Calcium Based Test Method for Evaluation of Photovoltaic Edge-Seal Materials

Michael Kempe,
Arrelaine Dameron,
Matthew Reese

2011 NREL PV Module Reliability Workshop

February 16, 2011

NREL/PR-5200-50839
Experimental Objectives

Many PV technologies are sensitive to moisture. Even with impermeable front- and back-sheets, moisture can penetrate from the sides. Edge seals are incorporated around the perimeter to prevent this ingress.

Here we use a Ca-based method to evaluate the moisture ingress time for edge seal materials.

Then we use this data to model the performance when deployed outdoors.
Test Sample Designed to Mimic Module Edge

Module Edge $\text{H}_2\text{O}$ $\rightarrow$ Glass

Seal

Encapsulant

Glass

$w$ 50 mm

Test Sample $\text{H}_2\text{O}$ $\rightarrow$

Glass (3.18 mm)

Polymer Film (~0.5 mm)

Ca (100 nm)

Glass (3.18 mm)

$\text{Ca} + 2\text{H}_2\text{O} \rightarrow \text{Ca(OH)}_2 + \text{H}_2$
Oxidation of Ca Indicates Moisture Ingress

\[ \text{Ca} + 2 \text{H}_2\text{O} \rightarrow \text{Ca(OH)}_2 + \text{H}_2 \]

Mirror-Like $\rightarrow$ Transparent
Moisture Ingress Varies Greatly in Encapsulants

**Distance (cm)** vs **Time (h)**
Edge Seal Modeling

The use of fillers, pigments, and desiccants makes the determination of modeling parameters much more difficult.

$$S_m = S_0 e^{-\frac{E_{a_s}}{kT}} \frac{RH \%}{100 \%}$$

$$D_{\text{eff}} = D_0 e^{-\frac{E_{a_D}}{kT}}$$

Mobile phase water absorption is split between the polymer matrix and the mineral components. Assume linearity with relative humidity.

Mobile phase water diffusivity is an effective diffusivity. This accounts for a rapid equilibration between adsorbed and dissolved water.

A non-reversible reaction with water.
Getting the Modeling Parameters

$R_{H_2O}$

Measured by weighing samples before humidity exposure, after humidity exposure, and after drying.

$S_o, Ea_S$

In progress: Measured by exposing to controlled humidity then drying in a TGA to determine moisture loss. Currently assuming $Ea_S$ of 16 KJ/mol.

$D_o, Ea_D$

Estimate from other parameters and fit to Ca data.
Ingress Estimated Using Finite Element Analysis

Denver Colorado

\[ X = K \sqrt{t} \]

Used TMY3 Data and Temperature estimates similar to King et al., and Kurtz et al.
Square Root Relation Works to Longer Times

Distance (cm)

Time (years)

 insulation Back, Glass/Polymer

A sensitivity analysis gave about ±15% on K and Width, and ±30% on 20 yr equivalent time.
What edge seal parameters are important?

1. Adhesion is the most important parameter.
   a) Must be maintained after environmental exposure.
   b) Residual stress in glass may affect adhesion.
   c) Material may expand as it absorbs water.
   d) Good surface preparation is necessary.

2. Breakthrough time is the next most important.
   a) The 12 mm edge delete perimeter should be wide enough to keep moisture out.

3. Module mounting configuration is not important.
   a) Hotter installations tend to dry out the module partially countering the effects of increased diffusivity.

4. The steady state transmission is less important.
   a) The amount of permeate is very low.
   b) Ideally one will not reach steady state.
Conclusions:

1. An edge seal width of 1 cm can be capable of keeping moisture out for 20 years in almost any climate.

2. The mounting configuration is not a significant factor for determining the diffusion based lifetime of an edge seal.

3. The climate a module is deployed in very significantly impacts edge seal performance.

4. Exposure to between 500 h and 3000 h of 85C and 85% RH will equate to about 20 years of moisture ingress through an edge seal.
