ACKNOWLEDGMENTS

Research for this project was sponsored by the Office of Environmental Restoration, U. S. Department of Energy, under contract DE-AC05-84OR21400 with Lockheed Martin Energy Systems, Inc. The authors wish to acknowledge the contributions of V. P. Patania, D. A. Roberts, D. A. Rose, and J. M. Lovegrove of the Measurement Applications and Development Group for participation in the sample preparation and analyses, editing, graphics, and reporting of data for this survey. The surveying assistance of the staff on the survey team is also gratefully acknowledged.

ABSTRACT

The U. S. Department of Energy (DOE) conducted remedial action during 1993 at the Pompton Plains railroad spur and eight vicinity properties in the Wayne and Pequannock Townships in New Jersey as part of the Formerly Utilized Sites Remedial Action Program (FUSRAP). These properties are in the vicinity of the DOE-owned Wayne Interim Storage Site (WISS), formerly the W. R. Grace facility. The property at the Pompton Plains Railroad Spur, Pequannock, New Jersey is one of these vicinity properties.

At the request of DOE, a team from Oak Ridge National Laboratory conducted an independent radiological verification survey at this property. The purpose of the survey, conducted between September and December 1993, was to confirm the success of the remedial actions performed to remove any radioactive materials in excess of the identified guidelines. The verification survey included surface gamma scans and gamma readings at 1 meter, beta-gamma scans, and the collection of soil and debris samples for radionuclide analysis.

Results of the survey demonstrated that all radiological measurements on the property at the Pompton Plains railroad spur were within applicable DOE guidelines. Based on the results of the remedial action data and confirmed by the verification survey data, the portions of the site that had been remediated during this action successfully meet the DOE remedial action objectives.

**Radiological Verification Survey Results
at the
Pompton Plains Railroad Spur (PPRS),
Pequannock, New Jersey (PJ008V)***

INTRODUCTION

As part of the Formerly Utilized Sites Remedial Action Program (FUSRAP), the Department of Energy (DOE) conducted a remedial action project in 1993 at several residential vicinity properties in the Townships of Pequannock and Wayne, New Jersey, and at the Pompton Plains railroad spur (PPRS) in Pequannock, New Jersey. Figure 1 shows the general location of these vicinity properties.

From September to December 1993, a team from the Measurements Application and Development Group, Oak Ridge National Laboratory (ORNL), conducted radiological verification surveys of these properties in the Wayne and Pequannock, New Jersey areas. The PPRS in Pequannock was one of the properties that had previously been surveyed and designated for remedial action. After completion of the remediation, the team from ORNL conducted a radiological verification survey of this property at the request of DOE. The verification survey consisted primarily of a complete gamma scan of the area and the collection of soil samples for radionuclide analysis.

This report describes the radiological verification survey of the now-abandoned Pompton Plains railroad spur, Pequannock, New Jersey conducted by ORNL at the request of the Department of Energy's Office of Environmental Restoration.

The PPRS is an old railroad spur located at the east end of Peck Ave. in Pequannock Township, owned by the New York, Susquehanna, and Western Railroad. The PPRS is a flat, open area approximately 1 mile west of the former processing plant (the now DOE-owned Wayne Site). The plant received and processed monazite sand containing high concentrations of ^{232}Th . The spur was used to transfer the raw source material from rail cars to trucks for delivery to the processing plant on Black Oak Ridge Road. The portion of the property where Peck Ave. abuts the railroad spur (see Fig. 2) became radioactively contaminated by spills of unprocessed monazite sands that occurred during transfer of the material from rail cars to trucks.

A walkover survey of the property (a technician walks slowly over the property swinging a detection probe at ~1-2 inches from the ground surface) was conducted in October, November, and December 1993 by ORNL's Measurement Applications and Development Group. The purpose of the survey, which included the remediated area and adjacent tracks, was to determine whether any radiological residues above guidelines remained on the property.

A field survey drawing showing 10-m grids and indicating soil sampling locations and gamma radiation measurements is included in this report as Fig. 2.

* The survey was performed by members of the Measurement Applications and Development Group of the Health Sciences Research Division at Oak Ridge National Laboratory under DOE contract DE-AC05-84OR21400.

SCOPE OF THE SURVEY

A comprehensive description of the survey methods and instrumentation used in this survey is given in *Procedures Manual for the ORNL Radiological Survey Activities (RASA) Program*, ORNL/TM-8600 (April 1987), and *Measurement Applications and Development Group Guidelines*, ORNL-6782 (January 1995).

The radiological survey of this property included: (1) a surface gamma scan of the remediated area of the spur, with supplementary beta-gamma scans of the tracks, and (2) the collection of surface and subsurface soil samples for analysis.

Gamma radiation levels were determined using a portable sodium iodide (NaI) gamma scintillation detector connected to a Victoreen ratemeter. Measurements were recorded and converted to $\mu\text{R/h}$. Because NaI gamma scintillators are energy dependent, measurements of gamma radiation levels in counts per minute (CPM) are normalized to pressurized ionization chamber (PIC) measurements to estimate gamma exposure rates in $\mu\text{R/h}$. Beta-gamma measurements were taken with a Geiger-Mueller (GM) pancake to help detect surface contamination.

Surface (0-15 cm, or 0 to 6 in) and subsurface (15-45 cm, or 6 to 18 in) soil samples were collected randomly over the property. Confirmatory samples were taken from the remediated area where slightly elevated gamma or beta-gamma levels had been identified. These are referred to as biased samples and are labeled as B1 - B15. Systematic samples (S1-S8) were taken at locations irrespective of gamma exposure rates. Locations of the samples are shown in Fig. 2, and results of the analysis are shown in Table 1.

Direct measurement results presented in this report are gross readings; background radiation levels have not been subtracted. Similarly, background radiation levels have not been subtracted from radionuclide concentrations measured in environmental samples.

VERIFICATION SURVEY AND ANALYSIS

Gamma measurements at one meter from the surface ranged from 8 to 13 $\mu\text{R/h}$ as shown in Fig. 2. Surface gamma measurements generally ranged from 10 to 33 $\mu\text{R/h}$ on contact with the surface soil in the remediated area.

Surface and subsurface soil samples were collected from the remediated area. During beta and gamma scans, several small areas of surface contamination were detected on top of the railroad ties. Some samples were scraped from between and on top of the railroad ties where contaminated soil had inadvertently been deposited during the remediation process (samples B3, B5, B6, B7, B8 and B9). Because these areas on the tracks were subsequently remediated and re-scanned for beta and gamma radiation to ensure the removal of all contamination, these samples do not appear in Table 1. All samples were analyzed for radium (^{226}Ra), thorium (^{232}Th), and uranium (^{238}U).

Results of the soil analyses are in picocuries per gram (pCi/g) and are shown in Table 1. Radionuclide concentrations of ^{226}Ra and ^{232}Th in systematic soil samples ranged from 0.58 to 0.97 pCi/g and from 0.92 to 3.0 pCi/g, respectively. Concentrations of ^{226}Ra and ^{232}Th in biased samples ranged from 0.6 to 2.1 and 1.4 to 11 pCi/g, respectively. The maximum concentration of 11 pCi/g ^{232}Th was found in sample B11. Although samples B11, B12, B14, and B15 were slightly above guidelines (Table 1), all the areas of elevated gamma radiation in which the samples were taken were no more than 1 m² in size. Thus, all these values are well below the DOE guideline for these radionuclides in soil which is 5 and 15 pCi/g above background when averaged over 100 m² for surface and subsurface soil, respectively.*

Concentrations of ^{238}U in soil ranged from 0.64 to 1.3 pCi/g in the systematic samples, and from 0.71 to 4.5 pCi/g in biased samples. These values are well below the site specific guidelines for uranium in soil.**

CONCLUSIONS

Generally, gamma measurements on the property at the Pompton Plains railroad spur in Pequannock, New Jersey were comparable to the average values for the area. Although slightly elevated gamma measurements were detected on surface contact with the remediated area and railroad tracks, they were within the range of background levels.

The previously remediated area was thoroughly investigated for radionuclide residues. The results of soil radionuclide analysis for ^{238}U , ^{226}Ra , and ^{232}Th indicate that all soil concentration measurements are within the limits prescribed by DOE radiological guidelines.

Based on the results of the remedial action data and confirmed by the verification survey data, all radiological measurements fall below the limits prescribed by DOE radiological guidelines established for this site. It is concluded that the portions of the site which had been remediated during this action successfully meet the DOE remedial action objectives.

* For residential properties in this area, the guideline for ^{232}Th is 5 pCi/g for both surface and subsurface soil.

** DOE guidelines for uranium are derived on a site-specific basis. Guidelines of 100 pCi/g have been applied to this FUSRAP site. Source: J. W. Wagoner II, Director, Division of Off-Site Programs, Office of Environmental Restoration, U. S. Department of Energy, personal communication to L. K. Price, Director, Former Sites Restoration Division, Oak Ridge Field Office, U. S. DOE, April 25, 1995.
