1. Purpose

The purpose of this analysis is to calculate the thermal response of the repository host rock and near-field surface temperatures due to the heat produced by drift-emplaced waste packages (WPs). The main objective of the evaluation is to predict time-dependent WP surface temperatures for later use as boundary conditions for detailed thermal evaluations of large and small Multi-Purpose Canisters (MPCs), defense high-level waste (DHLW), and uncanistered spent fuel (UCF) waste package conceptual designs. This analysis will also provide a parametric evaluation of the thermal effects of thermal loading and various emplacement parameters to determine what parameters are important to repository thermal behavior.

2. Quality Assurance

The Quality Assurance (QA) program applies to this analysis. The work reported in this document is part of the thermal analysis for the License Application Design phase. This activity can impact the proper functioning of the Mined Geologic Disposal System (MGDS) waste package; the waste package has been identified as an MGDS Q-List item important to safety and waste isolation (pp. 5,16, Ref. 5.1). The waste package is on the Q-List by direct inclusion by the Department of Energy (DOE), without conducting a QAP-2-3 evaluation. The work performed for this analysis is covered by a Waste Package Development (WPD) QAP-2-0 work control Activity Evaluation entitled "Perform Criticality, Thermal, Structural, and Shielding Analyses" (Ref. 5.2). The QAP-2-0 evaluation determined such activities to be subject to *Quality Assurance Requirements and Description* (QARD) (Ref. 5.3) controls. Applicable procedural controls are listed in the evaluation.

All design inputs which are identified in this document are for pre-Title II (conceptual or preliminary) designs; some or all of these design inputs will require subsequent qualification (or superseding inputs) as the waste package design proceeds. For design documents subject to the QARD requirements, unqualified design inputs must be considered as TBV (to be verified) items subject to tracking, in accordance with applicable procedures. The design inputs identified and documented in Section 4 have been assigned the single tracking number TBV-217-WPD, to meet tracking requirements.

3. Method

Finite element analysis was the analytical model employed. A finite element representation of the geometry of a waste package in repository emplacement was developed and solved using the solid modeling and thermal analysis capabilities of the commercially available ANSYS finite element software. A range of thermal loadings (waste package and drift spacings) and waste package sizes was considered.

4. Design Inputs

All design inputs are for pre-Title II designs; some or all of these design inputs will require subsequent qualification (or superseding inputs) as the waste package design proceeds. The design inputs identified and documented in Section 4 have been assigned the single tracking number TBV-217-WPD, to meet tracking requirements in accordance with applicable procedures.

4.1 Design Parameters

Table 2 of Section 1.12 of the Yucca Mountain Project Reference Information Base (RIB, p. 5, Ref. 5.4) provides corrected depths to rock unit lower contacts from borehole USW G-4 (see Assumption 4.3.5). These depths are listed here in Table 4.1-1 for the rock units considered in this analysis (see Assumption 4.3.14). Table 2 of Section 1.1326 of the RIB (p. 9, Ref. 5.4) provides mean-value in-situ-saturation estimates for the rock mass thermal conductivity for some of the rock units. These values are also listed here in Table 4.1-1.

Table 4.1-1. Stratigraphy for Borehole USW G-4 (Ref. 5.4)

Rock Unit	Corrected Lower Contact	Thermal Conductivity
Ground Level	0 m (0 ft)	N/A
Undifferentiated Overburden	9.1 m (30 ft)	(see Assumption 4.3.10)
TCw Lithophysae Poor TCw Lithophysae Rich (TCw Average)	36.0 m (118 ft)	1.73 W/m·K 1.59 W/m·K (1.66 W/m·K) (see Assumption 4.3.11)
PTn Welded, Devitrified PTn Non-welded or Bedded	74.1 m (243 ft)	1.60 W/m·K 0.85 W/m·K (see Assumption 4.3.12)
TSw1 Lithophysae Poor TSw1 Lithophysae Rich (TSw1 Average)	204.2 m (670 ft)	1.70 W/m·K 1.60 W/m·K (1.65 W/m·K) (see Assumption 4.3.11)
TSw2	393.5 m (1291 ft)	2.10 W/m·K
TSw3	409.3 m (1343 ft)	1.28 W/m·K
CHn1v	414.5 m (1360 ft)	1.20 W/m·K

CHn1z	518.5 m (1701 ft)	1.28 W/m·K
CHn2v CHn2z (CHn2 Average)	535.2 m (1756 ft) (see Assumption 4.3.14)	1.20 W/m·K 1.56 W/m·K (1.38 W/m·K) (see Assumption 4.3.13)

Table 6 of Section 1.1326 of the RIB (p. 11, Ref. 5.4) gives the thermal capacitance of the rock mass at selected temperatures for nine of the thermal/mechanical rock units. They are repeated here in Table 4.1-2. Thermal capacitance is the product of specific heat and density. Therefore, for the emplacement thermal model, the below values were converted to $\text{J/m}^3\cdot\text{K}$ (multiplied by 1×10^6) and entered as temperature-dependent specific heats with all rock densities equal to 1.0 kg/m^3 (see Assumption 4.3.16).

Table 4.1-2. Thermal Capacitance of Rock Units ($\text{J/cm}^3\cdot\text{K}$) (Ref. 5.4)

Temp.	TCw	PTn	TSw1	TSw2	TSw3	CHn1v	CHn2v	CHn2*
25°C	1.9263	2.1164	1.9779	2.0324	1.8443	2.4436	2.6032	2.4309

* CHn2 values are the average of CHn2v and CHn2z (see Assumption 4.3.13)

Table 4.1-3 lists the thermal properties of typical concrete to be used as the drift invert (see Assumption 4.3.20). These values were taken from Tables A.3 and A.8 of a standard heat transfer textbook (pp. 679, 692, Ref. 5.5) for a temperature of 300 K. To be conservative, a lower bound for emissivity was used.

Table 4.1-3. Material Properties of Concrete Invert (Ref. 5.5)

	Conductivity	Density	Specific Heat	Emissivity
Concrete Invert	1.4 W/m·K	2300.0 kg/m ³	880.0 J/kg·K	0.88

Table 4.1-4 lists the thermal properties of ASTM A 516 carbon steel (see Assumption 4.3.28). Values for thermal conductivity and thermal diffusivity of A 516 (C-Mn-Si) were taken from Table I-4.0, Appendix I of the 1986 ASME Boiler and Pressure Vessel Code (p. 97, Ref. 5.6) and are converted here to conductivity and specific heat in SI units. The conversion of thermal diffusivity (defined in Equation 4.1-1 below, p. 107, Ref. 5.6) to specific heat requires the density listed in Table 4.1-5.

$$\text{Thermal Diffusivity (ft}^2\text{/hr)} = \frac{\text{Thermal Conductivity (Btu/hr}\cdot\text{ft}\cdot^\circ\text{F)}}{\text{Density (lb/ft}^3\text{)} \times \text{Specific Heat (Btu/lb}\cdot^\circ\text{F)}}$$

(Equation 4.1-1)

Table 4.1-4. Thermal Properties of A 516 Carbon Steel (Ref. 5.6)

Temperature		Thermal Conductivity (Btu/hr·ft·°F)	Thermal Diffusivity (ft ² /hr)	Thermal Conductivity (W/m·K)	Specific Heat (J/kg·K)

1500	815.56	15.1	0.169	26.13	736.90

Table 4.1-5 lists the density and emissivity of A 516 carbon steel. The density of A 516 (C-Mn-Si) was taken from Table A.1 of a standard heat transfer text (p. 670, Ref. 5.5) and the emissivity (average for smooth oxidized iron) was taken from Table 4.3.2 of Marks' Handbook (p. 4-68, Ref. 5.7). The density of 316 stainless steel (see Assumption 4.3.30) was taken from Table 17 of the Metals Handbook (p. 423, Ref. 5.8).

Table 4.1-5. Steel Material Properties (Refs. 5.5, 5.7, and 5.8)

	Density	Emissivity
A 516 Carbon Steel	8131.0 kg/m ³	0.80
316 Stainless Steel	8000.0 kg/m ³	Not Applicable

Table 4.1-6 lists the specific heat of 316 (16Cr-12Ni-2Mo) stainless steel (see Assumption 4.3.30). Values for thermal conductivity and thermal diffusivity were taken from Table I-4.0, Appendix I of the 1986 ASME Boiler and Pressure Vessel Code (p. 102, Ref. 5.6) and are converted here to specific heat with Equation 4.1-1 and the density from Table 4.1-6. A value for specific heat at 100°C was interpolated.

Table 4.1-6. Thermal Properties of Stainless 316 (Ref. 5.6)

Temperature		Thermal Conductivity (Btu/hr·ft·°F)	Thermal Diffusivity (ft ² /hr)	Specific Heat (J/kg·K)
°F	°C			
200	93.33	8.4	0.141	499.38
	100.00			501.9
250	121.11	8.7	0.143	509.98

4.2 Criteria

The design of the engineered barrier system (EBS) will depend on thermal analyses of the repository host rock and near-field. Criteria that relate to the thermal analysis of the EBS are derived from the applicable requirements and planning documents. Upper-level systems requirements are provided in the Mined Geologic Disposal System Requirements Document (Ref. 5.9). The requirements flow down to the Engineered Barrier Design Requirements Document (EB-DRD, Ref. 5.10) as specific requirements for engineered barrier segment design. The Waste Package Implementation Plan (WPIP, Ref. 5.11) also provides criteria and goals for the thermal design of the EBS. The criteria applicable to thermal analysis of waste package emplacement are equivalent to the applicable requirements, interface requirements, and criteria cited in the MGDS-RD, EB-DRD, and WPIP and they are listed in this section.

4.2.1 EB-DRD Requirements (pp. 3-8, 3-14, 3-19, 3-25, 3-47, 3-49, 3-53, 3-54, Ref. 5.10)

"3.1.5 MAJOR CONSIDERATIONS AND ASSUMPTIONS

- ...
- B. The assumption used in developing this EB-DRD is that the extent of blending (ie., the mixing in waste packages of SNF and/or HLW of different thermal outputs) required is limited to that which can be accommodated by the WA process

Thermal loading studies will determine the extent of blending that must occur. Limited blending can be accomplished at the MRS through the WA process. If significant blending is required, this could have a major impact on the MRS and/or MGDS design and operations, and will be the subject of system studies. If these studies show that changes in system design requirements are necessary, the RDs will be revised."

"3.2.2 RADIOLOGICAL PROTECTION

3.2.2.1 GENERAL REQUIREMENTS

- ...
- C. The Engineered Barrier Segment, together with the Repository Segment, shall provide adequate shielding from radioactive components and high ambient temperatures.

[Derived]"

"3.2.3.3 ENGINEERED BARRIER SEGMENT - REPOSITORY SEGMENT INTERFACE REQUIREMENTS

...

- A.8 The Repository Segment will accommodate the emplacement concept (TBD) selected during ACD.

[Derived]

- ...
- b. The Repository Segment will prevent free-liquid-phase water from contacting the waste package during the period from package insertion until repository closure.

[Derived]

- c. The Repository Segment layout will be designed so that a combination of characteristics will assist in keeping liquid water from contacting the waste packages for the first 300 to 1000 (TBV) years after closure.

[Derived]

- d. The Repository Segment layout will also ensure that the design limit temperatures (TBD) for waste forms are not exceeded.

[Derived]

- ...
- A.10 If the design requires the waste form to be transferred for any purpose (such as from shipping casks to waste packages), the Repository Segment is responsible for the following:

- ...
- b. Repository Segment operations at the surface handling facility will be designed so that cladding failure from mechanical abrasion or deformation considering thermally-induced effects will result in less than five percent (TBV) cladding strain.

[Derived]

- ...
- A.17 The underground facility will be designed so that the performance objectives will be met taking into account the predicted thermal and thermomechanical response of the host rock, and surrounding strata, and groundwater system.

[MGDS-RD 3.7.3.4.C] [10 CFR 60.133(i)]"

"3.2.3.4 ENGINEERED BARRIER SEGMENT -WASTE ACCEPTANCE INTERFACE REQUIREMENTS

- ...
- A. WA will provide standard HLW meeting the following criteria:

- ...
- 1.e. Total heat generation rate: Up to 1500 watts per canister (TBV) at the year of shipment.

- 1.f Waste temperature: Will not have exceeded 400°C (TBV) during transit to ensure the glass transition temperature was not exceeded.

[MGDS-RD 3.2.3.2.2.B.1]

- ...
C. WA will provide standard SNF meeting the following criteria:

- ...
1.d Cooling: The minimum cooling time for fuel is five (5) years.

...
[MGDS-RD 3.2.3.2.2.A.1] [10 CFR 961.11, App. E, B.3]

- ...
2. Temperature will not have exceeded 350°C (TBV) during storage under inert gas.

[Derived]"

"3.7

ENGINEERED BARRIER SEGMENT MAJOR COMPONENT CHARACTERISTICS/REQUIREMENTS

The major components of the Engineered Barrier Segment are the waste packages, the underground facility, any backfill placed in the emplacement drifts, and any emplacement hardware provided to support and protect the emplaced waste package. (The underground facility portion of the Engineered Barrier Segment and the associated requirements allocated to the EB-DRD by the MGDS-RD are identified as interfaces with the Repository Segment in Section 3.2.3.3.) These major components shall be capable of contributing to the assigned function, Isolate Waste (1.4.3), by containing waste in the waste package during the containment period of 300 to 1,000 years (TBR), and then by limiting the release of radionuclides during the post-containment period.

[MGDS-RD 3.7.3.1.A, B] [CRD 3.7.4.1.1]

- ...
G. To limit the predicted thermal and thermomechanical response of the host rock and surrounding strata, and groundwater system, the Engineered Barrier Segment configuration and loading shall:

1. Limit borehole wall temperature (if a borehole is used) to 275°C (TBV)
2. Limit the maximum temperature 1 meter into the rock to 200°C (TBV)
3. Limit the TSw3 (vitrophyre tuff) maximum temperature to 115°C (TBV)

4. Limit the maximum ground surface temperature change in the vicinity of the repository to 6°C (TBV)
5. Limit the emplacement drift maximum temperature to 100°C (TBV)
6. Limit the access drift maximum temperature to 50°C (TBV)
[MGDS-RD 3.7.3.4.C] [10 CFR 60.133(i)]"

"3.7.1 WASTE PACKAGE SUBSYSTEM REQUIREMENTS

- ...
- B. The design of waste packages shall include, but not limited to, consideration of the following factors: solubility, oxidation/reduction reactions, corrosion, hydriding, gas generation, thermal effects, mechanical strength, mechanical stress, radiolysis, radiation damage, radionuclide retardation, leaching, fire and explosion hazards, thermal loads, and synergistic interactions.
[MGDS-RD 3.7.3.3.B] [10 CFR 60.135(a)(2)]"

"3.7.1.3 INTERNAL STRUCTURE REQUIREMENTS

- ...
- G. The internal structure shall maintain functionality under the thermal and chemical conditions generated by the waste form.
[Derived]"

"3.7.2 BACKFILL REQUIREMENTS

- ...
- C. The transfer of heat from the waste package to the geologic setting by the backfill material shall not have an adverse effect on the long term performance of the WP.
[Derived]
- F. The chemical and mechanical stability of the backfill when subjected to the maximum thermal environment anticipated in the repository shall not have an adverse effect on the long term performance of the waste package.
[Derived]"

4.2.2 MGDS-RD Requirements (pp. 26, 42, 107, Ref. 5.9)

The following requirements from the MGDS-RD (Ref. 5.9) apply to the thermal analysis of the EBS but were not explicitly echoed in the current revision of the EB-DRD (Ref. 5.10).

"3.1.5 Major Considerations and Assumptions

- ...
- M. It is assumed that loaded MPCs emplaced for disposal will have a maximum thermal output of 14.2 kilowatts. Accommodation of this condition will require management of the waste delivery schedule or storage of loaded MPCs with a higher thermal output until the thermal output has decreased to 14.2 kilowatts. This 14.2 kilowatts is equivalent to the thermal output of 21 PWR assemblies with 40 GWd/MTU burnup and 3.75% initial enrichment 10 years after discharge from a reactor. (Twenty-one assemblies represents the capacity of one of several potential MPC configurations.)"

"3.2.3.2.3 MGDS-Transportation Interface Requirements

- ...
- J. The MGDS shall provide an emplacement environment (e.g., waste package design, underground facility design, emplacement mode or orientation, spacing between waste packages, etc.) for the MPC with disposal container, such that an emplaced waste package with a thermal output of 14.2 kW will not result in an MPC surface temperature higher than 225°C <TBR>. [Ref. 2.4.2.C] [RW-0199] [10 CFR 60.135(a)(2)] [Derived by 3.2.1.1.H]

The MPC design is responsible for maintaining the peak SNF cladding temperature below the maximum temperature designated for disposal. To meet this requirement, the peak cladding temperature in a loaded MPC with a thermal output of 14.2 kW may not exceed 350°C when subjected to an MPC external wall temperature of 225°C."

"3.7.3.3 Waste Package Requirements

- ...
- B.2 Waste packages shall be emplaced in an environment (e.g., waste package design, underground facility design, emplacement mode or orientation, spacing between waste packages, etc.), such that SNF cladding temperatures in an emplaced waste package do not exceed 350°C <TBR>. [10 CFR 60.135(a)(2)] [Derived by CRD 3.2.1.1.H]"

4.2.3 WPIP Criteria (pp. 2-4, 3-2, 4-30, 5-1, Ref. 5.11)

The impetus to perform thermal evaluations of the waste package and near-field is provided by the Waste Package Implementation Plan (WPIP, Ref. 5.11). Design goals and the activities supporting these goals are listed in the WPIP. Design goals related to thermal analysis are listed in Section 2.4 of the WPIP and provide basic thermal criteria for the design of the EBS. Activities to support the design goals related to thermal analysis are indicated in Sections 3.4, 4.5, and 5.1 of the WPIP.

"2.4 DESIGN GOALS

- ...
- Center line fuel pin temperature limit of (to be determined (TBD)) °C
 - Rock wall temperature limit of (TBD) °C
 - Thermal loading of the repository (TBD)
- ...

The maximum temperature of the glass waste forms must be maintained below limits established for them. This limit is about 500°C (to be verified) for West Valley Defense High-Level Waste glass. The YMP and the glass producers have the responsibility to maintain the peak temperature below the transition temperature."

Table 2-1 Listing of Design Goals*

- ...
- Meet temperature limits for components
 - Provide for a range of thermal loads⁺
 - Provide capability to adjust repository thermal loading after emplacement⁺

*The source of the design goals is, for the most part, the Engineered Barrier Design Requirements Document.

⁺The source of these design goals is engineering judgement."

"3.4 PERFORMANCE ALLOCATION

... Thermal analyses will be performed to determine the temperature profiles across the drifts for drift emplacement. Limited thermal analyses will also be performed for the borehole emplacement modes, assuming various package sizes and thermal loadings. These analyses will permit the re-evaluation of the goals given in the SCP for performance measures. ..."

"4.5 ENVIRONMENT INFORMATION NEEDS

4.5.2 Hydrologic Properties

Determine hydrologic (and thermal) properties of the WP environment in order to:

- Develop a comprehensive model of the thermal and hydrologic behavior of the waste package environment as a function of overall repository thermal loading and rock properties, including two-phase flow
- Use the model to forecast the near field temperature and fluid flow; these near field parameters will be used by M&O Waste Package Development, M&O PA, and LLNL to calculate/forecast the WP temperatures (surface and centerline) and the distribution of corrosion rates and package lifetimes (as input to the models determined by the chemical and mineralogical properties investigation described above)."

"5.1 WP/EBS DESIGN ACTIVITIES

- 2. Thermal Evaluation (time dependent)
 - 2.1. Internal
 - 2.1.1. SNF and HLW
 - 2.1.2. WP basket
 - 2.1.3. WP internal barrier(s)
 - 2.1.4. WP body
 - 2.1.5. Closure
 - 2.2. External, EBS and near field
 - 2.3. Receipt rate and thermal variability"

4.2.4 Thermal Goals for EBS Design

Based on Assumption 4.3.1, the requirements of Section 3.7.G of the EB-DRD (Ref. 5.10), and the design goals of the WPIP (Ref. 5.11), the following thermal criteria are established for the design of the EBS:

- Keep the rock mass temperature at 1 meter from a vertical borehole less than 200°C.
- Keep the emplacement drift wall temperature less than 200°C.
- Limit the TSw3 (basal vitrophyre) maximum temperature to less than 115°C.
- Limit the maximum ground surface temperature change in the vicinity of the repository to less than 2°C.

- Limit the emplacement drift maximum temperature for borehole emplacement to less than 100°C.
- Limit the access drift wall rock maximum temperature to less than 50°C during preclosure.
- Limit the CHn maximum temperature to less than 115°C.
- Limit the PTn (Upper Paint Brush non-welded) maximum temperature to less than 115°C.
- Limit the SNF cladding maximum temperature to less than 350°C.
- Limit the high-level waste glass maximum temperature to less than 500°C.
- Maximize the time the waste package container stays above boiling consistent with the thermal strategy developed.
- The structural strength of any material component of the waste package shall not be compromised by temperature/environment of the EBS environment.

The above thermal criteria are in addition to those listed in Sections 4.2.1, 4.2.2, and 4.2.3.

4.2.5 Thermal Goals/Criterion Addressed by this Analysis

Based on Assumption 4.3.1, the requirements listed in the previous sections, and the design goals of the WPIP (Ref. 5.11), the following criteria are to be addressed by this analysis:

- Keep the emplacement drift wall temperature less than 200°C.
- Limit the TSw3 (basal vitrophyre) maximum temperature to less than 115°C.
- Limit the CHn maximum temperature to less than 115°C.
- Limit the PTn (Upper Paint Brush non-welded) maximum temperature to less than 115°C.
- Limit the SNF cladding maximum temperature to less than 350°C.
- Maximize the time the waste package container stays above boiling consistent with the thermal strategy developed.

4.3 Assumptions

All design inputs are for pre-Title II designs; some or all of these design inputs will require subsequent qualification (or superseding inputs) as the waste package design proceeds. The design inputs identified and documented in Section 4 have been assigned the single tracking number TBV-217-WPD, to meet tracking requirements in accordance with applicable procedures.

4.3.1 The following thermal criteria are assumed to apply to the design of the Engineered Barrier Segment. These criteria are consistent with current program decisions in the Controlled Design Assumption Document (CDA, Ref. 5.12). The criteria are originally based on a reevaluation of the Site Characterization Plan (SCP) thermal goals (Table 3, p. 22, Ref. 5.13). Each thermal criteria is listed here followed by its CDA or SCP reference. This assumption is used in Section 4.2.4.

- Keep the rock mass temperature at 1 meter from a vertical borehole less than 200°C. (CDA EBD RD 3.7.G.2, p. 6-76, Ref. 5.12)
- Keep the emplacement drift wall temperature less than 200°C. (CDA EBD RD 3.7.G.2, p. 6-76, Ref. 5.12)
- Limit the TSw3 (basal vitrophyre) maximum temperature to less than 115°C. (CDA EBD RD 3.7.G.3, p. 6-77, Ref. 5.12)
- Limit the maximum ground surface temperature change in the vicinity of the repository to less than 2°C. (CDA EBD RD 3.7.G.4, p. 6-78, Ref. 5.12)
- Limit the emplacement drift maximum temperature for borehole emplacement to less than 100°C. (CDA EBD RD 3.7.G.5, p. 6-79, Ref. 5.12)
- Limit the access drift wall rock maximum temperature to less than 50°C during preclosure. (CDA EBD RD 3.7.G.6, p. 6-80, Ref. 5.12)
- Limit the CHn maximum temperature to less than 115°C. (CDA DCSS 025, p. 6-155, Ref. 5.12)
- Limit the PTn (Upper Paint Brush non-welded) maximum temperature to less than 115°C. (CDA DCSS 031, p. 6-160, Ref. 5.12)

- Limit the SNF cladding maximum temperature to less than 350°C.
(CDA DCWP 001, p. 6-165, Ref. 5.12)
 - Limit the high-level waste glass maximum temperature to less than 500°C.
(CDA DCWP 002, p. 6-166, Ref. 5.12)
 - Maximize the time the waste package container stays above boiling consistent with the thermal strategy developed. (Table 3, p. 23, Ref. 5.13)
 - The structural strength of any material component of the waste package shall not be compromised by temperature/environment of the EBS environment..
(Derived from p. 2-4, Ref. 5.11 and Section 3.7.1.3.E, p. 3-53, Ref. 5.10)
- 4.3.2 The waste package will be emplaced in-drift in a horizontal mode. This is consistent with large waste packages such as the MPC with disposal container and is a current program decision (CDA Key 011, p. 6-18, Ref. 5.12). This assumption is used in Section 7.4.1.
- 4.3.3 A pillar model of repository emplacement with a single modeled waste package will be used to determine the average drift wall and waste package surface temperatures. A single modeled waste package implies that all packages in the repository generate the same heat. This assumption results in a prediction of average repository temperatures, neglecting hot and cold spots due to the variability of waste package heat loads. The assumption is necessary to allow a detailed evaluation of emplacement geometry while maintaining reasonable model size. This assumption is used in Sections 7.4.1 and 7.4.2.
- 4.3.4 The repository emplacement model assumes an infinite repository horizon such that heat losses at the repository sides (edge effects) are neglected. The assumption of an infinite repository is applicable to the interior of the repository, which is not affected by cooling at the edge. This region includes most of the repository area during the first 1000 years (p. 5, Ref. 5.14). This assumption follows as a result of Assumption 4.3.3 and is necessary to maintain a reasonable model size. This assumption is used in Section 7.4.2.
- 4.3.5 A layered rock stratigraphy for the repository emplacement model is assumed consistent with that measured at borehole USW G-4 (Table 2, Section 1.12, p. 5, Ref. 5.4). Borehole USW G-4 is near the proposed repository main block. This assumption is used in Sections 4.1, 7.4.1, and 7.4.2.

- 4.3.6 The repository horizon (bottom of drift cut) for the repository emplacement model is at a depth of 311 m (measured from borehole USW G-4). This assumption has been used in previous near-field thermal evaluations (Appendix E, p. 9, Ref. 5.15) performed by Sandia National Laboratories (SNL). Historically, this value represents the location (107 m below the lower contact of TSw1 measured from borehole USW G-4) of a proposed canister-scale heater test (p. 3, Ref. 5.16). This value is consistent with an approximate depth of 350 m provided in the SCP (p. 7-8, Ref. 5.17) and places the repository horizon within the TSw2 rock unit (CDA Key 022, p. 6-26, Ref. 5.12). This assumption is used in Section 7.4.1.
- 4.3.7 The repository emplacement model thermal evaluation will predict temperatures for up to 1000 years after emplacement. After about 1000 years, depending on the emplacement spacings, the 3-D pillar model of emplacement will tend to over-predict average temperatures due neglected edge effects (see Assumption 4.3.4) during the cool-down phase of repository thermal response. This effect was quantified in benchmark calculations against Lawrence Livermore National Laboratory (LLNL) evaluations (p. 7, Ref. 5.18). This assumption is used in Section 7.4.2.
- 4.3.8 A repository emplacement model lower boundary that extends to a depth of 1300 m will ensure lower boundary condition isolation for at least 1000 years. Analyses performed at LLNL (p. 853, Ref. 5.19) have found that there may be insufficient water circulation at the water table, due to low permeabilities, to maintain a constant temperature at that depth (about 611 m). A constant temperature boundary condition will not affect solution results if the heat conduction wavefront does not reach the boundary condition before the end of model solution time (1000 years, see Assumption 4.3.7). This assumption is used in Sections 7.4.1 and 7.4.2.
- 4.3.9 The ground surface and rock at 1300 m temperatures can be assumed constant values of 18.7°C and 53.05°C respectively. Assumptions for the average ground surface temperature and the ambient thermal gradients in the rock are provided in the CDA (TDSS 002, p. 6-182, Ref. 5.12). The temperature at 1300 m is calculated as the sum of the ground surface temperatures plus the thermal gradients [$18.7^{\circ}\text{C} + 0.019^{\circ}\text{C/m}$ (0 to 150 m) + 0.018°C/m (150 to 400 m) + 0.030°C/m (400 to 541 m)], where the last thermal gradient is assumed to extend to 1300 m. Also, since the surface temperature is fixed in this model, the temperature rise at the ground surface due to thermal loading of the repository will not be calculated. Temperature boundary conditions are required for a thermal analysis. This assumption is used Section 7.4.2.
- 4.3.10 Material properties for the Undifferentiated Overburden (UO) are assumed to be the same as the material properties of TCw. There are no material properties provided in the RIB (Ref. 5.4) for UO; therefore, there is no reason to track or distinguish between UO and TCw. This assumption is used in Sections 4.1, 7.4.1, and 7.4.2.

- 4.3.11 The thermal conductivities for TCw and TSw1 are assumed the average of their lithophysae poor and rich components. There is no data given in the RIB (Ref. 5.4) that would indicate what proportion of these rock units are lithophysae rich compared to lithophysae poor; therefore, an average will be representative. This assumption is used in Sections 4.1 and 7.2.
- 4.3.12 The thermal conductivity of PTn is assumed that of non-welded PTn. There is no data given in the RIB (Ref. 5.4) for what portion of the PTn unit is welded; therefore, the lower value has been selected to be conservative. This assumption is used in Sections 4.1 and 7.2.
- 4.3.13 The thermal conductivity and thermal capacitance of CHn2 are assumed to be the average of the values given for CHn2v and CHn2z in the RIB (Table 2, Section 1.1326, p. 9, Ref. 5.4). There is no data given in the RIB for the lower contact depths of CHn2v and CHn2z; therefore, an average will be representative. This assumption is used in Sections 4.1 and 7.2.
- 4.3.14 Material properties of the CHn2 unit are assumed to persist below its lower contact down to 1300 m. There are no material properties provided in the RIB (Ref. 5.4) for rock units below CHn2; therefore, there is no reason to track or distinguish units below CHn2. This assumption is used in Sections 4.1, 7.2, and 7.4.1.
- 4.3.15 The effects of water movement (fluid flow) in the rock units (layers) on temperatures at the waste package and near-field are minor such that the system can be approximated by a model that considers conduction and radiation heat transfer only. While "conduction-only" codes cannot predict water movement or humidities, they have been shown to provide a reasonable estimate of rock temperatures in benchmarking evaluations (p. 7, Ref. 5.18). This assumption is used in Section 7.4.2.
- 4.3.16 The temperature-dependent thermal capacitances provided in the RIB (Table 6, Section 1.1326, p. 11, Ref. 5.4) will approximate the latent heat absorption due to boiling of water in the rock units. The model and analysis code used in this analysis does not consider fluid flow (see Assumption 4.3.15) and the temperature-dependent thermal capacitances have higher values near the boiling point to represent the heat of vaporization of the in-situ water. This formulation is consistent with previous conduction/radiation thermal evaluations performed by SNL (Appendix E, p. 5, Ref. 5.15). It is important to note, however, that as described in the RIB, these capacitances are applicable only for the heating phase of the rock units. This limitation does not affect the estimation of peak temperatures which occur before repository cool-down begins. This assumption is used in Sections 4.1, 7.2, and 7.4.2.

- 4.3.17 The repository horizon will be limited to the TSw2 geologic unit in the primary area. This assumption is consistent with current repository conceptual designs (p. 8-12, Ref. 5.20) and is a current program decision (CDA Key 022, p. 6-26, Ref. 5.12). This assumption is used in Section 7.4.1.
- 4.3.18 The emissivity of the TSw2 rock unit is 0.85. This value is an historic value that was used in numerous evaluations performed by SNL and can be compared to 0.75 used by LLNL (p. 539, Ref. 5.21) and the range of 0.88 to 0.95 given for rocks in a standard heat transfer textbook (Table A.8, p. 693, Ref. 5.5). This assumption is used in Section 7.2.
- 4.3.19 The waste package is emplaced in a circular drift with a diameter of 5.0 m. This drift diameter is consistent with recent repository subsurface conceptual designs for center-in-drift emplacement using permanent rail carts (p. 2, Ref. 5.22 and Section 8.6.1.G, p. 8-76, Ref. 5.20). This assumption is used in Section 7.4.1.
- 4.3.20 The emplacement drift invert will be cast-in-place concrete with a depth of 0.7 m. This invert material and thickness is consistent with recent repository sub-subsurface conceptual designs for center-in-drift emplacement using permanent rail carts (p. 2, Ref. 22 and Section 8.6.1.S, p. 8-78, Ref. 5.20). Given a distance between the drift centerline and the top of the invert of 1.8 m (p. 2, Ref. 5.22) and a drift diameter of 5.0 m (Assumption 4.3.18), then the invert height would be 0.7 m $[5.0/2 - 1.8]$. This assumption is used in Sections 4.1, 7.2, and 7.4.1.
- 4.3.21 The center of the large waste package, with 21 pressurized-water reactor (PWR) assemblies, is 0.137 m below the drift centerline. This WP position is consistent with recent repository subsurface conceptual designs for center-in-drift emplacement using permanent rail carts (p. 2, Ref. 5.22 and Section 8.6.1.H, p. 8-77, Ref. 5.20). This assumption is used in Section 7.4.1.
- 4.3.22 The permanent rail cart for the smaller WP (12 PWR) will have similar dimensions to the rail cart for the large WP (21 PWR) such that the clearance between the bottom of the WP and the top of the invert is the same for both WPs. To allow both large and small WPs in the same repository, the emplacement methods should be compatible (same rail spacing, wheel diameter, etc.). This assumption is used in Section 7.4.1.
- 4.3.23 The waste package is assumed to "float" in the emplacement drift such that thermal effects due to the emplacement support device can be neglected. Designs for WP support devices (pedestals, rail carts) are conceptual (Section 8.7.2.2, p. 8-131, Ref. 5.20) and specific designs are not available. Therefore, the support device and any conductive or insulative properties it may have are neglected. This assumption is used in Sections 7.4.1 and 7.4.2.

- 4.3.24 The emplacement drift will not be backfilled at repository closure. No backfill material has been specified; however, the assumption of possible drift backfilling is a current program decision (CDA Key 046, p. 6-39, Ref. 5.12). The evaluation of the thermal impact of emplacement drift backfill is beyond the scope of this analysis and will be considered in future emplacement scale evaluations. This assumption is used in Section 7.4.2.
- 4.3.25 The emplacement drifts are not ventilated. While some ventilation is likely during the actual emplacement operations, it may not be possible (cost effective) to continuously ventilate all of the emplacement drifts. Studies of repository ventilation (Ref. 5.23) are in progress; however, it is conservative to assume that the emplacement drift is unventilated after emplacement operations have been completed. This assumption is used in Section 7.4.2.
- 4.3.26 Thermal radiation is the dominant heat transfer mechanism between the waste package and the drift wall such that air convection in the drift can be neglected. Given that the emplacement drifts are not ventilated (see Assumption 4.3.25) and conduction through the WP supports is neglected (see Assumption 4.3.23), thermal radiation and natural convection will transfer the WP heat to the drift wall. Reference 5.24 (p. 59) showed that radiation heat transfer in a closed drift above borehole emplaced WPs is an order of magnitude greater than convective heat transfer. Therefore, radiation is considered the dominant heat transfer mechanism in the open emplacement drifts as well. This assumption, which is consistent with evaluations performed by SNL (Appendix E, p. 5, Ref. 5.15), simplifies the model and will result in slightly conservative WP temperatures. This assumption is used in Section 7.4.2.
- 4.3.27 The waste package in the repository emplacement model will be a smeared-property homogeneous heat-generating cylinder with dimensions based on the 21 PWR and 12 PWR MPC conceptual designs with disposal container. MPC conceptual designs are described in Volume II.A of the MPC Conceptual Design Report (pp. II.A.4-1 to II.A.4-22, Ref. 5.25). The two sizes of MPC disposal containers are represented by preliminary sketches prepared in support of Waste Package Development Advanced Conceptual Design (Ref. 5.26 and Ref. 5.27) and the outer dimensions are listed in Table 4.3-1. Details of internal construction will not effect the determination of emplacement near-field surface temperatures; therefore, the WP can be represented by a homogeneous cylinder. This assumption is used in Sections 7.2 and 7.4.1.

Table 4.3-1. MPC with Disposal Container Dimensions (Refs. 5.26 and 5.27)

	21 PWR MPC/WP	12 PWR MPC/WP
Outer Diameter	1.8016 m	1.5305 m
Outer Length	5.682 m	5.647 m

- 4.3.28 The homogeneous waste package in the repository emplacement model will include a 0.1 m layer of A 516 carbon steel to properly distribute temperatures along its length. In previous iterations of the development of this model (p. 3, Ref. 5.18), a purely homogeneous model of the WP had slightly over-predicted the temperature difference between the end and mid-length of the WP. A metal layer was found to spread the heat more evenly over the surface of the WP as would be expected in the metallic multi-barrier design. A 0.1 m outer barrier of A 516 carbon steel is indicated by preliminary sketches prepared in support of Waste Package Development Advanced Conceptual Design (Ref. 5.26 and Ref. 5.27) and the CDA (Key 042, p. 6-37, Ref. 5.12). This assumption is used in Sections 4.1, 7.2, and 7.4.1.
- 4.3.29 The density of the homogeneous waste package can be represented by the estimated total mass of the 21 PWR MPC with disposal container (p. 5, Ref. 5.28) divided by its volume derived from Table 4.3-1. Since accurate temperatures internal to the waste package are not required of this model, a density based on a weighted average of constituent materials is adequate. This assumption is used in Section 7.2.
- 4.3.30 The specific heat of the homogeneous canister can be represented by that of 316 stainless steel at 100°C. Since accurate temperatures internal to the waste package are not required of this model, a specific heat that is representative of internal materials is adequate. With the A 516 carbon steel outer barrier removed, the remaining materials are dominated by the MPC shell and basket which can be assumed to be primarily stainless steel (pp. II.A.4-1 to II.A.4-22, Ref. 5.25). A reference temperature of 100°C is an engineering estimate of the average waste package temperature over time. This assumption is used in Section 4.1 and 7.2.
- 4.3.31 The conductivity of the homogeneous canister can be represented by an average value derived from previous discrete analyses of the MPC with disposal container. Since accurate temperatures internal to the waste package are not required of this model, an effective conductivity for the homogeneous WP can be calculated based the peak cladding temperature, MPC shell surface temperature, and decay heat load from a previous MGDS thermal analysis of the MPC/WP reported in the MGDS MPC Design Considerations Report (pp. 57 and 63, Ref. 5.29). It is also assumed that the heat load

at initial emplacement (p. 57, Ref. 5.29) can substituted for the heat load at one year without significant impact to the calculation of the homogeneous canister conductivity. This assumption is used in Section 7.2.

- 4.3.32 Thermal loading will be calculated as a function of area mass loading (AML) in MTU/acre (kgU/m^2). Local AML is defined as the mass of the waste package (MTU/WP) divided by the product of WP spacing and drift spacing. Thermal loadings can be defined by AML, initial areal power density (APD), and equivalent energy density (EED). APDs can vary depending on the age of the SNF, and no reference deposition period for EED has been established. Therefore, an AML, which does not change with time after emplacement, is the most consistent method of defining lifetime repository thermal behavior. This assumption is used in Section 7.5.
- 4.3.33 Two primary high thermal loadings (100 MTU/acre and 83 MTU/acre) and a couple variations of a low thermal loading (25 MTU/acre) will be considered in this analysis. These values are consistent with the range (20 - 100 MTU/acre) of thermal loadings given in the CDA (Key 019, p. 6-24, Ref. 5.12). Systems Engineering (p. 2, Ref. 5.30) recommended thermal loadings of 25 and 83 MTU/acre be used for M&O thermal loading evaluations in order to facilitate the comparison of analysis results. A thermal loading of 100 MTU/acre represents the likely maximum possible without violating thermal goals according to the FY 93 Thermal Loading System Study Final Report (p. 10-2, Ref. 5.15) and is a bounding case for this analysis. This assumption is used in Section 7.5.
- 4.3.34 In determining emplacement spacings for a given thermal loading, the minimum center-to-center WP spacing for the large (21 PWR) WP will be 16 m and the maximum WP spacing will be no longer than the drift spacing for that case. An estimated minimum WP spacing for a large WP (21 PWR assemblies) was derived from previous scoping thermal evaluations (p. 3, Ref. 5.31) with conservative assumptions such as a 4.3 m emplacement drift and young/hot SNF. That preliminary evaluation predicted that for 21 PWR WPs, an 11 m WP spacing would exceed WP internal thermal goals and a 15.9 m WP spacing would not. WP spacings that are larger than the drift spacing are considered undesirable because they are inefficient from a drift excavation point of view. This assumption is used in Section 7.5.
- 4.3.35 In determining emplacement spacings for a given thermal loading, the emplacement drift spacing will be limited to multiples of 22.5 m. This assumption is consistent with current repository conceptual designs (Section 8.6.1.U, p. 8-70, Ref. 5.20). Also, a drift spacing of 22.5 m permits AMLs up to 100 MTU/acre (see Assumption 4.3.33) given the minimum WP spacing of 16 m (see Assumption 4.3.34). This assumption is used in Section 7.5.

- 4.3.36 In determining emplacement spacings for a given thermal loading, the large (21 PWR, see Assumption 4.3.38) waste package will be used as the reference, and the smaller waste packages (12 PWR) will be placed with the same drift spacings with smaller WP spacings. Both large and small waste packages may be emplaced in the repository. To achieve a uniform thermal loading, the smaller waste packages must be placed closer together. This assumption is used in Section 7.5.
- 4.3.37 In determining emplacement spacings for a given thermal loading, it is assumed that the DHLW packages are positioned between SNF waste packages, but that their heat output does not contribute to the thermal loading of the repository. That DHLW packages may be positioned between SNF packages is consistent with current repository conceptual designs (Section 8.6.1.O, p. 8-78, Ref. 5.20). The heat output of a DHLW package is sufficiently less than that for a SNF WP such that the contribution of DHLW can be neglected in this evaluation. Parametrics documenting the contribution of DHLW will be performed in future evaluations. This assumption is used in Section 7.5.
- 4.3.38 Large and small boiling-water reactor (BWR) WPs are assumed to have the same heat load and uranium mass loading as the large and small PWR WPs, respectively. Average BWR SNF characteristics were not available at the time of the calculations reported here; therefore, only PWR characteristics (see Assumption 4.3.39) are used in this evaluation. Typically, BWR WPs would generate less heat than PWR WPs and their inclusion in the calculation would result in slightly cooler near-field temperatures. This assumption is used in Sections 7.3 and 7.5.
- 4.3.39 The average SNF characteristics are represented by a PWR assembly that is 22 years old with 42.2 GWd/MTU burnup and 0.428 MTU/assembly. This average SNF type was a current program decision in Rev. 00 of the CDA (Key 004, p. 6-4, Ref. 5.39). Current average SNF characteristics (CDA Key 004, p. 6-12, Ref. 5.12), which indicate slightly older (and therefore cooler) SNF, were not available at the time of the calculations reported here. An older SNF average would result in slightly cooler short-term near-field temperature peaks.

The age and burnup of the assumed average SNF were derived from a preliminary waste stream analysis (Table 7b, Ref. 5.32) in support of the FY 93 Thermal Loading System Study (Ref. 5.15). Table 1 of the waste stream analysis (Ref. 5.32) indicates that there could be 4532 waste packages with a capacity of 21 PWR assemblies each. This results in 95,172 PWR assemblies which divided into a total 40,747.22 MTU of PWRs (Table 7b, Ref. 5.32) gives an average assembly weight of 0.428 MTU. This assumption is used in Sections 7.3 and 7.5.

4.3.40 Time histories of SNF decay heat are interpolated from values derived from the Characteristics Database (CDB, Ref. 5.33). The CDB LWR Radiological PC Database (Ref. 5.33) has been qualified by the Office of Civilian Radioactive Waste Management (OCRWM) for use in work subject to the requirements of the QARD (Ref. 5.3). Tables of energy (heat) production due to activation products, actinides and daughters, and fission products in the CDB provide a source of SNF decay heat loads. This assumption is used in Section 7.5.

4.4 Codes and Standards

Not Applicable. Thermal design of the waste package is not controlled by codes and standards. The American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (Ref. 5.6) has been used only as a source of material properties for ASTM A 516 carbon steel (C-Mn-Si) and 316 stainless steel (16Cr-12Ni-2Mo).

6. Use of Computer Software

The primary computer code used for this analysis is ANSYS Revision 5.0A which is identified with the Computer Software Configuration Item (CSCI) identifier B00000000-01717-1200-30003, Ver. 5.0A. ANSYS is a commercially available finite element thermal and mechanical analysis code and is appropriate for the thermal analyses of waste package emplacement. The analyses using the ANSYS software were executed on a Hewlett-Packard 9000 Series 735 workstation. The software qualification of the ANSYS software, including problems of the type analyzed in this report, is summarized in the ANSYS 5.0A Verification and Validation Final Report (p. 1, Ref. 5.34). The ANSYS evaluations performed for this design analysis are fully within the range of the validation performed for the ANSYS 5.0A code. Access and use of the code for the analysis were granted and performed in accordance with the ANSYS 5.0A Life Cycle Plan (p. 1, Ref. 5.35) and the QAP-SI series procedures. Inputs and outputs to the ANSYS software are included as attachments as described in the following design analysis.

A secondary computer code used for this analysis is the Characteristics Database (CDB) LWR Radiological PC Database, CSCI: A00000000-02268-1200-20002, Ver. 1.1. The CDB has been qualified by the Office of Civilian Radioactive Waste Management (OCRWM) for use in work subject to the requirements of the QARD (Ref. 5.3). The CDB was installed on an IBM-compatible PC in accordance with the User Manual for the CDB_R (p. 1, Ref. 5.36) and was obtained in accordance with the QAP-SI series procedures. While this software was not actually run for this analysis, values of energy production were extracted from a database file included with the software distribution. A detailed description of the data extracted is given in Section 7.3. Use of the energy production values from the CDB is appropriate for this design analysis and is within the range of validation performed for the CDB.

Limited use of Computational Support Software (defined in QAP-SI-0) is also included in this design analysis. Borland dBASE, Ver. IV, a database management code run on an IBM-compatible PC, was used to perform a summation of records in a database file included with the CDB distribution. A detailed description of formulas and data extracted is given in Section 7.3. Lotus 1-2-3, Ver. 1.1, a spreadsheet package, was used to tabulate the ANSYS results output for presentation in a table. No calculation or modification beyond cut-and-paste and presentation style operations were performed on the ANSYS output. Harvard Graphics, Ver. 2.0, a presentation graphics package run on an IBM-compatible PC, was used to plot ANSYS solution results. No calculation or modification beyond cut-and-paste operations with tabular ANSYS output was performed in Harvard Graphics.

7. Design Analysis

7.1 Introduction

As part of an engineered barrier system for the containment of radionuclides, the waste package (WP), which can include the MPC, must be shown to comply with all regulations and requirements that govern the conditions of the emplaced SNF and the near-field rock at the repository horizon. Temperatures in the WP and near-field host rock are key to radionuclide containment, as they directly affect oxidation rates of the metal barriers and the ability of the rock to impede particle movement. Postclosure release rates are regulated by 10 CFR 60, 10 CFR 960, and 40 CFR 191.

Maximum allowable temperatures are based on material performance criteria and are specified as design goals for the WP/EBS design (see Section 4.2.4). For SNF, the Commercial Spent Fuel Management Program (p. xii, Ref. 5.37) at Pacific Northwest Laboratory recommended a 380°C temperature limit for the cladding to prevent creep rupture failure. A more conservative limiting value of 350°C has been selected (CDA DCWP 001, p. 6-165, Ref. 5.12) to account for uncertainties in source characteristics as well as heat transfer calculations. To limit the predicted thermal and thermo-mechanical response of the host rock and surrounding strata, maximum temperatures of 200°C for TSw2 (at the emplacement drift wall) and 115°C in the TSw3 (vitrophyre tuff) layer have been specified. Specific characteristics and requirements for the engineered barrier system are discussed in Section 4.2.

The method for WP thermal evaluations involves a three-model approach to determine the time-dependent WP thermal behavior. A three-dimensional (3-D) transient finite element model of the WP emplacement provides the WP surface temperature history for use as a boundary condition in a detailed WP model. Resulting SNF basket wall temperature predictions from the WP model provide the boundary for an estimation of peak SNF cladding temperatures. Cladding temperatures are predicted in the WP model using an effective conductivity defined to represent an homogeneous SNF assembly. The effective conductivity was determined using a detailed third model of an intact SNF assembly. Cladding temperatures are also conservatively estimated using an empirical correlation. This design analysis describes the first step of this three-model approach.

The thermal environment of the WP in the repository will change with time and is affected by the heat produced in the WP. Therefore, the WP thermal evaluation must be a transient analysis that takes into account the time varying heat load of the WP. This can be contrasted to an SNF storage cask analysis where the thermal environment is assumed constant and is provided by regulations.

7.2 Material Properties

As inputs to the design analysis, the thermal properties of the WP, surrounding materials, and the host repository rock will be key to the resulting temperatures in the near and far field.

Assuming a layered rock stratigraphy (Assumption 4.3.5), the rock layers around the repository must conduct away the heat generated by the WPs. Thermal conductivities and thermal capacitances for each of the rock layers used in this analysis (see Section 7.4 for model development) are listed in Table 4.1-1 and Table 4.1-2. They are derived from values given in the RIB (Ref. 5.4) using assumptions 4.3.10, 4.3.11, 4.3.12, 4.3.13, 4.3.14, and 4.3.16. The emissivity of the TSw2 rock layer is assumed an historic value of 0.85 (Assumption 4.3.18).

Assuming a concrete invert (Assumption 4.3.20), the conductivity, specific heat, density, and emissivity of the emplacement drift invert are listed in Table 4.1-3.

Assuming a WP outer barrier of A 516 carbon steel (Assumption 4.3.28), the thermal conductivity and specific heat are listed in Table 4.1-4 and the density and emissivity are listed in Table 4.1-5.

To meet the level of detail required in a thermal evaluation of WP emplacement, the WP can be assumed a smeared-property homogeneous heat-generating cylinder (Assumption 4.3.27). The WP density can be represented by the estimated total mass of a large WP (65,900 kg, p. 5, Ref. 5.28) divided by its volume (Assumption 4.3.29). The volume can be estimated as 14.491 m^3 based on dimensions given in Table 4.3-1 [$\pi * 1.802^2 * 5.682 / 4.0$]. Dividing the volume into the mass gives 4547.65 kg/m^3 (truncated to 4547). Excluding the outer barrier, the specific heat of the WP will be dominated by the MPC shell and basket which can be assumed to be primarily stainless steel (Assumption 4.3.30). The specific heat of 316 stainless steel at 100°C is listed in Table 4.1-6. An estimated effective thermal conductivity for the homogeneous WP can be calculated based on previous scoping calculations (Assumption 4.3.31). The following values for a previous evaluation were reported in the MGDS MPC Design Considerations Report (pp. 57 and 63, Ref. 5.29).

Assembly Heat ($Q/21$) =	676 watts	(At emplacement, p. 57, Ref. 5.29)
Peak SNF Cladding (T_o) =	354°C	(At 1 year, p. 63, Ref. 5.29)
MPC Surface (T_s) =	222°C	(At 1 year, p. 63, Ref. 5.29)

Equation 3.52 of a standard heat transfer text (p. 92, Ref. 5.5) describes the temperature distribution in a solid cylinder with uniform heat generation. Solving at a radius (r) of zero gives Equation 7.2-1.

$$T_o = \frac{q r_o^2}{4k} + T_s$$

(Equation 7.2-1)

Substituting $q^* = Q/(\pi r_o^2 L)$ and solving for conductivity (k) gives Equation 7.2-2.

$$k = \frac{Q}{4\pi L(T_o - T_s)}$$

(Equation 7.2-2)

Using a value of $L=5.682$ m from Table 4.3-1 and the values for Q , T_o , and T_s provided above, an effective thermal conductivity of 1.5 W/m·K can be calculated (see Assumption 4.3.31). Table 7.2-1 summarizes the conductivity, density, and specific heat resulting from the calculations here.

Table 7.2-1. Material Properties of the Homogeneous Waste Package

	Conductivity	Density	Specific Heat
Homogeneous Waste Package	1.5 W/m·K	4547 kg/m ³	501.9 J/kg·K

The material properties identified in this section were formatted into ANSYS commands and placed in a data file to be read by the software during the analysis. The file "proprep.dat" is included in this design analysis as Attachment I. Material property values listed in Attachment I for "Packed Crushed Tuff" and "Eff. Radiation" were developed during previous scoping evaluations and were not used in this design analysis.

7.3 SNF Decay Heat Loads

The purpose of a thermal evaluation of an emplaced waste package is to determine the effect of the WP decay heat on the repository host rock. The decay heat of individual WPs can vary greatly depending on the age, burnup, etc. of the loaded SNF. Design basis spent nuclear fuel characteristics have been developed for waste package design (p. 32, Ref. 5.38), but they do not represent average characteristics. The initial heat output from a design basis PWR assembly can be much greater than average and this can affect the early (short-term) temperatures of the repository. However, long-term thermal behavior of the repository rock will primarily be a function of the area mass loading or tons of SNF emplaced per acre. The repository response will be determined more by the integrated heat (the area under the curve) from the emplaced SNF and less by the initial heat of the individual WPs. Thus, an initial areal power density (APD) in kW/acre (or W/m²) will not adequately determine the thermal response because the APD will change differently with time depending on the average SNF characteristics. To determine a thermal response that is representative of the entire repository, average (instead of design basis) SNF characteristics must be developed. For a given AML and assuming average SNF characteristics, the average host rock and near field temperatures can be determined and then applied as the thermal environment for a detailed thermal analysis of individual WPs.

A set of average SNF characteristics have been conservatively based on a youngest fuel first (YFF10) waste receipt scenario (Assumption 4.3.39). The time dependent WP heat load is based on the decay heat of a 22 year old PWR assembly with 42.2 GWd/MTU burnup and 0.428 MTU/assembly (Assumptions 4.3.38 and 4.3.39). Using these characteristics, a table of assembly decay heat as a function of time can be developed. The process for creating a table of decay heats (ASCII data file named "heatdat.dat") is described as follows.

When installed, the Characteristics Database (CDB) LWR Radiological PC Database (Ref. 5.33) includes several supporting data files concerning SNF characteristics. One file, "totals.dbf", contains totals for activation products (V), actinides and daughters (A), and fission products (F) in units designated W, G, E, C, X, S, and P for each reactor type, burnup, enrichment, and decay time. A database management code, dBASE IV (computational support software), was used to sum the records labeled W (for watts or energy output) over segments V (activation), A (actinides), and F (fission products). This summation was performed for each reactor type (B or P), burnup, enrichment, and decay time given in "totals.dbf" and output as an ASCII data file named "heatdat.dat". The file "heatdat.dat", included in this design analysis as Attachment II, is a formatted table of SNF assembly heats as a function of reactor type (B or P), burnup, enrichment, and decay time (out of reactor) and provides a reference table for an interpolation program described next (Assumption 4.3.40).

As a sample calculation of this data manipulation, the heats from a selected SNF assembly type (similar to the average above) is calculated. The file "totals.dbf" contains a data point for a 20 year old PWR assembly with 40,000 MWd/MTU burnup and 3.72% enrichment. Given this assembly type, the total (over all isotopes) energy production (W) records are $1.072\text{E}+01$, $3.429\text{E}+02$, and $7.646\text{E}+02$ watts/MTIHM for activation products (V), actinides and daughters (A), and fission products (F), respectively (Ref. 5.33). The sum of these values is $1.118\text{E}+03$ watts/MTIHM which is same as the record reported in Attachment II for a PWR with 40,000 MWd/MTU burnup, 3.72% enrichment, and 20 years out of reactor.

A short C++ code was developed to provide the integrated heats over time and the instantaneous heats for assembly types that are between the data points given in the CDB tables. Attachment II, "heatdat.dat", is read by subroutine "buildheat()" of the code. The coding, titled "inheat.cpp" and included in this design analysis as Attachment III, is a double (simple and logarithmic) interpolation and integration routine that produces a table of integrated heat and instantaneous heat as a function of time for given SNF characteristics. The capabilities for the calculation of volumetric heat load (peak and average) in the "inheat.cpp" code were not used in this design analysis.

As a test of the code, PWR SNF characteristics of 10 years old, 40,000 MWd/MTU burnup, 3.72% enrichment (average), and 0.428 MTU/assembly were entered as inputs to "inheat.cpp". The output file, "rep1040.txt", is included in this design analysis as Attachment IV. After an emplacement period of 10 years (total age 20 years) the PWR SNF assembly produces 478.5 watts of heat, according to Attachment IV. For comparison, if the total heat production of that assembly ($1.118\text{E}+03$ watts/MTIHM) derived (above) from the CDB is multiplied by the assumed 0.428 MTU/assembly, a total instantaneous heat (20 years out-of-reactor) of 478.5 watts results which is the same as that calculated by "inheat.cpp".

Entering the average SNF characteristics (22 years old, 42.2 GWd/MTU burnup, etc.), described above, into "inheat.cpp" results in an output data file, "rep2242.txt", included in this design analysis as Attachment V. The data file provides the instantaneous heat of the assumed average PWR assembly as a function of time. The average fuel type has a somewhat higher burnup than the test case above; and therefore, should have a higher heat production at about 20 years out-of-reactor (486.7 watts versus 478.5 watts from Attachments V and IV respectively).

To be usable in an ANSYS evaluation, the table of assembly heats must be formatted into a set of commands that will store the values in an ANSYS readable array parameter. Therefore, the column of heat outputs in Attachment V were reformatted into ANSYS commands and placed in a data file to be read by the software during the analysis. The file "snf2242.dat" is included in this design analysis as Attachment VI. Some time steps from the original table were omitted, and some were added (by linear interpolation) to ensure that a heat load value was available for each solution time step used in the analysis.

The heat load is applied as a volumetric heat generation (W/m^3) in the homogeneous WP by multiplying the assembly heat by the number of assemblies and dividing by the volume of the homogeneous WP (volume inside of the outer barrier). This calculation is performed within the ANSYS computation using variables (Fortran) for the dimensions and other model parameters. (See Section 7.4.3 for a discussion of the ANSYS input commands used in model development and to perform the evaluation.)

7.4 Model Development

7.4.1 Model Geometry

To fully investigate the thermal loading effects in the near field (especially WP surface temperatures), a 3-D transient model is required. In previous 2-D thermal models created by the M&O and national laboratories, WP surface and drift wall temperatures represent the average down the length of the drift. While average drift wall temperatures can be predicted by a 2-D drift scale model for small WP spacings, WP surface temperatures will be under-predicted due to the axial smearing of the WP heat load. Therefore, a 3-D thermal model of an emplacement drift and waste package has been constructed to capture WP-to-WP interactions as well as drift-to-drift interactions. The ANSYS Ver. 5.0A finite element code was used to create the 3-D repository emplacement thermal model.

Figure 7.4-1 displays a cross section (not to scale) of the geometry used in the model. Yucca Mountain is composed of a layered rock stratigraphy. The rock units are distinguished by their physical properties noted from borehole samples. Data from borehole USW G-4 (Table 2, Section 1.12, p. 5, Ref. 5.4) provided the stratigraphy and contact depths for each of the rock units used in this analysis (Assumption 4.3.5). Contact depths for each unit (shown on Figure 7.4-1) are listed in Table 4.1-1. For this analysis, the Undifferentiated Overburden and unit TCw are grouped together as one material (Assumption 4.3.10), and the properties of unit CHn2 are assumed to persist below its actual contact depth of 535.3 m (Assumption 4.3.14).

The location of the proposed repository is limited to the TSw2 geologic unit (Assumption 4.3.17). While its exact design and location have not yet been determined, advanced conceptual design evaluations have been performed which suggest likely configurations (Section 8, Ref. 5.20). For this analysis, the WP is assumed to be horizontally emplaced (Assumption 4.3.2) in a circular drift with a 5.0 m diameter (Assumption 4.3.19). The drift floor will be cast-in-place concrete with a depth of 0.7 m (Assumption 4.3.20), and the bottom of the drift cut is 311 m (Assumption 4.3.6) below the ground surface measured from borehole USW G-4. The geometry and location of the drift in this model are schematically shown in Figure 7.4-1.

Two sizes of WPs were considered in this analysis, the 21 PWR MPC conceptual design with disposal container, and the 12 PWR MPC conceptual design with disposal container (Assumption 4.3.27). Since temperature details internal to the WP are not required of this model, the WP is assumed a homogeneous heat-generating cylinders (Assumption 4.3.27) with outer dimensions given in Table 4.3-1. The representation of the WP does, however, include a 0.1 m layer of A 516 carbon steel (the conceptual outer barrier) at the surface of the WP (Assumption 4.3.28). Since the purpose of this design analysis is to predict WP surface temperatures, it is important to adequately model the heat transfer characteristics at the

FIGURE 7.4-1. Repository Emplacement Model

surface. A purely homogeneous model of the WP will over-predict axial temperature distributions due to the low "average" (or "effective") thermal conductivity of the homogeneous WP. By including a metal outer layer, the heat will be more accurately distributed over the WP outer surface.

As seen in Figure 7.4-1, the WP (not to scale) is "floating" near the center of the drift (Assumption 4.3.23). Concepts for WP support devices are preliminary, and it is conservative to neglect the effect of the supports in transferring heat from the waste package. However, to be consistent with a permanent rail cart emplacement scenario, the WP is assumed to be 0.137 m below the drift center (Assumption 4.3.21). The smaller WP (12 PWR) will likely be emplaced on a similar sized rail cart (Assumption 4.3.22) such that the distance to the drift floor (invert) is the same. The clearance distance between the bottom of the 21 PWR WP and the invert is: drift radius (5.0/2) minus invert height (0.7) minus WP radius (1.8016/2) minus center offset (0.137) = 0.7622 m. Therefore, the center offset for the 12 PWR WP is: drift radius (5.0/2) minus invert height (0.7) minus WP radius (1.5305/2) minus clearance (0.7622) = 0.27255 m.

The 2-D cross section formed in Figure 7.4-1 can be extruded into 3-D to form a single WP in a unit cell of surrounding rock. As described in the following two sections, the model is a pillar of rock (Assumption 4.3.3) with width equal to the drift spacing, depth equal to the waste package spacing, and a height of 1300 m (Assumption 4.3.8). Attachment VII provides a graphical ANSYS display of the geometry and mesh density for one representative case (c21b5a described in Section 7.5). Attachment VII, page 1 displays a perspective end view of the WP in the emplacement drift. Page 2 displays a side view cut through the centerline of the WP (note the 0.1 m outer barrier around the WP). Page 3 displays the element mesh density in the entire model, from ground surface to 1300 m. Page 4 displays an end view with the WP cut through the mid-length. A description of the ANSYS input files used to generate the models is given in Section 7.4.3.

7.4.2 Boundary Conditions

The 3-D model is a pillar section of the repository (Assumption 4.3.3) with planes of symmetry represented by two adiabatic boundaries halfway between the drifts and halfway between two waste packages. The single modeled waste package is assumed to be in an infinite repository (Assumption 4.3.4). The approximation of an infinite repository is reasonable up to 1000 years or so after emplacement when repository thermal edge effects (not modeled here) will begin to influence the cool-down of the center of an actual repository. After about 1000 years, depending on the spacings, the model used here will tend to over-predict near-field temperatures, so care must be taken in extrapolating to such long times. Benchmarks against V-TOUGH calculations at Lawrence Livermore National Laboratory (LLNL) quantify the effects of neglecting repository edge effects after 1000 years (p. 7, Ref. 5.18). The thermal model of WP emplacement developed in this design analysis will be solved over only the first 1000 years after emplacement (Assumption 4.3.7).

Analyses performed at LLNL (p. 853, Ref. 5.19) have shown that there may be insufficient water circulation at the water table, due to low permeabilities, to maintain a constant temperature at that depth. Therefore, the 3-D emplacement thermal model has a bottom boundary condition at a depth of 1300 m instead of at the water table depth of about 611 m (Assumption 4.3.8). This depth will ensure that the thermal behavior of the repository horizon will not be affected by this boundary condition assumption for over 1000 years of model time.

The thermal model of WP emplacement interfaces with the environment at the top and bottom planes. Constant temperature boundary conditions are applied at the top and bottom to represent the ground surface and the underlying rock as heat sinks. The ground surface can be assumed a constant (average) temperature of 18.7°C (Assumption 4.3.9), and the rock temperature at 1300 m can be assumed 53.05°C (Assumption 4.3.9) based on thermal gradients reported in the RIB and in the CDA (TDSS 002, p. 6-182, Ref. 5.12). The calculation is included here as Equation 7.4-1.

$$[18.7^{\circ}\text{C} + 0.019^{\circ}\text{C}/\text{m}*(150 \text{ m}) + 0.018^{\circ}\text{C}/\text{m}*(400 - 150 \text{ m}) + 0.030^{\circ}\text{C}/\text{m}*(1300 - 400 \text{ m})]$$

(Equation 7.4-1)

While the thermal model includes radiation and conduction heat transfer, it is referred to as a "conduction-only" code because it does not predict water movement (matrix and fracture flow, or equivalent continuum) in the repository host rock. Temperatures in the rock have a major impact on water movement; however, water (besides boiling and condensation) has less of an impact on the temperature distribution, such that the system can be approximated by a model that considers conduction (and radiation) only (Assumption 4.3.15). While "conduction-only" codes cannot predict water movement or humidities, they have been shown to provide a reasonable estimate of rock temperatures in benchmarking evaluations (p. 7, Ref. 5.18). To

capture the thermal effects of boiling water in the host rock, the heat capacitance of the rock units include the latent heat absorbed due to boiling at temperatures near the boiling point (Assumption 4.3.16). Temperature dependent specific heats for rock are listed in Table 4.1-2. This formulation is consistent with previous conduction/radiation thermal evaluations performed by Sandia National Laboratories (SNL) (Appendix E, p. 5, Ref. 4.15). It is important to note that the capacitance formulations are applicable only for the heating phase of the rock units, if it is assumed that the water has mobilized (escaped) after vaporization.

For this evaluation of temperatures of WP emplacement, it is assumed that there is no forced ventilation of the emplacement drifts (Assumption 4.3.25), and that the emplacement drift is not backfilled at repository closure (Assumption 4.3.24). Calculations of ventilation or backfill are not within the scope of this evaluation; however, they will likely be considered in future design analyses.

Assuming no ventilation or backfill, the only heat transfer paths between the waste package and the drift wall would be thermal radiation and natural convection of the drift air (neglecting the WP supports, see Assumption 4.3.23). Reference 5.24 (p. 59) showed that radiation heat transfer in a closed SCP-type emplacement drift is an order of magnitude greater than convective heat transfer. To be conservative, the complex calculations of natural convection have been neglected and thermal radiation is assumed to be the only heat transfer path between the waste package and the drift (Assumption 4.3.26). This assumption, which is consistent with evaluations performed by SNL (Appendix E, p. 5, Ref. 5.15), simplifies the model and will result in slightly conservative temperatures.

7.4.3 ANSYS Input Files

This section briefly describes the ANSYS 5.0A commands and format used to develop the WP emplacement thermal model. One basic input file was created, and then the file was copied to different case names (see Section 7.5) and modified by varying model parameters such as drift spacing and WP spacing to create other thermal loadings. Mesh densities were changed for each case to accommodate changes in dimensions, and the geometry was checked for each case before initiating the solution. While dimensions changed between cases (diameters and spacings), the solid model geometry and numbering remained the same.

The input files used to generate the ANSYS solutions are echoed to the output file for each batch run performed. A list of the individual evaluations performed is given in Section 7.5 along with the case name and the parameters used. Each output file has been included in this design analysis as an attachment. At the beginning of the output file, the input batch commands are numbered and printed, including comments.

Each input file is a self-contained solution which uses as input only the material properties file (Attachment I) and the heat load file (Attachment VI). While the input files have been commented such that another engineer experienced with ANSYS can understand the analysis, the following discussion explains each section in general.

The first step in the analysis is to define model parameters and dimensions (such as radii, lengths, and spacings) using the ANSYS Parametric Design Language. By defining key dimensions as parameters, the model is very flexible and can be easily modified (for parametric evaluation here and in the future). Other derived dimensions used in the model are defined with formulas as functions of the key parameters such that arithmetic mistakes are kept to an absolute minimum (human errors). An example of this process is the homogeneous WP volume (variable: WPVOL) which is defined as $\pi \cdot \text{radius}^2 \cdot \text{length}$. Definition of key and derived variables is done at the beginning of the input file.

The second step is to define which ANSYS element types will be used, and to read in the material property and heat load files described in the previous sections.

The third step is to define the 2-D plane of the model geometry (solid modeling) using a "bottom up" approach. Key-points are defined; followed by lines; and then areas. Element mesh densities (how many element divisions along each line) are then defined. The density of the element mesh used depends on what regions will have high temperature gradients and is largely determined by engineering judgement. Finer meshes typically provide higher accuracy; however, there is a limit to the total number of elements used based on computer disk and memory space limitations and the length of time required to converge the solution. High thermal loadings and small WPs required as few as 7,265 elements compared to low loadings with large WPs which used as many as 14,289 elements in this design analysis.

Meshes were generated in the 2-D plane and then extruded into 3-D bricks (elements). The resulting 3-D model is displayed graphically for a representative case (c21b5a described in Section 7.5) in Attachment VII. Attachment VII, page 1 displays a perspective end view of the WP in the emplacement drift. Page 2 displays a side view cut through the centerline of the WP. Page 3 displays the element mesh density in the entire model, from ground surface to 1300 m. And, page 4 displays an end view with the WP cut through the mid-length. Smaller elements were defined in and around the WP where thermal gradients are expected to be the highest.

After generation of the solid meshes, radiation surface elements are generated on the WP and drift wall faces. The AUX12 utility of ANSYS is then invoked to create a matrix of explicit thermal radiation view-factors between the exposed element faces. With this method, radiation energy is exchanged between surfaces only if the surfaces can "see" each other. This explicit method can be more accurate than an alternate method of defining a calculated effective radiation conductivity (Appendix E, p. 5, Ref. 5.15).

With the finite element model complete, the next step is to apply temperature and heat load boundary conditions and solve over several time steps. Volumetric heat loads on the homogeneous WP are calculated based on the SNF decay heat as a function of time defined in Section 7.3. The temperature boundary conditions are applied to the top (ground surface) and bottom as described in Section 7.4.2. The first solution uses no WP heat load and established the initial thermal gradient (temperature distribution) conditions in the repository host rock. The second solution applies the drift ambient temperature as a fixed condition on the drift wall and determines initial temperature gradient in the waste package using the SNF heat load at time of emplacement. The following solutions solve the transient thermal response of the WP and repository rock for 1,000 years after emplacement in the drift. Table 7.4-1 gives a conversion between the emplacement time (in years), the ANSYS solution time (in seconds) as printed in the output files, and the ANSYS analysis load step number. The load steps have been defined on a logarithmic time scale because the heat load decays exponentially and the system response is expected to follow the decay curve of the SNF.

The last step in the analysis is to report the resulting temperatures in and around the emplacement near field. The WP top, side, and bottom temperatures as a function of time are stored in array parameters that can be read as inputs into future ANSYS analyses of the WP. WP and drift wall temperatures are written to an output file with the name suffix ".parm" (one for each case, included here as attachments). Future detailed thermal evaluations of WP internals will use these surface temperatures as boundary conditions. The thermal evaluation of WP emplacement described here is the first step of a three model approach used to determine temperatures in the EBS. Finally, a couple mesh plots are written (represented by Attachment VII) and several sample color contours plot. The end of the output deck contains a listing of the temperature as a function of time for 54 different locations in the model. Some of these temperature outputs are plotted in Section 7.6.

Table 7.4-1. ANSYS Solution Time/Load Steps

Time (years)	Time (seconds)	ANSYS Load Step	Time (years)	Time (seconds)	ANSYS Load Step
Initial Rock	.100E-06	1	9	.284E+09	21
Initial WP	.200E-06	2	10	.316E+09	22
0	31.56	3	20	.631E+09	23
0.1	.316E+07	4	30	.947E+09	24
0.2	.631E+07	5	40	.126E+10	25
0.3	.947E+07	6	50	.158E+10	26
0.4	.126E+08	7	60	.189E+10	27
0.5	.158E+08	8	70	.221E+10	28
0.6	.189E+08	9	80	.252E+10	29
0.7	.221E+08	10	90	.284E+10	30
0.8	.252E+08	11	100	.316E+10	31

7.5 Thermal Loading

The 3-D thermal model of WP emplacement described in Section 7.4, was used to evaluate waste package and near field thermal behavior at a range of representative "high" and "low" thermal loadings. A parametric set of thermal loadings cases is required because the thermal loadings for the repository has been specified as a range in the CDA (Key 019, p. 6-24, Ref. 5.12) and the WP must be shown to meet thermal goals and requirements over that range.

For the purpose of this design analysis, the thermal loading will be calculated as a function of area mass loading (AML) in MTU/acre (or kgU/m²) (Assumption 4.3.32). Since the WP heat load changes with time, defining an AML is more consistent (and a better predictor of long term temperatures) than defining an initial areal power density (APD) in kW/acre (or kW/m²). Two primary high thermal loadings (100 MTU/acre and 83 MTU/acre) and one low thermal loading (25 MTU/acre) were selected to represent the range (Assumption 4.3.33). These values are consistent with the range in the CDA (Key 019, p. 6-24, Ref. 5.12) and with recommendations by Systems Engineering (p. 2, Ref. 5.30). A thermal loading of 100 MTU/acre provides a bounding case for the highest loading that may be used.

A few variations on WP spacing at 100 and 25 MTU/acre were considered to determine the impact of WP spacing on meeting near-field thermal goals. At 100 MTU/acre, the question is: "What is the smallest WP spacing achievable without violating thermal goals?"; and at 25 MTU/acre, the question is: "What WP spacings are required to keep the WP surface temperature below 100°C and 70°C?" The thermal loading cases for the large (21 PWR) WP, including drift and WP spacings used, are listed in Table 7.5-1.

In determining the emplacement spacings for each of the thermal loading cases, a few guidelines were followed for consistency with previous evaluations. It has been previously estimated (p. 3, Ref. 5.31) that the minimum WP spacing for the large (21 PWR) WP should be no less than 16 m. This minimum spacing has been used in the thermal loadings cases (Assumption 4.3.34) except those cases (c21c5a and c21a5a) devised to confirm the minimum spacing. It is expected that one (or both) of these cases will demonstrate that thermal goals are violated at spacings less than 16 m and confirm the previous analysis. It is also assumed that any WP spacing that is longer than the drift spacing for a given thermal loading is inefficient (for construction), and therefore, undesirable (Assumption 4.3.34).

Current repository conceptual designs (Section 8.6.1.U, p. 8-70, Ref. 5.20) indicate drift spacings in multiples of 22.5 m. Therefore, except in case c21c5a where it could not be achieved, the emplacement drift spacing is limited to multiples of 22.5 m (Assumption 4.3.35). Also, the emplacement spacings are based on the large (21 PWR) WP and the smaller (12 PWR) WP would be placed in the same drifts (and drift spacings) with smaller

WP spacings (Assumption 4.3.36). This allows consideration of a repository that contains both large and small packages.

While it is expected that defense high-level waste (DHLW) packages may be placed between the SNF packages, their low heat output is assumed not to contribute to the thermal loading of the repository (Assumption 4.3.37). Parametrics documenting the contribution of DHLW is not within the scope of this analysis and will be documented in future evaluations.

The calculation of emplacement spacings for different thermal loadings is straightforward as described in Equation 7.5-1. The assembly weight is 0.428 MTU/assy (average SNF as described in Section 7.3 and Assumption 4.3.39), the number of assemblies is 21 and 12 for the large and small WPs (see Assumption 4.3.38), and the spacings are as listed in Table 7.5-1.

$$AML(MTU/acre) = \frac{\text{Assembly Weight}(MTU/assy) \times \text{No. of Assemblies}}{WP\text{ Spacing}(m) \times \text{Drift Spacing}(m) \times 2.4711E-4 \text{ acres/m}^2}$$

(Equation 7.5-1)

Table 7.5-1. Large (21 PWR) Thermal Loading Scenarios

Case Name	Area Mass Loading (AML)		Initial APD (kW/acre)	WP Spacing	Drift Spacing
	(MTU/acre)	(kg/m ²)			
c21x5a	100	24.7	113.7	16.165 m	22.5 m
c21c5a	100	24.7	113.7	12.124 m	30.0 m
c21a5a	100	24.7	113.7	8.0825 m	45.0 m
c21b5a	83	20.5	94.4	19.477 m	22.5 m
c21w5a	25	6.18	28.4	32.331 m	45.0 m
c21j5a	25	6.18	28.4	21.554 m	67.5 m
c21h5a	25	6.18	28.4	16.165 m	90.0 m

The second and third cases, at 100 MTU/acre, are intended to determine at what WP spacing the near field thermal goals are violated compared to the first case which describes a base case for the upper bound thermal loading. The last three cases, at 25 MTU/acre, provide a

study of the effect of WP spacing on temperatures at a low thermal loading and represent the utilization of even multiples of the high thermal loading drift spacing (every other drift, every third, etc.).

Case c21w5a achieves the longest reasonable WP spacing and should result in the lowest near field temperatures; case c21j5a has a WP spacing similar to c21b5a (83 MTU/acre); and case c21h5a has a short WP spacing (similar to c21x5a at 100 MTU/acre) and represents the "localized disturbance" concept for low thermal loadings. The "localized disturbance" concept depends on high temperature gradients (due to the closely spaced WPs) to drive local water in the rock away from the emplacement drifts. The viability of this concept depends on the drift-scale hydrothermal effects which are not modeled here; however, the temperature response has been determined.

Table 7.5-2 lists the emplacement spacings (thermal loadings) evaluated for the small (12 PWR) WP. The set of cases are similar to Table 7.5-1 except that no minimum WP spacing evaluation was performed at 100 MTU/acre. As described above, the 12 PWR packages are assumed emplaced with the same drift spacings and assumed average SNF used for the 21 PWR packages (see Assumptions 4.3.32 through 4.3.40). Again, representative "high" and "low" thermal loadings were selected with drift spacings in multiples of 22.5 m.

Table 7.5-2. Small (12 PWR) Thermal Loading Scenarios

Case Name	Area Mass Loading (AML)		Initial APD (kW/acre)	WP Spacing	Drift Spacing
	(MTU/acre)	(kg/m ²)			
c12x5a	100	24.7	113.7	9.237 m	22.5 m
c12b5a	83	20.5	94.4	11.129 m	22.5 m
c12w5a	25	6.18	28.4	18.475 m	45.0 m
c12j5a	25	6.18	28.4	12.317 m	67.5 m
c12h5a	25	6.18	28.4	9.237 m	90.0 m

Each of the cases in Table 7.5-1 and Table 7.5-2 was submitted as an ANSYS batch job on a Hewlett-Packard 9000 Series 735 workstation. The output files and parameter files are included in this design analysis as attachments (example: Attachment XXI - c21x5a.old.out, and Attachment IX - c21x5a.parm). A summary of temperature results is given in the following section.

7.6 Thermal Results

The parameter and ANSYS output files for each of the twelve cases are included in this design analysis as Attachments IX through XX, and XXI through XXXII, respectively. At the end of the ANSYS output file for each case, tables of temperatures as a function of time are printed for various locations in the thermal model. Temperatures inside and outside the outer barrier, above and below the invert, at the drift wall, at 1 and 3 meters into the rock, at the drift-to-drift midplane, and at various contacts between rock layers are printed.

A portion of these results were summarized in tabular format using the Lotus 1-2-3 spreadsheet package (computational support software). The tabular results are included in this design analysis as Attachment VIII. Attachment VIII, pages 1 and 2 summarize select temperatures at the WP mid-length for the large (21 PWR) WP. Pages 3 and 4 summarize select temperatures for the small (12 PWR) WP. Attachment VIII, page 5 provides a comparison of the three cases at 100 MTU/acre (results from c21x5a are repeated here from page 1 for ease of comparison). The results presented in Attachment VIII are also graphically presented in this section using Harvard Graphics.

Figure 7.6-1 displays a comparison of maximum large (21 PWR) WP surface temperatures for the five base thermal loading (TL) scenarios on a logarithmic time scale. Cases c21c5a and c21a5a are discussed later. As expected, low TL case c21h5a actually has higher near-field temperatures than high TL case c21b5a for the first 5 years due to its shorter WP spacing. However, by 500 years, the three low thermal loading temperatures have nearly converged to a single temperature which is much lower than that for the high loadings. Peak WP surface temperatures occur in 40-50 years for the high loadings and in about 8 years for the low loadings. The figure demonstrates a significant difference in short-term near-field temperatures between short and long WP spacings. If the goal of a low thermal loading scenario is to maintain low near-field temperatures, a low AML and a long WP spacing are needed.

Figure 7.6-2 compares maximum drift wall temperatures for the five loadings, and Figure 7.6-3 compares the maximum temperature at 3 m into the drift wall. Maximum temperatures always occurred at axial locations corresponding to the mid-length of the WP. Just as for the WP surface temperatures, the peak temperatures occurred earlier for the low loadings than for the high thermal loading. Figure 7.6-4 compares the drift-to-drift midplane temperatures and demonstrates that the waste package spacing has little effect on temperatures half-way between drifts. At the drift-to-drift midplane, temperatures are primarily a function of thermal loading in MTU/acre. For all of the thermal loading scenarios, the drift wall temperature limit of 200°C was not exceeded; however, the TSw2/TSw3 interface reached 118°C (greater than the limit of 115°C) at 1000 years for the highest loading (c21x5a). The TSw2/TSw3 interface reached 106°C at 1000 years for high TL case c21b5a.

Figure 7.6-1. Large (21 PWR) WP Surface Temperatures

Figure 7.6-2. Large (21 PWR) WP, Drift Wall Temperatures

Figure 7.6-3. Large (21 PWR) WP, 3 m from Drift Temperatures

Figure 7.6-4. Large (21 PWR) WP, Drift/Drift Midplane Temperatures

Thermal goals for the CHn and PTn rock units (115°C) were not exceeded for any of the thermal loadings. At 1000 years, for the highest thermal loading (c21x5a), the TSw3/CHnv interface reached 108°C and the PTn/TSw1 interface reached 56°C. In all cases, both of these interfaces had temperatures below that of the TSw2/TSw3 interface making the TSw3 thermal goal (115°C) the limiting criterion.

The evaluation results indicate lower near-field temperatures for the small (12 PWR) WP compared to the large (21 PWR) WP; however, the temperatures at 3 m into the drift wall and beyond are virtually identical for the different WP capacities. The greatest difference between the 12 and 21 PWR WP surface temperatures was 21°C, and it occurred six months after emplacement for the low TL cases with the longest WP spacings. Figure 7.6-5 plots a comparison of maximum 12 PWR WP surface temperatures for the five thermal loading scenarios. Again the shorter WP spacing of low TL case c12h5a resulted in higher near-field temperatures than high TL case c12b5a for the first 5 years. The long-term near-field temperatures for the 12 PWR WP are the nearly the same as for the 21 PWR WP.

Figure 7.6-6 compares the maximum drift wall temperatures for the five loadings, and Figure 7.6-7 compares the maximum temperature at 3 m into the drift wall. Maximum drift wall temperatures were no more than 16°C lower for the small (12 PWR) WP (compared to the large WP), and maximum 3 m rock temperatures were less than 3°C lower. Like the large (21 PWR) cases, the small (12 PWR) cases all had peak WP surface temperatures at or above the boiling point. Only low TL case c12w5a with the long WP spacing had maximum drift wall temperatures below boiling. Figure 7.6-8 compares the drift-to-drift midplane temperatures which differed from the large WP cases by less than 1°C.

Figures 7.6-9 and 7.6-10 investigate the effect of shorter WP spacings on maximum WP surface temperatures and drift wall temperatures respectively. The results of cases c21x5a, c21c5a, and c21a5a demonstrate that WP spacing is a key factor for near field temperatures. Thermal goals are clearly violated for the 8 m WP spacing with a peak drift wall temperature of 227°C (greater than 200°C drift wall temperature) and are near the limits with the 12 m WP spacing. Compared to the base 16 m WP spacing case, WP peak surface temperatures were 46°C hotter for the 8 m spacing and 10°C hotter for the 12 m spacing. Further analysis using detailed WP thermal models and design-basis SNF will be required before it can be determined if the drift wall temperature criterion or the peak cladding temperature criterion is the limiting thermal goal. However, if peak cladding temperatures were raised proportional to the WP surface temperature, it can be estimated (based on previous evaluations: p. 63, Ref. 5.29) that a 12 m WP spacing would be marginal and an 8 m WP spacing would violate cladding thermal goals. Given a peak drift wall temperature of 192°C for the 12 m WP spacing cases, WP spacings less than 12 m will likely exceed the drift wall thermal goal. And, given calculational and waste stream uncertainties, a minimum WP spacing of 16 m provides a conservative lower bound for large waste packages such as the 21 PWR capacity MPC with disposal container. This confirms the results of previous scoping analyses (p. 3, Ref. 5.31) which made similar judgements.

8. Conclusions

It is important to note that the analyses described here are for a 22 year old PWR assembly with a burnup of 42.2 GWd/MTU (an assumed average). Therefore, the results describe only the average waste package (i.e., about half of the waste packages will be hotter). The detailed waste package evaluations, which use the results of these analyses as boundary conditions, estimate internal waste package temperatures for design basis SNF characteristics to ensure that thermal goals have been attained. For a pillar model which represents one average WP in the repository, the heat of that package must be the average of all of the emplaced waste packages. While all the waste packages (hot and cold) will collectively influence repository temperatures (average SNF characteristics), every waste package must meet thermal goals (design basis characteristics).

The emplacement thermal evaluations described above provide the boundary conditions for more detailed evaluations of specific waste package concepts. In the 3-D emplacement model, the WP is represented by a homogeneous heat source such that the resulting near-field temperatures can represent any similar capacity WP (in this case 21 PWR or 12 PWR). However, it should be noted that (at this revision) unqualified inputs to this design analysis have been identified and used (TBV-217-WPD), and the results presented here should be considered unqualified (unverified).

The thermal results presented in this design analysis provide reasonable estimates of the near field temperatures around drift emplaced waste packages. They are consistent with previous analyses performed by the M&O and national laboratories, and they provide trending for near field temperatures as a function of thermal loading and emplacement layout. Important trends include the significance of WP spacing (as opposed to just thermal loading) in maintaining temperatures below the thermal goals listed in Section 4.2. As predicted in the FY 1993 Thermal Loading System Study (p. 10-2, Ref. 5.15), loadings above or near 100 MTU/acre were found to stress thermal temperature limits and should be considered an upper bound. The analysis indicates that long WP spacings are needed to maintain rock temperatures below boiling at low thermal loadings, and that near field rock temperatures for the 12 PWR WP are similar to those for the 21 PWR WP. This analysis also confirmed that WP spacings less than 12 m will violate thermal goals, and that a 16 m WP spacing is a conservative lower bound for large (21 PWR) waste packages. The repository thermal loading has not been specified and will not be finally established for years; therefore, this analysis provides a parametric trending of possible thermal loading scenarios.

9. Attachments

Attachments to this design analysis are summarized in Table 9-1.

Table 9-1. List of Attachments

Attachment Number	Title / Description	Date	Number of Pages
I	ANSYS 5.0 MPC Material Property Tables (File Name: proprep.dat)	01/06/95	2
II	Data Table of SNF Energy Output Derived from the CDB LWR Radiological PC Database (File Name: heatdat.dat)	06/16/92	2
III	Listing of C++ Program INTHEAT (File Name: intheat.cpp)	02/25/93	3

/*PROGRAM INTHEAT.C calculates heat and integrated (over time) heat as a function of age and burnup (assuming average enrichment for the specified burnup) for a series of years, up to an upper limit, all of which are input by the user according to a set of onscreen instructions. The heat calculation is performed by interpolation in a table of heat values for specified values of age, burnup, and initial enrichment for both PWR and BWR fuel types. This table is read from the file "heatdat.dat" which is derived from the CDB LWR Radiological PC Database,

MEDIA ID: VA-M04-20002.024.C013

CSCI: A00000000-02268-1200-20002 VER 1.1

When this disk is unzipped to the harddrive, a file called "totals.dbf" is generated. The records in "heatdat.dat" (read in the buildheat() subroutine) are generated from the records in "totals.dbf" by adding the units W (Watts) records for segment records V (activation), A (actinides), and F (fission products) for each reactor type (B or P), burnup, and enrichment given in the table. In this process the records of "totals.dbf" having units designated G, E, C, X, S, P are not used.*/

** Compiled by R. Bahney III on 6-16-94 **

TYPE	MATERIAL	
1	TCW	Top Rock layer
2	PTn	
3	TSw1	
4	TSw2	Repository Horizon
5	TSw3	
6	CHn1v	
7	CHn1z	
8	CHn2	Extends to Water Table
9	Packed Crushed Tuff	Alternate invert
10	Hom. Canister	Smearred Props for WP Center
11	Concrete	Trackbed for Rail Emplacement
12	Eff. Radiation	Effective Cond. in drift air
13	A516 Mild Steel	Outer barrier of waste package

** Density: DENS (kg/m^3) **

** Emissivity EMIS **

** Conductivity: KXX (W/m/K) **

** Specific Heat: C (J/kg/K) **

Define densities for all materials with constant values.
Density of rock (1,2,3,4,5,6,7,8,9) is 1.0 because
heat capacitances (J/m^3/K) are entered for C

Clear 2-D mesh

SELECT FOR ITEM=TYPE COMPONENT=
 IN RANGE 1 TO 1 STEP 1

40 AREAS (OF 364 DEFINED) SELECTED BY ASEL COMMAND.

CLEAR NODES AND ELEMENTS FROM ALL SELECTED AREAS

*** NOTE *** CP= 102.050 TIME= 19:43:30
 Nodes cannot be cleared from area 1 because volume 55 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.060 TIME= 19:43:30
 Nodes cannot be cleared from area 2 because volume 56 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.060 TIME= 19:43:30
 Nodes cannot be cleared from area 3 because volume 53 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.070 TIME= 19:43:30
 Nodes cannot be cleared from area 4 because volume 54 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.070 TIME= 19:43:30
 Nodes cannot be cleared from area 5 because volume 51 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.080 TIME= 19:43:30
 Nodes cannot be cleared from area 6 because volume 52 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.090 TIME= 19:43:30
 Nodes cannot be cleared from area 7 because volume 47 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.100 TIME= 19:43:30
 Nodes cannot be cleared from area 8 because volume 48 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.120 TIME= 19:43:30
 Nodes cannot be cleared from area 9 because volume 49 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.130 TIME= 19:43:30
 Nodes cannot be cleared from area 10 because volume 50 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.140 TIME= 19:43:30
 Nodes cannot be cleared from area 11 because volume 57 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.150 TIME= 19:43:30

Nodes cannot be cleared from area 12 because volume 58 is meshed. Only elements are deleted.

*** NOTE *** CP= 102.150 TIME= 19:43:30
Nodes cannot be cleared from area 13 because volume 59 is meshed. Only elements are deleted.

***** ANSYS ANALYSIS DEFINITION (PREP7) *****

ELEMENT TYPE 1 IS PLANE55 2-D THERMAL SOLID
 KEYOPT(1-12)= 0 0 0 0 0 0 0 0 0 0 0 0

CURRENT NODAL DOF SET IS TEMP
 TWO-DIMENSIONAL MODEL

ELEMENT TYPE 2 IS SOLID70 3-D THERMAL SOLID
 KEYOPT(1-12)= 0 0 0 0 0 0 0 0 0 0 0 0

CURRENT NODAL DOF SET IS TEMP
 THREE-DIMENSIONAL MODEL

ELEMENT TYPE 16 IS SHELL57 THERMAL SHELL
 KEYOPT(1-12)= 0 0 0 0 0 0 0 0 0 0 0 0

CURRENT NODAL DOF SET IS TEMP
 THREE-DIMENSIONAL MODEL

ELEMENT TYPE 17 IS LINK32 2-D CONDUCTING BAR
 KEYOPT(1-12)= 0 0 0 0 0 0 0 0 0 0 0 0

CURRENT NODAL DOF SET IS TEMP
 THREE-DIMENSIONAL MODEL

ELEMENT TYPE 18 IS MATRIX50 SUBSTRUCTURE MATRIX
 KEYOPT(1-12)= 1 0 0 0 0 0 0 0 0 0 0 0

CURRENT NODAL DOF SET IS TEMP
THREE-DIMENSIONAL MODEL

ELEMENT TYPE 19 IS LINK31 RADIATION LINK
KEYOPT(1-12)= 0 0 0 0 0 0 0 0 0 0 0 0

CURRENT NODAL DOF SET IS TEMP
THREE-DIMENSIONAL MODEL

Proprep.dat describes material properties and
thier reference numbers related to ET's above

READ IN MATERIAL PROPERTY LIBRARY FROM FILE= proprep.dat

/INPUT FILE= proprep.dat LINE= 0

** ANSYS 5.0 MPC MATERIAL PROPERTY TABLES **

** Filename: proprep.dat **

** Compiled by R. Bahney III on 6-16-94 **

TYPE	MATERIAL	
1	TCW	Top Rock layer
2	PTn	
3	TSw1	
4	TSw2	Repository Horizon
5	TSw3	
6	CHn1v	
7	CHn1z	
8	CHn2	Extends to Water Table
9	Packed Crushed Tuff	Alternate invert
10	Hom. Canister	Smearred Props for WP Center
11	Concrete	Trackbed for Rail Emplacement
12	Eff. Radiation	Effective Cond. in drift air
13	A516 Mild Steel	Outer barrier of waste package

** Density: DENS (kg/m^3) **

** Emissivity EMIS **

** Conductivity: KXX (W/m/K) **

** Specific Heat: C (J/kg/K) **

Define densities for all materials with constant values.
Density of rock (1,2,3,4,5,6,7,8,9) is 1.0 because
heat capacitances (J/m^3/K) are entered for C

Model is 6 elements wide
(3+7=10 divisions)

Extrude WP 5 elements

1 element thick steel

Extrude drift 4 elements with smallest
elements at WP mid-length

Set element sizes in rock layers

3 element thick ICw

3 element thick PTn

9 element thick TSw1

12 elements above and below near field
with smaller elements near drift

3 element thick TSw3

2 element thick CHn1v

7 element thick CHn1z

12 element thick CHN2 with smaller elements
near the top

Concatenate lines for mapped meshing
(L's 107,108,109,110,111,112)

Mesh 2-D areas
(first WP, then invert, DF wall and rock layers)

Waste package

Invert

Drift wall and TSw2 areas

```

Mesh waste package volumes

FOR ELEMENT TYPE(S) ALLOWING MULTIPLE SHAPES:
PRODUCE ALL QUADRILATERAL OR BRICK ELEMENTS.

MATERIAL NUMBER SET TO 10

ELEMENT TYPE SET TO 2

GENERATE NODES AND ELEMENTS
IN VOLUMES 1 TO 4 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 4
MAXIMUM NODE NUMBER = 1639
MAXIMUM ELEMENT NUMBER = 1466

MATERIAL NUMBER SET TO 13

GENERATE NODES AND ELEMENTS
IN VOLUMES 5 TO 8 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 4
MAXIMUM NODE NUMBER = 1759
MAXIMUM ELEMENT NUMBER = 1586

GENERATE NODES AND ELEMENTS
IN VOLUMES 17 TO 24 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 8
MAXIMUM NODE NUMBER = 1904
MAXIMUM ELEMENT NUMBER = 1718

MATERIAL NUMBER SET TO 10

GENERATE NODES AND ELEMENTS
IN VOLUMES 9 TO 12 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 4
MAXIMUM NODE NUMBER = 2509
MAXIMUM ELEMENT NUMBER = 2258

MATERIAL NUMBER SET TO 13

GENERATE NODES AND ELEMENTS
IN VOLUMES 13 TO 16 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 4
MAXIMUM NODE NUMBER = 2629
MAXIMUM ELEMENT NUMBER = 2378

GENERATE NODES AND ELEMENTS
IN VOLUMES 25 TO 32 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 8
MAXIMUM NODE NUMBER = 2774
MAXIMUM ELEMENT NUMBER = 2510

Extrude 2-D rock into front half 3-D
Invert
(V's 33,34)

FOR ELEMENT TYPE(S) ALLOWING MULTIPLE SHAPES:
PRODUCE ALL QUADRILATERAL OR BRICK ELEMENTS.

ELEMENT TYPE SET TO 2

Model is 6 elements wide
(3+7=10 divisions)

Extrude WP 5 elements

1 element thick steel

Extrude drift 5 elements with smallest
elements at WP mid-length

Set element sizes in rock layers

3 element thick TCw

3 element thick PTn

9 element thick TSw1

12 elements above and below near field
with smaller elements near drift

3 element thick TSw3

2 element thick CHn1v

7 element thick CHn1z

12 element thick CHN2 with smaller elements
near the top

Concatenate lines for mapped meshing
(L's 107,108,109,110,111,112)

Mesh 2-D areas
(first WP, then invert, DF wall and rock layers)

Waste package

Invert

Drift wall and TSw2 areas

Mesh waste package volumes

FOR ELEMENT TYPE(S) ALLOWING MULTIPLE SHAPES:
 PRODUCE ALL QUADRILATERAL OR BRICK ELEMENTS.

MATERIAL NUMBER SET TO 10

ELEMENT TYPE SET TO 2

GENERATE NODES AND ELEMENTS
 IN VOLUMES 1 TO 4 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 4
 MAXIMUM NODE NUMBER = 1561
 MAXIMUM ELEMENT NUMBER = 1382

MATERIAL NUMBER SET TO 13

GENERATE NODES AND ELEMENTS
 IN VOLUMES 5 TO 8 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 4
 MAXIMUM NODE NUMBER = 1681
 MAXIMUM ELEMENT NUMBER = 1502

GENERATE NODES AND ELEMENTS
 IN VOLUMES 17 TO 24 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 8
 MAXIMUM NODE NUMBER = 1826
 MAXIMUM ELEMENT NUMBER = 1634

MATERIAL NUMBER SET TO 10

GENERATE NODES AND ELEMENTS
 IN VOLUMES 9 TO 12 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 4
 MAXIMUM NODE NUMBER = 2431
 MAXIMUM ELEMENT NUMBER = 2174

MATERIAL NUMBER SET TO 13

GENERATE NODES AND ELEMENTS
IN VOLUMES 13 TO 16 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 4
MAXIMUM NODE NUMBER = 2551
MAXIMUM ELEMENT NUMBER = 2294

GENERATE NODES AND ELEMENTS
IN VOLUMES 25 TO 32 IN STEPS OF 1

NUMBER OF VOLUMES MESHED = 8
MAXIMUM NODE NUMBER = 2696
MAXIMUM ELEMENT NUMBER = 2426

Extrude 2-D rock into front half 3-D
Invert
(V's 33,34)

FOR ELEMENT TYPE(S) ALLOWING MULTIPLE SHAPES:
PRODUCE ALL QUADRILATERAL OR BRICK ELEMENTS.

ELEMENT TYPE SET TO 2

MATERIAL NUMBER SET TO 11

DRAG AREAS
27, 28,
ALONG LINES
58,

MAXIMUM NODE NUMBER = 2810

*** WARNING ***

CP= 61.250 TIME= 14:57:35

Same node numbers associated with more than one solid model entity.

Future mesh clearing operations could produce unexpected results.

NUMMRG,KP could correct this problem.

MERGE COINCIDENT KEYPOINTS WITHIN TOLERANCE OF .10000E-03
