRETE SLAB FOR STORAGE OF SNF AND HLW CASKS			

Soil Bearing Stresses and Stability:

Soil bearing stresses are well below the allowable values. The aging pad should not experience overturning or soil failures.

Stability with respect to sliding is acceptable as well. Even though the sliding safety of factor of 1.1 for earthquake loads is not met, an evaluation of sliding using a rigid body analysis shows the pad would only move about 0.036 inches, which indicates that sliding is negligible and won't adversely affect the structural performance of the aging pad. Also, in the evaluation of sliding, the effects of passive soil pressures acting at the edges of the slabs are not considered. These effects would provide more resistance to sliding than has been utilized in this calculation.

The results of the soil bearing stress and stability evaluations are reasonable compared to the size of the slab being designed and the high loads to which it is designed. They are suitable for their intended use, namely the design and evaluation of a large slab for the storage of SNF and HLW storage casks.

A 1.1 Input Parameters to the GT-STRUDL Model

Determine Input Parameters for the GT-STRUDL Model:

The base slab is modeled as a plate structure that is 150 ft. wide and 74.5 ft. long. The model simulates the storage area for 8 storage casks.

Set the Origin of Matrices to 1,1:

ORIGIN := 1

Define Non-Standard Units:

$$\text{kip} := 1000 \cdot \text{lbf} \quad \text{ksi} := \frac{\text{kip}}{\text{in}^2} \quad \text{ksf} := \frac{\text{kip}}{\text{ft}^2} \quad \text{TON} := 2 \cdot \text{kip}$$

$$\text{pcf} := \frac{\text{lbf}}{\text{ft}^3} \quad \text{psf} := \frac{\text{lbf}}{\text{ft}^2} \quad \text{TSF} := \frac{\text{TON}}{\text{ft}^2} \quad \text{TCF} := \frac{\text{TON}}{\text{ft}^3}$$

Determine concrete material properties for input into GT-STRUDL:

$$f_c := 5000 \cdot \text{psi} \quad w_c := 150 \cdot \text{pcf} \quad \text{Concrete compressive strength and unit weight; see section 6.4 of this calculation.}$$

$$E_c := \left(w_c \cdot \text{pcf}^{-1} \right)^{1.5} \cdot 33 \cdot \sqrt{f_c \cdot (\text{psi}^{-1})} \cdot \text{psi} \quad \text{See section 8.5.1 of ACI 349 (ACI 2001) for Young's Modulus}$$

$$E_c = 4287 \text{ ksi}$$

$$v_c := 0.17 \quad \text{Poisson's ratio; see section 6.4 of this calculation.}$$

$$G_c := \frac{E_c}{2 \cdot (1 + v_c)} \quad G_c = 1832 \text{ ksi} \quad \text{Modulus of Rigidity; see formula 14, pg. 86 of Roark (Young 1989)}$$

SKETCH - LAYOUT FOR 1000 MTHM

Determine the Location of the Nodes in the first quadrant of the mesh in the pad area under the casks; see the figure below:

Basic Grid Spacing

$$\Delta := \frac{13.0}{4} \cdot \text{ft} \quad \Delta = 3.25 \text{ ft}$$

$$\Delta_{in} := 1 \cdot \text{ft} \quad \text{Grid Spacing of Nodes at Center of Cask Storage Area (Nodes 9 - 18 and 21-24)}$$

$$D := \left(11 + \frac{10.5}{12} \right) \cdot \text{ft} \quad \text{Approximate diameter of Cask Anchor Bolt Circle to use in locating nodes 5-8 and 20}$$

$$D = 11.875 \text{ ft}$$

$$B := 13 \cdot \text{ft}$$

$$\text{Mid} := \frac{\left[\left(\frac{D}{2} \right) + 3 \cdot \text{ft} \right]}{2} \quad \text{Mid} = 4.469 \text{ ft}$$

$$\text{Mid2} := \frac{\left[\sqrt{2 \left(\frac{B}{2} \right)^2} + \frac{D}{2} \right]}{2} \quad \text{Mid2} = 7.565 \text{ ft}$$

$$\theta := \frac{(360 \cdot \text{deg})}{24} \quad \theta = 15 \text{ deg}$$

Angle between the horizontal and a radial line through node 4 or the angle between the vertical and a radial line through node 2

$$X_c := 68.5 \cdot \text{ft} \quad \text{Location of the center point of the first cask storage area.}$$

$$Z_c := 29.0 \cdot \text{ft}$$

Once the identification numbers and the coordinates for the nodes and elements in the first quadrant are input into GT-STRUDL, the other nodes and elements in the remaining portions of the cask storage area are generated in GT-STRUDL using successive object copy commands. The nodes and elements in the border areas on either side of the cask storage areas are also generated using standard GT-STRUDL mesh generation techniques and object copy commands. The complete mesh of concrete pad nodes and elements are shown below:

Determine the Soil Spring Stiffnesses:

The supporting soil will be modeled as a set of non-linear springs. The stiffnesses of the vertical springs will be based on the vertical modulus of subgrade reaction and will be linear but will only resist compressive forces. The stiffness of the lateral springs will be based on the horizontal modulus of subgrade reaction. The lateral springs will also be linear, but will resist compressive and tensile forces. Since the loads of concern are due to short term tornado and seismic loads, the moduli will be doubled as mentioned in Section 6.4 of this calculation.

The soil stiffnesses are equal to the moduli of subgrade reaction times the area of the element supported by the springs. To accurately model the soil behavior under bearing loads, the vertical springs must be modeled to resist compressive forces only. This will require both the vertical and horizontal springs to be modeled as non-linear springs. The spring stiffnesses are calculated as follows:

$$k_s := 2 \cdot 1000 \cdot \frac{\text{kip}}{\text{ft}^3}$$

$$k_s = 2000 \frac{\text{kip}}{\text{ft}^3}$$

Modulus of Subgrade Reaction per Section 6.4 of this calculation; use the value for short term loads.

$$\mu := 0.81$$

Coefficient of friction between concrete and soil per Section 6.4 of this calculation.

Vertical Springs:

Spring Elements at the 120 Elements of the 13 ft. by 13 ft. Cask Storage Areas:

$$B_1 := \sqrt{\frac{13 \text{ ft} \cdot 13 \text{ ft}}{120}} \quad B_1 = 1.187 \text{ ft}$$

$$k_{v1} := k_s \cdot \left(\frac{B_1 + 1 \text{ ft}}{2 \cdot B_1} \right)^2 \cdot B_1^2 \quad k_{v1} = 199.2 \frac{\text{kip}}{\text{in}}$$

Modulus of subgrade reaction for a B_1 square footing based on testing using a 1' by 1' plate; see formula 9-4 of Bowles (Bowles 1996).

GT-STRUDL requires Non-Linear Spring data to be input as a set pairs of load vs deflection points. This data is determined below based on the above stiffness:

$$\Delta_{v1a} := 1 \cdot \text{in} \quad P_{v1a} := k_{v1} \cdot \Delta_{v1a} \quad P_{v1a} = 199.2 \text{ kip}$$

$$\Delta_{v1b} := 20 \cdot \text{in} \quad P_{v1b} := k_{v1} \cdot \Delta_{v1b} \quad P_{v1b} = 3984.8 \text{ kip}$$

Spring Elements in left and right aprons (52 ft. by 62 ft area modeled with 200 elements) except at the edges; spring elements at the edges will have 1/2 the stiffnesses of these elements:

$$B_{2a} := 52 \cdot \text{ft} \quad B_{2b} := 62 \cdot \text{ft} \quad mb := \frac{B_{2b}}{B_{2a}}$$

$$k_{v2} := k_s \cdot \left(\frac{mb + 0.5}{1.5 \cdot mb} \right) \cdot \frac{(B_{2a} \cdot B_{2b})}{200} \quad k_{v2} = 2542 \frac{\text{kip}}{\text{in}}$$

Modulus of subgrade reaction for a rectangular footing based on testing using a 1' by 1' plate; see formula 9-5 of Bowles (Bowles 1996).

$$\Delta_{v2a} := 1 \cdot \text{in} \quad P_{v2a} := k_{v2} \cdot \Delta_{v2a} \quad P_{v2a} = 2542.2 \text{ kip} \quad \frac{P_{v2a}}{2} = 1271.1 \text{ kip}$$

$$\Delta_{v2b} := 20 \cdot \text{in} \quad P_{v2b} := k_{v2} \cdot \Delta_{v2b} \quad P_{v2b} = 50844.4 \text{ kip} \quad \frac{P_{v2b}}{2} = 25422.2 \text{ kip}$$

Spring Elements in the top apron (22.5 ft. by 150 ft. area modeled with 168 elements) except at the edges; spring elements at the edge will have 1/2 the stiffnesses of these elements:

$$B_{3a} := 22.5 \cdot \text{ft} \quad B_{3b} := 150 \cdot \text{ft} \quad mb := \frac{B_{3b}}{B_{3a}}$$

$$k_{v3} := k_s \cdot \left(\frac{mb + 0.5}{1.5 \cdot mb} \right) \cdot \frac{B_{3a} \cdot B_{3b}}{168} \quad k_{v3} = 2400 \frac{\text{kip}}{\text{in}}$$

Modulus of subgrade reaction for a rectangular footing based on testing using a 1' by 1' plate; see formula 9-3 of Bowles (Bowles 1996).

$$\Delta_{v3a} := 1 \cdot \text{in} \quad P_{v3a} := k_{v3} \cdot \Delta_{v3a} \quad P_{v3a} = 2399.6 \text{ kip} \quad \frac{P_{v3a}}{2} = 1199.8 \text{ kip}$$

$$\Delta_{v3b} := 20 \cdot \text{in} \quad P_{v3b} := k_{v3} \cdot \Delta_{v3b} \quad P_{v3b} = 47991.1 \text{ kip}^* \quad \frac{P_{v3b}}{2} = 23995.5 \text{ kip}$$

*Note: 4799.1 kip used in the GT-STRUDL model; difference doesn't seriously affect results; deflections are such that reactions are below 2399.6 kip; will leave as is.

Horizontal Springs:

"Modulus of Subgrade Reaction" to use for Horizontal Springs:

$$k_{sh} := 2 \cdot 104 \cdot \frac{\text{kip}}{\text{ft}^3} \quad k_{sh} = 208 \frac{\text{kip}}{\text{ft}^3}$$

Modulus of Subgrade Reaction per Section 6.4 of this calculation; use the value for short term loads.

Spring Elements at the 120 Elements of the 13 ft. by 13 ft. Cask Storage Areas:

$$k_{h1} := k_{sh} \cdot \left(\frac{B_1 + 1 \cdot \text{ft}}{2 \cdot B_1} \right)^2 \cdot B_1^2 \quad k_{h1} = 20.7 \frac{\text{kip}}{\text{in}}$$

Modulus of subgrade reaction for a B_1 square footing based on testing using a 1' by 1' plate; see formula 9-4 of Bowles (Bowles 1996).

GT-STRUDL requires Non-Linear Spring data to be input as a set pairs of load vs deflection points. This data is determined below based on the above stiffness:

$$\Delta_{h1a} := 1 \cdot \text{in} \quad P_{h1a} := k_{h1} \cdot \Delta_{h1a} \quad P_{h1a} = 20.7 \text{ kip}$$

$$\Delta_{h1b} := 20 \cdot \text{in} \quad P_{h1b} := k_{h1} \cdot \Delta_{h1b} \quad P_{h1b} = 414.4 \text{ kip}$$

Spring Elements in left and right aprons (52 ft. by 62 ft area modeled with 200 elements) except at the edges; spring elements at the edges will have 1/2 the stiffnesses of these elements:

$$B_{2a} := 52 \cdot \text{ft} \quad B_{2b} := 62 \cdot \text{ft} \quad mb := \frac{B_{2b}}{B_{2a}}$$

$$k_{h2} := k_{sh} \cdot \left(\frac{mb + 0.5}{1.5 \cdot mb} \right) \cdot \frac{B_{2a} \cdot B_{2b}}{200} \quad k_{h2} = 264 \frac{\text{kip}}{\text{in}}$$

Modulus of subgrade reaction for a rectangular footing based on testing using a 1' by 1' plate; see formula 9-5 of Bowles (Bowles 1996).

$$\Delta_{h2a} := 1 \cdot \text{in} \quad P_{h2a} := k_{h2} \cdot \Delta_{h2a} \quad P_{h2a} = 264.4 \text{ kip}$$

$$\frac{P_{h2a}}{2} = 132.2 \text{ kip}$$

$$\Delta_{h2b} := 20 \cdot \text{in} \quad P_{h2b} := k_{h2} \cdot \Delta_{h2b} \quad P_{h2b} = 5287.8 \text{ kip}$$

$$\frac{P_{h2b}}{2} = 2643.9 \text{ kip}$$

Spring Elements in the top apron (22.5 ft. by 150 ft. area modeled with 168 elements) except at the edges; spring elements at the edge will have 1/2 the stiffnesses of these elements:

$$B_{3a} := 22.5 \cdot \text{ft} \quad B_{3b} := 150 \cdot \text{ft} \quad mb := \frac{B_{3b}}{B_{3a}}$$

$$k_{h3} := k_{sh} \cdot \left(\frac{mb + 0.5}{1.5 \cdot mb} \right) \cdot \frac{(B_{3a} \cdot B_{3b})}{168} \quad k_{h3} = 250 \frac{\text{kip}}{\text{in}}$$

Modulus of subgrade reaction for a rectangular footing based on testing using a 1' by 1' plate; see formula 9-3 of Bowles (Bowles 1996).

$$\Delta_{h3a} := 1 \cdot \text{in} \quad P_{h3a} := k_{h3} \cdot \Delta_{h3a} \quad P_{h3a} = 249.6 \text{ kip}$$

$$\frac{P_{h3a}}{2} = 124.8 \text{ kip}$$

$$\Delta_{h3b} := 20 \cdot \text{in} \quad P_{h3b} := k_{h3} \cdot \Delta_{h3b} \quad P_{h3b} = 4991.1 \text{ kip}$$

$$\frac{P_{h3b}}{2} = 2495.5 \text{ kip}$$

Attachment A1.2 Determination of Loads and Cask Stability Under Extreme Loads:

Determine Loads:

Dead Weight:

The design storage casks weigh 200 tons (see Assumption 2 in Section 4.0 of this calculation). This weight will be distributed to the 24 nodes at the general location of the anchor bolts as follows:

$$W_{\text{cask}} := 200 \cdot \text{TON} \quad F_{y\text{dead}} := \frac{W_{\text{cask}}}{24} \quad F_{y\text{dead}} = 16.67 \text{ kip per node}$$

The dead weight forces will also include the self weight of the concrete pad using a weight density of 150 pcf.

Live Load:

The live load includes the weight of the cask transporter. Information from J & R Engineering (2003) gives the maximum transporter weight as 135000 lbs. The center-to-center spacing of the tracks is about 14 feet. A spacing in the order of 10 feet will be used in the analysis to coincide with the grid spacings between the nodes in the apron area of the model. The track length (center-to-center spacing between the driving wheels of the tracks) is about 20 feet. Based on the grid spacings of the model in the apron areas, nodal point loads will be thus be applied to two rows of 4 nodes, therefore:

$$W_{\text{trans}} := 135 \cdot \text{kip} \quad F_{y\text{livetans}} := \frac{W_{\text{trans}}}{8} \quad F_{y\text{livetans}} = 16.875 \text{ kip per node- unloaded}$$

$$F_{y\text{livetansloaded}} := \frac{W_{\text{trans}} + W_{\text{cask}}}{8} \quad F_{y\text{livetansloaded}} = 66.875 \text{ kip per node- loaded}$$

The live load also includes a distributed load of 150 psf per section 6.4 of this calculation.

The Transporter Live Loads are shown below.

Snow Load - use the provisions of Section 7 of ASCE 7-02; the resulting snow loads will be at least equivalent to those from 4" of snow:

$$C_e := 0.9 \quad C_t := 1.0 \quad I := 1.2 \quad p_g := 5 \text{ psf} \quad \text{See table 7-2 for } C_e; \text{ see table 7-3 for } C_t; \text{ see Table 7-4 for } I; \text{ see Fig. 7-1 for } p_g.$$

$$p_f := 0.7 \cdot C_e \cdot C_t \cdot I \cdot p_g \quad p_f = 3.78 \text{ psf} \quad \text{Formula 7-1 of ASCE 7-02.}$$

Seismic Load Factors - Determine load factors to apply to the unit seismic forces determined below; these are used to scale the unit case to obtain the appropriate loads to use in the various load cases involving seismic loads:

$$\alpha_{HZPA} := 0.5802 \quad \alpha_{VZPA} := 0.5188 \quad \text{Horizontal and Vertical ZPA g levels per DTN MO0402SDSTMHIS.004.}$$

$$\alpha_H := .7287 + \left[\frac{(0.0209 - 0.020)}{0.03 - 0.020} \right] \cdot (0.8589 - 0.7287) \quad \text{Horizontal and Vertical g levels per DTN MO0402SDSTMHIS.004 at 7\% damping and } T = 0.0209 \text{ sec., the approximate fundamental period of the cask per sht. A20 of this calculation (the wind load calculation).}$$

$$\alpha_H = 0.7404$$

$$\alpha_V := .7126 + \left[\frac{(0.0209 - 0.020)}{0.03 - 0.020} \right] \cdot (0.7946 - 0.7126)$$

$$\alpha_V = 0.72$$

$$\beta_1 := \alpha_H \quad \beta_2 := 0.4 \cdot \beta_1 \quad \beta_3 := \alpha_V \quad \beta_4 := 0.4 \cdot \beta_3 \quad \beta_5 := 1.5 \cdot \alpha_H \quad \beta_6 := 0.4 \cdot \beta_5$$

$$\beta_7 := 1.5 \cdot \alpha_V \quad \beta_8 := 0.4 \cdot \beta_7 \quad \beta_9 := \beta_7 + 1.0 \quad \beta_{10} := \beta_7 + 0.9 \quad \beta_{11} := \beta_7 + 1.0$$

$$\beta_{12} := -\beta_7 + 0.9 \quad \beta_{13} := \alpha_{HZPA} \quad \beta_{14} := 0.4 \cdot \beta_{13} \quad \beta_{15} := \alpha_{VZPA} \quad \beta_{16} := 0.4 \cdot \beta_{15}$$

$$z = \begin{pmatrix} 5.938 \\ 5.735 \\ 5.142 \\ 4.198 \\ 2.969 \\ 1.537 \end{pmatrix} \text{ ft}$$

$$P_1 := \left[\frac{M}{2 \cdot z_1 + 4 \cdot \sum_{i=2}^6 \frac{(z_i)^2}{z_1}} \right]$$

$$P_1 = 62.351 \text{ kip}$$

The pullout forces are based on the ring of anchor points acting like a series of bolts in a column base; the individual forces are directly proportional to the distance from the center; location 1 is the furthest from the center; on each side of the cask there is one anchor point at this location and 2 each at the other locations.

$$j := 2..6$$

$$P_j := \frac{(P_1 \cdot z_j)}{z_1} \quad P = \begin{pmatrix} 62.351 \\ 60.226 \\ 53.998 \\ 44.089 \\ 31.175 \\ 16.138 \end{pmatrix} \text{ kip}$$

$$v_E := \beta_5 \cdot \frac{W_{\text{cask}}}{7} \quad v_E = 63.464 \text{ kip}$$

The cask is anchored such that shear is transferred to anchor bolts on only one side to the cask (see Attachment A2.0). Let the shear be conservatively transferred to only 7 bolts.

$$m_E := v_E \cdot \frac{t}{2} \quad m_E = 174.5 \text{ ft} \cdot \text{kip}$$

$$V_E := 7 \cdot v_E \quad V_E = 444.251 \text{ kip}$$

$$SAH_{DEM_{final}} := SAH_{DEM_{KK-1}} + \left[\frac{(0.0 - SS_{KK-1})}{(SS_{KK} - SS_{KK-1})} \right] \cdot (SAH_{DEM_{KK}} - SAH_{DEM_{KK-1}})$$

$$SAH_{DEM_{final}} = 1.041$$

$$SAH_{CAP_{final}} := SAH_{CAP_{KK-1}} + \left[\frac{(0.0 - SS_{KK-1})}{(SS_{KK} - SS_{KK-1})} \right] \cdot (SAH_{CAP_{KK}} - SAH_{CAP_{KK-1}})$$

$$SAH_{CAP_{final}} = 1.041$$

Since the demand horizontal acceleration equals the horizontal acceleration capacity at a very low angle that is well below the maximum of 28.902° indicates the casks will be stable with respect to rocking.

Evaluate the Potential Sliding Displacements:

Utilize the procedures in Appendices B.1 and B.2 of the Seismic Analysis and Design Approach Document (BSC 2004d) to determine the potential sliding displacements.

$\mu_{steel} := 0.3$ Coefficient of friction between steel components; standard value.

$$\mu_e := [\mu_{steel} \cdot (1 - 0.4 \cdot \alpha_V)] \quad \mu_e = 0.214 \quad \text{Effective coefficient of friction per Eq. B.2-1 of BSC 2004d}$$

$$c_s := 2 \cdot \mu_e \cdot g \quad c_s = 13.745 \frac{\text{ft}}{\text{sec}^2} \quad \text{Sliding coefficient per Eq. B.2-4 of BSC 2004d}$$

$$SA_{VH} = (1.16 \cdot SA_H^2)^{0.5} \quad SA_{VH} = 1.077 \cdot SA_H \quad \text{Determination of the vectral horizontal spectral acceleration from Eq. B.2.8 of BSC 2004d.}$$

$$SA_{VH} = c_s$$

$$\text{Therefore, } SA_H := \frac{c_s}{1.077} \quad SA_H = 12.762 \frac{\text{ft}}{\text{sec}^2} \quad SA_H = 0.3967 g$$

Extrapolating in the table for the Horizontal Spectra for 7% damping in MO0402SDSTMHIS.004 gives the following period:

$$T := 0.85 \text{sec} + \left(\frac{0.4310 - 0.3967}{0.4310 - 0.3525} \right) \cdot 0.15 \cdot \text{sec} \quad T = 0.916 \text{sec}$$

$$f_{es} := \frac{1}{T}$$

$$f_{es} = 1.092 \text{ Hz}$$

Per Appendix B of BSC 2004d, f_{es} is the effective frequency of the equivalent sliding system of the rigid body; it is equal to the lowest natural frequency at which the 7% damped vector spectral acceleration SA_{VH} equals c_s .

$$\text{Therefore, } \delta_s := \frac{c_s}{(2 \cdot \pi \cdot f_{es})^2}$$

$$\delta_s = 3.502 \text{ in}$$

See Eq. B2-7 of BSC 2004d. This is only a moderate displacement. The cask will be stable under seismic loads.

Wind Loads:

Since the casks are cylindrical structures wind loads are evaluated by using the provisions of both ASCE 7-02 and Section 32, "Chimneys," of the Structural Engineering Handbook (Chu et al. 1997). Pressures due to winds in the along wind direction are calculated using the provisions of the former reference while potential pressures in the crosswind direction are calculated using the provisions of the latter reference.

Determine the Natural Frequency of the Casks:

Use formula 10 of Chu 1997:

$$D_c = 11.042 \text{ ft}$$

$H := 245 \text{ in}$ Diameter and height of the casks; see Assumption 2.0 of this calculation and Detail B of Attachment 2.0

$$I := 1.15$$

Importance factor; see Table 1604.5 of the IBC (ICC 2000)

$$HD := \frac{H}{D_c} \quad HD = 1.849$$

$$f_{ccask} := 4000 \cdot \text{psi}$$

$$w_{ccask} := 146 \cdot \text{pcf}$$

See Section 6.4 of this calc.

$$E_{ccask} := \left(w_{ccask} \cdot \text{pcf}^{-1} \right)^{1.5} \cdot 33 \cdot \sqrt{f_{ccask} \cdot (\text{psi}^{-1})} \cdot \text{psi}$$

See section 8.5.1 of ACI 349 (ACI 2001a) for Young's Modulus

$$E_{ccask} = 3682 \text{ ksi}$$

$$w_s := \frac{W_{cask}}{(\pi \cdot D_c^2) \cdot H} \quad w_s = 205 \frac{\text{lb}}{\text{ft}^3}$$

Average weight density of a loaded cask.

$$f_t := \frac{3.52 \cdot D_c}{4\pi(H)^2} \cdot \sqrt{\frac{E_{ccask} \cdot g}{2w_s}}$$

$$f_t = 47.907 \text{ Hz}$$

Formula 10, Chu et al. 1997.

$$T_t := \frac{1}{f_t} \quad T_t = 0.02087 \text{ sec}$$

$$S := 0.20$$

Strouhal number, mid-range, pg.
32-3, Chu et al. 1997.

$$V_{cr} := \frac{(f_t \cdot D_c)}{S} \quad V_{cr} = 2645 \frac{\text{ft}}{\text{sec}}$$

Critical wind velocity,
Formula 3, Chu et al. 1997

$$Vel_w := 90 \cdot \text{mph} \quad Vel_w = 132 \frac{\text{ft}}{\text{sec}}$$

Extreme Wind Velocity, see
Section 6.2 of this calc.

$$Vel_t := 189 \cdot \text{mph} \quad Vel_t = 277.2 \frac{\text{ft}}{\text{sec}}$$

Maximum Tornado Wind Velocity,
see Section 6.2 of this calc.

Since $V_{cr} \gg Vel_w$ and Vel_t , the dynamic influence of vortex shedding, including cross wind forces, need not be considered per pg. 32-3 of Chu et al. 1997.

Determine wind loads based on the above wind speeds:

$$K_d := 0.95 \quad \text{Table 6-4, ASCE 7-02; } K_d \text{ for a round structure}$$

$$K_{zt} := 1.0 \quad \text{Min topographic factor for a structure not located on top of a hill or escarpment, Fig. 6-4, ASCE 7-02.}$$

$$K_z := 0.90 \quad K_z \text{ for exposure C at a 20 ft. height, Table 6-2, ASCE 7-02.}$$

$$q := 0.00256 \cdot (K_z \cdot K_{zt} \cdot K_d) \cdot \left[Vel_w \cdot \left(\frac{\text{ft}}{\text{sec}} \right)^{-1} \right]^2 \cdot I \cdot \text{psf} \quad q = 43.86 \text{ psf} \quad \text{Equation 6-15, ASCE 7-02.}$$

$$Dq := D_c \cdot \text{ft}^{-1} \cdot \sqrt{q \cdot \text{psf}^{-1}} \quad Dq = 73.124 > 2.5 \quad \text{See Figure 6-19, ASCE 7-02.}$$

$$C_f := 0.5 + \frac{(HD - 1) \cdot 0.1}{6} \quad C_f = 0.514 \quad \text{Interpolated value from Fig. 6-19, ASCE 7-02.}$$

$$G := 0.85 \quad \text{See Section 6.5.8.1 of ASCE 7-02.}$$

$$p := q \cdot G \cdot C_f \quad p = 19.17 \text{ psf} \quad \text{Formula 6-25, ASCE 7-02}$$

$$F_p = 4.609 \text{ ksi} > f_p = 3.244 \text{ ksi} \quad \text{OK}$$

Coupler:

The coupler must be long enough to accomodate both the connection bolt and the embeded . The minimum length of thread engagement is:

$$L_e := 1.777 \cdot \text{in} \quad \text{See pg. 21 of Calc. PGE-009-CALC-001 (included in Womack 2001).}$$

Use a 2 in. long thread in the top of the coupler for the connection bolt, a 3 in. long thread in the bottom for the embeded bolt, and a 1 in. long space in between. The longer thread distance is used for the embeded bolts to provide additional tolerance on bolt position to help in setting the position of the base plates and the anchor plates. Therefore:

TITLE AGING AREA – DESIGN OF A CONCRETE SLAB FOR STORAGE OF SNF AND HLW CASKS			

A3.1 - Pertinent GT-STRUDL Output

The GT STRUDL model has been organized into a pad area where the casks will be stored and an apron area where the transporter will operate. The cask storage area is comprised of 8 pads with apron areas on either side and at the top as shown below:

GT STRUDL MODEL LAYOUT

Contours for enveloped element internal reactions are printed for plate elements making up the model of the slab.

Also output are the sum of the reactions around the origin. These are used to verify slab stability.

Finally, reactions at the spring elements associated with the highest displacements are output to aid in checking soil bearing.

TITLE AGING AREA – DESIGN OF A CONCRETE SLAB FOR STORAGE OF SNF AND HLW CASKS

POSITIVE GT-STRUDL SIGN CONVENTION FOR RESULTS

(VIEW IS OF THE BOTTOM OF A PLATE ELEMENT – THE +LOCAL Z AXIS IS DOWN)

(SEE FIG. 2.3-11 OF VOL. 3 OF THE GT-STRUDL USER MANUAL)

NOTE: FOR THE MODEL OF THIS DESIGN, THE POSITIVE GT-STRUDL MOMENTS PRODUCE TENSION ON THE BOTTOM OF THE PLATE ELEMENTS, WHICH IS THE SAME AS THE NORMAL REINFORCED CONCRETE DESIGN CONVENTION WHEREBY MOMENTS PRODUCING TENSION ON THE BOTTOM ARE POSITIVE.

TITLE AGING AREA – DESIGN OF A CONCRETE SLAB FOR STORAGE OF SNF AND HLW CASKS			

The slabs will be designed for reactions that act over large areas of the model and., more or less, represent average reactions. The very high reactions that are concentrated in very small areas won't be used as design reactions as they act over too small an area of the slab. Based on this and the resultant ranges given in the contour plots above the following are used as design reactions:

SNF Cask Storage Area:

Mxx+, Positive Design Moment (tension in the bottom of the slab; "max" moments from the model) = 1845 ft-kip/ft

Mxx-, Negative Design Moment (tension in the top of the slab; "min" (or negative) moments from the model)

= -78 ft-kip/ft (since the resulting negative moments on pg. A40 have similar magnitudes and signs as the positive design moments, when they should have negative signs and different magnitudes, indicates that there is little tension in the top of the slab; for design (of the reinforcing in the top of the slab), however use the same value as used for the minimum Myy moment as the moments can be dependent on the position of the transporter.)

Myy+, Positive Design Moment = 400 ft-kip/ft

Myy-, Negative Design Moment = -78 ft-kip/ft (see note above for Mxx-)

Vxx, Design Shear (can be based on the + or – shear) = 56 kip/ft

Vyy, Design Shear (can be based on the + or – shear) = 54 kip/ft

Inner Apron Area at the sides of the SNF Cask Storage Areas:

Mxx+, Positive Design Moment = 1600 ft-kip/ft

Mxx-, Negative Design Moment = -50 ft-kip/ft

Myy+, Positive Design Moment = 360 ft-kip/ft

Myy-, Negative Design Moment = -50 ft-kip/ft (use the same value as Mxx-)

Vxx, Design Shear (can be based on the + or – shear) = 64 kip/ft

Vyy, Design Shear (can be based on the + or – shear) = 45 kip/ft

CALCULATION SHEET

JOB NO. 24540	CALC. NO. 170-00C-HAP0-00100-000	REV. NO. 00B	SHEET NO. A45
TITLE AGING AREA – DESIGN OF A CONCRETE SLAB FOR STORAGE OF SNF AND HLW CASKS			

Top Apron at the SNF Storage Cask Areas:

M_{xx+} , Positive Design Moment = 800 ft-kip/ft

M_{xx-} , Negative Design Moment = -20 ft-kip/ft (use the same value as M_{xx-} for the outer areas; see below)

M_{yy+} , Positive Design Moment = 240 ft-kip/ft (use the same value as for the positive M_{yy} moment in the outer apron areas since this moment depends on the position of the transporter)

M_{yy-} , Negative Design Moment = -20 ft-kip/ft (see above note for M_{xx+} for the SNF Cask storage area)

V_{xx} , Design Shear (can be based on the + or – shear) = 24 kip/ft

V_{yy} , Design Shear (can be based on the + or – shear) = 40 kip/ft

Outer (Sides and Top) Areas:

M_{xx+} , Positive Design Moment = 600 ft-kip/ft

M_{xx-} , Negative Design Moment = -50 ft-kip/ft (see above note for M_{xx+} for the SNF Cask storage area)

M_{yy+} , Positive Design Moment = 160 ft-kip/ft

M_{yy-} , Negative Design Moment = -60 ft-kip/ft (see above note for M_{xx+} for the SNF Cask storage area)

V_{xx} , Design Shear (can be based on the + or – shear) = 32 kip/ft

V_{yy} , Design Shear (can be based on the + or – shear) = 30 kip/ft
