ABSTRACT

In this quarter, the field, theoretical and programming works have been performed toward achieving the research goals set in the proposal. The main accomplishments in this quarter included: (1) two more sets of field tests have been conducted in an underground coal mine, (2) optimization studies of the control parameters have been conducted, (3) method to use torque to thrust ratio as indicator of rock relative hardness has also been explored, and (3) about 97% of the development work for the roof geology mapping program, MRGIS, has completed, (4) A special version of the geology mapping program for a limestone mine has been developed. The field test for the software and hardware has been successfully finished.

Executive Summary

This research is to develop a method for identifying the geological features in the mine roof strata in real time during roof bolting operation. Based on such information, better decision on roof bolting can be made to reduce the risks of roof falls.

In this quarter, the field, theoretical and programming works have been performed toward achieving the research goals set in the proposal. The main accomplishments in this quarter included:

1. Two more sets of field tests have been conducted in an underground coal mine where roof strata within the drilling horizon were consist of sandstone. The purposes of these tests were to account for the changes made to the hardware and software of the roof bolter and to test the real-time geology mapping software that is still in development process.

2. Optimization studies of the control parameters have been conducted to determine the best combination of the control parameters (i.e., penetration rate, rotational rate and thrust cap) that can produce more accurate interpretations.

3. About 95% of the development work for the roof geology mapping program, MRGIS, has completed.

4. A mine roof geology mapping system has been successfully developed. This system consists of a special version of Mine Roof Geology Information System (MRGIS) and a compact touch screen computer installed on a production roof bolter in a limestone mine. It can automatically interpret and display the roof geological features in real-time as the roof bolting operation is performed. All the recorded data is stored in the computer and can be downloaded and transferred to the surface for further analysis and comparison. It has performed very well in underground production condition.

5. Three technical papers have been published in the proceedings of the 23rd International Conference on Ground Control in Mining to be held on Aug. 3-5, 2004.

Research Objectives

Roof bolting is the most popular method for underground openings in the mining industry, especially in the bedded deposits such as coal, potash, salt etc. In fact, all U.S. underground coal mine entries are roof-bolted as required by law.

However, roof falls still occur frequently in the roof bolted entries. The two possible reasons are: the lack of knowledge of and technology to detect the roof geological conditions in advance of mining, and lack of roof bolting design criteria for modern roof bolting systems.

This research is to develop a method for predicting the roof geology and stability condition in real time during roof bolting operation. Based on such information, roof bolting design criteria for modern roof bolting systems will be developed for implementation in real time.

For the prediction of roof geology and stability condition in real time, a microprocessor will be used and a program (ROOFSTAB) developed to monitor the drilling parameters. These parameters include thrust, penetration rate, rotation torque, rotation...
rate, drill position, and vacuum condition. At the same time, rock cores will be obtained a borehole drilled immediate next to bolt hole for the determination of the mechanical properties and structure of the rock strata within the bolting horizon. A relationship or relationships will be established between these drilling parameters and the mechanical and structural data of the roof strata. A roof bolter control system will be developed to monitor these drill parameters. For the development of ROOFSTAB drilling parameters will be obtained from four different coal seams in four mine sites. With this information, a computer program will be developed for use in conjunction with the roof bolter for real-time prediction of strata mechanical properties and structures in roof strata within the bolting horizon.

For the development of roof bolting design criteria, numerical simulations will be performed to investigate the mechanisms of modern roof bolting systems including both the tension and non-tensioned (or fully grouted) bolts. Parameters to be studied are: bolt size/strength, bolt length, bolt spacing, grout annulus and length, and roof geology (massive strata, fractured, and laminated or thinly-bedded). The results of these experiments will be analyzed to develop a roof bolting criterion or criteria program (ROOFBOLT) that will be combined with the ROOFSTAB for use in conjunction with roof bolt installation.

The following main tasks are to be performed for achieving the proposed research objectives:

B. Laboratory and Underground Testing.
C. Drill Parameters Data Analysis and Correlation with Roof Stability Conditions
   Software Development for Mapping of Roof Geological Conditions
D. Laboratory Tests to Investigate the Mechanisms of Roof Bolting Using Simulated Materials
E. Development of Roof Bolting Design Criteria for Implementation in Primary Roof Bolting Cycle

**Experimental**

- **Field Tests**
  - In this quarter, two more field tests have been conducted in an underground coal mine in southern West Virginia where hard sandstone roof strata were presented in the roof bolting horizon. The purposes of the tests were: (1) to accounts for the software and hardware changes made on the dedicated roof bolter for this research, and (2) test the real-time geological mapping software developed so far. The locations of the drill holes are shown in Fig. 1.
  - The penetration and rotational rates were controlled at various levels during these tests. The thrust was also been capped at a number of levels.

- **Optimization of Drilling Control Parameters Studies**
  - Optimization of the drilling control parameters for the purposes of
    - Improving the drilling productivity under safe operation
- Improving the accuracy and resolution of the geology interpretation using the data.

Results and Discussion

1. Development of Data Interpretation Methodologies

The development of data interpretation methodology is still continuing in this quarter. Development of the systematic and mechanics-based approach for interpreting the drilling parameters is continuing.

A method to use torque to thrust ratio as indicator of relative rock hardness and to identify the fractures and voids has also been developed and tested. It seems that torque/thrust ratio is a good indicator for relative rock hardness based on the testing results.

One technical paper on the developed methodologies for data interpretation has been presented at and included in the proceedings of the 23rd International Conference on Ground Control in Mining to be held on Aug. 3-5, 2004.
2. Exploring the Roof Bolting Mechanisms

Finite element method has been used to explore the mechanisms of tensioned and resin roof bolts in enhancing the roof strata. Most of the work in this stage has been completed. Two technical papers on the roof bolting mechanisms have been presented at and included in the proceedings of the 23rd International Conference on Ground Control in Mining to be held on Aug. 3-5, 2004.

3. Development of On-Board Data Visualization and Database Program

The development of a computer program, Mine Roof Geological Information System (MRGIS), to display the original and derived drilling parameters, the estimated rock strengths and geological structures in the bolting horizon in 2-D and 3-D is continuing in this quarter. The program is a Windows-based stand-alone database PC program. It provides an engineer-friendly working environment for importing AutoCAD mine map into this program and to display the interpretation results for easy comprehension. It also provides a platform for incorporating the developed data interpretation methods for nearly real-time geological visualization of the strata drilled during the roof bolting operation. Using the roof geology information, the suitability of the current roof bolting design will be assessed.

A special version of the geology mapping program for a limestone mine has been developed. The field test for the software and hardware has been successfully finished. The whole system was displayed in MineExpo 2004 held in Las Vegas.

CONCLUSIONS

The project proceeds well as proposed. The status of various tasks is listed in Table 1. The main accomplishments in this quarter included: (1) two more sets of field tests have been conducted in an underground coal mine, (2) optimization studies of the control parameters have been conducted, (3) method to use torque to thrust ratio as indicator of rock relative hardness has also been explored, and (3) about 97% of the development work for the roof geology mapping program, MRGIS, has completed, (4) A special version of the geology mapping program for a limestone mine has been developed. The field test for the software and hardware has been successfully finished.
