Organic Contaminant Levels in Three Fish Species Downchannel from the Los Alamos National Laboratory

G.J. Gonzales, P.R. Fresquez, and J.W. Beveridge

Abstract

Three species of fish from sites upriver and downriver of the Los Alamos National Laboratory (LANL) in the Rio Grande were analyzed for pesticides and polychlorinated biphenyls (PCBs). Data were used to implicate potential sources of the contaminants and to discuss potential risk to fish, the bald eagle, and humans. Eight of 28 contaminants were measurable in at least one sample of fish muscle tissue. Of 18 samples total, there were 18 detections of dichlorodiphenylethylene (DDE), eight of Aroclor-1254, five of dichloroethane, two of dichlorodiphenyltrichloroethane (DDT), two of endosulfan sulfate, two of gamma-chlordane, and one of Aroclor-1260. The LANL contribution, if any, to organic contaminant levels in the common carp (*Carpiodes carpio*), the channel catfish (*Ictalurus punctatus*), and the white sucker (*Catostomus commersoni*) in the Rio Grande appear to be small. The source of the DDT-related compounds was probably a pest control event in 1963 in which approximately 500,000 acres of forest west of the Rio Grande in the Santa Fe and Carson National Forests were sprayed with approximately one pound per acre of DDT (~141,044 ppm-wt/wt). DDE concentration between fish species was significantly different: the white sucker had significantly lower levels of 4,4' - DDE than the common carp and the channel catfish. This may have affected location treatment means of 4,4' - DDE; therefore, studies on the effect of the Laboratory on organic contaminant levels in fish in the Rio Grande should consider the effect of species, feeding habits, and other factors. Maximum DDE concentrations in all three fish species (0.03 to 0.15 mg kg^{-1}) were slightly below the minimum range in concentration (0.2 to 1.0 mg kg^{-1}) in prey of sensitive bird species that have been associated with reproductive effects. Assuming a maximum total fish ingestion of 21 kg yr^{-1} and a 70-kg human consumer body weight, the maximum DDT consumption by humans would be $6.7 \times 10^{-5} \text{ mg g}^{-1} \text{ d}^{-1}$, which is lower than the U.S. Environmental Protection Agency (EPA) human risk value of $5 \times 10^{-4} \text{ mg kg}^{-1} \text{ d}^{-1}$. The mean total DDT concentration of $82 \text{ } \mu\text{g kg}^{-1}$ results in an EPA recommendation of no consumption restrictions for chronic systemic health endpoints for the general human population. Depending on meal size and acceptable risk levels, there are minor consumption restrictions recommended for chronic systemic health endpoints for children and for carcinogenic health endpoints for the general population. Maximum Aroclor-1254 concentrations in all three fish species (0.05 to 0.66 mg kg^{-1}) were well below the minimum range in concentration (50 to 100 mg kg^{-1}) that may adversely affect growth and reproduction of fish. Assuming a maximum total fish ingestion of 21 kg yr^{-1} and a 70-kg consumer body weight, the maximum Aroclor-1254 consumption would be $1.1 \times 10^{-4} \text{ mg kg}^{-1} \text{ d}^{-1}$. This is above the EPA human risk value of $2 \times 10^{-5} \text{ mg kg}^{-1} \text{ d}^{-1}$. Regarding the mean Aroclor-1254 concentration in fish, 0.13 mg kg^{-1} , minor consumption restrictions are recommended by the EPA on the basis of chronic systemic health endpoints for the general population and on developmental health endpoints for women of reproductive age.

Introduction

In early 1998 a preliminary risk assessment was performed at the Los Alamos National Laboratory (LANL) on the potential for environmental contaminants to adversely impact the bald eagle (Gonzales et al. 1998). The assessment was conducted as part of a three-year study on threatened and endangered species to comply with the Endangered Species Act of 1973. Although hazard index results indicated no appreciable impact to the bald eagle, this was predicated on the lack of detection of organic contaminants in sediment samples from the Rio Grande for several years (LANL 1997). Therefore, the only contribution of organic contaminant values to the bald eagle risk assessment was for the portion of the simulated eagle diet that was terrestrial, which was varied from 10% to 25%. Literature has since been found that reports detections of organics in sediment of the Rio Grande (Miller et al. 1997; Carter 1997). Additionally, uncertainties about the appropriate bioaccumulation and biomagnification factors for a freshwater system and consultations with the New Mexico Environment Department and the U.S. Fish and Wildlife Service were factors that established the need for further study. Rather than conducting additional empirical modeling, we decided to analyze three species of fish collected at five locations (one "control" and four "treatment") of the Rio Grande in 1997 for the presence of organic contaminants. Although the eagle prefers freshwater fish species such as trout, three bottom feeder species – the white sucker (*Catostomus commersoni*), the channel catfish (*Ictalurus punctatus*), and the common carp (*Carpionides carpio*) – were sampled in order to maximize potential exposure to the eagle. These fish ingest relatively high amounts of contaminant-laden sediment and have high fat contents; therefore, exposure to contaminants through

the ingestion of sediment and accumulation of lipophilic organic contaminants would maximize contaminant loads. The concentration of radionuclides and trace metals in fish from these same sites have been reported previously (Fresquez et al. 1999).

Methods

On September 22, 1997, three or four fish samples were collected at each of five locations at the confluences of drainages from the Jemez Mountains that transect LANL and the Rio Grande (Figure 1). A raft-mounted Smith-Root Electrofisher shocking device was used to collect the fish. The San Ildefonso Pueblo served as the control site because it is upstream from LANL. Pajarito, Los Alamos, and Mortandad drainages traverse the Laboratory and terminate in the Rio Grande. The Frijoles drainage is south of the Laboratory, intersects Bandelier National Monument, and terminates at the Rio Grande. Portions of fish muscle sample (three or four fish per site) were frozen, packaged, and transported to Paragon Analytics, Inc., for chemical analysis. Samples were analyzed for 21 organochlorine (chlorinated hydrocarbon) pesticides and seven aroclors. Aroclors are mixtures of individual polychlorinated biphenyl (PCB) congeners at varying ratios. There are 209 different PCB congeners that differ in the number and/or position of chlorine atoms. The 28 analytes are listed in the Appendix.

Samples were extracted and analyzed according to Environmental Protection Agency (EPA) Solid Waste-846 procedures (EPA 1986). Specifically, the samples were extracted using soxhlet procedures based on Method 3540. The extracts were then processed using gel permeation chromatography cleanup by Method 3640. Samples containing PCBs were also

Figure 1. Locations of sites along the Rio Grande where fish were collected.

processed using sulfuric acid cleanup by Method 3665. Extracts were analyzed using gas chromatograph/electron capture detectors with a pesticides capillary column according to protocols based on EPA Method 8081. All positive results were confirmed on a RTX-50 column.

Analytes that were detected at least once within a treatment (location) were pooled with replacement values for "nondetects" that consisted of one-half the detection limit per Gilbert (1987). This was done for all sampling sites including the control. Data were then transformed to the natural logarithm and analyzed for significant differences using analysis of variance (ANOVA), where locations were considered treatments. Dunnett's procedure was used to compare all location-treatment means with the control (San Ildefonso Pueblo) (Steel et al. 1997).

Substantial differences may exist between fish species in bioaccumulation of organic contaminants because of different feeding habits, different fat levels, and other factors (Beyer et al. 1996). Since the number of each fish species differed between sampling locations, fish species as an uncontrolled "treatment" could confound results and conclusions regarding the effect of location. Therefore, contaminant data were segregated on the basis of species and analyzed statistically using ANOVA. The least significant difference (LSD) test was used as the test criterion to discern differences between any two means. The size of sample for each species within each location was insufficient to perform a two-way ANOVA that would test for interaction of the location and species term.

Although only catfish are typically consumed by people in northern New Mexico, comparisons of treatment means were made to risk-based fish consumption limit values recommended by the EPA (EPA 1997). This was done only for

dichlorodiphenyltrichloroethane (DDT) and its metabolites and Aroclor-1254 because there was a substantial number of detections only for these analytes. Ecological risk screening values, with the bald eagle as a potential receptor, were cited for these two analytes with a recommendation to estimate exposure doses for the bald eagle and compare them to the risk screening values.

Results

The detailed analytical results or raw data are presented in the Appendix. Table 1 shows the arithmetic mean concentration by location of the eight analytes that were detected at least once at any of the five sampling locations. Of 18 samples total, there were 18 detections of dichlorodiphenylethylene (DDE), eight of Aroclor-1254, five of dichloroethane (DDD), two of DDT, two of endosulfan sulfate, two of gamma-chlordane, and one of Aroclor-1260. Only DDE had detections in over 50% of the samples.

Including replacement values, only DDT, endosulfan sulfate, and gamma-chlordane had significant *F*-values at $\alpha = 0.05$; however, there were only two detections of these analytes, and the ANOVA was based on only replacement values for the control samples of all three analytes. Therefore, the statistical significance may be artificial for these three analytes. The only analyte detected in a substantial number of samples, DDE, had treatment means that were not significantly different ($P = 0.3$). However, these analyses suffered from relatively low sample sizes, high variance, and may have been confounded by species effect. Concentrations of DDE by location are plotted in Figure 2. Mean concentrations of DDE in the common carp, channel catfish, and white suckers were 0.096 ppm ($n = 8$), 0.075 ppm ($n = 5$), and 0.019 ppm ($n = 5$),

Figure 2. 4,4' - DDE concentrations in fish upriver and downriver of the Los Alamos National Laboratory.

respectively (Table 2). The ANOVA for species effect resulted in a significant ($P = 0.002$) F -value of 9.6. Suckers had significantly ($\alpha = 0.05$) less DDE than carp and catfish. Thus, although the mean DDE concentration for the control was higher than all downriver means, the mean concentration at the Pajarito sampling location may have

been biased downward as three of its four samples were suckers. Also, the mean DDE concentration at the control sampling location may have been biased upwards as all three of its samples consisted of the relatively high-concentration species – carp and catfish – with no samples of sucker.

P = Confluence of Pajarito Canyon and Rio Grande;

SI = San Ildefonso at the Rio Grande.

Discussion

Maximum DDE concentrations in all three fish species (0.03 to 0.15 mg kg⁻¹) were slightly below the minimum range in concentration (0.2 to 1.0 mg kg⁻¹) in prey of sensitive bird species that have been associated with reproductive effects (Blus 1996).

The EPA consumption limits for DDT and its metabolites are based on the total concentration, i.e., sum of 4,4'-DDT, 4,4'-DDE, and 4,4'-DDD (referred to as "total DDT"). To compare to this limit, the

concentrations of DDT, DDD, and DDE were averaged across the five sampling sites, and the means were summed. Assuming a maximum total fish ingestion of 21 kg yr⁻¹ and a 70-kg consumer body weight (EPA 1993), the maximum DDT consumption would be 6.7×10^{-5} mg DDT kg⁻¹ d⁻¹. This is lower than the EPA human risk value of 5×10^{-4} mg kg⁻¹ d⁻¹. The mean DDE concentration for all sampling locations was 0.069 mg kg⁻¹ (ppm). This is higher than concentrations of 0.005, 0.064, and 0.028 mg kg⁻¹ (ppm), measured in white

sucker at upriver locations of the Rio Grande in New Mexico and Colorado in 1992/1993 (Carter 1997). For the mean concentration of 0.069 mg kg^{-1} (ppm), there are no human consumption restrictions for chronic systemic health endpoints for the general population (EPA 1997). Depending on meal size and acceptable risk levels, there are minor consumption restrictions recommended for chronic systemic health endpoints for children and for carcinogenic health endpoints for the general population (EPA 1997).

Estimates of potential exposure dose to bald eagles based on the DDE concentrations measured in fish in this study should be made and could be compared to the conservative "no observed adverse effects level" (NOAEL) of $2.2 \times 10^{-5} \text{ mg/kg/d}$ (Longcore et al. 1971), which has been used for ecological risk screening at LANL (Gonzales et al. 1998; Kelly et al. 1998).

It is not surprising that the control site had higher levels of DDE than the treatment sites because DDT was applied to expansive and isolated areas in numerous events between the years 1950 and 1963 (Brown et al. 1986; Allen 1989). The most recent large-scale application of DDT was a 1963 aerial broadcast of approximately 455,860 acres of the Carson and Santa Fe National Forests west of the Rio Grande (Brown et al. 1986; LASL 1963). This application included treatment of areas upriver of LANL. The rate of application was one pound of DDT per gallon of fuel oil per acre, which roughly equals 141,044 ppm (wt/wt). At a breakdown rate of approximately 90% for each 8.5 years since the DDT was applied (Stoker and Seager 1976), up to 14 ppm DDT could have existed in its original form in 1997 when the fish samples were collected, barring dilution by abiotic media such as soil, sediment, or water. At the high rate of application it also

is not surprising that DDT in its original form was still detectable. Numerous isolated applications of DDT at Bandelier National Monument (Allen 1989) may be responsible for the elevated levels of DDE measured in this study at the Frijoles sampling site.

The ANOVA *F*-value for Aroclor-1254 was not significant ($\alpha = 0.05$), and a comparison of the treatment means to the control mean revealed no significant differences. Although the difference between the Frijoles mean (234 ppm) and the control mean (110 ppm) was relatively large ($\Delta = 124 \text{ ppm}$) in comparison to differences associated with the other treatment means, the small sample sizes and high variation within the data set contributed to a non-significant LSD test. The Frijoles Canyon/Rio Grande confluence is immediately downriver from LANL, but Frijoles Canyon does not enter into LANL property. The fact that concentrations of Aroclor-1254 upriver from the Frijoles/Rio Grande confluence are noticeably lower suggests sources other than LANL.

Maximum Aroclor-1254 concentrations in all three fish species (0.05 to 0.66 mg kg^{-1}) were well below the minimum range in concentration (50 to 100 mg kg^{-1}) that may adversely affect growth and reproduction of fish (Niimi 1996).

Assuming a maximum total fish ingestion of 21 kg yr^{-1} and a 70-kg consumer body weight (EPA 1993), the total Aroclor-1254 consumption would be $1.07 \times 10^{-4} \text{ mg kg}^{-1} \text{ d}^{-1}$. This is higher than the EPA human risk value of $2 \times 10^{-5} \text{ mg kg}^{-1} \text{ d}^{-1}$. The mean Aroclor-1254 concentration for all sampling locations was 0.13 mg kg^{-1} (ppm). At this concentration, and depending on meal size and level of risk accepted, minor consumption restrictions are recommended by the EPA on the basis of chronic systemic health endpoints for the general population and on developmental health endpoints for

women of reproductive age (EPA 1997). Depending on meal size and acceptable risk levels, minimal consumption restrictions are recommended for developmental health endpoints for children (EPA 1997).

Estimates of potential exposure dose to bald eagles based on the DDE concentrations measured in fish in this study should be made and could be compared to the conservative NOAEL of 5.2×10^{-3} mg/kg/d (Lillie 1974), which has been used for ecological risk screening at LANL (Gonzales et al. 1998; Kelly et al. 1998).

Aroclors are mixtures of individual PCB congeners at varying ratios. There are 209 different PCB congeners. Aroclor-1254 is a compound of several PCBs (penta-, hexa-, and heptachlorobiphenyls) with 54% chlorine by mass. Water quality criteria in the Clean Water Act that are intended to protect wildlife are based on aroclor values, therefore analysis of aroclors is typically favored over analyses of congeners. Determining potential impact only on the basis of aroclors is not sufficient because

1. The biological behavior, or toxicology, of individual PCB congeners can vary substantially,
2. Risk assessment guidelines recommend the measurement of congener-specific PCBs, and
3. Aroclor analyses are estimations that are prone to error.

Because of these problems, characterization of PCB congeners at LANL should be investigated.

Concentrations could potentially be predicted from aroclor concentrations by developing site-specific regression equations. Newman et al. (1998) developed equations for quantitation of aroclors from PCB congeners, e.g.,

$$y_{99} = 0.0828x^{-0.0667}; r^2 = 0.97,$$

where x = Aroclor-1248

concentration and

y = congener 99:Aroclor-1248
conversion factor.

Conclusions

The LANL contribution, if any, to organic contaminant levels in the common carp, the channel catfish, and the white sucker in the Rio Grande appear to be small; however, low sample sizes, high variation, and potential interaction of species effect with location treatment effect require additional sampling and analysis.

Pesticides / PCBs Case Narrative

Los Alamos National Laboratory SMO

4275R

Order Number - 9805229

1. This report consists of 18 fish tissue samples received by Paragon on 05/28/98.
2. These samples were extracted and analyzed according to SW-846, 3rd Edition procedures. Specifically, the solid samples were extracted using soxhlet procedures based on Method 3540. The extracts were then processed using GPC cleanup by Method 3640 in an attempt to remove potential interferences. Because samples 1, 2, 3, 8, 9, 11, 12, 16 and 18 contained targets compounds for PCB's, the extracts for these samples were also processed using sulfuric acid cleanup by Method 3665 in an attempt to remove interferences for additional PCB only analyses.
3. The extracts were then analyzed using GC/ECD (electron capture detectors) with a RTX-CL Pesticides capillary column according to protocols based on Method 8081. All positive results were then confirmed on a RTX-50 column. The quantitation of each analyte is taken from the primary column unless interferences were encountered, in which case the secondary column was used.
4. The percent breakdown criteria for Endrin, 4,4'-DDT and the combined breakdown met acceptance criteria.
5. All initial and continuing calibration criteria were met with the following exceptions;

Initial calibration verification - Endrin aldehyde was out high on the primary column.
Continuing calibration #2 - TCMX and heptachlor were out high on the secondary column.
Continuing calibration #3 - Endosulfan sulfate was out low on the primary column.
Continuing calibration #4 and #5 - A majority of the compounds were out high on the secondary column.

Because the sensitivity of the instrument increased, no further action was taken. For compounds that were detected in the samples the results were reported from the column that did meet calibration criteria.

6. The method blanks associated with this project were below the reporting limits for all analytes.
7. All laboratory control spike and laboratory control spike duplicate recoveries and RPDs were within the acceptance criteria.
8. All matrix spike and matrix spike duplicate recoveries and RPDs were within acceptance criteria with the following exceptions:

Spiked Compound	QC Sample	Direction
Dieldrin	MS and MSD	high
4,4'-DDT	MS and MSD	high

The recoveries of these compounds in the laboratory control spike and laboratory control spike duplicate were within control limits, which suggest the outliers in the matrix spikes may have been due to matrix effects. No further action was warranted. Blank spike and blank spike duplicate results have been included.

9. Samples 1-18 were sampled on 9/22/97, received by Paragon on 5/28/98, and per LANL's approval, extracted on 6/16/98. The samples were frozen after collection, and were stored, shipped, and kept frozen until extraction. The USEPA has not established sample holding times for this matrix, and the analytes of concern are known to persist in similar environmental matrices for decades.
10. All surrogate recoveries were within acceptable limits with the following exceptions:

Surrogate	Sample	Direction
DCB	EX980616-4MB	high

The method states that one surrogate may be outside control limits without further action.

11. Samples -1, -2, -4, -5, -8, -12, and -18 were analyzed at a higher dilution in order to bring targets within the calibration range of the instrument. The reporting limits have been adjusted accordingly.
12. Results for Samples -1, -2, -3, -4, -8, -12, & 18 were reported twice, (at 2 dilution's) to give the lowest possible detection limits at the lower dilution, and to report the large hits within calibration.

The data contained in the following report have been reviewed and approved by the personnel listed below. In addition, Paragon Analytics, Inc. certifies that the analyses reported herein are true, complete and correct within the limits of the methods employed.
