The integration of two-phase flow models with the key effects necessary for simulation of an operational cell at typical conditions of temperature, pressure, and inlet states has continued. Initial testing and validation simulations were for the Ballard MK902 cell. This cell and operating conditions were selected for the detailed diagnostic data and past modeling results available for comparison [1,2]. The simulation utilized two-phase flow in the channels and porous media, electrochemistry, and heat transfer. The coupling between gas phase chemical species transport and liquid water formation was primarily through the treatment of the oxygen reduction reaction. For this reaction, the water product is formed as either vapor or liquid phase water based on the local thermodynamic state. The resulting liquid water fraction distribution at the level of the cathode GDL for an average current density of 0.85 A/cm² indicated that liquid water is predominantly under the lands. The predicted current density distribution, Figure 3, is below the experimental...
curve because we were unable to obtain a converged solution at the desired 1 A/cm² average current. The two-phase model does show improved agreement with the experimentally measured trends compared to simpler models, particularly near the inlet where the current density starts low and rapidly increases in the single phase solution. During these tests, improvement of the numerical stability and accuracy of the heat transfer solution was identified as the highest priority for further model improvements.

Two main thrusts have emerged for concepts to improve cell performance, GDL materials modification and channel design. In the area of GDL material properties, during the second year of this project BCS Fuel Cells demonstrated improved performance in a self-humidified cell operated under dead-end conditions for an intermediate loading of poly-tetrafluoroethylene (PTFE) in the microporous layer. Within the last year, these results have been confirmed, and the initial interpretation of the basis for improved performance has been supported by improved diagnostics using impedance spectroscopy. The best performance is observed at the intermediate PTFE loading because less hydrophilic GDL materials do not maintain adequate membrane ionomer hydration, while additional loading blocks pores and introduces mass transfer limitations for the gaseous reactants between the channels and the catalyst. For channel designs, the specific objectives are to minimize the pressure drop variation between ‘wet’ and ‘dry’ operation and the amplitude of pressure drop transients caused by liquid water in the cells while maintaining or improving cell power density. Initial experiments at Ballard have identified wicking channel designs, in conjunction with channel surface treatments to control the water contact angle, as promising approaches to meet these objectives. In those experiments, several channel design concepts either achieved the wet pressure drop performance improvements, or had promising CFD output, but none met both objectives.

### Conclusions and Future Directions

In the past year, we have identified advantageous operating regimes while completing the planned characterization of two-phase transport in cell components and assemblies. The predictive capabilities of the cell-scale CFD models for two-phase flow in fuel cell microchannels, and in porous components such as GDLs and catalyst layers, have been improved and are integrated with electrochemistry and heat transfer to enable analysis of operational cells. Specific accomplishments for the past year include:

- Generated flow regime map from experimental studies of droplet emergence at a GDL-channel interface studies; demonstrated improved model agreement with the transition from film flow to droplet regime;
- Implemented experimental setup for collecting wet pressure drop and transient pressure signatures in two-phase flows in channels and cells; improved agreement of model predictions and observed wet pressure drop;
- Integrated electrochemistry, heat transfer, and phase change with the CFD two-phase flow models and demonstrated improvement in current density distribution for initial validation test case; and
- Identified materials and design modifications to focus on for improved water management.

Key activities planned for the coming year include:

- Improve numerical stability of electrochemistry, heat transfer and phase change models integrated with the two-phase CFD models; test and validate the developed integrated models using operational cell-scale steady and transient data.
- Apply validated measurements and simulation tools to the identified optimization strategies: channel design, surface finish, and GDL design for effective water removal with low pressure drop and minimal transients; GDL design and treatment for improved cell performance.

Future work will consist primarily of testing and improving the developed models, while applying validated capabilities to support the development and demonstration of improved water management approaches.

Contract Number: DE-FG3607GO17018

Subcontractors:
• General Motors, Honeoye Falls, NY
• Michigan Technological University, Houghton, MI

Project Start Date: March 1, 2007
Project End Date: February 28, 2010

Objectives

• Improve fundamental understanding of the water transport processes in proton exchange membrane fuel cell (PEMFC) stack components under freezing and non-freezing conditions.
• Optimize materials, design, and surface properties of gas diffusion layer (GDL) and bipolar plate to alleviate flooding and suppress regions of dehumidification.
• Develop experimental and modeling tools to evaluate ex situ and in situ performance of PEMFC stack components.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies (FCT) Program Multi-Year Research, Development and Demonstration (RD&D) Plan:

(A) Durability
(C) Performance
(D) Water Transport within the Stack

Technical Targets

This project is directed at developing a better water management strategy within PEMFC stacks. Insight gained will be applied toward the design and demonstration of a robust fuel cell that meets the following DOE technical targets as outlined in the FCT Multi-Year RD&D Plan:

• Unassisted start from low temperature: -40°C
• Durability with cycling at operating temperature of ≤80°C: 5,000 h
• Energy density: 2 kW/L

Accomplishments

In this project, Rochester Institute of Technology (RIT), General Motors (GM) and Michigan Technological University (MTU) have focused on fundamental studies that address water transport, accumulation and mitigation processes in the GDL and flow field channels of the bipolar plate. These studies have been conducted with a particular emphasis on understanding the key transport phenomena which control fuel cell operation under freezing conditions. Technical accomplishments during this period are listed below:

• Demonstrated that shutdown air purge is controlled predominantly by the water carrying capacity of the purge stream and the most practical means of reducing the purge time and energy is to reduce the volume of liquid water present in the fuel cell at shutdown. The GDL thermal conductivity has been identified as an important parameter to dictate water accumulation within a GDL.
• Found that, under the normal shutdown conditions, most of the GDL-level water accumulation occurs on the anode side and that the mass transport resistance of the membrane electrode assembly (MEA) thus plays a critically important role in understanding and optimizing purge.
• Identified two-phase flow patterns (slug, film and mist flow) in flow field channel, established the features of each pattern, and created a flow pattern map to characterize the two-phase flow in GDL/channel combination.
• Implemented changes to the baseline channel surface energy and GDL materials and evaluated their performance with the ex situ multi-channel experiments. It was found that the hydrophilic channel (contact angle \( \theta \sim 10^\circ \)) facilitates the removal of liquid water by capillary effects and by reducing water accumulation at the channel exit. It was also found that a GDL without a microporous layer (MPL) promotes film flow and shifts the slug-to-film flow transition to lower air flow rates, compared with the case of GDL with MPL.

• Identified a new mechanism of water transport through GDLs based on Haines jump mechanism. The breakdown and redevelopment of the water paths in GDLs lead to an intermittent water drainage behavior, which is characterized by dynamic capillary pressure and changing of breakthrough location. MPL was found to not only limit the number of water entry locations into the GDL (thus drastically reducing water saturation), but also stabilizes the water paths (or morphology).

• Simultaneously visualized the water transport on cathode and anode channels of an operating fuel cell. It was found that under relatively dry hydrogen/air conditions at lower temperatures, the cathode channels display a similar flow pattern map to the ex situ experiments under similar conditions. Liquid water on the anode side is more likely formed via condensation of water vapor which is transported through the anode GDL.

• Investigated the water percolation through the GDL with pseudo-Hele-Shaw experiments and simulated the capillary-driven two-phase flow inside gas diffusion media, with the pore size distributions being modeled by using Weibull distribution functions. The effect of the inclusion of the microporous layer in the fuel cell assembly was explored numerically.

• Developed a new method of determining the pore size distribution in GDL using scanning electron microscope (SEM) image processing, which allows for separate characterization of GDL wetting properties and pore size distribution.

• Identified a drop size dependency of the static contact angle on GDL, which is measured using an adaptation of the classical sessile drop method and is calculated using an in-house code specially developed for measuring static contact angles on rough, porous substrates.

• Determined the effect of surface wettability and channel cross section and bend dihedral on liquid holdup in fuel cell flow channels.

---

**Introduction**

Water management is critical to the successful implementation of PEMFCs in various industry sectors. Water management is especially challenging under low temperature conditions due to the low water carrying capacity of the reactant stream and the possibility of water freezing within the fuel cell assembly, which results in premature degradation. This project is directed at developing a better water management strategy within PEMFC stacks. To achieve these objectives, the project has been focused on the following technical issues:

1. Two-phase (water and gas) transport in the fuel cell stack, including the GDL, flow channels, and their interfaces.
2. Structural and surface properties of materials and how they change during operational events, such as freeze/thaw.
3. Experimental and modeling tools to evaluate ex situ and in situ performance as well as local variations in current density and water distribution.

**Approach**

The objectives of this project were accomplished through an iterative approach that starts at the component level, synthesizes this fundamental learning into combinatorial ex situ experiments with nearly full visual access, and then progresses to increasingly more complex in situ experiments that utilize advanced diagnostic methods such as current density, high-frequency resistance distributions and neutron radiography. The success of the project lies in new materials, improved design concepts and operating strategies. Both experimental and modeling tools will be used to evaluate ex situ and in situ performance.

**Results**

Previous studies under this project have identified the most important GDL material properties that affect the water accumulation within GDLs are thermal conductivity and thickness. Decreased thermal conductivity effectively increases the MEA temperature and thus, the saturation pressure gradient that drives water vapor from the electrode to the channel, resulting in lower steady-state liquid water accumulation within GDLs. Thinner GDLs simply hold less water. To minimize the quantity of water that accumulates within the GDLs, the effects of variations in GDL thickness and thermal conductivity have been evaluated by GM for optimized water removal at various shutdown conditions. A series of experiments were conducted with Toray 030 and 090 (nominal thicknesses of 100 and 300 \( \mu \text{m} \), respectively) diffusion media, which are more thermally conductive than the baseline GDL, that
combined different combinations on the anode and cathode (MPL used in all cases). As shown in Figure 1, the steady-state water content with fully humidified inlet reactant streams was greatest when a thick cathode GDL was used; this impact is also observed in the significantly higher mass transport loss at high current density. By contrast, the thickness of the anode GDL had a relatively small effect on both water content and fuel cell performance.

Water removal during shutdown purge is critical for a robust freeze start. Conversely, the ionomer must not become over dried during purge because poor proton conductivity at sub-freezing start conditions will occur. In order to investigate the relationship between ionomer drying (as indicated by high frequency resistance, HFR) and water removal, GM employed the distributed current and temperature measurement tool with simultaneous neutron radiography [1]. The results in Figure 2 demonstrate that there is a very strong correlation between HFR and effective water thickness, and that a significant increase in local HFR due to ionomer drying does not occur until water in the GDL substrate has been removed. For the purge condition in Figure 2, this transition occurs at a measured water thickness of about 20 μm. The results indicate that purge time is constrained by GDL saturation properties.

Water accumulation in the through-plane dimension was directly measured with high resolution neutron imaging instruments at the National Institute of Standards and Technology. These measurements were executed with the baseline material set and same operating conditions that have been previously reported. When preconditioned and purged at 55°C, the majority of water accumulation was observed to occur within the anode GDL layer. This result directly confirms the previously inferred water accumulation location in the through-plane dimension. The data clearly demonstrates that the water removal rate during shutdown purge for freeze is constrained by water transfer through the membrane.

Various changes to the baseline GDL-channel systems, including channel surface treatment (hydrophobic or hydrophilic), channel geometries (sinusoidal, trapezoidal or rectangular), GDL Teflon® (poly-tetrafluoroethylene, PTFE) content and GDL thickness, were implemented in order to obtain the combination of GDL materials and flow channel design which give out the optimal ex situ performance. The channel surface energy displays significant impact on channel two-phase flow. The hydrophilic channel (contact angle, \( \theta \approx 10^\circ \)) was found to facilitate the removal of liquid water and decrease the slug formation tendency compared to the case of non-treated channels (\( \theta \approx 60^\circ \)), while the hydrophobic channel (\( \theta \approx 105^\circ \)) displays a large number of stationary water droplets or small slugs. The effects of different channel geometries, including sinusoidal geometry representing the stamped metal bipolar plate and trapezoidal geometry representing the molded carbon composite bipolar plate, on the two-phase flow in channels, were compared to the rectangular geometry (maintaining same hydraulic diameter) and no significant impact was found in terms of the two-phase flow pattern map. This confirms the validity of the selection of the baseline rectangular channel design. The effects of GDL PTFE content and thickness on channel two-phase flow were carried out
using Toray GDL with different thickness (190 μm for TGP-H-060 and 380 μm for TGP-H-120) and different PTFE contents (0-40 wt%). While GDL thickness shows little influence on the ex situ two-phase flow, the PTFE content shows remarkable impact on the flow pattern map. Plain GDL (non-PTFE treated) was shown to be completely wetted by water and a continuous water film was developed on GDL surface. In contrast, PTFE treatment promotes the formation of water slugs and films along the channel walls and little water resides on the GDL surface due to its hydrophobicity. As PTFE content increases, the transition from slug to film flow shifted to higher superficial air velocity, and no significant difference in flow pattern was found with further increasing hydrophobicity at PTFE content above 20 wt%.

Water breakthrough dynamics, characterized by the capillary pressure and water saturation, were determined ex situ with baseline and single gas layer GDLs with and without MPL. The water breakthrough in GDLs has been found to occur at a few preferential locations in both baseline and single gas layer GDLs, with the dynamic characteristics of this process having been observed. The dynamic behavior was reflected in two aspects: dynamic capillary pressure (or recurrent breakthroughs) and dynamic breakthrough locations (or changing of breakthrough locations with time). Generally small water saturations (less than 10%) were observed for GDLs at breakthrough and MPL was found to further reduce the water saturation in GDL. No changing of water breakthrough locations was observed in GDLs with MPL. This result suggests that MPL play a role in stabilizing the preferential water pathways.

Based on these observations, we have proposed a new water transport mechanism to account for the water breakthrough in GDLs (Figure 3). This mechanism is based on Haines jump dynamics [2,3]. Water drainage through a GDL occurs in a step-wise process. The water in GDLs remains unmoved until the point at which the pressure in water increases above the capillary pressure at the largest restriction and, at this point, the invading water suddenly moves into the adjacent pores. In the case of water breakthrough on the GDL surface, the bursting droplet grows fast as it carries away water from adjacent GDL pores. However, the supply of water is often not sufficient for the droplet to fill the gas channel. This “choke off” effect leads to empty pores in the GDL, which break down the continuous water paths. These emptied pores are refilled afterwards as water is constantly injected and the bursting process occurs again, leading to the recurrent breakthrough behavior. As the “choke offs” break down the original water paths and water spontaneously readjusts its interfaces inside GDL pores. This water/air interface relaxation process may lead to a new preferential pathway in the GDL and result in a new breakthrough location.

The pseudo-Hele-Shaw experiment was conducted to determine the water distribution inside the fuel cell and to quantify the amount of water held in the GDL. The two measurements derived from the experiment, wetted area and percolation pressure, were combined into a single variable by defining a new scaling for water percolation in porous media. The scaling is based on the ratio between the energy required to inject the water and the energy dissipated due to the viscous stress. When this energy ratio (Ce) is plotted against the non-dimensional time (t*) a simple logarithmic dependence was observed.

A series of two dimensional numerical simulations using a network model approach were conducted to study the effect the most significant variables affecting the water percolation within the GDL. The numerical model consists of the cross-sectional portion of GDL under a single gas channel. The impacts of the morphological and wetting properties of the GDL on the water transport were studied. The impact of the morphology was analyzed by varying the pore size distribution. These distributions were generated by defining pore size histograms using the Weibull distribution function. Even though the water percolates, forming a different array of fingers for different pore size distributions, it was found that the percolation pressure is the same for GDLs having the same pore size histogram. The effects of wetting properties were studied by varying the contact angle. In contrast to the morphology properties, varying the contact angle only modifies the percolation pressure while water moves through the same set of pores. Additionally, three different GDL scenarios were investigated corresponding to GDL without MPL, GDL with MPL and GDL with an MPL have defects. It was found that the overall water content in the GDL was reduced by the addition of the MPL between the GDL and the catalyst layer. This effect was enhanced when considering the addition of a perforation or defect in the MPL.

**FIGURE 3.** Schematic of water drainage in a GDL (a) without MPL, displaying a large number of water entry points into the GDL; and (b) with MPL, restricting water entry into GDL only at the crack/defect locations in the MPL.
The two-dimensional network model was extended to a three-dimensional version and a series of numerical simulation were performed imitating the conditions occurring in a pseudo-Hele-Saw experiment. The wetted area and percolation pressure were extracted from the simulations. The energy ratio was calculated and compared with experimental data. The comparison between the numerical and the experimental pseudo-Hele-Shaw experiments are plotted in Figure 4. An effective internal contact angle of 135 degrees collapsed the numerical simulation onto the experimental data. Thus, the behavior of liquid water in GDLs can be effectively characterized experimentally and can be captured in a simple computational tool.

A new model for predicting the morphology of water in the flow field has been developed using Surface Evolver. A parametric study of the critical volume at which a liquid drop will transform spontaneously into a liquid plug in a channel has been completed for variations in the channel bend dihedral, channel contact angle and GDL contact angle. This model can be used to predict the rate of liquid plug formation for a given current density and flow field configuration.

Conclusions and Future Directions

A major driving force for this research project has been the development of an optimal combination of materials, design features and cell operating conditions that achieve a water management strategy which facilitates fuel cell operation under freezing conditions. Based on our various findings, we have made the final recommendation relative to GDL materials, bipolar design and surface properties, and the combination of materials, design features and operating conditions:

- GDL materials: use lower thermal conductivity cathode GDL and decrease the anode GDL thickness.
- Bipolar plate design: use a channel geometry that can be produced using a high-speed manufacturing process, with a hydrophilic coating.
- Shutdown and gas purge protocol: incorporate above findings in developing cost effective and energy efficient shutdown purge protocol.

It should be noted that a comprehensive fuel cell operating strategy must consider the entire range of operating conditions under which the system needs to perform. Although the recommendations above will benefit fuel cell performance under conditions where liquid water is expected to be present, they must also be fully assessed to understand their impact under relatively dry conditions.

Project Start Date: October, 2007
Project End Date: March, 2011

Objectives

• Investigate effects of impurities on catalysts, membranes and other fuel cell components.
• Understand the effect of catalyst loadings on impurity tolerance.
• Investigate the impacts of impurities on catalyst durability.
• Develop methods to mitigate negative effects of impurities.
• Develop models of fuel cell-impurity interactions.
• Determine impurity tolerance limits in view of the technical targets for catalyst loading, performance and durability.
• Provide experimental data to hydrogen suppliers for defining fuel specifications.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(B) Cost: the cost of fuel cells limits their use:
- Fuel and air impurity removal systems increase cost, weight and complexity.
- Higher platinum group metal loading required for maintaining performance, in the presence of impurities, increases cost.

(A) Durability: Durability may decrease in the presence of impurities.

(C) Performance: Fuel cell performance is degraded by impurity effects.

Technical Targets

The technical targets for catalyst loading are indicated in Table 1. These targets were formulated with the assumption that fuel cell performance will not be degraded by fuel and/or air impurities or contaminants. One of the specific goals of this project is the experimental determination of the limits of impurity tolerance within those technical targets. The results of this project will provide data for defining the fuel cell hydrogen fuel specifications and intake air quality and assess the role of impurities in fuel cell performance degradation.

Accomplishments

• H₂S anode poisoning/durability test completed with current generation membrane electrode assemblies (MEAs) (milestone).
• SO₂ long-term testing was completed (milestone).
• Long-term NOₓ fuel cell poisoning was characterized (milestone).
• NH₃ effect on oxygen reduction on Pt/C was studied by rotating disk electrode voltammetry.
• Iridium oxide solid state pH sensors were developed for local proton activity measurements in polymer electrolyte membrane fuel cells.
• Neutron imaging at the National Institute of Standards and Technology (NIST) showed some cationic impurities change local water concentration in fuel cells (milestone)
**Introduction**

Fuel cells efficiently convert flows of chemical fuel and oxygen to electrical power. Fuel cell performance may be severely impacted by contaminants or impurities that decrease the electrochemical catalytic rates, interfere with proton transport across the polymer electrolyte, or impede the flow of reactants to/or reaction products away from the anode or cathode charge transfer interfaces. The impurities may be generated by the fuel synthesis process or be present as ambient air impurities. The platinum metal catalyst surfaces may be deactivated by strongly adsorbing species such as sulfur containing molecules and carbon monoxide. The strongly bound species both block surface sites for catalytic activation and alter the electronic structure of the surface decreasing charge transfer rates. Positively charged contaminant ions often times have much greater chemical affinity to the ion transport sites within the polymer than protons. The foreign cations typically have lower mobilities than protons and reduce ionic conductivity. The presence of impurities may also decrease the operational lifetime of the fuel cell by decreasing performance irreversibly to an unacceptable value or by increasing component failure rate.

**Approach**

Our approach to understanding impurity interactions with fuel cell components utilizes both experimental and modeling efforts. We carry out fuel cell performance measurements in the presence of known quantities of introduced impurities and then study the impurity interactions with fuel cell components using electrochemical diagnostic methods such as adsorbate stripping voltammetry and alternating current impedance spectroscopy. Sometimes the experiments are performed in neutron imaging systems to visualize the effect of the impurity upon the water content and transport properties of fuel cell components. Post-experimental analysis includes trace level chemical analysis of fuel cell components and effluent water, electron microscopy and X-ray diffraction of the solid materials. We also experimentally determine impurity thermodynamic behavior (ion-exchange, proton and water activity coefficients) and transport properties such as membrane permeability and ionic conductivity.

Theoretical studies include computer models of impurity interactions with anode and cathode electrocatalysis. We also model the effects of foreign cations upon fuel cell performance. The modeling results are validated with experimental measurements such as hydrogen pump experiments and X-ray and electron beam microscopy of impurity distribution.

**Results**

Sulfur compounds are well known electrode catalysis poisons, however tolerable impurity levels at low Pt catalyst loading have not been yet determined. Last year we completed a long-term drive cycle test with hydrogen spiked with 10 ppb hydrogen sulfide. The degradation rate was the same as the control cell. However, both cells were using experimental membrane electrode assemblies that exhibited a higher performance loss than desirable. We obtained second generation fuel cell membrane assemblies from commercial suppliers and repeated the tests. An anode loading of 0.10 mg Pt/cm², cathode-0.20 mg Pt/cm², cycled in constant voltage mode between 0.85 V-0.6 V. After a pre-exposure run of 100 hours, the test cell received 10 ppb H₂S, for 1,000 hours.

Figures 1a, 1b, and 1c respectively show the baseline fuel cell performance at differing time intervals, the performance of an identical fuel cell with 10 ppb hydrogen sulfide and the electrochemical surface area of the electrodes after ~1,000 hours of operation. There was no significant difference in performance loss or electrochemical surface area loss between the control sample and the fuel cell fed with contaminated hydrogen thus supporting the earlier results.

The most prevalent sulfur containing air species is sulfur dioxide from fossil fuel combustion. The Fuel Cells sub-program targets call for a decrease in anode and cathode Pt loading. We evaluated the response of two 50 cm² fuel cells: a LANL-prepared Nafion® 212 fuel cell and a commercial fuel cell membrane with anode/cathode loading: 0.1/0.2 mg Pt/cm², to 100 ppb SO₂ in air (2.0 stoichiometry) injection at the cathode inlet past the humidification system (100% saturation). The fuel cell tests were performed at constant current 1 A/cm² for 500 hr. The fuel cell operating voltages at constant current decreased rapidly with approximately 200 mV of loss for both cells after sulfur dioxide injection was terminated. Unfortunately air concentrations of >100 ppb of sulfur dioxide are still common in industrial areas of the developing world.

Another common class of emission species from fossil fuel combustion systems is oxides of nitrogen. High combustion temperatures and pressures promote the reaction of nitrogen with air to form these acid gases. We studied by cathode injection, the long-term effects of 5 ppm NO₂ into an operating fuel cell similar to the one used for the sulfur dioxide experiments. Figure 2 illustrates the results of an over a 350-hour test. NO₂ reduces the fuel cell voltage by ~150 mV but reaches steady-state after about 50 hours of operation. The NO₂ is probably being reduced by hydrogen to ammonium cations; their concentration may be controlled by the ammonium ion-aqua ammonia equilibrium reaction.
Ammonia is also present as an impurity in hydrogen fuel from reforming and as an air impurity from the decomposition of urea and agricultural activities. Ammonia reacts strongly with protons in the perfluorsulfonic acid membrane, forming ammonium cations and increasing the pH of the membrane. A decrease in membrane acidity shifts fuel cell open circuit potential, decreases fuel cell electrocatalytic rates and reduces proton conductivity. We completed a rotating ring disk electrode (RRDE) study of the effect of ammonium ions on oxygen reduction on Pt-C catalysts. The study was carried out by measuring the oxygen reduction reaction (ORR) on carbon-supported platinum in 0.1 mol dm$^{-3}$ HClO$_4$ solutions containing different quantities of ammonium perchlorate. ORR current losses and increases in hydrogen peroxide generation were seen in two distinct potential regions, namely at $E > 0.7$ V vs reference hydrogen electrode (RHE) and at $E < 0.4$ V vs RHE. In order to better understand the observed effects, similar experiments were performed with solutions containing different concentrations of sodium perchlorate. Qualitatively similar, but different in magnitude effects were observed. It appears that the electrochemical oxidation of ammonia is responsible for the more significant effects of ammonium in the range of higher potentials, whereas the losses in the range of less positive potentials are mostly due to the coadsorption of ammonium and ClO$_4^-$.

A concentrated solution theory model was previously developed by us to describe the one-dimensional cation impurity profiles as a function of current density. The slow removal rate of foreign cations coupled with lower mobilities than protons was shown to produce non-uniform impurity profiles. The concentration ratio of protons to impurity ions decreases from anode to cathode when current spontaneously flows in the fuel cell. Increasing the current density deceases the proton concentration in the cathode leading to decreased proton transport to the oxygen reduction inhibiting fuel cell performance. However our cation poisoning experiments show impacts to performance in both electrokinetic and mass transport segments of the fuel cell polarization curve. We suspected that foreign cations might also changing the water concentration in the electrode layer. We verified these results by studying cation contaminated fuel cell membranes at the NIST neutron imaging beam line. Figure 3 shows the presence of cesium ions significantly changes the local water concentration.

The most likely effects of the impurities on the ORR kinetics are associated with changes in pH and water activity, which both depend on the cell operating conditions. Consequently, there is a need for a quantitative evaluation of these effects in situ.
Iridium oxide-coated electrodes have been used as pH sensors in various environments due to their chemical inertness and fast response and offer promise for pH measurements and indirect determination of cationic impurities in Nafion®. Iridium oxide (IrOx) can be deposited on a variety of substrates using three different techniques: electrochemical, sputtering, and high temperature oxidation. Gold and platinum were selected as substrates for the electrochemical deposition of the oxide. Gold was selected because of its inertness in a wide potential range and a common use as a substrate for iridium oxide-based pH sensors. On the other hand, platinum was tested to determine the viability of platinum interdigitated array electrodes for use in experiments aimed at monitoring local pH changes during oxygen reduction on Nafion®-coated platinum.

Iridium oxide layers were grown electrochemically employing various electrodes, including standard disk electrodes (1 mm diameter), ultramicroelectrodes (100 μm diameter), interdigitated electrodes (5 μm interdigitated bands separated by 5 μm gaps), and wire electrodes (1 mm diameter). The deposition was performed using a solution containing 4 mmol dm⁻³ IrCl₄⁻ and 40 mmol dm⁻³ H₂C₂O₄. The pH of the solution was adjusted to ~10.5 using solid K₂CO₃. The electrode potential was cycled at a rate of 100 mV s⁻¹ between +0.6 V and -0.75 V vs. Ag/AgCl (3 M NaCl) reference electrode. The rate of growth of iridium oxide under such conditions was equivalent to ~3 monolayers per 100 potential cycles.

The films grown electrochemically on platinum exhibited approximately linear potential (E) vs. pH characteristics between pH = 1 and pH = 3.7. The slopes of E vs. pH plots were lower than 60 mV per 1 pH unit and the response time was very short, in a sub-second to a few seconds range. While the fast response of the sensors utilizing electrochemically grown films made them an excellent choice for real time monitoring pH changes during oxygen reduction on platinum interdigitated electrodes, their other characteristics made them unsuitable for this application. Specifically, the films were very permeable which could lead to the participation of platinum in electrochemical equilibrium and, consequently, to a mixed potential. Despite the interference of redox agents with the electrochemical equilibrium of electrochemically grown IrOx films, iridium oxide sensors offer a great promise for the determination of cationic impurities in polymer electrolyte fuel cells.

In pursuit of ways to mitigate the problem of sensitivity of the sensors to oxygen, we employed chemical oxidation of iridium metal in molten lithium...
carbonate. The process produces thick and compact layer of black iridium oxide. The initial response of the sensor prepared this way upon immersion in acidic aqueous medium is relatively slow most likely because the equilibration is associated with a slow penetration of the initially dry film by water. Upon film hydration, the potential of the sensor was found to be virtually insensitive to oxygen and hydrogen in solution. Moreover, the response time of the hydrated film was significantly improved. The potential vs. pH dependence for the hydrated film is described by an excellent linear relationship with a slope of 42 mV as shown in Figure 4. Optimized sensors of this type will be used to monitor changes in pH (and concentration of cationic impurities) inside the membrane of an operating fuel cell.

Conclusions and Future Directions

- Low concentrations 10 ppb hydrogen sulfide do not appear to affect durability of current generation fuel cell MEAs.
- 100 ppb of SO$_2$ in air substantially decreases fuel cell performance of low-loading thin-ionomer polymer electrolyte fuel cells.
- NO$_2$ in air decreases fuel cell performance:
  - Fuel cells reach a steady-state equilibrium at constant concentration exposure.
- NH$_4^+$ ions hamper oxygen reduction on Pt-C catalysts in acid environments.
- The impurity cation species type is important in determining local water of hydration concentrations.

**FY 2010 Publications**

Objectives

- Investigate the effect of impurities in the hydrogen fuel streams on the operation and durability of fuel cells. These impurities include water, hydrocarbons (including formaldehyde, formic acid), oxygen, inert gases (He, N₂, Ar), CO₂, CO, sulfur-containing gases, ammonia, halogenated compounds and particulates.
- Propose mechanisms for how impurities in the hydrogen fuel stream affect the components of the fuel cell catalyst and polymer membrane.
- Determine strategies to reduce the poisoning effect of these impurities.
- Disseminate findings so that they are available to other members of the DOE Hydrogen Quality team and to FreedomCAR technical teams.

Technical Barriers

This project addresses the following technical barrier from the Fuel Cells section of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

Technical Targets

This project is addressing fundamental research into effects and mechanisms of impurities on the performance and durability of polymer electrolyte membrane (PEM) fuel cell systems. The activity broadly supports the following technical targets established by DOE:

- Transportation Fuel Cells
  - Durability with cycling: 5,000 h by 2015
- Stationary PEM Fuel Cell Power Systems:
  - Durability @ <10% rated power degradation:
    - 40,000 h by 2011

Accomplishments

- It was confirmed that the effects of CO₂, C₂-C₇ paraffins, HCOOH and N₂ on Nafion® conductivity and on Pt for H₂ activation are insignificant.
- A simple acid catalyzed reaction (esterification) was used to quantitatively predict conductivity of a contaminated membrane and/or catalyst layer under typical fuel cell conditions and the predicted values agree well with experimental data.
- The effects of ammonium distribution on the conductivity of Nafion® membrane in the liquid and gas phase were studied. In the gas phase, the conductivities of uniformly poisoned membranes considerably differed from those of non-uniformly poisoned membranes having equivalent ammonium concentrations.
- The surface concentration of hydrogen on Nfn-Pt/C (Nafion®-loaded Pt/C) under fuel cell operation conditions was obtained using H₂/D₂ switching and it was found that:
  - Hydrogen activation occurred only on Pt.
  - Transport of protons between the sulfonic sites of Nafion® and the Pt particles was extremely fast.
- Humidity has been determined to have a minimal effect on the apparent activation energy of H₂ activation on Pt/C under typical fuel cell conditions. However, the humidity significantly influences the degree of CO poisoning on Nfn-Pt/C and the final rate of H₂ activation.
PEM fuel cell studies on the effects of 18 ppm tetrahydrofuran (THF) found ~40% loss in performance and full recovery once THF was removed from the fuel stream.

Investigation of long-term NH₃ poisoning at 0.1 ppm (maximum International Organization for Standardization [ISO] specified level) found no appreciable degradation at 60°C and 80°C.

CO poisoning experiments were performed to study the performance decay at ISO limits. Even a small concentration of CO (0.2 ppm) led to 10% performance decay in a few hours, but this could be recovered by electrochemical oxidation.

CO poisoning experiments were also performed to correlate and compare results from PEM fuel cell tests at SRNL to the results from H₂ activation on Nfn-Pt/C experiments at Clemson. The results match well.

**Results**

The investigation of the effects of H₂O on the surface hydrogen coverage and dissociation on Pt/C under fuel cell operation conditions suggests that:

1) in the absence of a poison like CO, equilibrium is still reached for H₂ activation on Nfn-Pt/C at 80°C in the presence of water vapor; 2) humidity has minimal effect on E_r for H₂ activation on Nfn-Pt/C in 10 ppm of CO at typical fuel cell conditions; 3) however, the humidity significantly influences the degree of poisoning by CO of Nfn-Pt/C and the final rate of H₂ activation.

Esterification was used as a diagnostic tool to investigate the proton availability of Nafion® components of a PEM fuel cell. It was found that a simple acid catalyzed reaction (esterification) can be used to quantitatively investigate the number of proton sites in a Nafion® membrane and can be further used to predict conductivity of a contaminated membrane under typical fuel cell conditions, as shown in Figure 1. In addition, this methodology can be used to determine the effects of impurities on the number of proton sites in a catalyst layer of a PEM fuel cell, which can be further used to predict the conductivity of the catalyst layer.

With respect to the effects of impurities on the ionic conductivities of Nafion® membranes, the effects of NH₄⁺ distribution in the liquid and gas phase were studied using physically assembled membranes with known ammonium compositions. Under typical fuel cell operations, the conductivities of non-uniformly poisoned membranes were ca. 1.07–1.86 times larger than those of uniformly poisoned membranes, depending on humidity, contamination level, and ammonium ion distribution.

The effect of Nafion® on H₂ activation on Pt was studied. It was found that while the impregnation of...
30 wt% Nafion® on Pt/C has dramatic effects on the physical characteristics of Pt/C, such as a reduction in Brunauer-Emmett-Teller surface area from 170 m² (g.cat)⁻¹ to 37 m² (g.cat)⁻¹, the overall effect of the Nafion® on the adsorption capability of hydrogen and CO by Pt is small. However, a clear blocking of cyclopropane from reacting during cyclopropane hydrogenolysis, a structure sensitive reaction, on a large portion of surface Pt sites by the Nafion® can be observed. This inhibition of cyclopropane by Nafion® appears to be due, mainly, to steric hindrance rather than the direct blocking of significant numbers of surface Pt atoms.

The DOE provided conditions for desired experiments at low levels of NH₃ and wanted 1,000-hour tests to be completed as soon as possible. SRNL worked on the required ammonia tests with the provided GORE membrane electrode assemblies. A baseline and 0.1 ppm poisoning at 60°C or 80°C and 50/50 percent relative humidity (RH) with an Ion Power MEA to determine the impact of NH₃ at the ISO limit were performed. As shown in Figure 2, no appreciable degradation from the introduction of NH₃ at the ISO specified level was observed over 800 hr.

THF was used to characterize the performance effects that hydrocarbons can have on fuel cell performance since THF is a popular solvent used in many chemical synthesis which include hydrogen storage materials. Approximately 40% loss in performance was observed within 1 h after 18 ppm THF was injected to the feed as indicated in Figure 3. It also can be seen that full recovery was observed as soon as THF was removed from the fuel stream.

SRNL is finishing the runs with CO poisoning experiments at the ISO limits and suggested new lower limits. It was found that even a small concentration of CO (0.2 ppm) led to 10% performance decay in a few hours (Figure 4a). Electrochemical oxidation after CO poisoning was able to successfully remove all traces of CO and the MEA performance was recovered (Figure 4b).

CO poisoning experiments were also performed under similar conditions at SRNL and Clemson to correlate and compare results from PEM fuel cell tests at SRNL to the results from H₂ activation on Nfn-Pt/C experiments at Clemson. The cyclic voltammetry data before and after PEM poisoning runs with CO were analyzed to characterize the number of electrocatalyst active sites poisoned. It was found that the electroactive surface areas of Pt obtained with the CO desorption peak matches closely with those obtained with the hydrogen desorption peaks. Also, the electroactive surface area of Pt was reduced with CO poisoning at 60°C and 80°C. However, after the cell was left at open circuit and 25°C with 8 ppm CO the electroactive area was recovered.

![Figure 2](image-url)

**Figure 2.** H₂/Air potentiostatic polarization baseline (a) without NH₃ and (b) in the presence of 0.1 ppm NH₃ for a GORE MEA with 0.1/0.4 mg/cm² catalyst loadings at 80°C and 50%/50% RH.

### Conclusions and Mitigation Strategies

Major conclusions are covered in the Accomplishments section.

To date, the following preliminary impurity mitigation strategies can be proposed based on the findings of this project:

- Fuel cells can tolerate up to 0.1 ppm of NH₃ (maximum ISO specified level) for long periods of time.
- Use of higher percent RH results in a smaller decrease in conductivity with NH₃ poisoning. Thus, a higher percent RH is recommended for fuel cell operation to increase the performance and lifetime when trace amounts of NH₃ are present in the fuel.
- Since during CO poisoning, CO does not fully cover all the Pt sites regardless of CO concentration, in order to maintain better fuel cell performance, the use of higher loadings of Pt is recommended if better CO-resistant catalysts are not available.
- Preliminary data suggest that in the presence of CO, lower humidity appears to decrease the effect.
Obviously, the actual materials and operational conditions chosen for use in a fuel cell must be determined by an optimization of material properties, operation conditions, possible mitigation strategies to minimize the effect of impurities, and desired fuel cell performance.

The project is on track for completion of the major objectives of this research in 2011.

2. “Esterification as a Diagnostic Tool to Predict Proton Conductivity Affected by Impurities on Nafion Components for PEMFCs,” *Journal of Power Sources* 195 (2010) 3416-3424 (Kitiya Hongsirikarn, Xunhua Mo, and James G. Goodwin, Jr.).

**Presentations**

Objectives

- Identify the specific impurities and impurity families and their concentrations present in the fuel.
- Develop analytical chemistry protocols to detect the fate of contaminating species within fuel cells.
- Determine through controlled laboratory experiments and literature the main drivers for decay.
- Develop analytical models and computer simulations that explain and predict these effects.
- Validate contaminant models through single cell experimentation using standardized test protocols.
- Develop and validate novel technologies for mitigating the effects of contamination on performance.
- Disseminate results through outreach activities.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the

Technical Targets

This project is conducting fundamental research into the effects of impurities on fuel cell performance and durability. This activity broadly supports the following technical targets established by DOE:

- By 2010, 5,000 hours based on a test protocol issued by DOE in 2007.
- By 2015, 5,000 hours based on a test protocol issued by DOE in 2007.

Accomplishments

Hydrocarbon Testing

- Completed testing of the most critical hydrocarbon species likely to be present in hydrogen fuel streams including: formic acid, formaldehyde, methane, ethane, ethylene and acetaldehyde.
- Developed analytical procedures and mixing protocols for evaluating concentrations of acetaldehyde, formic acid, and formaldehyde in the fuel stream.

Other Impurities

- Evaluated the effects of several likely concentrations of ammonia on polymer electrolyte fuel cells (PEFCs) and characterized its effects on membrane integrity in the ammonium form.
- Characterized the effects of methyl chloride on PEFC performance.

Introduction

PEFCs show significant promise in providing efficient, clean power for stationary and transportation applications. The technology has shown limitations relative to long-term durability goals, particularly with regard to the operational lifetime of membrane electrode assemblies (MEAs). One of the causes for this is the introduction of impurities into the fuel stream that impacts the functionality of ion exchange groups within the electrolyte, degrades catalyst activity, and function causing voltage to degrade.
The technical issues addressed center around the identification of impurity species located in the fuel stream that may have an effect on overall fuel cell performance, and evaluation of these effects against standard test protocols. The U.S. Fuel Cell Council in conjunction with Japanese Automobile Research Institute and others have been developing hydrogen quality standards and procedures for contaminant testing of PEFCs. These studies provide the background and basis for the initiation of our research.

**Approach**

This project is focused on the experimental determination of the effects of key impurities on the performance of PEFCs. Experimental data collected from test protocols will be leveraged to create mathematical models that predict performance of PEFCs exposed to specific impurities. These models will be validated through laboratory experimentation and will be utilized to develop novel technologies for mitigating the effects of impurities on fuel cell performance. The effects of cationic impurities on the fundamental physio-chemical properties of perfluoroionomer membranes are also being evaluated. Results will be publicly disseminated through papers, conference presentations, and other means.

**Results**

**Hydrocarbon Impurities** – Based on input from working groups and industry, our team has focused our efforts on the evaluation of hydrocarbons and halogenated compounds using very specific test protocols developed as part of a multi-laboratory collaborative effort. We have focused our efforts on the evaluation of molecules that may be present in a candidate hydrogen fuel stream in order to evaluate the effects of functionality and molecular size (e.g. number of carbon atoms).

In support of this, our team has developed techniques to prepare accurate mixtures of impurities in hydrogen and to determine the level of impurities entering the fuel cell through the hydrogen stream. A gas chromatograph has been utilized to characterize both the mixtures entering the fuel cell and those exiting the fuel cell in an effort to assess accumulation and reaction of impurity species within the fuel cell reactor. Studies have focused on the evaluation of gaseous impurities, volatile liquids and less volatile liquids. Testing of many of the less volatile liquids requires the use of a saturator apparatus (Figure 1) that we developed specifically for these experiments.

Testing has been established as a series of 100-hour test runs using up to 5% of the contaminant in the fuel stream with the cell construction as defined in Table I. Testing was conducted at 200, 600 and 800 mA/cm² with standard test conditions defined below in Table 2. Conditions were modified as defined to achieve better performance stability during testing.

**Acetaldehyde** - The effect of acetaldehyde (CH₃CHO) on cell performance was investigated at an impurity concentration of 30 ppm. Cell performance immediately dropped with 30 ppm acetaldehyde in the fuel stream. At the conclusion of the contaminant test, recovery was attempted using pure H₂ as fuel to run the fuel cell, and cell performance was restored to pre-contaminant injection performance. Figure 2a provides these test results. Our conclusion is that a

RH - relative humidity
A moderate effect on cell performance was found during this impurity test. Further tests are being conducted to determine the mechanism.

**Formaldehyde** - Testing of the effect of formaldehyde (HCHO) on cell performance was investigated at impurity concentrations of 1 ppm and 5 ppm. No significant influence on cell performance was found during these lower concentration impurity tests (Figures 2b and 2c).

**Ethylene** - Testing of the effect of ethylene (C₂H₄) on cell performance was investigated at impurity concentrations of 5%. No significant effect on cell performance was observed (Figure 2d).

**Formic Acid** - Testing of the effect of formic acid (HCOOH) on cell performance was investigated at impurity concentrations of 2 ppm and 100 ppm. No significant effect on cell performance was found during the 5 ppm impurity tests (Figure 2e). Some degradation was found in the 100 ppm formic acid test (Figure 2f). Cyclic voltammetry (CV) scans performed at 20 mV/sec before and after the impurity tests showed that electrochemical area of the cathode decreased, signifying that HCOOH has a negative effect on the cathode catalyst. Similar scans were also performed every 20 hours (Figure 3a) during contamination and recovery periods to provide detail of the mechanism for contamination on the cathode. Pure nitrogen was
fed to the cathode at 250 sccm, while HCOOH/H\textsubscript{2} was fed to the anode at 250 sccm. The CV scans indicate a decrease in H\textsubscript{2} absorption peaks and an oxidation peak at 0.6 V which could be caused by absorbents on Pt surface. An individual CV scan is shown in Figure 3b. Each scan consists of four cycles. In the first CV cycle, the hydrogen absorption peak nearly disappeared. The Pt surface seems to be covered by absorbents (peaks at 0.4 V and 0.6 V that are not seen with pure H\textsubscript{2}). Absorbents are oxidized around 0.4 V and 0.6 V in the 1st cycle. In the next three cycles, recovery of H\textsubscript{2} absorption peak is observed, but evidence of surface coverage still exists. Mechanistic studies to evaluate the specific effect of formic acid on cell components using analytical tools, rotating disk electrodes and hydrogen pump experiments are underway.

**Methyl Chloride** - Testing of the effect of methyl chloride (CH\textsubscript{3}Cl) on cell performance was investigated at impurity concentrations of 1 ppm and 19 ppm. No significant effect on cell performance was found during these impurity tests (Figures 2g and 2h).

Testing is summarized in Table 3. Testing has indicated little effect of simple hydrocarbon species on fuel cell performance; however, more complex species do seem to affect performance.

**Cationic Impurities** - The effect of ammonia contamination on PEFCs was investigated with pseudo-reversible hydrogen electrodes. It was found that NH\textsubscript{4}\textsuperscript{+} affects the anode causing an increase in the overpotential in a hydrogen pump cell. Figure 4a shows the overpotential variations of the anode and the cathode respectively during contamination and recovery. 50 ppm NH\textsubscript{3} in H\textsubscript{2} can significantly affect the electrochemical kinetics on the electrodes. The initial drop of the overpotential is due to the poisoning effect of NH\textsubscript{4}\textsuperscript{+} on pseudo-reversible hydrogen electrodes. In a fuel cell, NH\textsubscript{4}\textsuperscript{+} was also found to affect the anode, however, the anode performance loss was less than on the cathode (Figure 4b).

**Conclusions and Future Directions**

**Conclusions**

- Simple hydrocarbons including methane, ethane, ethylene and acetaldehyde, particularly in low concentrations do not significantly affect fuel cell performance.
- Simple halogenates such as methyl chloride in low concentrations do not affect performance
- Acetaldehyde impurities show some effect on performance at higher concentrations.
- Formic acid impurities affect performance at higher concentrations likely due to adsorption on the electrode surface as well as the formation of reaction byproducts such as CO.
- Testing has shown both anode and cathode performance impacts of ammonia.

**Future Directions**

- Mechanistic evaluation of formic acid and acetaldehyde to support International Organization for Standardization standard development.
- Finalizing testing on aromatic hydrocarbons.
- Study the impact of catalyst ageing on sensitivity to hydrocarbon contamination.
- Finalizing modeling of impurity effects.
- Developing mitigation techniques for key impurities that show an impact on cell performance.

V.C.4 Effect of System and Air Contaminants on PEMFC Performance and Durability

Objectives

Our overall objective is to decrease the cost associated with system components without compromising function, fuel cell performance, or durability. Our specific project objectives are:

- Identify and quantify system derived contaminants.
- Develop ex situ and in situ test methods to study system components.
- Identify severity of system contaminants and impact of operating conditions.
- Identify poisoning mechanisms and investigate mitigation strategies.
- Develop models/predictive capability.
- Develop material/component catalogues based on system contaminant potential to guide system developers on future material selection.
- Disseminate knowledge gained to community.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program’s Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost

Technical Targets

This project focuses on determining the effect of system components on fuel cell performance and durability. Insights gained from these studies will be applied toward the development of a catalogue of system component materials that help meet the following DOE 2010 targets:

- Cost: $30/kW for transportation, $750/kW for stationary
- Lifetime: 5,000 hours for transportation, 40,000 hours for stationary

Accomplishments

- Established a standard set of experimental protocols for analysis, including leaching, cyclic voltammetry, and analytical characterization protocol(s).
- Performed leachant experiments on 10 polymeric material sets.
- Evaluated and applied multiple techniques for analyzing leachants (e.g., gas chromatograph mass spectroscopy [GCMS], Fourier transform infrared-attenuated total reflectance [FTIR-ATR], inductively coupled plasma [ICP], pH, conductivity, total organic content [TOC], contact angle).
- Identified leachants via GCMS for the ten polymeric materials studied.
- Performed electrochemical tests on leachants to determine effect on electrocatalysts and recovery after exposure.

Introduction

Cost and durability issues of proton exchange membrane fuel cell (PEMFC) systems have been challenging in the fuel cell industry. The cost of the balance of plant (BOP) ($51/kW in 2010 [1]) system has risen in importance with decreasing fuel cell stack
lowering the cost of PEMFC system components requires the understanding of the materials used in the system components and the contaminants that derive from them, which have been shown to affect the performance and durability of fuel cell systems. Unfortunately, there are many possible contamination sources from system components [3-5]. Currently deployed high-cost, limited-production systems are not limited to low-cost materials for system components. In order to make fuel cell systems commercially competitive, the cost of the BOP components needs to be reduced without sacrificing performance and durability. Fuel cell durability requirements limit the performance loss due to contaminants to at most a few mV over required lifetimes (thousands of hours), which means close to zero impact for system contaminants.

As catalysts loadings decrease and membranes are made thinner, both are current trends in automotive fuel cell research and development, fuel cells become even more susceptible to contaminant effects. In consumer automotive markets, low-cost materials are typically required but lower cost typically implies higher contamination potential. The results of this project will provide the information necessary to help the fuel cell industry make informed decisions regarding cost of specific materials versus the potential contaminant impact on fuel cell performance and durability.

**Approach**

Our goal is to provide an increased understanding of fuel cell system contaminants and help provide guidance in the implementation, and where necessary the development, of system materials that will help enable fuel cell commercialization. While much attention has been paid to air and fuel contaminants, system contaminants have received very limited attention publicly and very little has been publicly reported [6-9]. Our approach is to perform parametric studies of the effects of system contaminants on fuel cell performance and durability to identify poisoning mechanisms, recommend mitigation strategies, develop predictive modeling, and disseminate material catalogues that benefit the fuel cell industry in making cost-benefit analyses of system components. We will identify and quantify potential contaminants derived from stack/component fabrication materials and quickly screen the impact of the leachants on fuel cell catalyst and membrane via ex situ tests. Model compounds capable of replicating the deleterious impact of system-based contaminants are also studied. Developing standard test protocols to evaluate materials is important as this approach will allow for broader studies to be performed. Furthermore, information obtained from ex situ methods will be validated with in situ testing.

Our system materials selection is based on properties such as exposed surface area, total mass/volume, fluid contact, function, cost, and performance implications. Current material prioritization to study is based on perceived impact of potential system contaminants (based on GM internal knowledge): structural materials, coolants, elastomers for seals and (sub)gaskets, assembly aids (adhesives, lubricants), hoses, membrane degradation products, bipolar/end plates, ions from catalyst alloys. Our project has a strong polymer focus, as much of the system is polymer-based. Furthermore, our approach is to study commercially available, commodity materials. These materials are generally developed for other applications, where common additives/processing aids may not be a concern, but may present problems for fuel cells.

**Results**

We investigated 10 commercially available polymers (see Table 1) for their potential impact as system contaminants in fuel cell systems. These 10 polymeric materials underwent leaching protocols for two months to derive potential contaminants from the parent materials into solution. The leaching protocols were provided to the group by GM prior to the kick-off of the project. We tested three different leaching conditions (deionized water, 0.1 M H₂SO₄, and 0.1 M H₂SO₄ + 3% H₂O₂ at 80°C) and found that soaking in deionized water was the best leaching condition as it reflected the most realistic fuel cell condition. Acid solutions were eliminated as test conditions as they were found to be excessively aggressive compared to a fuel cell environment.

We evaluated various techniques for analyzing leachants. These include GCMS, FTIR-ATR, ICP pH, conductivity, TOC, contact angle, and electrochemistry. The results of the GCMS and electrochemistry are summarized below.

The leachant solutions derived from soaking the ten polymeric materials were analyzed via FTIR-ATR for functional groups and by GCMS to determine the identity of the leachants in solution for each polymer. TOC was measured in the final solutions at the end of the trials to determine quantitatively the total amount of leachant from the solid that made it into solution. Table 1 summarizes the starting materials, the TOC values in parts per million (ppm), and the predominant leachants identified for each sample. Due to the number of materials tested, discussion will be limited to styrene-butadiene-rubber (SBR). SBR was chosen because it was a good example to illustrate the type and number of contaminants that leached from the material as well as the effect of contaminants on catalysis.

SBR is synthetic polymer, derived from styrene and butadiene and an alkyl mercaptan chain transfer agent,
and is widely used in car tires. Identified contaminants, aniline and other thiol-based aromatics, seem reasonable given the chemical structure of the polymer and possible additives. TOC values for SBR rubber show final amounts of carbon at levels of 314.7±0.3 ppm. Aniline was the major leachant identified, and was present at levels nearly an order of magnitude higher than other identified constituents. Calculated areas show that it comprised 80% of the total leachant.

Cyclic voltammetry (CV) is extremely useful to quickly screen changes in electrochemical response of Pt catalysts in the presence of leachants. Two types of experiments were used: a quick screen, and a recovery screen (protocols provided by GM). Figure 1 shows a baseline polycrystalline Pt CV in leachant-free electrolyte solution compared to the response of this electrode with increasing amounts of SBR rubber leachant added to the solution. The CV shows that SBR rubber leachant decreases the active surface area, and is oxidized at high potential. The presence of the leachant reduces the extent of Pt oxidation as witnessed by the decreased charge associated with oxide reduction. After removing the electrode from the leachant containing solution and testing again in leachant-free electrolyte, it was observed that the leachants impact on electrochemical response was not permanent (Figure 2).

**Conclusions and Future Directions**

- Leaching experiments should be performed in deionized water for most BOP materials. Acid solutions are not representative of the state-of-the-art fuel cell system and are too aggressive for many materials.
- Ten polymeric sealant materials were characterized with GCMS, FTIR-ATR, pH, conductivity, and TOC. Most of the materials analyzed leached out a number of organic compounds common in the

synthesis and processing of the materials, as was expected.

- Based on CV results, extracted molecules from SBR rubber are a potential source of performance loss in fuel cells when operated at low potentials. At high potentials when the exposure to the contaminant was removed, changes in the electrochemical response were found to be recoverable.
- We have selected to focus our studies on polymeric structural materials because they have the highest perceived impact of potential system contaminants.
- We will continue establishing standard ex situ and in situ testing protocols to evaluate system contaminant materials.
- We will benchmark equipment and testing methods among all project partners.
- We will establish correlations between analytical screening of extract solutions, CV results, and fuel cell performance loss.

Project Start Date:  March 1, 2007
Project End Date:  February 28, 2011

Objectives

- Develop durable water-free membrane materials with properties that meet the 2015 DOE targets as set out in the Multi-Year Research and Development Plan:
  - Conductivity: 0.1S/cm at operating temperatures ($\leq$120\degree C) and inlet water vapor partial pressures $<1.5$ kPa.
  - Durability with cycling $>5,000$ hours at $>80$\degree C.
  - Oxygen and hydrogen cross-over currents $\leq$2mA/cm\textsuperscript{2}.
  - Durable membrane electrode assemblies (MEAs) with rated power at 1,000 mW/cm\textsuperscript{2} and less than 5\% performance degradation over lifetime.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the

Technical Targets

- Development of membranes that contain tethered heterocyclic bases (imidazole, triazole), which do not require added water to achieve adequate conductivity and can achieve performance with only the presence of the water produced by the fuel cell reaction: 0.1 S/cm (120\degree C), 0.07 S/cm (20\degree C) and 0.01 S/cm (-20\degree C) at relative humidity (RH) values between 25 and 50\%.
- Achieved 0.005 S/cm at 120\degree C under bone dry conditions and 0.01 S/cm at 25\% RH.
- Conductivities at ambient temperatures ($10^{-2}$ S/cm >80\degree C) are too low to be practical without a high degree of morphological control to provide connectivity through the membrane.
- Demonstrated that morphological control to achieve high connectivity through the membrane is possible through use of phase separating polymers (block and random copolymers) but is hard to maintain.
- Plasticization of the polymers by water can lead to significantly improved conductivities but at a potential cost of loss of connectivity.
- The presence of imidazole and other heterocyclic bases in the polymers leads to increased conductivity at low water content (RH 25-50\%) and to significantly lower water uptake in some cases.
- Three-dimensional (3-D) modeling shows that loss of connectivity can be compensated for by multiple pathways through the membrane.

The provision of membranes and MEAs that need no humidification provides significant system simplifications and large cost advantages over conventional materials

Accomplishments

- It has been determined that solid state membranes with imidazole as proton solvating solvent cannot achieve 0.1 S/cm without added mobile solvents such as water unless a high degree of connectivity through the membrane can be achieved.
• It has been shown that the presence of imidazoles tethered to the polymer backbones improved the conductivities of sulfonated polyetherpolysulfones and poly fluoro sulfonic acid (PFSA) polymers at low water content (25% RH). It has been further shown that presence of bases affects the water uptake and can be used to control swelling as well as to improve conductivity.
• Synthesis of polymers with tethered imidazoles has been achieved with several different polymer backbones – polystyrene, polyether polysulfone, and polyfluorinated ethylene with different side chain lengths.
• Studies of proton conducting ionic liquids in polymer matrices show that they support Grothuss transport and morphological control in block copolymers can maintain high conductivities at lower temperatures.
• Composite electrode and MEA fabrication methods have been developed for hydrocarbon polyelectrolytes in anticipation of the availability of imidazole-containing material for testing.

Introduction

Presently available fuel cell membranes require the presence of liquid water in order to transport protons and support the current demands. Because of the poor performance of fuel cell electrocatalysts, nearly half of the fuel energy is converted to heat which requires a very complex and expensive heat and water management system in order to maintain the water content of the membranes. Kreuer pioneered the investigation of alternative proton conducting solvents that could replace water and, in particular, reminded the research community of the ability of heterocyclic bases such as imidazole to support proton conduction [1]. It has also been recently discovered that nature uses imidazoles for the purpose of moving protons through membranes in living systems [2] and also uses imidazole groups to bind metal ions in oxygen reduction enzyme catalysts such as copper laccase [3]. It has been noted previously that imidazole bases appear to be resistant to oxidation [4] by oxygen species, an important property for a fuel cell solvent. Previous work on the attachment of imidazoles to polyelectrolytes that showed that an all solid state proton conducting membrane was indeed possible [5]. While the conductivities achieved were low the polymer structures were not ideal and the purpose of this project is to understand how to optimize the polymer structures to achieve the desired properties.

Approach

Since the project involves the manipulation of a large number of molecular features of the target polymers, the approach taken is to use mixtures of easily obtained components to measure how the properties vary and to use these results to formulate the composition of the final polymer materials which are difficult to make. In the Fiscal Year (FY) 2008-2009 annual reports, measurements on proton conducting ionic liquids, both neat and dispersed in polymer matrices were described, as were measurements on polyelectrolyte materials doped with heterocyclic bases. Similar measurements have been continued on models that more closely resemble the tethered groups in the final target polymers and neutron scattering, and nuclear magnetic resonance relaxation measurements have been added to study the mechanisms of proton transport. Models of the proton transport through the membrane have been constructed to isolate the consequences of bottlenecks due to slow proton transport and this knowledge helps guide the polymer synthesis and morphology control, which is critical to achievement of the conductivity goals, adequate mechanical properties and control of gas crossover. Synthesis of polymer materials with imidazole attached to side chains has been carried out and these polymers have been blended with polymer bound acids to give fully tethered materials using the results with the model ionic liquids to formulate the relative concentrations of imidazole and acid. Conductivity, water uptake and degradation studies are carried out on both the models and the completed fully-tethered polymers. Since the synthesized membrane materials must be used with electrodes to be useful, methods of preparing composite electrodes with novel, non-Nafion® binders are investigated to determine the polymer properties that lead to good electrode performance. Less expensive ionomer materials are used first to develop the methodology to be applied with the target imidazole-containing ionomer materials.

Results

Figure 1(a) shows a schematic of the type of polymer structure that appears to be desirable to achieve fast proton transport through the membrane. Results obtained in FY 2009 on ionic liquid models and on synthesized polymers with tethered imidazoles indicate that the nanoscale morphology shown is necessary to promote the Grothuss mechanism of proton transport. For this it is necessary to develop phase separation so that a pore-like structure is formed to provide some order for the imidazole structures to rapidly transport protons via a hopping mechanism. Figure 1(b) shows how the pore structure could be arranged on the microscopic scale in order to provide connectivity across the membrane. The molecular-level mechanism of
proton transport is shown schematically in Figure 1(a) where the arrows represent electronic rearrangements within the imidazole molecules and rotation around the tether bonds. The end result is that the proton is able to hop from one side to another without the need for the solvent molecules to move with it. In previous years of this project the low activation energy for proton transport associated with the Grotthuss mechanism has been inferred from the temperature dependence of the conductivity. Pulsed field gradient spin-echo nuclear magnetic resonance measurements on ionic liquid samples prepared from imidazole and bis(trifluoromethylsulfonyl)imide have indicated faster diffusion of the positively charged protons in the liquid than diffusion of the other solvent molecules. These results confirm the reports of Watanabe et al. [6] and support the proton hopping mechanism of proton transport. Experiments are now underway to examine the effect of a block co-polymer matrix on the mechanism to observe whether ordering may result in more efficient operation of the proton hopping mechanism.

The phase separation is best promoted by use of block copolymers with appropriate backbones. Figure 1(c) shows two examples of the polymer structures that have been prepared for this purpose (polystyrene and polyether polysulfone) and which are under continuing study. Also shown are two fluorinated polymers which can be used to immobilize heterocyclic bases. The imidazole group (e.g. Z in Figure 1(c)) is shown as tethered to the polymer through the 2-position. The tether can also be through the 4- or 5-positions. However, the tether cannot be through the 1-position, which is the nitrogen as this would block the operation of the Grotthuss mechanism of proton transport. The attachment of the imidazole through positions other than the nitrogen is not trivial and generally requires the use of protecting groups on the nitrogen which can be cleanly removed once the polymer is prepared. However, some success has been obtained with syntheses that avoid the use of protecting groups. The use of triazoles has also been explored to avoid some of the synthetic difficulties involved with the imidazoles although in general triazoles have shown slightly lower conductivity that imidazole.

Figure 2(a) shows the results of conductivity measurements made on polymers that contain the imidazole tethered in the 2-position as shown by the structure of the polymer denoted IMBVCl. The polymers are blended with Nafion® where the
numbers 4-1 represent the ratio of the imidazole molecules to the acid groups in the blend. The unblended, neat polymer exhibits very low conductivity as expected since the self-dissociation of the imidazole does not provide a sufficient concentration of charge carriers. Provision of acid groups from the Nafion® results in higher conductivity under dry conditions. Measurements performed under 25% and 50% RH show increasing conductivity as the water content is increased although they are still too low to be practical. The shape of the conductivity curve as a function of temperature is very characteristic of ion transport control by segmental motion of the polymer indicating that no proton hopping occurs in this case. Dynamic mechanical analysis (DMA) of the polymer blends indicate that considerable plasticization of the polymers occurs which results in inefficient phase separation. This hypothesis remains to be confirmed with small angle X-ray scattering measurements.

Figure 2(b) shows the effect of humidity on the through-plane conductivity of 5M PFSA doped with imidazole. The undoped material measured at 25% RH shows a low dependence upon temperature that is characteristic of proton hopping. While the low ratio of imidazole to acid (1:1) blend has a poor conductivity even in the presence of water, the more highly doped blends (1:4 and 1:8) show better conductivity at these low RH values indicating that combinations of water with imidazole may well lead to higher conductivities. Interestingly, the bend in the curves at low temperatures for the doped polymers indicates that phase separation is not as complete with the doped polymers, which is consistent with the previously reported DMA of the doped polymers that shows increased plasticization of the PFSA by the imidazole. Figure 2(c) shows conductivities of polymer blends of imidazole and benzimidazole-containing polymers with sulfonated polyetherpolysulfone (BPSH-35). Again, the presence of
the heterocyclic bases clearly improves the conductivity at low water content. However, Figure 2(d) shows that the presence of the bases lead to lower uptake of water so that at a given RH value the actual conductivity of the blend is lower than that of the acid polymer alone. These results illustrate that the heterocyclic bases such as imidazole can provide increased conductivity at low water contents and they also potentially can be used to control water uptake and swelling of a polymer material. These results are intriguing and indicate how greater understanding of the action of the bases for both conduction and water uptake could lead to greater control of the behavior of membrane materials that includes more than just conductivity.

The plasticization effects of the solvent molecules such as water and imidazole upon the polymer morphology are of considerable importance. Figure 3 demonstrates the changes that result in morphology upon uptake of water that can seriously impact the conductivity. A block copolymer consisting of styrene and hydrogenated isoprene blocks was prepared with a variety of block lengths. The styrene units were sulfonated to different degrees. This resulted in various different morphologies which could be altered by variation of the block lengths and sulfonation degree. The morphologies were determined by tunneling electron, scanning electron, and atomic force microscopy and scattering measurements such as small angle X-ray scattering (SAXS) and small angle neutron scattering (SANS) an example of which is shown in Figure 3. During the course of SANS measurements at 90% RH it was noted that the morphology would change from one temperature to another. Conductivity measurements were also affected by the uptake of water and time at elevated temperature. The conductivity plot shown in Figure 3 shows that the initial high conductivity decreases irreversibly with time. These observations...
are rationalized by the schemes shown at the bottom of Figure 3. The left hand scheme represents the change in morphology from lamellar to cylindrical upon uptake of water while the right hand scheme represents the loss of connectivity across the membrane that results from the change in morphology and leads to the loss of conductivity. When experiments such as this are carried out with imidazole present in the polymer changes in the morphology were observed in SAXS experiments depending upon the amount of imidazole present. The presence of the imidazole did not suppress the water uptake and the conductivity was lower but stable over time. These results are consistent with plasticization of the polymer by the imidazole which results in lower conductivities but prevents the motion of the polymers that leads to loss of conductivity.

To understand the conductivity results and also the impact of morphology, acid and base site concentrations, etc. on conduction, a network model was developed in FY 2009 to ascertain the importance of bottlenecks on performance and provide guidance to the membrane synthesis efforts. The concept of the bottlenecks is shown in Figure 4 in the cartoon of the classical Gierke model of Nafion® where the fast proton transport pores are interspersed with bottlenecks where transport is controlled by segmental motion of the polymer. In the initial results shown in the top graph of Figure 4, relatively simple calculations in a one-dimensional mode showed that in a membrane with only a few linkages where the vehicle or segmental motion mechanism dominates, the overall conduction suffers greatly due to the much slower diffusion. Extension of the model to two-dimensional and 3-D cases where alternative connection pathways become available, shows that the effects of the segmental motion bottlenecks need not be so severe as can be seen in the lower two plots in Figure 4. Hence there is reason to believe that some degree of plasticization of the polymer morphology can be tolerated without ruining the connectivity through the membrane.

![Figure 4](image_url)

**FIGURE 4.** Models of the effect of segmental motion bottlenecks on overall conductivity. (a) Gierke model of Nafion® showing slow segmental motion segments and fast proton transport segments; (b) effect of bottlenecks on overall conductivity for one, two, and three dimensions.
Conclusions and Future Directions

Conclusions

- Conductivity of polyelectrolyte systems that contain no mobile solvents appears to be too low unless a high degree of connectivity is achieved through the membrane.
- Connectivity though the membrane is very difficult to achieve and to maintain.
- Conductivities of imidazole-containing systems are improved considerably by the presence of some water in the system. However, water uptake by many polymer systems is suppressed by the presence of the imidazole.
- Modeling shows that increasing the segmental motion transport by plasticization of the polymer by water or other solvents increases the overall conductivity but also increases the loss of connectivity. Polymer dynamics are of critical importance.
- The preparation of composite electrodes for use in MEAs with non-Nafion® polymer binders requires considerable experimentation with ink formulation (concentration, solvent polarity and volatility, particle size, etc) as well as processing conditions. The development of the methodology is important for preparing MEAs with the imidazole bases present.

Future Directions

- Synthesis and measurements of polymers as functioning membranes is the highest priority.
- Preparation of MEAs is a critical issue as conventional electrodes will not allow a proper test to be carried out. Studies on this topic are already underway at LANL.
- Stability of imidazole, the ionic liquids and the complete polymer architectures under oxidative conditions is a critical issue. Durability and degradation testing of membranes under fuel cell conditions is a priority.
- Gas permeability and crossover measurements will be initiated.
- Modeling of the system and cell issues (conductivity, low catalyst activity at low RH) will continue to guide experimentation.

Accomplishments

- Conductivity, fuel cell and diffusion measurements on a broad range of EWs and varied side-chains have provided insight into structure/conductivity relationship.
- We have synthesized new two and three acid-per-sidechain ionomers. These show:
  - Enhanced conductivity vs. starting PFSA.
  - Lower swelling in boiling water compared to PFSAs with the same EW.
  - High hydrolytic stability (no hydrolysis >1 week in hot H₂SO₄ or in 250°C H₂O).
  - One of these, the PFIA ionomer allows us to make membranes which have conductivity in excess of 100 mS/cm below 40% RH at 120°C.
- Hetero poly acids (HPAs) have provided enhanced conductivity and chemical resistance. Inorganic
oxide/HPA composites have shown partial stability to boiling water.

- We have shown that 825 EW 3M ionomer with new additives and optimized fabrication process provides:
  - >20,000 cycles in %RH cycle test.
  - >800 hours in OCV test.
  - >18,000 hour MEA lifetimes in accelerated tests.
- Polymer and model compound stability studies are providing insight into degradation pathways and relative stability.
- Dissipative particle dynamics simulations show morphologies consistent with clipped random wave analysis of small angle X-ray scattering (SAXS) data and conductivity measurements.
- Electron spin resonance (ESR) measurements indicate that the rate constant for the reaction of hydroxyl radicals with the 3M membranes is significantly slower compared to that for Nafion®.

Introduction

Proton exchange membrane fuel cells (PEMFCs) represent a promising power source for a variety of applications. While many breakthroughs have been made over the last few years in the development of PEMFCs, technical and economic barriers for their commercialization still exist. Key areas where improvements are still needed are in expanding the temperature range and lowering the humidification requirements of the stack [1]. Requirements of system size, efficiency, performance, start-up and cooling mean that fuel cells must be able to run robustly and exhibit adequate durability under a wide variety of operating temperatures, including temperatures up to 120°C. They must also be able to do this with little or no external gas humidification (i.e., “dry”), and during start-up, shut-down, or periods of lower stack temperatures, they must run in the presence of, and be stable to, some liquid water in the gas channels. Unfortunately, operation under these hot, dry conditions seriously compromises both the conductivity and durability of the ionomer membrane.

The objectives of this collaborative effort are to develop new PEMs for fuel cells capable of providing excellent durability and performance while operating under low humidification conditions and at temperatures ranging from -20°C to 120°C. Success on this project should result in PEMs with the performance and durability characteristics required for the development of fuel cells which meet commercialization targets for the automotive industry and other fuel cell applications.

The processes for making the new membranes, and the MEAs comprising them, should be scalable for manufacturing at high volumes and at costs that can meet industry targets.

Approach

The focus of this project is to develop a new PEM which can operate under hotter, drier conditions than the state-of-the-art membranes today. These membranes and MEAs made from them should meet the 2010 DOE technical targets for membranes. Activities include:

- Synthesize and test new polymer membranes, including both fluorinated and non-fluorinated polymers as well as composite or hybrid systems, and evaluate their conductivity and chemical and mechanical stability.
- Evaluate new membrane manufacturing methods for increasing membrane mechanical properties and improving MEA lifetime.
- Develop new membrane additives aimed at increasing conductivity and improving membrane stability/durability under these dry conditions.
- Perform both experimental and theoretical studies of factors controlling proton transport and mechanisms of polymer degradation and factors affecting membrane durability in an MEA.
- Focus on materials which can be made using processes which will be scalable to commercial volumes using cost-effective methods.

Results

In the past we have shown that lower EW ionomers, based on our 3M perfluorinated sulfonic acid (PFSA, Figure 1), provide higher proton conductivity under drier conditions. PFSA membranes with EW under about 700 can meet DOE conductivity targets [2]. Unfortunately, the mechanical integrity of these membranes is poor. The 3M ionomer swells excessively at EWs below about 750 and becomes soluble in boiling water at EWs below about 650-700. At an EW of 700 the tetrafluoroethylene (TFE) segments in the polymer backbone are short, and the crystallinity index, measured by wide angle X-ray scattering (WAXS) is nearly zero, this is shown in Figure 2. Even lower EW, non-soluble membranes (about 700 EW) swell excessively. Figure 3 shows that membranes prepared from ionomers with EWs above about 750 show a gradual increase in hydration in boiling water with decreasing EW, increasing from about 14 moles of water per sulfonic acid group ($\lambda = 14$) for an EW of 1100, to about 35 waters of hydration per sulfonic acid group ($\lambda = 33$) for an EW of 750. Below this EW water absorption increases dramatically. The 700 EW ionomer has a $\lambda$ value of >100. As shown in Figure 2, membranes from ionomers with EWs below...
700 partially dissolve in boiling water so this test cannot be performed [3]. This excessive swelling or membrane solubility is known to lower MEA durability during fuel cell operation [4].

One way to produce polymers with long enough TFE segments in the backbone for crystallization and low enough EW to provide high conductivity is to have more than one protogenic hydrogen on each functional side-chain. Towards this end, we have used the bis sulfonyl imide acid as a protogenic group and linking moiety to prepare several multi-acid side-chain ionomers, some of which are shown in Figure 1. The bis sulfonyl imide acid is highly acidic, in some cases more acidic than a structurally similar sulfonic acid [5]. Fuel cell membranes from polymers containing this functional group have been prepared in the past through the polymerization of imide functional monomers with TFE [6]. We have prepared new, very low EW ionomers from sulfonyl fluoride ionomer precursors with sufficient backbone crystalinity to prevent excessive swelling. Swelling data for examples of low-EW ionomer prepared by this method are shown in Figure 3. Membrane samples prepared from both the ionomer labeled Ortho Bis Acid and PFIA absorb about 40 waters per acid group, much lower than the 700 EW PFSA. We have prepared samples of the 625 EW PFIA with in plane linear swelling as low as 20%, similar to what we see for 825 EW membranes which have provided up to 18,000 hours in accelerated durability tests in 50 cm² MEAs [2]. We are optimizing the membrane construction and fabrication process for this ionomer.

Figure 4a shows conductivity of two PFSAs (825 and 700 EW), the same 625 EW PFIA whose water absorption is shown in Figure 3, and a 450 EW sample of the “Bis/Tris acid”. The Bis/Tris acid has very high conductivity at higher relative humidity compared to either PFSAs, but the conductivity drops off at lower %RH and is lower than both PFSAs below about 40% RH. This lower conductivity at lower %RH is similar to what is observed for sulfonated arene ionomers which show significant drop off in conductivity at lower

![FIGURE 1. Structure of Selected Ionomers Based on the 3M Ionomer Backbone](image1)

![FIGURE 2. Water solubility and crystalinity index for a range of different EW 3M PFSAs. Water solubility was measured after 3 hours in boiling water. The inset shows the WAXS spectra from which the crystallinity index was calculated.](image2)

![FIGURE 3. Water absorption in boiling water as a function of EW. Absorption is given as lambda (λ), or the number of water molecules per acid group.](image3)
%RH and may be due to the lower pKa of the aromatic sulfonic acid groups compared to the perfluoroalkyl sulfonic acid groups of the PFSA [7]. The 625 EW PFIA has conductivity at high %RH between the 700 and 825 EW PFSA, but shows higher conductivity than either at low EW. The higher conductivity at lower EW may be due to the higher acidity of the perfluoro bis sulfonyle imide (one of the most acidic acids known). Figure 4b compares the performance in a fuel cell of this 625 EW PFIA to our 825 EW PFSA. At the higher temperature and lowest humidity (120°C, 23 % RH) the fuel cell performance is over 100 mV higher and the through plane resistance is more than 0.100 Ohm-cm² lower than the 825 EW PFSA.

MEAs prepared from this ionomer have also lasted 450 hours in the DOE prescribed chemical durability (OCV) test and about 10,000 cycles in the DOE prescribed mechanical durability (RH Cycle) test (Table 1) [8]. Based on this and other testing, we have down-selected the PFIA as the ionomer to use in the remainder of this project and focus on further improvements in the chemical and mechanical durability of membranes made from this ionomer to allow them to meet these durability requirements.

During the course of this year we have also performed work to optimize the electrode. The early work looked at different ionomer equivalent weights, ionomer to carbon ratios, catalyst types, gas diffusion layer types, and process variables. Test methods were developed that screened electrodes over a variety of test conditions to optimize performance over the whole range of automotive operating conditions – cool/wet to hot/dry and high current. Results of that work led to gains in performance and a 38% reduction of catalyst loadings compared to the initial baseline. Gains were also realized in catalyst cycling stability and in the reduction of the overall MEA fluoride release rate. New processing methods and catalyst morphologies are showing promise of further gains in both performance and catalyst stability. As we demonstrated early during this contract, an important variable in electrode performance under dry conditions is the thickness of the PEM and its ability to maximize the water management [9]. Gains have also been achieved in chemical stability through use of additives in the electrode formulation that we have observed diffusing into the PEM. We have evaluated stabilized HPAs that have reduced fluoride release rate at no cost to conductivity at levels added so far. These HPAs show partial stability to boiling water.

Conclusions and Future Directions

The focus of this project has been to develop new polymers and new stabilizing or conductivity enhancing membrane components to provide a membrane which can meet all DOE 2010 and 2015 targets including both conductivity and durability. We have also focused on gaining a better understanding of structure property relationships relevant to conductivity and durability to aid in this development. We have met all of the DOE membrane targets with at least one of the materials tested, and our new PFIA ionomer met the 30°C and 80°C conductivity targets, has nearly met the 120°C conductivity target (>100 mS/cm above 40% RH), has come very close to meeting all conductivity targets and has come very close to meeting all durability targets as well. We are confident that we will meet our goal in the final year of this project. Future activities include:

- Continue preparation and optimization of the conductivity and durability of the PFIA ionomer with membrane additives.
- Continue to probe factors in transport using nuclear magnetic resonance relaxation and diffusion, SAXS, conductivity, modeling and other spectroscopic measurements. Continue to develop a better understanding of effect of low lambda on proton transport.
- Evaluate impact of new protogenic groups, multi-acid side-chains and additives on membrane oxidative and chemical stability using ESR, ex situ tests, model compound tests and fuel cell tests.

**FIGURE 4.** a) The conductivity at 80°C for selected ionomer membranes. Conductivity was measured using a 4-point, in-plane conductivity cell inside a constant humidity oven. b) The voltage of two 50 cm² MEAs with an 825 EW PFSA and a 625 EW PFIA membrane at 0.8 A/cm² running on hydrogen/air at ambient pressure. The cell inlet humidification is held constant with an 80°C dew point and the cell temperature is raised from 80°C to 120°C. This causes the relative humidity to drop from 100% to about 24%.
• Develop a better understanding of role of crystallinity on swelling in new polymers using X-ray scattering, mechanical properties testing and modeling.
• Use atomistic and mesoscopic simulations to study the hydrated morphology of 3M PFSA and multi-acid side-chain membranes.
• Provide completely water stable membranes comprising HPAs. Evaluate additional stabilizers.
• Describe degradation pathways and rates for current group of model compounds and correlate with membrane stability.

V.D.3 Dimensionally Stable Membranes (DSMs)

Objectives

- Determine the effect of pore size and substrate thickness on conductivity and water uptake.
- Demonstrate polymerization conditions suitable for bulk polymerization of perfluorinated sulfonic acids (PFSA).
- Demonstrate, by the 3rd quarter 2007, membrane conductivity of 0.07 S/cm, at 80% relative humidity, at room temperature (RH), and using non-Nafion materials. Samples will be prepared and delivered to the Topic 2 Awardee.

Go/No-Go Decision: Demonstrate, by the 3rd quarter, membrane conductivity >0.1 S/cm, at 25% RH at 120°C, using non-Nafion materials. Samples will be prepared and delivered to the Topic 2 Awardee.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost
(C) Performance

Technical Targets

Progress has been made in achieving the DOE 2010 Fuel Cell Technologies Multi-Year Research, Development and Demonstration Plan. Table 1 lists the DOE’s technical targets and where our research stands to date. There are two other DOE targets for membranes relating to durability, which we have not yet addressed.

Accomplishments

- Successfully demonstrated that DSMs based on laser drilling pores restrain x-y swelling (<5%) with a wide range of pore size and thickness and substrate materials.
- Effective methods of generating new PFSA polymers have been generated. These have been generated via bulk polymerizations which will allow for the direct formation of the composite membrane.
- Short-term (DOE 2008 High Temperature Membrane) conductivity targets have been met for room temperature conductivity, promising results confirmed by independent lab (Bekktech) using a 2DSM support material, resulting in passing the...
go/no-go project decision point and continuation of the project:
- 0.0852 S/cm at 30°C and 80% RH vs. goal of 0.07.
- 0.031 S/cm at 25% RH and 120°C is below DOE target, but getting closer.
- 0.093 S/cm achieved at 120°C and 50% RH close to DOE upper target for RH.

- New PFSA material generated at SUNY and incorporated in three-dimensional support material (3DSM).
  - Demonstrates 0.08 S/cm conductivity at 30% RH, approaching DOE ultimate target of 0.10 S/cm at 25% RH.
  - DOE conductivity targets met with 3DSM and homopolymer; GES results significantly higher than Bekktech.

- Demonstrated improved fuel cell performance at 95°C and 25% RH 7 psig H₂/air (0.68 V at 500 mA/cm²).

- Both commercially available polyether sulfone (PES) and ultra-high molecular weight polyethylene (UPE) successfully incorporated as porous supports in 3DSM:
  - Swelling reduction similar to 2DSM.
  - Conductivity penalty of support ~33%.

- Increased mechanical durability with 2DSM and 3DSM, demonstrated through RH cycling (10,000 cycles, 2 min bone-dry, 2 min 95°C dew point).
- Collaborating with Millipore for thinner 3DSM support samples.

**Introduction**

PFSA materials have demonstrated promising high temperature/low RH conductivity, yet are still unsuitable for automotive applications. Increasing acid content and making the membranes thinner are two methods for lowering the resistance of these materials. However, each of these methods has a negative impact on mechanical durability of the membrane. GES is trying to combine the good conductivity properties of high acid content PFSA materials and improve their mechanical properties by making composite materials.

**Approach**

GES’s approach is to use very high acid content PFSA materials and support them with high-strength non-acidic materials. This involves using commercially available PFSA materials as well as generating new PFSA polymers, generating the supports, and finally forming and characterizing the composites.

**Results**

GES has successfully imbedded high acid content PFSA materials in laser-drilled supports consisting of either polysulfone or polyimide (Kapton®). Figure 1 shows the laser-drilled support, as well as the composite DSM. A matrix of support material, pore size, support thickness and equivalent weight (EW) of PFSA fill has been completed. When the supports are 10% of the total material and have no greater than 60% void space, they nearly eliminate swelling in the x-y direction. This is true regardless of hole size, acid content of the PFSA fill material, or whether polysulfone or polyimide was used as the support. Fuel cell testing has been carried out on a 2-mil DSM membrane consisting of a 1/3-mil polyimide support filled with 700 EW PFSA and the 2DSM far outperforms Nafion® 112 performance.

A sample composite material with low EW PFSA and 10% support material has demonstrated 2-3x the conductivity of Nafion® 112, the PFSA standard, over the entire range of relative humidity as shown in Figure 2. This conductivity still falls short of the DOE target however, as seen in the figure. Previously it appeared that this approach would not be able to reach the DOE’s cost target, however in a separate DOE contract GES has demonstrated a successful method of micro-molding these substrates.

Commercially available porous supports offered an alternative to the cost-prohibitive 2DSM supports: an unforeseen development from the original proposal but very promising as the 3DSMs demonstrated the dimensional stability and improved mechanical properties of the 2DSM. We successfully incorporated both 1,100 EW and 830 EW PFSA ionomers into commercially available PES and UPE and tested the membranes under electrolysis conditions. Figure 3 compares the electrolysis performance of a 3-mil 3DSM prepared with 830EW ionomer and UPE support to that of an 1,100 EW electrolysis membrane electrode assembly with comparable thickness. Electrolysis
conditions were used as the poor membrane-electrode interface in fuel cell membranes contributes to the overall resistance and thereby decreases fuel cell performance. Electrolyzer testing allows us to test the membranes in an electrochemical cell and determine the performance penalty due to the support, even with a thick membrane. The thinnest PES porous support commercially available is 4 mils thick. We are currently working with Millipore on thinner supports, and they have supplied us with 1- and 2-mil-thick UPE. We have successfully incorporated low EW PFSA ionomers into these thinner supports and tested through plane conductivity, shown in Table 2. As seen in the table we are now able to generate very thin membranes without a large conductivity penalty. For example the 0.7 μm UPE membrane has a final thickness of 0.4 mil with only a 20% conductivity penalty compared to neat 1,100 EW PFSA.

The mechanical durability of the 3DSMs was tested through RH-cycling performance of the resultant thinner 3DSMs prepared with the materials from Millipore and the low EW ionomers at 80°C. Cast Nafion®, NR211, failed around 4,500 cycles, before the 1-mil 3DSM, as seen in Figure 4. The 3DSM Condition B, which failed early, was sintered to 200°C, well above the supports melting temperature. The sample (3DSM Condition A) which was sintered to 140°C, just below the support melting temperature lasted longer than NR211, the cast Nafion® reference. The 2-mil 3DSM which was also sintered to 200°C did not fail in the first 5,000 cycles. The samples were taken off test at 5,000 cycles because the test stand was needed for another project.

To further increase conductivity PFSA with even higher acid content are being synthesized at SUNY-ESF under the direction of Israel Cabasso. A large number of materials have been synthesized, including the homopolymer of just the active monomer. Improvements in the synthesis of this polymer have led to a film-forming ionomer that can be readily incorporated in GES’s 3DSM structures. In the previous years we demonstrated that this material has a conductivity that is approximately twice that of the

The best 2DSM material to date and approximately five times that of Nafion® 112 over an entire range of RH as seen in Figure 2. Also seen in the figure is that this material comes very close to meeting the DOE target for conductivity down to 25% RH. Unfortunately this material swelled excessively in water.

Work at SUNY in this past year has centered on reducing this swelling while maintaining the high conductivity at low RH. A highly cross-linked perfluoro (4-methyl-3,6-dioxaoct-7-ene) sulfonyl fluoride (PVEPVE)-based polymer was cast and characterized for conductivity at GES. The conductivity of this polymer was quite high at low levels of RH as seen in Figure 2. Surprisingly, the conductivity at higher levels of RH does not increase as quickly as the non-crosslinked materials. We believe that this is due to the lower water contents at higher RH due to the cross-linking. Water sorption isotherms of this material will be conducted to confirm this conclusion.

Conclusions and Future Directions

The DSM with laser-drilled supports successfully has been shown to restrain x-y swelling in high-acid content PFSAs over a range of composite dimensions and compositions. Though 2-3 times more conductive than Nafion® 112, it still is short of the DOE’s conductivity targets. Work has been done to synthesize PFSAs with even higher-acid content, including the homopolymer that contains only the functional monomer. This polymer, when incorporated in the 3DSM has come very close to meeting the DOE targets. This polymer is water soluble however, and eventually leaches out of the 3DSM support. Efforts have begun to cross-link this polymer to make it insoluble and resulted in a polymer with similar low RH performance that is hydrolytically stable. RH cycling of the 2DSM and 3DSM materials has been completed to demonstrate these materials superior mechanical attributes; each of them surpassing 5,000-10,000 cycles, including a 1-mil 830 EW membrane. We are currently focusing on preparing even thinner (~15 μm) 3DSMs with lower EW (700 EW) ionomer for fuel cell testing. Millipore and the Solar Energy Research Center in Florida are assisting in this effort.

FY 2010 Publications/Presentations
V.D.4 Lead Research and Development Activity for DOE’s High Temperature, Low Relative Humidity Membrane Program

Objectives

- Fabricate membrane electrode assemblies (MEAs) from Team membranes.
- Test Team MEAs for fuel cell performance.
- Standardize methodologies for in-plane and through-plane membrane conductivity measurements.
- Provide High Temperature Membrane Working Group (HTMWG) members with standardized tests and methodologies.
- Organize HTMWG bi-annual meetings: http://www1.eere.energy.gov/hydrogenandfuelcells/htmwg.html

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(C) Electrode Performance

Technical Targets

FSEC plays a supporting role to the six teams who are tasked with developing an improved high-temperature, low relative humidity (RH) membrane for proton exchange membrane (PEM) fuel cells. FSEC has developed standardized experimental methodologies to:
- measure conductivity (in-plane and through-plane);
- characterize mechanical, mass transport and surface properties of the membranes as working MEAs;
- and predict durability of the membranes and their MEAs.

This project manufactures, tests and evaluates MEAs for performance and stability. Test results will be evaluated against DOEs 2010 membrane targets:

- Oxygen Cross-Over 2 mA/cm²
- Hydrogen Cross-Over 2 mA/cm²
- Membrane Conductivity at 120°C 0.10 Siemens/cm

Accomplishments

- Verified ability to prepare an MEA using the DOE-recommended Pt/Co on carbon catalyst from Tanaka.
- Developed procedure for making and spraying ink based upon the use of 3M ionomer, as recommended by DOE.
- Prepared and tested MEAs fabricated from membranes provided by Giner, Fuel Cell Energy and Case Western.
- Established pinhole test method.
- Obtained and tested mechanical test apparatus.

Introduction

Generally, two regimes of PEM fuel cell operation exist: the typical operating temperatures between 60–80°C, and elevated temperatures higher than 100°C. The ability for current automotive radiators to reject heat is insufficient at continuous full power waste heat loads for 60–80°C fuel cell stack temperatures. Running the stack at 120°C under full load would allow the use of radiators similar to those available in automobiles today. This has driven the need for development of high-temperature membranes and MEAs that could
operate at temperatures of up to 120°C, low RH and near atmospheric pressure.

The objective of this phase of the program is to fabricate and test MEAs from fuel cell membrane materials that meet the goals outlined by the DOE in the multi-year plan. Specific goals are: operation at elevated temperatures (up to 120°C), with a demonstrated conductivity of >0.1 S/cm at 120°C and 1.5 kPa inlet water vapor partial pressure to the fuel cell stack (50% RH measured at room temperature).

**Approach**

The High Temperature, Low Relative Humidity Membrane program encompasses six teams, each of which is skilled in producing novel membranes expected to meet the goals of the program. Some of these teams are not necessarily skilled in the ability to produce an MEA, or to test the MEAs in a fuel cell. FSEC's objective is to provide the expertise to test the membranes under fuel cell conditions. FSEC is working closely with the membrane manufacturers to develop appropriate methods for manufacture of the MEA and to test the MEAs according to a procedure that has been developed at FSEC. This approach involves a detailed logic flow chart that itemizes each step of the manufacture, fuel cell testing and post test analysis of the MEA. Each membrane manufacturer approves the steps of the logic flow chart in advance of the process. Furthermore, FSEC iterates with the teams to optimize the results.

**Results**

During this year, a total of 19 membranes were received from four of the teams. These varied from an extremely brittle membrane that required recasting to some high quality materials. Each was tested for material characteristics to determine suitability for fabrication into MEAs, see material characterization box of logic flow chart, Figure 1. Eight of the membranes were fabricated into MEAs and tested, and the procedures developed for the testing. For each MEA tested, a detailed report was prepared and sent to the supplier, along with photos of each step, data collected

---

**FIGURE 1. Logic Flow Chart**
and, when possible, a coupon that was prepared identically to the MEA.

All membranes received to date were preliminary or baseline materials. The goal of using these materials for the development of MEAs was to resolve any issues resulting from the use of these novel materials. This will allow easier handling of the final membranes, which are not yet available. Three of the six teams have indicated that they are prepared to send next generation or final membranes for testing.

A previous method [1] for determining pinhole locations in MEAs from tested fuel cells was found not to be reproducible and was potentially damaging to the MEAs. This method was based upon the location of bubbles that appeared in a liquid injected to the cathode flow field of a transparent plate with controlled gas pressure applied to the anode. An alternative method has been developed based upon applying 4% hydrogen to the anode side of a fuel cell, with controlled flow and with the cathode side of the MEA exposed to the atmosphere. This results in the development of “hot-spots” at pinhole locations due to the direct reaction of hydrogen with oxygen. An infrared camera was used to determine the locations of these hot-spots. This method has been found to be reproducible and since the MEA is not exposed to substances it would not be exposed to during fuel cell testing, damage to the MEA is minimized. An example of an image of the pinholes taken using an infrared camera is shown in Figure 2. In this image hot spots are noted with approximate temperatures based on the emissivity of carbon.

An in-house built stress-strain setup was acquired and a procedure was formalized for stress-strain testing of team member membranes. Reproducibility and repeatability will be established as a part of completing the protocol. Team member membrane samples will be tested once the protocol is finalized, to ensure all samples were tested to the same procedure.

Conclusions and Future Directions

• Reached agreement with all six Teams on logic flow chart for MEA development.
• Developed and tested MEAs from eight Team member membranes.
• Established collaboration with 3M to obtain advanced ionomer for use in MEAs.
• Fabrication and testing of additional MEAs will be done as membranes are received.
• Formalize the procedure for pinhole testing, and characterize the observed pinholes with scanning electron microscopy.

V.D.5 Poly(p-Phenylene Sulfonic Acids): PEMs with Frozen-In Free Volume

Objectives

The project objectives are to optimize routes to rigid rod poly (phenylene sulfonic acids), polymers that retain high conductivity at low humidity, develop methods to make water insoluble polymers and characterize the materials as proton exchange membranes (PEMs). The requirements are:

- Analyze the Ullman polymerization reaction in order to increase polymer molecular weights and decrease reaction time.
- Increase the polymer sulfonic acid density and water absorption: use phenylene disulfonic acid monomer to make homo- and co-polymers.
- Develop reliable methods for grafting non-polar groups on the backbone to make water insoluble, dimensionally stable PEMs.
- Synthesize comonomers that can be copolymerized to produce water insoluble copolymers either directly or in a subsequent step.
- Characterize polymers, copolymers and grafts to understand the relationship between molecular structure, supramolecular organization and PEM properties.

- Submit the most successful materials for intensive testing.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost

Technical Targets

This project involves the synthesis and characterization of homo- and co-polymer rigid-rod aromatic sulfonic acids.

- Our ionomers have passed the 2005 goals for membrane conductivity and probably reach the 2015 goals.
- Earlier tests of MeOH permeability (<0.04 mA/cm² for a 20 μ thick film at 100°C with a 2/1 MeOH/H₂O gas input) imply that the very polar membrane environment should reduce oxygen and hydrogen cross-over to values much lower than the target values.
- The starting materials are relatively cheap; there are only two steps from commercial starting materials, fuming sulfuric acid and dibromo-biphenyl or dibromo-benzene, to the homopolymer sulfonic acids. Copolymers will raise the cost.
- Some of our early graft copolymers showed 27% expansion (z direction only) from 22 to 100% relative humidity (RH) while retaining high conductivity at 50% RH and 80°C.

Since the polymers have not yet been tested in a fuel cell configuration, we cannot be certain that they meet the requirements but the indications are that they will do so.

Remaining Barriers:

- The homo- and graft polymers tested so far have very low elongation; the best was 8% at 40% RH. They are brittle when very dry. However, these were low molecular weight polymers, molecular weight at 10,000.
- Homopolymer molecular weights are limited because they crystallize from solution and stop growing. The maximum molecular weight for poly(p-biphenylene disulfonic acid) is ~10,000. It is higher for poly (p-phenylene disulfonic acid),
PPDSA, up to 100,000, but the homo and graft polymers become very soft above 50% RH.

- We have not yet developed a reliable, scalable method for making water insoluble copolymers by direct grafting of a large non-polar moiety. Grafting is difficult to control since it is a heterogeneous reaction. Normal copolymerization approaches have failed. Other approaches are being studied.
- Long chain alkyl benzenes grafted on PPDSA-generated water insoluble materials that could form good films but swelled rapidly and disintegrated in water to a suspension of particles. We think that grafting is inhomogeneous, which is why they shear easily above 50% RH and are not water stable.

Accomplishments

- The two base monomers were found to copolymerize well. The copolymer precipitated from solution but at higher molecular weight.
- The grafting procedure has been improved; oxygen is now completely excluded. Recent grafts are light in color and cast films are easily handled. They hold water very well and have high conductivity at low humidity; the best conductivity found was 0.1 S/cm at 30% RH and 80°C. The copolymer and its grafts hold more water than the homopolymers and their grafts at a given RH, but they have comparable conductivities.
- We have finally developed a polar comonomer that copolymerizes well with the base monomers. It contains a weakly acidic CH2 group. Once copolymerized, these hydrogens can be replaced by non-polar chains to generate water insoluble copolymers. This has been demonstrated but films have not yet been cast.
- We have made nano-pore containing two-dimensional (2-D) polymers (ion exchange capacity [IEC] = 5.5 mEq/gm) that have no non-polar groups but are water insoluble; they aggregate during preparation. We are still learning how to handle them to cast good films. We expect that the volume will be independent of humidity.

Introduction

There are many problems associated with the normal aromatic sulfonic acid PEMs. The better conducting materials swell very much in water. Even with these materials, conductivity drops rapidly as humidity is lowered [1]. Block polymers swell less at high humidity, but conductivity is still poor at low RH [2]. They can be used only at high humidity which limits the fuel cell operating temperature to <90°C. The materials described below were designed to hold water...
very strongly at low humidity. They could be used effectively at higher temperatures, up to at least 120°C, with little or no added water in the fuel stream since the water generated in the reaction should be sufficient to maintain high conductivity. High temperature operation has the additional advantages that kinetics are faster, lower purity hydrogen can be used and heat can be removed easily.

**Approach**

Our approach derives from a combination of polymer structure analysis and cost considerations. What type of polymer backbone can have high sulfonic acid content, hold water strongly, and yet have dimensional stability. The analysis suggested that PPDSA, rigid rod liquid crystals that organize with all molecules locally parallel, should be suitable. These structures have small cross-section backbones with projecting sulfonic acid groups. Absorbed water separates the chains. As water is lost at low humidity, the sulfonic acids hit other acid groups or a neighboring polymer backbone. The molecules still have voids which hold water (frozen in free volume): further water loss generates compression which distorts bond angles and requires high energy. The last few waters are removed with difficulty and are reabsorbed rapidly. As water is added, this structure can only expand perpendicular to the parallel polymer axes. It can be dimensionally stabilized by addition of non-polar groups that promote hydrophobic bonding, or by cross-linking [3]. Non-polar groups that protrude further from the backbone than the acid groups can be incorporated; this increases the minimum chain (rigid rod) separation and thus increases the frozen-in free volume [4]. This structural design generates non-collapsible nanopores lined with a high density of sulfonic acid groups which hold water very strongly.

Attached non-polar groups interact by hydrophobic bonding which restricts swelling as humidity rises. Because the molecules are rigid rods, non-polar groups on a chain can interact only intermolecularly, with similar groups on neighboring chains. Thus, a relatively low mole fraction of non-polar groups should make such polymers water insoluble and dimensionally stable with little loss of conductivity. This was demonstrated earlier for poly(p-biphenylene disulfonic acid), PBPDSA, grafts but has not yet been achieved for PPDSA grafts [3].

**Results**

**Copolymerization:** Over the past year we have copolymerized several mole ratios of the two base monomers. They reacted well but we have not yet determined how random the copolymerization is. During the reaction the copolymer takes longer to precipitate and the solution (2 to 3% copolymer) becomes viscous, showing that high molecular weight copolymer is soluble. The copolymers hold water very strongly. The best PPDSA reduced viscosities (0.5% solution) were in the range of 0.7–0.9 dL/gm. A copolymer (80/20 ratio, P80B20) had a reduced viscosity of 1.1 dL/gm. An earlier copolymer (P55B45) had a reduced viscosity of 1.5 dL/gm.

We have made a new comonomer, 2,7-dibromofluorene 3,5-disulfonic acid, F. It copolymerized well with the two base monomers to give water soluble copolymers. The fluorene group has two active hydrogens which can be replaced easily with alkyl groups, see Scheme 1. We have demonstrated this

**SCHEME 1.** Approach to Synthesis of New Random Copolymer, P10F1, and Preparation of Water Insoluble Materials for PEMs
with one of its copolymers, P10F1, adding two \(\text{C}_{22}\text{H}_{45}\) groups to each residue. (Calculated IEC = 6.7 mEq/gm.) Unfortunately, we have not been able to find a solvent for the reacted copolymer; it does not swell in water even with such a high IEC. Work is continuing in this area.

**Grafting:** PPDSA homopolymer and the P80B20 copolymer were grafted with n-octyl benzene (nOB) and/or n-dodecyl benzene (nDDB). Various mole ratios of alkyl benzene to sulfonic acid were used during grafting. At 100/40 and 100/100 (SO\(_3\text{H}/\text{alkyl benzene}), grafting went smoothly; grafts containing between 7 and 23 mole\% alkyl benzene were obtained. The grafting procedure was improved during the year; oxygen was systematically excluded. Films cast early in the year were black and very brittle. It was difficult to get strips large enough to make conductivity measurements. After oxygen was excluded, cast films were pale yellow and could be easily handled. The new procedure was used for most of the nOB grafts. Figure 1 shows before and after cast films.

Grafted polymers with more than 10 mole\% graft were water insoluble. However, all the films swelled rapidly in water and eventually disintegrated to a cloudy suspension. The films became very soft above 50% RH. We think this is because the grafting of non-polar groups was inhomogeneous, with regions of high graft density and long stretches of ungrafted polymer. The homopolymer loses modulus rapidly as humidity rises and becomes a gel above 75% RH.

**Water Absorption:** Homo and graft polymer water absorption was measured in several ways: weight gain, \(^1\text{H}\) nuclear magnetic resonance analysis and titration. Figure 2 shows the average \(\lambda\)s as a function of RH for the homopolymer, copolymer, and their grafts with n-octyl benzene. The copolymer holds more water at a given RH than the PPDSA homopolymer. The grafted copolymers hold more water than the starting material, possibly because the hydrocarbon groups force the chains apart. This is best seen at 0% RH (drying at 10 mm and 90°C for one day); the P80B20 grafts have \(\lambda\)s of two versus one for the starting copolymer. Lambda decreased slightly for the PPDSA graft polymers compared to the starting polymer.

Water absorption was compared to that of Nafion117\(^®\). The copolymer and its grafts have \(\lambda\)s about 1.5 to 2 higher over the whole RH range. New preparations of PPDSA have lower \(\lambda\)s than those reported earlier [5], possibly due to higher molecular weight and better crystallinity, but are still higher than Nafion117\(^®\). Grafting lowered \(\lambda\) but did not seem to affect conductivity.

**Conductivity:** Conductivity versus RH data for the nOB grafts on PPDSA and the P80B20 copolymer are shown in Figure 3. Conductivity of the PPDSA/nDDB grafts, not shown, was about the same at a given mole fraction of graft. Samples were sent to the Florida Solar Energy Center. The P80B20 GnOB 7.3% conductivity at 80°C was measured there and also at Case; the
values agreed within experimental error. This gives us confidence in our measurement procedures. The data show that conductivity at lower RH remains high for these PEMs if there is less than 10% grafting. It parallels the PPDSA homopolymer at 80°C [5] but is slightly lower, dropping to 100 mS/cm at 50% RH. At 16 to 18% grafting, conductivity drops further by a factor of two, but is still very high.

When the new PEM conductivities are compared to that of Nafion212®, it is obvious that the better retention of water generates much higher conductivity at low RH. The 20 to 50% RH conductivity of the best materials is an order of magnitude higher than that of Nafion212®. The conductivity drop at 120°C is unexpected and is possibly due to starting the testing at 50% RH. The sample would be so soft at that RH and temperature that the electrode pressure could thin it at the electrode edges, raising its resistance. Several attempts were made at the Florida Solar Energy Center to make a membrane electrode assembly (MEA) using a film of P80B20 GnOB 16%. Under their preparation conditions, the polymer was so soft that it was pressed into the gas diffusion layer; no testable MEA could be made. We expect this problem to vanish when we have dimensionally stable PEMs.

2-D Polymers: These were discussed fully in a special report sent in as a quarterly report, dated April 6, 2010. Unfortunately, Casey Check had to stop research in order to write up his his doctorate thesis. We expect to start research again in September.

We have succeeded in finding procedures and reagents that enabled us to make very large planar molecules in the form of a hexagonal lattice of p-biphenylene disulfonic acids interconnected through benzene rings at the 1, 3, 5 positions (Suzuki reaction using starvation polymerization conditions). The hexagons are calculated to be about 2.2 nm from side to side with a central hole about 1.5 nm in diameter. Wide angle X-ray diffraction scans do not show any sharp reflections; this implies that there may be some pentagonal or heptagonal holes in the structure.

Because the molecules were very large, they coalesced towards the end of the polymerization into water insoluble aggregates. Since the IEC is ~5.5 mEq/gm and there are no large non-polar groups, this was unexpected. If crosslinking had occurred, the whole solution would have gelled early in the reaction rather than becoming cloudy towards the end. The aggregates could be dispersed by sonication into smaller particles. Films of the sonicated materials were cast from water; they were stable to water after drying and could be handled easily. However, they were brittle in water. Preliminary characterization of initial aggregates by scanning electron microscopy and atomic force microscopy (AFM) showed that the molecules had coalesced into large stacks, showing that they were planar. Figure 4 shows an AFM scan of one of the better polymerizations, after sonication to break up secondary association. Such stacks should contain nano-pores parallel to the stack direction. Water was held very tightly; lambda for the best preparations was ~6 at 50% RH. For such systems, conduction would be one dimensional, along the pore axis. These must be perpendicular to the film surface to get high through conductivity. We have not found casting conditions that would do this properly; the work is suspended for the time being.

**Conclusions and Future Directions**

- Since grafting of long chain alkyl benzenes on PPDSA did not give water-stable materials, probably due to heterogeneous grafting, we are shifting to the production and study of cross-linked films. Biphenyl groups can be grafted homogeneously on the sulfonic acids; they are too small to promote inhomogeneous grafting. Because the biphenyl reactivity is reduced after one end is grafted, it is possible to get water-soluble polymer with as much as 15% grafting. Materials with 5 to 15% graft will be cast and the films will be crosslinked by heating under vacuum at 175°C or higher. (Preliminary studies show that these conditions can be used.) We are determining the reaction conditions needed to get complete crosslinking at a degree of substitution that gives dimensionally stable films, hopefully with high conductivity.
The new copolymers made using dibromo fluorene disulfonic acid did not have as high viscosity as the homopolymers. We are studying reaction conditions and have made copolymers with higher viscosity. Molecular weight is very important in improving mechanical stability at high humidity. We will make a series of copolymers with various mole ratios of fluorene comonomer (5 to 20 mole%) and graft on alkyl chains, C₈ to C₂₂, to determine which combination gives the best final properties. If these cannot give satisfactory mechanical properties, fluoroalkyl groups can be grafted on the backbone.

Work will continue on the 2-D polymers. The first task is to find counterions or additives that will keep the material soluble throughout the polymerization to enable us to cast good films. The additive and/or counterion should also be easily removable or replaceable by protons. We have some ideas that will be tested soon. The second task is to make sure that the final structure is completely regular, a purely hexagonal lattice. We will be working on that problem also. Cast films should have the molecules parallel to the film surface and very well stacked. Molecular overlap should be high between the primary stacks to give materials with reasonable strength, though low elongation. Such films should have good conductivity, high modulus and constant dimensions, independent of RH.

Special Recognitions & Awards/Patents Issued

1. A patent application on Liquid crystal poly(phenylene disulfonic acids) by Morton Litt and Junwon Kang was submitted to the U. S. Patent Office early in 2008. It is still pending.
2. An invention record for the 2-D polymers is being processed.

Start Date:  March 1, 2006
Projected End Date:  February 28, 2011

Objectives

• Fabricate a new class of nanocapillary network (NCN) proton conducting membranes using different sulfonated polymers.
• Add sulfonated molecular silica to the polymers prior to fiber spinning.
• Characterize the membranes in terms of swelling, proton conductivity, thermal/mechanical stability, and gas permeability.
• Optimize the membrane structure (fiber diameter, mat density, polymer ion-exchange capacity, choice of impregnation polymer, etc.) to achieve the DOE’s technical targets for membranes.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost
(C) Performance

Technical Targets

This project is focused on the fabrication and characterization of a new class of proton conducting membranes for high temperature hydrogen/air fuel cells. The technical targets of this project are listed in Table 1 for 2010.

¹Proton conductivity at 120°C and 50% relative humidity (RH) – data from Bekktech LLC

Accomplishments

• A new nanofiber membrane fabrication method was developed, where a separate impregnation step for the inert (uncharged) polymer was eliminated and where Norland Optical Adhesive 63 was replaced with a commercially-available polyphenylsulfone.
• Fabricated nanofiber composite membranes via a dual-fiber electrospinning, where perfluorosulfonic acid (PFSA) proton conducting nanofibers and uncharged polyphenylsulfone (PPSU) nanofibers are simultaneously electrospun.
• Developed two methods for processing the dual fiber mat into a fuel cell membrane: (i) “melting” PFSA ionomer around a PPSU nanofiber mat (where the nanofiber mat acts as a reinforcement)
Introduction

Proton exchange membrane (PEM) hydrogen/air fuel cell operation with lightly humidified gases at 120°C would be highly advantageous with regards to heat rejection from a fuel cell stack, compatibility with automotive radiators, tolerance to CO impurities in the hydrogen gas stream, and fast electrode kinetics. For PEM fuel cell operation at T ≤80°C and high RH conditions, PFSA proton conductors (e.g., Nafion®) are the membrane material of choice due to their high conductivity and chemical/mechanical stability. Unfortunately, the conductivity of PFSA membranes drops dramatically at T >100°C under low humidity conditions [1] due to an insufficient number of membrane-phase water molecules for protons to dissociate from sulfonic acid sites, a loss of percolation pathways for proton movement, and structural changes in the polymer which cause membrane pores to collapse.

In order to overcome the limitations of existing membrane materials, a new approach to fuel cell membrane design and fabrication has been developed, where a three-dimensional interconnected network of proton-conducting polymer nanofibers/nanocapillaries is embedded in an inert/impermeable polymer matrix. The nanocapillary network is composed of a high ion-exchange capacity sulfonic acid polymer to ensure high water affinity and a high concentration of protogenic exchange capacity sulfonic acid polymer to ensure high water swelling of the nanofibers/nanocapillaries and structural stability. The inert (hydrophobic) polymer matrix controls water swelling of the nanofibers/nanocapillaries and provides overall mechanical strength to the membrane. First-generation membranes [2] were made using sulfonated poly(arylene ether sulfone) with sPOSS to further boost conductivity. Norland Optical Adhesive 63 was employed as the inert embedding polymer. Second-generation membranes were fabricated with nanofibers containing 850 EW PFSA (from 3M Corporation) with/without sPOSS [3]. Films with sPOSS met the DOE’s Year 3, 3rd quarter Go/No-Go conductivity target of 100 mS/cm at 120°C and 50% RH.

Approach

Membranes were prepared by a newly developed dual nanofiber electrospinning technique using either 1,100 EW Nafion® or 825 EW PFSA from 3M Corporation as the proton conducting material and Radel® R-5500NT PPSU from Solvay Advanced Polymers LLC as the inert/uncharged polymer. PFSA materials were electrospun using a high molecular weight (MW) polymeric carrier, 500,000 MW poly(ethylene oxide) (PEO) for Nafion® or 400,000 MW PEO for 3M 825 PFSA (where the PEO concentration was 1-2 wt% of the total polymer content). PFSA/PEO and PPSU nanofibers were electrospun simultaneously using two separate spinnerets. Suitable post-treatment converted the dual-fiber mats into fully dense and defect-free membranes, while maintaining the nanofiber morphology of one polymer component. Membranes were made where: (i) PFSA nanofibers were surrounded by an inert (uncharged) PPSU matrix and (ii) inert (uncharged) PPSU nanofibers were surrounded by PFSA ionomer. After processing, membranes were boiled in acid and then water to remove the PEO carrier polymer. Both membrane structures were fabricated, but characterization work was only performed on the morphology where PFSA was surrounding a PPSU nanofiber mat. Membranes were evaluated in terms of: (i) in-plane proton conductivity (in room temperature water), (ii) in-plane volumetric and gravimetric swelling in boiling water, (iii) mechanical properties of dry films (from stress-strain curves), and (iv) H2/air fuel cell tests (after converting the membrane into a membrane-electrode-assemblies).

Results

Preparing Dual Fiber Electrospun Mats with PFSA and PPSU – High quality dual fiber mats (Nafion®/PEO and PPSU nanofibers), of uniform thickness and fiber volume fraction were prepared, where approximately 70% of the fibers in the mat were composed of Nafion®/PEO. PFSA fibers were electrospun using a rotating drum collector, where the total polymer concentration in the electrospinning solution was 20 wt% (with a 99/1 PFSA/PEO wt ratio), the solution flow rate was 0.60 ml/hr, the electrospinning solvent was a 1-propanol/water mixture (2/1 vol ratio), the applied voltage was 4 kV, and the spinneret-to-collector distance was 5.5 cm. For PPSU electrospinning, a 25 wt% polymer solution was used with a N-methylpyrrolidone/
acetone solvent (4/1 vol ratio), with 7.5 kV potential, 8.5 cm spinneret-to-collector distance and a solution flow rate of 0.12 ml/hr. The mat was then compacted and annealed to produce a functional fuel cell membrane (a scanning electron microscope [SEM] image of the membrane is shown in Figure 1).

Membrane Evaluation - Physical property data for a nanofiber composite membrane (PPSU nanofiber mat surrounded by Nafion® PFSA polymer) are contrasted with data for Nafion® 212 in Table 2 for a 60 μm thick membrane containing 70 vol% PFSA nanofibers. Proton conductivity scaled linearly with PFSA content, but water swelling did not. Of particular note is the very low in-plane (areal) swelling (six-times lower than that of commercial Nafion®). As expected, the mechanical properties of the nanofiber composite membrane improved, as compared to Nafion® 212; the proportional limit stress of a dry nanofiber membrane at 80°C was 50% higher than that of Nafion®.

The low in-plane swelling of the nanofiber composite membrane improved membrane electrode assembly (MEA) in a fuel cell humidity cycling durability test. A 30 μm thick nanofiber composite membrane was fabricated into a H₂/air fuel cell MEA, using the decal method of electrode attachment (0.4 mg/cm² Pt loading for the anode and cathode with 30% Nafion® binder content). Voltage-current fuel cell performance curves (5 cm² MEA) at 80°C with fully humidified feed gases are shown in Figure 2. The performance of the nanofiber membrane MEA is very good and essentially identical to that of Nafion® 212. To evaluate durability, a 25 cm² MEA was subjected to an open circuit voltage (OCV) humidity cycling experiment (80°C with repeated cycling of 2 minutes 100% RH H₂ and air and then 2 minutes 0% RH H₂ and air). The OCV was monitored with time during humidity cycling and the hydrogen crossover was periodically measured in situ at 100% RH using a standard limiting current technique [4]. Durability results are shown in Figure 3. With a failure criteria defined as a drop in the OCV below 0.8 volts, it was found that Nafion® 212 failed after 546 hours whereas the nanofiber composite MEA failed after 842 hours (a 54% increase in lifetime vs. Nafion® 212). There was a dramatic increase in hydrogen crossover current density when the OCV dropped below 0.8 V, from 2 mA/cm² to 13 mA/cm².

Conclusions and Future Work

Conclusions

- Norland Optical Adhesive was replaced by polyphenylsulfone as the inert/uncharged component in nanofiber composite membranes.

1 In water at 23°C; 2 - In water at 100°C; 3 - Dry membrane at 80°C; 4 - 70 vol% Nafion® PFSA, 30 vol% polyphenylsulfone
A new method for nanofiber composite membrane fabrication was developed (dual polymer fiber electrospinning followed by mat processing) with the elimination of a separate polymer impregnation step. Using the dual fiber approach, two types of nanofiber composite membranes were made: (1) a PPSU nanofiber mat embedded in PFSA polymer and (2) a PFSA nanofiber mat embedded in (surrounded by) a PPSU matrix. The proton conductivity of the processed dual fiber mats (where the PFSA polymer is either DuPont’s Nafion® or an 825 EW polymer from 3M Corporation) scaled linearly with the membrane  ionomer content.

All dual fiber membranes exhibited very low in-plane (areal) swelling and reduced volumetric and gravimetric swelling. MEAs fabricated from a nanofiber composite membrane (Nafion® polymer with a reinforcing mat of PPSU nanofibers) performed well in a H₂/air fuel cell at 80°C and 100% RH. The fuel cell polarization curve (power output) of a 30 µm thick composite membrane was identical to that of commercial Nafion® 212.

The durability of MEAs made with a nanofiber composite membrane was significantly improved, as compared to Nafion® 212 (a 70% increase in MEA lifetime, as determine from OCV humidity cycling tests).

Future Work
- Prepare and test nanofiber composite membranes with PFSA + sulfonated polyphenylene + polyphenylsulfone (using the dual fiber electrospinning approach).
- Examine different inert/uncharged polymers
- Prepare and test MEAs with nanofiber network composite membranes.
- Investigate and test electrospun nanofiber fuel cell electrodes (focus on the cathode).

RH – relative humidity

Accomplishments

- Fabricated new HPA-based polymers based on three distinct polymer chemistries which are all designed to allow the fabrication of films that will be highly proton conducting, durable, cost-effective and have the required mechanical properties of the PEM fuel cell membrane.
- Showed that the HPA linkages in these systems are robust and will survive 10 hrs of boiling water.
- Demonstrated that the new polymers systems are able to show as high proton conductivities as the generation I model system films studied previously.

Introduction

Currently, fuel cells based on perfluorosulfonic acid (PFSA) PEMs are limited to operating conditions of ≤80°C and very high inlet relative humidities, because proton conduction in these materials depends strongly on the presence of water. For automotive applications it is desirable to operate the fuel cell at a temperature of ≤120°C and low relative humidity to enable the use of existing radiator technology and to eliminate the parasitic loads and system complications associated with externally humidifying the gas streams. Displacement of internal combustion engines by PEM fuel cells would dramatically facilitate the adoption of the H₂ economy and enable a smooth transition from fossil fuels to H₂ produced solely from renewable resources. Materials suitable for use in automotive PEM fuel cells are
being developed that have high proton conductivities, >0.1 S cm⁻¹ at 50% RH and operating temperatures of -30 to 120°C, low area specific resistance, <0.02 Ωcm⁻², and suitable for incorporation in a fuel cell membranes electrode assembly. We anticipate that the use of HPAs will generate membranes with oxidative stabilities higher than observed for any PFSA ionomer to date.

Of all the inorganic proton conductors that have been exploited for fuel cell applications the HPA may have the greatest potential as they not only have high proton conductivities but they have significant synthetic versatility [1]. In previous work we have shown that the HPAs have very high proton conductivities at room temperature and can be operated at ambient conditions in a fuel cell using dry gases [2]. Importantly, we demonstrated that some of the protons in HPA have very impressive rates of proton diffusion at elevated temperatures, >100°C under dry conditions. The residual protons in these systems are immobile at elevated temperatures resulting, however, in rather low conductivities. The two key challenges that need to be addressed, therefore, are utilization of all protons under elevated temperature, dry conditions, and immobilization of the water soluble HPA in practical membranes for fuel cell use.

**Approach**

Our approach is to functionalize HPA with monomers so that they can be fabricated into polymeric materials with the use of a suitable co-monomer. We initially chose to use acrylates as the co-monomers in this project as their commercial availability and large variation made them a virtual polymer system in a kit, leaving the synthetic effort to be devoted to making the HPA monomers. This polymer system allowed the chemistry to be easily varied so that the effect of morphology can be studied. In addition as these are free radical polymerizations the materials are obtained easily as films from the polymerization of the cast solutions of co-monomers. We are the first research group to fabricate proton conducting free standing films of these materials, but as they have previously been synthesized as gels [3], we are able to fully disclose our research using this model system. However, the system has certain inherent disadvantages that could include that the acrylate ester linkage is unstable to hydrolysis and that polymers contain readily oxidizable methylene groups.

The team assembled includes inorganic and polymer chemists and chemical and materials engineers from both CSM and 3M. CSM and 3M fabricate the HPA monomers and the extensive knowledge of polymers at 3M is heavily exploited. The polymer system in this project is not restricted, but the mode of proton conduction is mediated by the HPA. In this year’s work we have concentrated on making films with new polymer chemistries so that we can address the additional criteria, such as cost, durability, and mechanical integrity that are needed for a practical proton conducting polymer. We have also used nuclear magnetic resonance (NMR) to measure both the self diffusion coefficient of water and to quantify the amount of water. Comparing the NMR data with the proton conductivity data allows us to understand proton transport in these unique systems. In addition, we are correlating proton conductivity with morphology as observed by atomic force microscopy (AFM) and small angle X-ray scattering (SAXS) to enable us to understand structure proton conductivity relationships.

**Results**

We maximized the loading of HPA, the protogenic group in the acrylate model system. In Figure 1 we show data for an 85 wt% HPA substituted polymer. The proton conductivities at 95% RH are very impressive, 0.48 S cm⁻¹ at 90°C. The Ea for this is 10 kJmol⁻¹ similar to the 11 KJmol⁻¹ reported for PFSA polymers [4]. At an RH of ≤80% the Eₐ more than doubles to 23 kJmol⁻¹. At 50% RH the material achieves a proton conductivity of >0.1 S cm⁻¹ at 80°C. These results are extremely encouraging, but unfortunately the material is somewhat brittle and seems to undergo morphological changes with RH and time from film forming. In Figure 2 we show some details of the morphology of these generation I films. The AFM image shows that the protogenic HPA part of the polymer forms a channelized network with channel diameter around 50-100 nm. These same channels that facilitate proton conduction are also speculated by us to be the micro-structural cause of the films inherent brittleness. We also show in this figure the stacked SAXS patterns for the material hydrated from a RH of 30% to 95%. A strong ionomer peak is
observed at 5Å⁻¹ which shifts to the left with hydration. Using a unified Guinier and Porod fitting of the data gives a number of useful parameters, some of which are plotted at the bottom of the figure. The level 1 parameters are for the HPA moieties which maintain a diameter of 10 Å and spherical symmetry (p =4). The level 2 fit corresponds to the clustering of the HPA moieties, it can be seen that these clusters generally swell from 120 to 160 Å and become more symmetrical with more moisture (p increase from 3 to 4).

While the proton conductivities of these generation I acrylate films are impressive, they have a number of design flaws: 1) hydrolyzable ester linkages, and 2) a potentially oxidatively unstable methylene based backbone. To overcome these deficiencies and so that we can optimize the mechanical properties of the film we investigated two new generation II systems, designed to have no ester linkages. In system A the HPA was functionalized so that it could be co-polymerized into a perfluoro polymer. In system B a very simple polymerization scheme has been investigated. In a generation III approach, no ester linkages or methylene groups, being investigated at 3M, a perfluorinated polymer is functionalized such that the HPA can be directly attached to the preformed polymer. Great difficulty was found in forming insoluble films from systems A and B, however we have recently found success blending these co-polymers with similar non-ionomeric polymers and have formed robust thin films.

The generation III films are the most advanced. Robust thin films have been obtained. These materials have been boiled in water for 10 h to investigate the robustness of the linkages to the HPA. Thermogravimetric analysis data for this test is shown in Figure 3. This figure shows that before leaching that polymer contained 34 wt% inorganic material and that after the leaching study the organic material was reduced to 21 wt%. Considering the severity of the test and that this system is still not optimized this result is remarkable and bodes well for future development of the system. In Figure 4 we show the proton conductivity data for the generation 3 film compared with the 3M 825 equivalent weight PFSA ionomer at 95°C. The conductivity is lower than the 3M ionomer, but consider that there is only 34 wt% of HPA in this material. The material does achieve 0.1 Scm⁻¹ at 80% RH and 95°C. It should be obvious that the impressive conductivities obtained for

**FIGURE 2.** Morphological data for a co-85 wt% H₄[SiW₁₁O₄₀(Si(CH=CH₂))₂]–co-butyl acrylate-co-hexanediol diacrylate polymer, upper left AFM under ambient conditions, upper right, SAXS patterns, bottom, selected unified fit parameters from SAXS patterns.
We will continue to optimize generation II and III films for proton conductivity, oxidative stability and mechanical integrity. We will use SAXS, pulsed field gradient spin echo NMR and proton conductivity measurements to understand structure activity relationship sin these films.

**FY 2010 Publications/Presentations**

5. “Understanding the high proton conductivity observed in the polypoms in terms of morphology.”

**Conclusions and Future Directions**

- Very high proton conductivities were obtained for generation I films with high loadings of HPA at 50% RH.
- Two new co-polymer systems were developed which have now been fabricated into films.
- A generation III film was developed in which significant amount of HPA were immobilized with respect to boiling water and adequate proton conductivity was observed.

References

Objectives

- Develop humidity-independent, thermally stable, low equivalent weight composite membranes with controlled ion-cluster morphology, to provide high proton-conductivity at up to 120°C (Overall Goal: Meet DOE 2015 targets).
- Improve mechanical properties to significantly increase the durability and reduce the gas cross-over.
- Reduce the membrane area specific resistance (ASR) to increase cell performance and lower the capital and operating costs.

Technical Barriers

This project addresses the following technical barriers from the Multi-Year Research, Development and Demonstration Plan [1] of the DOE Fuel Cell Technologies Program:

(A) Durability
(B) Cost
(C) Performance

Technical Targets

This project is developing a composite membrane (mC²) to meet the following DOE 2015 technical targets for membranes:

- Membrane Conductivity: At ≤120°C: 0.1 S/cm; at room temperature: 0.07 S/cm; at -20°C: 0.01 S/cm
- Membrane ASR: 0.02 Ωcm²

Accomplishments

- Conductivity: Met DOE conductivity targets (both in-plane and through-plane).
- ASR: Met DOE membrane ASR target.
- Cross-Over: Almost met DOE hydrogen cross-over target.
- Polymer Development: Prepared three batches of improved low equivalent weight (EW) co-polymer, with increased molecular weight for higher mechanical strength.
- Additive Development:
  - Identified an improved protonic conductivity enhancer with 80% higher density of mobile protons.
  - Synthesized the improved protonic conductivity enhancer in 25 g batch size.
  - Fabricated and characterized nine additive batches (water retaining and proton conducting).
- Cost Reduction: Reduced the cost of the protonic conductivity enhancer by >80% by reducing cost of starting materials by 93%, reducing the number of processing steps from 12 to 7 and increasing the batch size by 25x.
- Composite Membrane Fabrication:
  - Developed new solvent system for better compatibility with the improved protonic conductivity enhancer.
  - Incorporated additives into mC² at the nano-scale, without significant agglomeration.
  - Synthesized over 13 batches of mC².
- Membrane Characterization:
  - Measured in-plane conductivity of over 18 membrane samples.
  - Measured through-plane conductivity of two membrane samples.
- Membrane Electrode Assembly (MEA) Fabrication:
Developed process compatible with mC² components in collaboration with the University of Central Florida (UCF).

Fabricated >8 MEAs of up to 25 cm² active area (UCF).

• MEA Testing: Two MEAs comprehensively tested by UCF in 11-day cell tests (DOE protocol).

Introduction

This project is focused on the development of composite proton exchange membranes (PEMs) that can operate at low relative humidity (RH) and over a wide temperature range (-20 to 120°C). Their main application is in transportation fuel cells. In addition, FCE is considering use of these membranes for co-production of hydrogen from high-temperature fuel cells. The higher operating temperature imparts improved tolerance to impurities, such as carbon monoxide, thereby increasing the co-production efficiency and simplifying the system.

The goal is to develop a structure in which ion conducting clusters remain intact at low RH. A major challenge is that current proton conducting polymers cannot sufficiently hold on to water under these conditions. Since the conduction mechanism relies on movement of hydrated species, the conducting path is compromised, resulting in low performance. Membranes that can operate at lower RH at elevated temperatures up to 120°C will reduce the fuel cell system complexity and cost. This project is developing a composite membrane, in which both the ionic conductivity and mechanical properties are enhanced to meet DOE’s 2015 goals for transportation fuel cells.

Approach

The approach to address each of the DOE target parameters is summarized in Table 1. The emphasis in the past year has been to develop and integrate additives with a greater density of highly mobile protons.

Results

This year’s efforts were focused on improving the performance and lowering the cost of the multi-component composite membrane, named mC². The efforts were centered on improving the following mC² components:

• Co-polymer
• Water retention additive
• Protonic conductivity enhancer

The co-polymer provides the basic building block for the membrane. It is an advanced perfluoro sulfonic acid polymer (PFSA) with a short side chain. It has a higher density of functional groups (lower EW) compared to long side chain polymers, such as Nafion®. The lower EW leads to significantly higher proton conductivity. It comes without a reduction in mechanical strength, due to a higher crystallinity of the short side chain PFSA. During this year, the molecular weight was increased. This leads to greater polymer chain entanglement and therefore better mechanical properties. The higher molecular weight has the added benefit of improving the film forming properties of the polymer dispersion.

The membrane additives are designed to retain water at the low RH conditions and to enhance the composite membrane’s proton conductivity by providing an alternate proton conduction path [2]. This path is designed to efficiently transport protons at high temperature as well as subfreezing conditions. Zeolite nanoparticles have been developed to retain water in the membrane. They have a high water uptake capacity without dimensional change, since the water is contained within the three-dimensional tunnel structure. To enhance the proton conductivity of the membrane, a novel superacid was developed. It has highly mobile protons to increase the transfer rate of protons through the membrane. During the past year, its further development was focused on increasing proton density and lowering the cost.
**mC² Conductivity:** The composite membrane concept has been validated by demonstrating conductivity exceeding the DOE conductivity target at 120°C (Figure 1). This data was obtained with mono-valent protonic conductivity enhancer. An improved, di-valent conductivity enhancer was identified, which contains two highly mobile protons per molecule. Compared to the mono-valent conductivity enhancer, the molecule size is only about 10% larger. Therefore, the proton density is increased by 80%. The conductivity of a composite membrane incorporating the water retaining additive as well as the improved conductivity enhancer is expected to exceed that shown in Figure 1. The benefits of the improved conductivity enhancer are summarized in Table 2.

**mC² Fabrication:** Due to the altered chemistry of the improved conductivity enhancer, the mC² fabrication process used successfully for the mono-valent conductivity enhancer resulted in undesirable additive interaction and a poor quality membrane. This made changes to the solvent system and processing conditions necessary. The requirements of the solvent system include: (i) ability to fully disperse the co-polymer as well as the nano-additives, (ii) prevent agglomeration of the nano-additives, (iii) favorable film forming properties, (iv) evaporate from the membrane film in a reasonably short period of time (minutes to hours) without affecting additive dispersion and, (v) do not affect the mobility of the protons in the additives or the co-polymer. Since the processing steps have to be compatible with all membrane components, the changes in conductivity enhancer and solvent system have also required changes in the processing conditions.

In order to facilitate mC² fabrication, the following improvements were made:

- Increased molecular weight of co-polymer to enhance chain entanglement and additive immobilization.
- Synthesized dispersion with 3x higher polymer content, to lower the solvent content and increase viscosity for improved film formation.
- Eliminated hot acid treatment step from mC² processing to avoid stability issues of the nano-additives.

While the membrane quality and conductivity have significantly improved after these changes, a stability problem has been identified. Further optimization of the solvent system and processing conditions are necessary to realize the full potential of the improved conductivity enhancer and obtain the expected conductivity results exceeding those shown in Figure 1. A systematic optimization study is underway. It includes microstructural analysis of the components and mC², in order to detect interactions at the nano-scale level and guide the materials and processing changes.

**Membrane Characterization:** Membrane samples were supplied to UCF for characterization. Through-plane conductivity and resistance measurements for these membrane samples were obtained by UCF from its team member Scribner Associates, Inc. Figure 2 shows the through-plane conductivity at 120°C as a function of RH. The solid squares represent the conductivity before correction for non-membrane ohmic resistance. The estimated corrected conductivity for sample #2 at 30% RH is 122 mS/cm, shown by the red empty circle. The extrapolated corrected conductivity up to 50% RH is shown by the dashed line. It significantly exceeds the DOE target. The correction is based on Scribner’s previous data obtained with Nafion® membranes.

Through-plane membrane ASR measurements at 120°C are shown in Figure 3. The uncorrected resistance values are shown by the solid squares. The corrected ASR for sample #2 is shown by the
empty circles at 20 and 30% RH. When this data is extrapolated to 50% RH, it suggests that the membrane itself meets the DOE target. The ASR correction is based on Scribner’s previous data obtained with Nafion® membranes. A study to determine the resistance contributions other than the membrane itself in the case of FCE’s membrane is planned. It will allow estimating the (corrected) membrane conductivity and ASR with greater accuracy.

**MEA Fabrication and Testing:** UCF has been tasked by DOE to fabricate MEAs using membrane samples supplied by FCE, to independently validate their performance. The MEA fabrication process developed by UCF was adapted for the mC², to avoid ion exchange with metal ions that could potentially have an adverse effect on additive stability. The modified process also significantly reduces the number of processing steps and processing time (lower cost). Using this process, MEAs were successfully fabricated by UCF, as shown in the inset in Figure 4. This MEA was fabricated using a 25 µm thick baseline membrane and matching co-polymer in the electrodes. The MEA was subjected to an 11-day cell test protocol developed by UCF in collaboration with DOE. The performance at 120°C, 35% RH and 7 psig on H₂/air was over 600 mV, and about 750 mV at 95°C and 83% RH. The hydrogen cross-over was determined by linear sweep voltammetry, as shown in Figure 4. It meets the DOE 2015 target of 2 mA/cm² at 95°C and closely approaches it at 120°C. It can be seen that the hydrogen cross-over did not increase (day 6 vs. day 4) after testing at 120°C (day 5). The area specific cell resistance was 0.045 Ωcm² at 95°C, 83% RH and 0.105 Ωcm² at 120°C, 35% RH. It includes contributions from membrane, electrodes, gas diffusion layers and interfacial resistances between all cell components. The increase in cell resistance with increasing temperature and decreasing RH suggests that incorporating the additives developed in this program for the membrane into the electrodes has the potential to lower the overall cell resistance and increase the cell performance, especially at high temperature and low RH.

**Conclusions and Future Direction**

A multi-component composite membrane design for high temperature and low RH operation has been implemented to fabricate membranes with enhanced performance at the DOE target conditions (Table 1). Accomplishments include:

- Validated mC² concept by demonstrating conductivity in excess of the DOE targets via in-plane (Figure 1) and through-plane measurements (Figure 2).
- Identified and synthesized a protonic conductivity enhancer with 80% greater proton density and lower cost (Table 2).
- Measured membrane ASR that is estimated to meet the DOE 2015 target (Figure 3).
- Determined that the hydrogen cross-over of a 25 µm membrane almost meets the DOE 2015 target (Figure 4).

In the final year of the current project we will continue the composite membrane development, with an emphasis on the following activities:

- Continue to develop advanced polymer dispersions with low equivalent weight (higher number of functional groups) and high molecular weight.
- Optimize and further simplify integration of the advanced additives.
- Continue to compare membrane conductivity and area specific resistance to the DOE 2015 targets (UCF).
Perform fuel cell testing at 95°C and 120°C.
Perform MEA characterization and durability testing per DOE protocol (UCF).

V.D.9 Improved, Low-Cost, Durable Fuel Cell Membranes

Technical Targets

This project aims at developing low-cost, durable membranes and membrane electrode assemblies (MEAs) according to the 2010 DOE goals:

- Cost: $20/m²
- Durability: 5,000 hr with cycling

Accomplishments

- Demonstrated and reproduced order-of-magnitude increase in conductivity for M70 lab-produced materials versus M43.
- Completed scale-up of novel monomer to multi-kilo scale for M70 polyelectrolyte (PE) synthesis.
- Identified (and eliminated) cause of PE leaching in initial batches of M70 membranes.
- Identified (and eliminated) cause of defects present in initial batches of M70 membranes.
- Completed successful M70 pilot blend production and membrane casting campaign.
- Demonstrated and optimized blending parameters to incorporate biPhenyl-based disulfonated polysulfone (BPSH)-type PEs into Kynar® poly(vinylidene fluoride) (PVDF) blend membranes.

Introduction

Proton exchange membrane (PEM) fuel cells rely on perfluorosulfonic acid containing perfluoropolymers (PFSA) for the construction of the membranes. The cost of these materials is high, largely due to the complexity and the number of steps involved in their synthesis. In addition, they suffer other shortcomings such as mediocre mechanical properties, poor gas barrier properties, and insufficient durability for automotive applications. To overcome these limitations, new membrane chemistries are needed, preferably based on readily available materials that will help keep the cost of commercial production of membranes low. The improvement of the proton conductivity of these materials under low RH conditions will allow for a wider range of operation of fuel cell stacks and reduce the complexity of the balance of plant, leading to lower overall cost and faster adoption of hydrogen fuel cells into automotive applications.
**Approach**

Arkema’s approach comprises the preparation of blends of PVDF and highly sulfonated PEs, in which, the two polymers are very intimately mixed. The originality of this approach is to have a methodology to independently vary material properties that govern ion conductivity from other requirements. Kynar® PVDF provides an exceptional combination of properties that make it ideally suited as the non-sulfonated component in the polymer blend membranes. It exhibits outstanding chemical resistance in highly oxidative environments (such as hydrogen peroxide and bromine), as well as in extreme acidic environments (such as HF, HCl and H₂SO₄). As evidence of the exceptional electrochemical stability and mechanical toughness of Kynar® PVDF, it is widely used as binder material in lithium ion batteries. Also, these novel materials exhibit a design flexibility inherent to their production process and can offer a much lower cost than PFSA-type membranes (at equal production volume) because synthetic requirements and their preparation process is simpler.

**Results**

The new PE family (M70), is based on novel monomers, each bearing more than one sulfonate group as depicted in Figure 1. This material (PE alone) has an extremely low equivalent weight of ~150 g/molH⁺. When incorporated into a blend with a non-sulfonated polymer (Kynar® PVDF), we have found that an optimum equivalent weight of between 400 and 600 g/molH⁺ is best to produce membranes displaying adequate mechanical properties as well as high proton conductivity. The new materials are hydrolytically stable at 80°C under hydrated, acidic conditions and we have optimized the blending process with Kynar® PVDF and the membrane activation (protonation). The process conditions have been found to significantly influence membrane appearance, morphology, and conductivity.

While the proton conductivity versus RH of M70 is below that of a PFSA-based membrane, particularly at low RH (Figure 2) we understand that ex situ conductivity measurements are only general trend indicators of in situ fuel cell performance. As such, we are moving forward with MEA fabrication and in situ testing of this material. In addition, we expect further improvement as work continues on the synthesis of this new PE, the blending process and membrane processing/activation.

The PE and the PVDF blend membrane produced using it are hydrolytically stable at 80°C, showing no chemical degradation in ex situ durability tests, but the blend membrane showed signs of sulfur loss due to leaching of the PE during aqueous processing/washing. The leaching was traced back to the synthesis of the PE. Specifically, one of the monomers used was not homogeneously distributed in the copolymer. A kinetic study of the polymerization revealed that this monomer is consumed at approximately twice the rate of that of the other species, and this problem was addressed by optimizing the monomer feed method during polymerization.

It was found that the M70 PE was not an exact ‘drop-in’ for the process previously used to produce M43 membranes. Therefore the blend formulation parameters were systematically explored to generate membranes with intimately-mixed PE and PVDF components (Figure 3). The new M70 membrane shows very impressive conductivity at 90% RH (>200 mS/cm), but has roughly half of the conductivity of NR-211 at 50% RH. MEA results of lab-produced membranes show that M70 has comparable beginning-of-life performance to PFSA membranes at high and moderate RH conditions at 80°C (Figure 4).
Based on these promising results, a pilot-scale campaign of M70 was run to perform more detailed studies of its properties, including beginning of life performance, open circuit voltage durability, and RH cycling. Early in the fourth quarter of 2009 we produced kg-scale quantities of M70 PE, which unfortunately produced severe defects in the lab-cast membrane made to qualify the material. After a careful analysis of the materials tested, we traced the problem back to two parameters associated with the polymerization. These parameters were adjusted to make a second kg-scale batch that has not produced any substantial amount of defects. A pilot production run of this material was conducted in May 2010 and is currently under evaluation.

As an alternative to the PE materials generated in-house, polyether-sulfone copolyelectrolytes (bisphenolsulfone [BPS]-type) have remained interesting due to their extreme thermal stability. BPS materials containing higher sulfonic acid contents (BPS-100) with and without crosslinkable endgroup functionality have been investigated in PVDF-blend membranes for conductivity under varying RH conditions. As these materials have vastly different chemical structures from those used in M43 and M70, reoptimization of blending parameters has been necessary. It was found that intimately-mixed blends of PVDF and BPS-100 without crosslinkable endgroups could be produced under the proper conditions. However, these materials showed a significant amount of PE leaching during processing and operation due to the lack of crosslinking in the BPS-100 materials. To address the polyelectrolyte leaching, Prof. McGrath’s group at Virginia Tech has provided BPS-100 materials bearing amine or alkyne end-group functionality to crosslink the BPS. We have investigated the blending of these materials as well as the concurrent crosslinking during membrane production on the laboratory-scale. We have seen success in reducing the amount of leaching observed using these materials but the conductivities of the membranes are not as high as M70 (Figure 2).

**Conclusions and Future Directions**

- Evaluated and addressed blending and defect problems in M70 materials.
- Completed successful pilot casting campaign of M70 membrane.
- Confirmed order-of-magnitude increase in conductivity of M70 versus M43.
- Confirmed improved in situ MEA performance under low RH conditions of M70 vs. M43.
- Evaluated and successfully blended BPS-100 materials.
  - Continuing testing of pilot-produced M70 membranes.
  - Continuing process development toward commercialization of M70 membranes.

- Wiley Youngs, University of Akron, Akron, OH

Project Start Date: January 15, 2006  
Project End Date: January 14, 2011

Objectives

The project objective is to make new proton-conducting solid polymer electrolyte membrane (PEM) materials with the following properties:
- High proton conductance at high temperature (-40 to up to 120°C) and up to 50% relative humidity (RH).
- Effectively no co-transport of molecular species with proton.
- Reduction of fuel cell overvoltage.
- Durable, good mechanical strength and stability.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Program Plan:

(A) Durability
(C) Performance

Technical Targets

The DOE goal is to make a stable electrolyte membrane that has a proton conductivity greater than 0.1 Siemens centimeter-1 at 120°C when supplied gases with low 25 to 50% RH and greater than 0.01 at -20°C.

Accomplishments

The DOE targets and summary of the major works and accomplishments in 2009 and 2010 for achieving the DOE technical targets are summarized in Table 1.

**TABLE 1.** Progress towards Meeting Technical Targets for Making a Proton-Conducting High Temperature Polymer Electrolyte Membrane

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
</table>
| **DOE Targets** | Make a membrane with conductivity of 0.1 S/cm at 0 to 50% RH over the full range of temperature (-40 to 120°C).  
Determine and report best membrane conductivity by February 2009.  
| **Current Year Summary** | Liquid and polymeric high temperature proton-conducting protic salt membranes were made and tested for conductivity and stability in fuel cell conditions, namely:  
(i) Seven new stable fluorinated protic ionic liquids (pILs).  
(ii) Protic ionic membranes (pIMs) with non-leachable salt moieties.  
Selected new inorganic indium tin phosphate (ITP) membranes were sent to Scribner and Bekktech for validation of conductivity at various temperatures and relative humidities. |
| **Accomplishments February 2009** | A neat ITP membrane [1] was made that has conductivity of 0.16 S/cm from 25°C to greater than 120°C and 0% RH.  
Crossover in pure ITP membrane was eliminated by blending 70 wt% ITP with 30 wt% of a proton-conducting organic polymer, polyvinyl pyridinium phosphate (PVPP) [2], but at a cost of reduced conductivity. |
| **Accomplishments 2010** | Improved synthesis and processing of ITP and organic polymer blended membranes. Mixing of reagents during heating was found to be critical for reproducibly making ITP.  
Membrane samples were sent to Scribner and Bekktech for conductivity testing |
Scribner and Associates checked the conductivity of an indium tin phosphate (In$_{0.1}$Sn$_{0.9}$P$_2$O$_7$ or ITP) sample that was 1.23 mm thick x 12 mm diameter. This sample was tested using electrochemical impedance spectroscopy (EIS) in a H$_2$ atmosphere at 30, 80, and 120°C from 20 to 95% RH and the result are shown in Figure 1. The conductivity was evaluated from the impedance data using an equivalent circuit model and the ITP data taken at 80°C, 70% RH with this model gives a membrane resistance of 0.754 ohm, which corresponds to a conductivity of ~1.40 mS/cm. The conductivity was found by Scribner to decrease when the temperature was raised to 120°C, which was unexpected, because for tests done at Arizona, the conductivity increased smoothly with increasing temperature from room temperature up to 250°C.

**Introduction**

A membrane that has high proton conductance at temperatures up to 120°C without the need for water would allow for a more efficient and compact PEM fuel cell. Presently PEM fuel cell electrolyte membranes need water as an ionizing solvent which results in three consequences: 1) operation below 80°C and complex humidifiers to maintain solvent water, 2) large radiators to reject waste heat, and 3) lower performance of platinum catalysts. At high potentials in the presence of solvent water, platinum oxides form that inhibit air-cathode activity, so that fuel cell efficiency drops from the theoretical 95% to no higher than ~65%. These three consequences of using water present barriers to the use of fuel cells as power sources. This project aims to make a membrane with anhydrous proton-containing salts to conduct proton from -40 to 120°C and to study the fundamental mechanism of proton conduction in these salt membranes. Our team discovered that neat pIL electrolytes and crystalline solid versions have high proton conductivities from ambient temperatures to over 200°C. A pIL forms when a proton is transferred from a Brönsted acid to a Brönsted base. The high proton conductivity of a protic salt evidently results from: i) the rotational freedom of the nearly symmetrical constituent ions and, from ii) having an optimal difference in pKa of the constituent acid and base.

**Approach**

The approach has two parts: 1) synthesis of pILs and solid membranes and 2) characterization of the membranes for conductivity, stability, and elucidation of the proton conduction mechanism.

Proton-conducting PEMs are being made based on concepts developed with pILs. The pILs are used to model membranes to help select acid and base moieties. Polymer backbones, acids and bases have been varied to optimize PEM proton conduction, stability, and other properties. Liquid and solid membrane salt-electrolytes are characterized for proton conductivity by EIS and for stability by thermal gravimetric analysis (TGA) and by monitoring fuel cell performance in time. The mechanism of the transport of protons, anions, and molecules in pILs and protic ionic membranes (pIMs) is being investigated by: 1) pulse field gradient nuclear magnetic resonance (NMR) to measure the diffusivity of ions in liquid and solid states, 2) multipulse solid-state NMR to measure the molecular motions and interactions of species in solid membranes, and 3) electrochemical NMR to measure distribution of species during proton conduction in solid membranes.

**Results**

The preparation and processing of the ceramic (ITP) membranes [1] were further developed so that these high-performance advanced materials can be made reproducibly. These ITP ceramic materials and blends with organic polymers, like PVPP [2] and polyphosphazenes (PPhz) have shown proton conductivities in excess of 0.1 S/cm.

**Preparation and Performance of ITP**

A mass of indium oxide (0.5027 g), tin oxide (4.8933 g) and aqueous phosphoric acid reagents (85%, 12.1685 g) were mixed in a ceramic crucible while stirring at 500°C for approximately 1 hour and then calcined in the crucible (uncovered) at 650°C for 2.5 hours. The calcined material was ground in a mortar and pestle and then cold pressed at 6,000 lbs for 1 minute to form a pellet membrane. The pellet was heated at 200°C for 1 hour. Each side of the membrane
pellet surfaces was coated with a 20 nm thick Pt layer by direct current sputtering. The ITP membrane was then characterized for proton conductivity as shown in Figure 2.

Recently a new inorganic/organic composite was made using 90 wt% ITP with 10 wt% of organic binder PVPP. The conductivity is shown in Figure 3.

This 90% ITP and 10% PVPP blend showed over an order of magnitude greater conductivity than 70% ITP and 30% PVPP shown last year.

**pILs**

In addition to the work on ITP, a number of fluorinated and heterocycle rich pILs were synthesized including: 2-fluoro-pyridinium triflate (2-FPTf), 2,6-difluoro pyridinium triflate (2,6–dFPTf), 2-fluoro-pyridinium trifluoromethyl sulfonimidate (2-FPTfSi), 2-fluoro-pyridinium trifluoromethyl sulfonimidide (2-FPTfSi), 1,2,5 triazole fluoroborate (1,2,5-tABF4), 1,2,4 triazole fluoroborate (1,2,4-tABF4), and guanadinium thiocyanate (GdSCN). These neat liquid salts had conductivity comparable to liquid aqueous electrolytes and were characterized in Walden plots (conductivity versus fluidity at different temperatures). Two of these, 2-fluoro-pyridinium triflate and guanadinium thiocyanate, displayed super protonic conductivity, that is, their proton conductivity increased with temperature more rapidly than their fluidity (inverse of viscosity) and both 2-FPTf and GdSCN showed proton conductivity >0.1 S/cm at 120°C and 0% RH. These two salts are recommended as the pendant groups in polymers for making a PEM with high conductivity with no need for hydration.

Non-platinum metals can be used for catalyzing oxygen electroreduction in these anhydrous proton conducting salts. In particular palladium and tungsten appeared good candidates as they had comparable oxygen reduction overpotentials as Pt as indicated by preliminary voltammetry experiments.

**Conclusions and Future Directions**

**Conclusions**

- Fiscal Year (FY) 2009: Protic liquid and solid salt electrolytes give “dry” proton-conducting membranes with conductivities found at Arizona to be ≥ 0.1 S/cm at 120°C and 0% RH but not confirmed at Bekktech or Scribner to date.
- FY 2010: Non-aqueous electrolytes could enable use of non-Pt catalysts.
- FY 2009–FY 2010: Inorganic/organic polymer blends of dry proton conductors give non-porous proton-conducting membrane for simplified fuel cell operation in more compact system (no humidifier and smaller radiator).
Future Directions

- Make and test proton conductivity and fuel cell behavior for membranes based on:
  - ITP
  - blends of ITP and organic polymers
- Send to Bekktech for confirmation of conductivity found at Arizona State University.
- Correlate NMR and conductivity measurements.
- Study voltammetry of Pt on a solid salt (ITP) membrane electrolyte to find electrochemical active area of Pt in a salt membrane electrode assembly (MEA) and compare to the Pt area in a well-engineered MEA. Normalize performance in terms of electrode area for fair comparison of these two systems.
- Interpret voltammetry of Pt on ITP for Pt-oxide. If Pt-oxide free, consider inspection by X-ray irradiation to confirm if Pt stays metallic at high potential (1.2 V) or not. This X-ray work would be done with Dr. Deborah Myers at the Advanced Photon Source at Argonne National Laboratory.
- Optimize membranes from inorganic (ITP) and organic polymer blends:
  - Synthesis of ceramic/organic membranes of ITP and organic polymers (such as polyphosphazene triazoles with various immobilized salts).
  - Process ITP/polymer blend membranes for higher conductivity, flexibility, and toughness.
  - Test the ITP membrane conductivity as a function of humidification of gases and test samples after exposure to water (to probe for conductivity/performance changes if any free ions are removed).

• Argonne National Laboratory, Argonne (ANL), IL (V. Stamenkovic, Dennis van der Vliet, Nenad Markovic)
• Jet Propulsion Laboratory (JPL), Pasadena, CA (Charles Hays, S.R. Narayanan)

Project Start Date:  April 1, 2007
Projected End Date:  March 31, 2011

Objectives

The objectives of this project are development of a durable, low cost (both Pt group metal [PGM] content and manufacturability), high performance cathode electrode (catalyst and support), which is fully integrated into a proton exchange membrane electrode assembly (MEA) characterized by:

• total PGM loading per MEA of ≤0.25 mg/cm²,
• short-stack specific power density of ≤0.3 g/kW at rated power,
• durability sufficient to operate at >80°C for 2,000 hours, ≤80°C for 5,000 hours, with cycling for transportation applications,
• high prospects for 40,000 hours durability under operating conditions for stationary applications, and
• high-volume manufacturability.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan (FCT MYRDDP):
(A) Durability
(B) Cost
(C) Performance
(D) Water Transport within the Stack

Technical Targets

This project is focused on improving the performance and durability of the 3M nanostructured thin film (NSTF) roll-good fabricated electrocatalysts and MEAs. Table 1 compares the NSTF current 2nd quarter, calendar year (CY) 2010 status with DOE electrocatalyst targets for 2010/2015 from Table 3.4.12 of the FCT MYRDDP. Additional rows were added to summarize recent accelerated durability test results. Unless noted otherwise, all metrics were obtained with the 2009 NSTF “best of class” catalyst-coated membrane (CCM) containing 0.10 mg-Pt/cm² on the cathode and 0.05 mg-Pt/cm² on the anode using a PtCoMn alloy catalyst. The MEAs used for the inverse specific power density values listed in the first row, PGM total content, had loadings of 0.05/0.10 mgPt/cm² on the anode and cathode respectively. The short stack results were obtained outside the project but evaluated catalysts and gas diffusion layer (GDL) developed within the project.

Accomplishments

Water Management for Cool/Wet Operation (Task 5.2)

• Demonstrated new paradigm for water management of thin layer electrodes based on sub-atmospheric anode pressure and high liquid water permeability anode GDLs that: a) enables steady-state current density up to 2.0 A/cm² at 30 to 35°C with NSTF MEAs in 50 cm² single cells, and b) 5 second 0 -1 A/cm² load transients at 50°C and 140% relative humidity (RH).
• Demonstrated hybrid MEA with gradient cathode catalyst construction that enables steady-state 1 A/cm² at 30°C, successful load transient 0 -1 A/cm² step at 40°C, 140% RH, and which does not reduce performance at 80°C over the standard NSTF CCM.

Catalyst Activity and Understanding (Task 1)

- Increased PtCoMn mass activity 30% to 0.24 A/mg and demonstrated Pt₃Ni₇ alloy with mass activity of 0.40 A/mg and absolute activity at 900 mV of 40 mA/cm² with 0.1 mg/cm².
- Developed a post-fabrication treatment process that is roll-good compatible and increases oxygen reduction reaction (ORR) mass activity up to 50% for as-made PtCoMn and Pt₃Ni₇ alloys.
- Made catalyst deposition process improvement that gives NSTF pure Pt performance equal to PtCoMn with much greater Pt face centered cubic (hkl) grain sizes.

Catalyst and MEA Durability (Task 2)

- Demonstrated MEA load cycling lifetime of >6,500 hours with 0.05/0.10 mg/cm² loaded 20 µm membrane having no reinforcement.
- Demonstrated that with chemical stabilizers in the membrane, the 500 hour DOE target for open circuit voltage (OCV) hold under H₂/air is exceeded by a factor of 2X for anode/cathode loadings of 0.05/0.15 mg_Pt/cm² respectively.

Large Area Short Stack Test Durability Testing (Task 3)

- Initiated large area short stack testing with Nuvera Inc. to evaluate for the first time, the combination of the 3M NSTF electrode technology with the Nuvera open flow field bi-polar plate technology. Three short stacks were built and initiated beginning of life testing.

Membrane-Electrode Integration and CCM scale-up (Task 5.1)

- Produced 37,000 linear ft combined of NSTF substrate, coated catalyst supports, and CCM for process development, qualification and customer use.

Break-In Conditioning (Task 6)

- Developed more user friendly MEA conditioning protocols that can provide 90% of full performance in 2 to 5 hours depending on the material set.

Introduction

State-of-the-art proton exchange membrane (PEM) fuel cell electrocatalyst technology utilized in today’s prototype fuel cell vehicles reveals limitations with respect to general durability and robustness under start-stop cycling, adequate performance with low PGM loadings, and low-cost manufacturability. To a large degree, these deficiencies are traceable to properties of the conventional carbon supported dispersed Pt catalysts in use today. The research and development of this contract are focused on overcoming these three
most critical barriers for fuel cell MEA automotive deployment by using an alternative catalyst support and deposition method.

**Approach**

The approach to achieve the above objectives builds on a 13-year DOE/3M funded development of the 3M NSTF catalyst and MEA technology. The NSTF catalyst fundamentally has higher specific activity for oxygen reduction [1,2], removes all durability issues with carbon supports, demonstrates much lower losses due to Pt dissolution and membrane chemical attack [3-6], and has significant high-volume all-dry roll-good manufacturing advantages [7].

The scope of work in the three-year initial budget period included extensive work at 3M to increase the NSTF catalyst support film surface area, fabrication and screening of new alloys in 50 cm² single cells, and evaluation of multiple deposition parameters to obtain increased catalyst surface area and utilization. Complementary to this work at 3M, collaborative work included high throughput fabrication and characterization of new multi-element Pt alloys (ternaries and quaternaries) with Dalhousie University, fundamental catalyst characterization studies with ANL, and development and evaluation of a pseudo-rotating disk electrode catalyst evaluation technique with JPL. Research during this third year has focused on: a) water management improvements for cool/wet operation through optimization of materials, electrode structure and operating conditions; b) continued investigation of multiple strategies for increasing NSTF support surface area, catalyst activity and durability with total loadings of ≤0.25 mg-Pt/cm² per MEA; c) continued fundamental studies of the NSTF catalyst activity for ORR in general and methods to achieve the entitlement activity for NSTF catalysts; d) more severe accelerated testing to benchmark the NSTF-MEA durability; e) development of faster, easier MEA break-in conditioning protocols; and f) work with system integrators to validate NSTF functional properties and issues in short stacks.

**Results**

The technical accomplishments for the third year fall into five areas of research and development corresponding to Project Tasks 1, 2, 3, 5 and 6. We briefly summarize the main results from each of these areas.

**Task 1**

Work under Task 1 had three primary areas of focus this year. The first and largest effort investigated a specific PtNi alloy in greater depth. At the end of 2008 and early 2009 we were investigating a broader compositional range for various PtM and PtMN alloys, when we noticed that for PtNi binaries, there appeared to be a significant and sharply defined increase in ORR activity around 70 at% Ni as best determined using thin film gravimetric methods. This year we fabricated many more samples over a broad range of composition with sufficient resolution to try to better reveal the peak width and composition. Although most accurate, the gravimetric measurement of the Pt/Ni content has only ±5% precision so higher precision X-ray fluorescence (XRF) and electron microprobe (EMP) were also used. Both show that there is indeed a finite peak width, although it is very narrow, with the mass activities approaching 0.4 A/mg. The results for mass activity vs at% Ni by EMP is shown in Figure 1(a). The peak position by EMP occurs at 60 at% Ni. By XRF the peak appears to be at about 75% Ni [8]. Since the more accurate gravimetric peak is at 69% Ni, we are calling this a PtₓNi₇ alloy composition. Once we saw this strong compositional effect with PtNi, we then investigated PtCo over a similar range of compositions, and although it also shows a sharp peak, it is not as dramatic as that for PtNi.

Figure 1(b) compares the mass activity as a function of Pt loading of the PtₓNi₇ with our more standard PtCoMn composition. Specific activity and absolute activity for ORR of the PtₓNi₇ and PtCoMn are shown in reference [8]. Increases in both specific activity and surface area of the PtₓNi₇ contribute to its higher mass activity. There is also a process affect in the catalyst deposition that has a significant effect on the PtₓNi₇ activity as indicated by the process A or process B labeled data points. The PtₓNi₇ alloy by process A was made on full-scale roll-good manufacturing equipment, while process B was lab-based and limited to 50 cm² areas.

The second focus area under Task 1 was development of a surface energetic treatment for treating the catalyst to effectively anneal it. It is roll-good compatible so it can eventually be done as the catalyst is made. Many process parameter values were studied and slide 10 of reference [8] shows examples of how mass activity and surface area of the PtₓNi₇ alloy made by process A and our standard PtCoMn are affected by these process parameter values. Compared to the untreated values, the activity of both catalyst types are increased by about 50% for the most effective treatment parameter values. The red stars data in Figure 1(b) are the activities from the process A-made PtₓNi₇ after the surface energetic treatment with the most effective treatment parameter. The surface energetic treatment has further increased the PtₓNi₇ activity made by process A to be similar to that of the PtₓNi₇ made by process B. The mass activity values are now even closer to the targets. Figure 1(c) is a summary plot of absolute activity versus mass activity, updated from last year’s report, for a variety of alloys we have made and
characterized in the past year. Compared to last year, we have now many more candidates closer to this DOE electrocatalyst target.

The Pt$_{1-x}$Ni$_x$ alloy is a unique model system, but not a practical catalyst yet. The as-made composition is not stable and quickly de-alloys in situ in the working fuel cell, giving the resultant state of high activity. Although the higher mass activity translates into higher $\mathrm{H}_2/\mathrm{air}$ polarization curve kinetics [8], due to the excess Ni diffusing into the PEM that in turn affects cathode to anode water transport, there are severe performance limitation above 1 $\mathrm{A/cm^2}$ from mass transport overpotential increases [8].

The final focus area under Task 1 was to revisit pure Pt with NSTF catalyst deposition process improvements in our manufacturing facility. Most notably the Pt(111) grain sizes of the Pt made by the improved process are substantially higher (8.5 nm at 0.1 mg/cm$^2$) than those made by the standard process conditions, or those of our standard PtCoMn (5 nm at 0.1 mg/cm$^2$) [8]. The polarization curves are very similar to those from our PtCoMn with nearly the same loading. There appears to be about a 10 mV improvement in the polarization curve of the pure Pt by the new process conditions versus the standard. The impact on durability of the larger grain size of the pure Pt made by the improved process is still being determined. We will be extending these process improvements to the Pt alloys in the future.

Task 2

Our work under the second area (Task 2) continued this year to focus on three types of accelerated durability tests using the 2009 ‘best of class’ NSTF MEA having 0.15 mgPt/cm$^2$ of total loading but with a thinner membrane and MEA modifications of the latter. These three tests are load cycling, high voltage cycling and OCV hold. Figure 2(a) is an update of the load cycling tests under 80°C that we have shown results from in previous years. Cell voltages at various current densities are measured versus time under an 80°C cell temperature, 64°C dew point, constant flow of gases to keep the membrane hydrated, and current densities are measured versus time under an 80°C cell temperature, 64°C dew point, constant flow of gases to keep the membrane hydrated, and OCVs (measured daily) are used to determine end of life in this test (<0.8 V). At the end of last year we had obtained ~5,000 hr lifetimes with the 2009 best of class NSTF CCM with the 0.05/0.10 mg/cm$^2$ Pt loadings on a 3M 850 equivalent weight PEM that did not contain any chemical stabilizer or mechanical reinforcement (blue crosshatched bars in Figure 2(a)). The set of black crosshatched bar graphs on the right side of Figure 2(a) are new results this year, and show that MEAs with our 2009 best of class CCM, with 0.05/0.1 loadings and a 20 micron 3M PEM with a chemical stabilizer, but still no reinforcement, have survived 6,500 hours without failure and are still going strong.
Cumulative results from the second type of durability test, OCV hold at 90°C under H₂/air at 22.1/14.7 psig, 30%/30% RH, 22.1/14.7 psig. GDLs were constant, only the membranes and catalyst loadings were varied.

Under this test we have found that chemical additives to the membrane are very important to enable exceeding the OCV hold targets (500 hours). Second, the Pt₃Ni alloy at the same 0.1 mg/cm² Pt loading on the cathode is slightly better than the standard PtCoMn (698±184 vs. 610±40 hrs.). Finally, higher loading helps to improve lifetime (1,145±195 hrs. for 0.1/0.15 mg/cm² vs. 610±40 hours for 0.05/0.10 mg/cm²) as does a thicker membrane. A number of combinations can exceed the new 500-hour targets for this test.

The third type of durability testing under Task 2 was testing of catalyst stability under high voltage cycling to simulate start-up and shut-down. The cathode under N₂ is cycled (relative to the anode under H₂) 4,000 times between 0.6 and 1.2 V at 20 mV/sec at 95°C and 100% inlet RH. Slide 15 of reference [8] summarizes results with both the low loading standard PtCoMn and the Pt₃Ni, under more severe conditions than we have reported previously. For this test we cycle from 0.6 to 1.2 V at 95°C and saturated inlets. Nine samples were tested with varying catalyst and membrane lots, and test cells. A key result was that the amount of surface area loss after 4,000 cycles depended on how the catalyst and CCM were made. The roll-good manufactured CCMs fared better than hand-laminated CCMs, loosing 23% versus 36% surface area respectively. Fuel cell polarization curves before and after cycling for the manufactured versus hand-made MEAs show the performance loss mirrors the surface area loss, with the manufactured MEA loosing less performance. A second key result is that the relative performance loss of the Pt₃Ni alloy, also at 0.1 mg/cm² loading of Pt, is less than the standard Pt₆₈(CoMn)₃₂. It doesn’t start with as high of performance above 1 A/cm², but after the 4,000 cycles, the Pt₃Ni, performance is similar or slightly better than the PtCoMn [8].

Task 3

Initiated about the first of this calendar year, Task 3.2 is focused on preliminary large area cell tests for performance and durability prior to starting the final stack testing under Task 5.3. An opportunity to combine the uniqueness of the 3M NSTF electrode technology with the Nuvera open flow field plate technology approach motivated going directly into full size area short stack testing of both the 2008 (0.1/0.15 mg/cm² loaded NSTF) and the 2009 (0.05/0.1 mg/cm² loaded) MEAs in 8 and 16 cell stacks at both 3M and Nuvera with the Nuvera Andromeda stack design. After just six months we are still investigating the best operating conditions to use (e.g. lower pressure and drier) and learning to marry the materials and the hardware. However fit and function went very smoothly, there does not seem to be contamination issues to any significant degree based on 3,000 hours of assembled shelf time and occasional operation. We have verified that there is a large opportunity to improve the performance by reducing the in-cell impedance that is roughly 50% larger than we expect based on single cell 50 cm² cells. Slides 16 and 41 in reference [8] compare the single cell 50 cm² test results with the first 16 cell stack tested at 3M and very preliminary 8 cell short stack performance at Nuvera. The average stack performances are roughly 75 mV below the single cell out to 2 A/cm², while the best cell performance of the 16 cell stack reduces this to about 50 mV.
Task 5

Task 5 embodies all work done under catalyst/membrane integration and scale up (Task 5.1) and GDL integration and water management (Task 5.2). Task 5.2 and the area of water management was our primary focus area for the year and the one with the most significant results. The NSTF electrodes are submicron in thickness and this leads to cathode flooding under cool/wet conditions if conventional water management approaches are used. This year we made significant changes in both material factors and operating conditions to demonstrate two independent paths to solve this cathode flooding issue.

Water Management – Path 1

For the first path, based on use of sub-atmospheric anode pressure, we changed the paradigm for conventional MEA water management by removing cathode product water (liquid and vapor) out the anode instead of the cathode. This is possible with the hydrophilic ultra-thin NSTF catalyst electrode layers because they are in intimate contact with the membrane, and have high permeability for liquid water. Key material parameters to enable this include removing the hydrophobic microporous layer (MPL) from the anode GDL, use of a thinner membrane, use of anode GDL backing layers with adequate liquid water permeability and thickness, use of higher cathode pressure than anode pressure, and most effective, use of subatmospheric anode pressure. Low temperature operation is critical for rapid stack start-up from temperatures below 60°C. Figure 3(a) shows steady-state current density at 0.4 volts versus absolute anode pressure at 30°C for various combinations of anode GDL, all with no MPL except the baseline GDL (open squares). The anode absolute pressure is seen to be a very effective boundary condition for reducing cathode flooding. The Freudenberg GDL backing layers are much more effective than the baseline Mitsubishi Rayon Co. (MRC)-type GDL backing layer we had been using, improving the effectiveness of the sub-atmospheric anode pressure significantly. Over the past two-three years we had made simple liquid water permeability measurements for a whole series of difference GDL backing materials, (see slide 18 of reference [8]) and it was on this basis that we started testing the Freudenberg GDL on the anode versus the MRC baseline GDL backing layer since it had a much higher liquid water permeability (6x). The improvement in fuel cell performance is consistent with that property, but since then we have determined that that measured property is not the only factor determining the fuel cell response at 30°C.

Figure 3(b) shows galvanodynamic scan (GDS) polarization curves as a function of 50 cm² cell temperature under 50/150 kPa anode/cathode absolute pressures of H₂/air. The MEA uses the 2009 best-of-class CCM and the as-received Freudenberg GDL backing layer on the anode (no MPL or Teflon® treatment). With the proper anode GDL and reduced anode pressure, it is possible to run the cell stably at 2 A/cm² even at 30°C. The high temperature curve at 80°C and 68°C dew points in Figure 3(b) also shows there is no impact of the anode GDL on standard higher anode pressure/temperature operation. Operating at equal anode/cathode pressures (150 kPa) or higher, the same MEA will flood out at a limiting current of <0.4 A/cm² at 30°C. But if the cathode pressure exceeds sufficiently the anode pressure, then the cell can hit 2 A/cm² even with the anode at atmospheric pressure (Reference [8], slide 19).

Load transient performance under cooler wet conditions is very important for stack operation. We find this is also significantly helped by this new water management strategy. Figure 4(a) shows 0.02 to
1 A/cm² load steps under 60°C and 140% RH, using the same MEA as discussed with Figure 3(b). The impact of the reduced anode pressure greatly improves load transient performance at 140% RH, and for values below 25 kPa, there is no delay in response with the 50 cm² cells. “Steady-state” (>15 seconds after the load step) performance is also improved with reduced anode pressure (+60 mV as anode pressure decreases from 100 kPa to 25 kPa.). Finally we note that reduced anode pressure also assists load transients at 50°C, 140% RH similarly [8]. Since the heat capacity of these single cells is much higher than one would have in a stack, this is a very good indicator that load transient power up in a stack will be improved even further. In summary, this approach of managing cathode flooding under cool/wet conditions by pulling the product water through the CCM and out the anode is very effective for steady state and transient operation.

**Water Management – Path 2**

The second path pursued for resolving the cool-start water management issue involves using a gradient cathode catalyst such as described in reference [9], to more effectively remove water from the cathode in a more conventional manner. This involves a hybrid electrode, consisting of both an NSTF catalyst layer and a lower loading of a conventional Pt/C dispersed catalyst layer. Slides 43-45 of reference [8] show other data relative to this water management approach, and in particular, slides 44 and 45 show an alternative solution which was nearly as effective in which a small amount of additional dispersed Pt/C (< 0.05 mg/cm²) of catalyst layer is added to the cathode electrode outside the NSTF cathode. With the right choice of Pt/C catalyst, this also helps improve the steady state and transient response under cool, wet conditions without loss of high temperature performance. Figure 4(b) shows comparative load transient responses of four hybrid MEAs, each slightly different, with the same test conditions as used for 4(a) except that the anode and cathode pressures are equal at 150 kPa. These hybrid MEAs use NSTF CCMs with 0.05 mgPt/cm² anode loadings, 0.1 or 0.15 mgPt/cm² cathode loadings, the same PEM type, the as-received Freudenberg GDL discussed above, and 0.05 mg/cm² of a specific Pt/C applied to the cathode GDL. All easily make the 0.02 to 1 A/cm² load step. Such a hybrid MEA shows promise for further extending the high temperature limiting current density as well, with recent results attaining 2.4 A/cm² (at 0.55 V) with only 40 mV of mass transport overpotential below a 70 mV/decade Tafel slope, with 0.2 mg/cm² total per MEA. Further optimization is underway.

**Task 6**

The last area of work focused on improving break-in conditioning of the NSTF MEAs. This activity was incorporated last year as a new Task 6. Significant work prior to the current project had identified many MEA component materials and their processes, and test station protocols that strongly affect the time for break-in conditioning of new MEAs. These include catalyst composition, surface area, fabrication conditions, membrane processing solvents and drying conditions, and GDL types. A thermal cycling protocol with liquid water injection has been used for years to break-in new NSTF MEAs to obtain full performance. The new task focuses on both materials effects and the protocol effects in order to significantly reduce the time and simplify the procedures for conditioning a new MEA. Last year new test station protocol work was successful in reducing the conditioning time with our current test stations from over 24 hours to less than 6 hours. In the current year protocols were developed that both reduced the time...
for reaching full power and were more stack friendly to implement. (Our standard protocol we call thermal cycling, requires at least 24 hours and the use of liquid water to flood the cells during the cool down periods.) Since this task started last year, over 40 new protocols were investigated. Slide 20 in reference [8] shows a recent fast conditioning protocol that produces nearly the same performance break-in as the standard thermal cycling, but requires 4-5 hours and operates with completely dry input gases. The same slide also shows a graph demonstrating a material effect, that is the Pt3Ni7 alloy conditions faster than our standard PtCoMn with the standard thermal cycling protocol.

Conclusions and Future Directions

This project has met or exceeded the currently specified DOE electrocatalyst and MEA performance and durability targets for 2015 using the same MEA component set in 50 cm2 cell tests. Furthermore, the NSTF catalyst based MEAs used outside this project in original equipment manufacturer 400 cm2 (>20 cell) short stacks have generated specific power densities of <0.2 gPt/kW, successful 10°C cold and -20°C freeze-start [8], and lifetimes of 2,000 hours under various automotive system relevant cycling. Significant improvements in ORR activity with new alloys and processing methods were demonstrated and further improvements are anticipated. Probably the most significant advances this past year were understanding and improving major water management issues associated with the ultra-thin NSTF electrodes. Future work will be strongly focused on down-selecting and incorporating these advanced components into a robust, durable, high-performance, roll-good manufactured MEA containing no more than 0.2 mg/cm2 of PGM total for the final stack testing-deliverable. Specific future directions include:

Water Management Improvement

- Continue to combine the improvement factors now identified that significantly enhance cool operation and load transient start-up; determine best synergistic combinations towards the 2010 best of class MEA for final stack testing.

Cathode Catalyst Mass Activity Gain

- Down-select the final catalyst and configuration to be scaled up for the final stack testing.
- Optimize fabrication processes for the down-selected catalyst.

MEA Integration

- Down-select the final 2010 best-of-class MEA (catalysts for each electrode, processes, etc.) under Task 5, for final stack testing.

Stack testing

- Continue Task 3 short stack evaluations with 2009 best-of-class MEA, upgrading to 2010 best of class MEA.
- Identify original equipment manufacturer stack for final stack testing under Subtask 5.3.

Start-up conditioning and reversible stability

- Continue to develop simplified break-in conditioning protocols and catalyst/membrane components to reduce MEA break-in conditioning time to <3 hours for full performance.

• Texas A&M University, College Station, TX
• Brookhaven National Laboratory, Upton, NY

Project Start Date: May 1, 2007
Project End Date: October 31, 2010

Objectives

• Develop structurally and compositionally advanced supported alloy catalyst system with loading ≤0.3 mg platinum group metal (PGM)/cm².
• Optimize catalyst performance and decay parameters through quantitative models.
• Demonstrate 5,000 cyclic hours below 80°C with less than 40% loss of electrochemical surface area and catalyst mass activity.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (section 3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:
(A) Durability
(B) Cost
(C) Performance

* Durability data measured after 30,000 cycles under UTC Power-defined accelerated test protocol.
† Based on current scaled-up 30% Pt₂IrCr MEA; anode/cathode loading – 0.1/0.3 mg/cm² (PGM).
† Five year average PGM price $51.55/g (Pt = $1234.33/troy oz; Ir = $369.06/troy oz); costs not projected to high volume production.

Accomplishments

• Down-selected a carbon (C4) that exceeds DOE’s corrosion targets and verified a 30% Pt/C4 and a more active PtIrCo/C4 alloy catalyst in a subscale fuel cell which showed that PtIrM/C4 are more active and durable compared to the Pt/C4. Scale up of a 30% Pt₂IrCr alloy on C4 is in progress.
• Completed the scale up of both down-selected dispersed catalysts PtIrCr and PtIrCo for MEA optimization. Currently testing performance and durability of first trial full size MEA of 30% Pt₂IrCr/C.
• Modeling results show that Ir in the dispersed PtIrM (M=Co or Cr) ternary alloy catalysts imparts stability to the surface Pt atoms. The benefit of Ir in PtIrM alloy catalysts was evaluated and compared to PtM alloys.
Sub-scale MEA catalyst layer optimization was completed to improve the ternary alloy MEA performance in H₂/air at high current densities with total PGM loading of 0.3 mg/cm².

Correlation between segregation energies, activity and stability of core-shell catalysts based on their composition and surface characterization during potential cycling explains differences in the surface activity during core metal dissolution and the durability of core-shell catalysts.

Activity and stability of Pt₅₆/Pd₃Co core-shell catalysts prepared using scalable chemistries were evaluated using both rotating disk electrode (RDE) and sub-scale fuel cell tests.

**Introduction**

It is well known that, in order for the proton exchange membrane fuel cell (PEMFC) technology to become commercially viable, the production cost of the components in a fuel cell must be reduced and, more importantly, the durability of the MEA must be improved. This project focuses on two distinct approaches to the DOE 2010 durability and performance targets. The first approach is the development of somewhat conventional but high performance highly dispersed Pt alloy catalyst on a carbon support. The second system utilizes a novel “Pt monolayer (ML) core-shell” approach capable of achieving very high Pt mass activities [1-3]. Under this latter concept, the main objectives are to improve the durability of the cathode catalyst by further optimizing the core material selection, shell thickness of the ML, and the particle size of the cores and to develop scalable fabrication methods.

**Approach**

To achieve the objectives on this project, UTC Power (UTCP) has teamed with Brookhaven National Laboratory (BNL), Texas A&M University (TAMU) and Johnson Matthey Fuel Cells (JMFC). The research focus and the role of all partners were reported previously [4]. BNL’s role on the project focuses on the development of Pt ML “core-shell” systems on various cores including ideal surfaces such as single crystals. In addition, BNL leads our efforts to understand the effect of electronic properties, crystal structure and particle size on activity and durability of this class of electrocatalysts. TAMU focuses on development of computational atomistic models to study parameters that influence the activity and durability of core shell and dispersed catalyst systems. The overall scope of JMFC activities in the project encompasses development of (i) dispersed Pt alloy catalysts including scale up on conventional and advanced carbon supports, (ii) novel synthesis methodologies to scale up Pt ML core-shell catalysts and (iii) MEA optimization and fabrication. Apart from overall project management, UTCP primarily focuses on the development of advanced dispersed Pt-based binary and ternary alloy catalysts. UTCP activities also include modeling support for MEA optimization, carbon support corrosion studies, fuel cell testing on single-cell level and fabrication and test of a 20-cell short stack for verification.

**Molecular Modeling**

The main topic that was studied this year was calculation of activity and stability of PtIrM ternary alloys based on surface segregation, Bader charge, d-band center analysis of Pt and potential shifts in the dissolution potential for Pt in these alloys. It was previously reported that, in Pt₅₆ binary alloys, electronically the Pt atoms on skin surfaces differ little from those on the non-segregated alloy surface [4]. In contrast, incorporating Ir into the bimetallic alloy increases the tendency of Pt-skin formation and enhances the stability of the alloy systems. Since Ir has a smaller atomic volume and higher surface energy than Pt, a much stronger Pt segregation trend is expected in the ternary PtIrM alloy system. The calculated segregation energies (in vacuum) of -2.90 eV for Pt₅₆IrCr, -2.10 eV for Pt₅₆IrCo, and -1.60 eV for Pt₅₆IrCo₇ suggests that the presence of Ir reduces the lattice mismatch between Pt-Co and favors the formation of a Pt monolayer skin surface. However, the trend to form Pt-skin in PtIrCr alloys is lower compared with the corresponding PtIrCo alloy surfaces. Bader charge analysis (shown in Table 2) on the Pt-skin surfaces, indicates that Pt surface atoms have an excess of electrons in their valence shell and a deficit of electron charge on the subsurface atoms (Ir, Co and Cr), which suggests a higher oxygen reduction reaction (ORR).

**Table 2.** Average valence charge for surface and subsurface atoms of PtₓIrₗₘ systems.

activity for these alloy catalysts compared to a pure Pt (111).

Ir also induces a larger average d-band center shift for the Pt-skin surfaces on PtIrM compared to PtM. For comparison, the average d-band center shift for Pt-skin on PtIrCo and PtIrCr is -2.23 eV and -2.18 eV respectively. This negative shift is due to the presence of Ir in the subsurface and thereby modifying the electronic structure of the surface Pt atoms. A d-band center shift to more negative values indicates that the Pt-skin surface is less reactive and hence, certain repulsion towards oxygenated species is expected due to the negative charges located on the surface atoms. The calculated d-band centers relative to the Fermi level also show a shift towards lower energies in the alloys as a function of the amount of Ir in the alloy as shown in Figure 1 for PtIrCo alloys.

The electrochemical stability of Pt atoms shown in Table 3 indicates that the Pt atoms are more stable on the alloy surfaces than on pure Pt (111) surfaces as shown by the positive shift in potentials on surfaces covered with 1/8 ML of O. The maximum values found for an intermediate amount of Ir suggests that further lowering the amounts of Ir in the alloy compositions may result in less stable surfaces due to the large lattice mismatch between Pt and transition metal atoms [5].

In the core-shell catalyst concept, the activity and stability trends of Pt ML on various Pd-containing metal cores such as PdCo, PdCr and PdTi were investigated. Adsorption energies of OH, O and H2O suggest that both Pt/PdCo and Pt/PdCr are more active than a pure Pt although the Pt/PdCo shows the weakest adsorption energies. The electrochemical stability investigation of Pd, Co and Cr in these core-shell catalysts shows that Pd, Co and Cr are more stable in the alloy cores than in their pure state and their stability towards leaching follows the order Pd > Co > Cr. Based on these activity and stability results, PtML/Pd3Co is estimated to be a more favorable core-shell system for ORR compared to Pt/Pd3Cr.

### Dispersed Pt Alloy Catalyst

Many factors such as structure, particles dispersion, particle size, type of carbon support used etc., influence the electro-catalytic activity of Pt and Pt alloy nanoparticles. Previously, within this project a 30 wt% Pt2IrCo and a 30% Pt4IrCo3 exhibited an activity almost two times higher than pure Pt based on RDE and MEA testing. The Ir containing ternary alloy catalysts also showed more durability in both their ECA and mass activity (MA) under potential cycling which show much lower loss (~30% ECA and MA) compared to the standard Gore Pt/C which showed ~50% loss. Based on these results the PtIrM ternary alloys were down-selected for further development [4]. In the past year, a significant amount of effort was focused towards scale up of a large size batch (200 g) of the down-selected ternary alloys 30% Pt4IrCo3 and 30% Pt2IrCr, development and optimization of the cathode catalyst layer in an MEA of PtIrM (M= Co, Cr) alloy catalysts to improve the catalyst utilization in an MEA keeping low PGM loading and enabling good performance at high current densities. This involved MEA iterations to identify key parameters such as catalyst ink formulations and ionomer content, to achieve optimum cathode catalyst layer capable of achieving good fuel cell performance operating on not only H2/O2 but also on H2/Air at high current densities.

Figure 2a shows the fuel cell performance curves in H2/Air for an optimized and un-optimized 50% PtIrCr/C MEA in a sub-scale size (25 cm2) solid plate fuel cell operating at 80°C, 100% relative humidity (RH) and 50 kPa backpressure compared to a commercial Gore 5710 Pt/C MEA. It should be noted that the Pt
loading in the commercial MEA is about two times of that of the alloy MEAs used in this project. The internal resistance for the PtIrCr MEA is also higher than the Gore 5710 MEA resistances which arise from differences in the membrane thickness and the catalyst layer fabrication process. The initial MA obtained for the alloy catalyst in the optimized and un-optimized MEA were 0.14 and 0.156 A/mg PGM, respectively compared to a MA of 0.17 A/mg PGM observed for the commercial Pt/C MEA. This observed low activity is attributed to the low utilization of the catalyst in the MEA as seen by their low ECA of ~30 m²/g. However, a clear evidence of improvement for high current density performance in H₂/Air in a solid plate fuel cell is observed from these catalyst layer optimization steps. The 30% PtIrCr ternary alloy MEA optimized for solid-plate fuel cell performance was also verified in a full-size UTC Water Transport Plate (WTP) fuel cell operating at 65°C, 100% RH and 0 kPa backpressure. Figure 2b shows the internal resistance (iR) corrected fuel cell polarization curves obtained in H₂/O₂ for the 30% PtIrCr in the WTP fuel cell. Our results shows clear evidence that lower catalyst loading of 0.2 mgPt/cm² in MEAs can achieve high initial performances, although lower than a commercial Pt/C which has 0.4 mg Pt/cm² in the cathode, in both solid plate and a WTP fuel cell. Our preliminary investigation into MEA fabrication process suggests that different ink formulations can significantly increase both mass transport properties and kinetic performance of alloy catalysts. Further optimization steps are currently being pursued to improve the MEA fabrication process and utilization of the catalyst in the MEA.

Core-Shell Pt Catalysts

The primary focus of core-shell development was (a) to synthesize Pt ML catalysts on Pd₃Co and Ir cores using scalable chemistries without compromising the intrinsic activity of the catalyst as demonstrated by BNL and (b) to incorporate these advanced catalyst concepts in an MEA. Previously, a large batch (30 g) of Pd₃Co and Ir cores and 5g batch Pt ML core-shell catalyst were synthesized successfully by JMFC via a chemical method.

Figure 3 shows the MA based on PGM loading for a scaled-up Pt₃ML/Pd₃Co core-shell catalyst prepared via chemical methods and a pure Pt/C catalyst obtained from RDE and MEA testing. Although the mass activity obtained on the pure Pt/C in an MEA is slightly lower than that obtained from RDE measurements, the Pt₃ML/Pd₃Co core-shell catalyst shows a significant lower activity in an MEA (0.044 A/mg PGM) than from RDE measurements (0.254 A/mg PGM). This is mainly attributed to (a) instability of Pt₃ML/Pd₃Co at 80°C under MEA test conditions and (b) to the incomplete or non-uniform coverage of Pt on the core Pd₃Co particles. Detailed studies of the Pt₃ML/Pd₃Co core-shell catalysts in 1M H₂SO₄ solution at 80°C using electrochemical and physical characterization using inductively coupled plasma shows substantial loss of Co and Pd on exposure to the acid which indicates incomplete coverage of Pt. Efforts are on currently to improve the Pt monolayer coverage by optimizing the catalyst preparation methods.

Durable Carbon Support

The main focus of this task was to explore alternate durable carbons capable of withstanding high voltage spikes relevant for automotive applications. In the past year, several carbon supports from a number of vendors available both commercially and under developmental proprietary agreements were investigated. Based on the ex situ testing of each of these carbon supports at a constant potential hold of 1.4 V in 0.5 M H₂SO₄ at 80°C for 5 hours and further testing in a fuel cell under the DOE 2008 carbon corrosion protocol, an alternate carbon C₄ was down-selected for incorporation of PtIrM ternary alloys into MEAs and demonstration in
a fuel cell. Figure 4a shows the iR-free performance curves at BOL for a 30% Pt/C4 compared to a standard 0.4 mgPt/cm² Gore 5710 Pt/C MEA obtained from 25 cm² WTP fuel cell testing at 80°C, 100% RH under H₂/O₂ at zero backpressure. Although the beginning of life performance for the 0.2 mgPt/cm² Pt/C4 low surface area carbon shows lower performance than that of a standard Gore Pt/C, its performance after the 1.2 V potential hold tests show considerable differences as shown in Figure 4b. The 30% Pt/C4 showed 59 mV loss after the fuel cell corrosion test of a total of 17 potential holds of 24 h each at 1.2 V at 80°C, 100% RH under H₂/O₂ at zero backpressure. All other carbons tested under this test protocol showed significant losses in performance after only 3-5 potential holds. Further, our preliminary sub-scale MEA testing of a 30% Pt₈IrCo₂/C4 under the 2008 DOE carbon corrosion protocol in a WTP cell at 80°C shows higher initial performance corresponding to 2x in MA compared to the Pt/C4. Figure 5 shows the performance curves for the 30% Pt₈IrCo₂/C4 and a 30% Pt/C4 in H₂/O₂ before and after 400 hours of potential hold at 1.2 V which shows that the PtIrCo/C4 is more stable than the Pt/C4 as it shows only ~12 mV loss at 1.5 A/cm² in O₂ after 1.2 V potential holds with negligible iR losses. Efforts to scale up and understand the stability of a 30% Pt₂IrCr alloy on C4 and mechanism for high current density performance loss is currently ongoing.

Conclusions and Future Directions

MAs of ~0.15 A/mg_{PGM} in sub-scale MEA testing have been reproduced and verified for a scaled-up 30% Pt₂IrCr and has been down-selected as the dispersed alloy catalyst system for full-scale fuel cell demonstration. The Pt₂IrCr alloy was chosen, over the PtIrCo alloy, based on the higher durability of Cr over Co in the alloy catalysts under the MEA fabrication process. Key barriers to overcome for the incorporation of the 30% Pt₈IrCr in an MEA are the low catalyst utilization in an MEA and the cathode catalyst layer optimization for high current density performance in a WTP fuel cell and are currently the main focus under this project. A key challenge for the core-shell catalysts is their poor durability in an MEA under operating fuel cell conditions and is an ongoing investigation in the project. All modeling activities under this project are complete and have clearly shown the benefit of Ir and the stability it imparts to the surface Pt atoms in the ternary PtIrM alloys. Also, our computational calculations played a significant role in identifying core materials and shell thickness and in understanding the activity and stability benefits of core-shell catalysts. A carbon support C4 with significant resistance to corrosion (<30 mV loss at 1.5 A/cm², 80°C in H₂/O₂) has been down-selected for further scale up of a 30% Pt₂IrCr alloy catalyst, MEA optimization and durability evaluation in a sub-scale fuel cell.
Future Directions

Our future objective is to demonstrate the durability of a highly active PtIrCr alloy catalyst in an MEA with a durable carbon support capable of withstanding high voltage spikes relevant for automotive applications. Some of the tasks undertaken to achieve these goals are listed below.

- Optimization of dispersed alloy catalyst systems in MEAs is in progress aiming to approach high mass activity and more importantly high current density performance in an operating fuel cell. This is being resolved by investigating:
  - MEA fabrication process to understand the gap between MEA and RDE data.
  - Electrode structure optimization for water-transport-plate cells.

- The fundamental benefit of PtlrM ternary alloys on C4 for activity and durability compared to Pt/C4 is being further investigated based on their particle size, particles dispersion and electronic properties.

- In the case of the core-shell catalysts, preventing dissolution of the core material from the bulk phase of nanoparticles is a major challenge that is being addressed by the development of various scalable methods specifically geared towards achieving uniform Pt coating.

Project Start Date: January, 2007
Project End Date: September, 2011

Objectives

Develop new classes of alternative support materials that meet the 2010 DOE performance targets by achieving the following specific objectives:

• Understand structural and compositional requirements of tungsten carbide (WC) and conductive metal oxides (CMO) for improved activity and durability over standard Pt/C.

• Demonstrate durability and performance advantages of alternative cathode supports such as carbon nanotubes (CNTs) ordered graphitic mesoporous carbon (OGMC) and grapheme.

• Demonstrate durability and performance of non-carbon CMO supports such as indium tin oxide (ITO).

Technical Barriers

This project addresses the following technical barriers from Fuel Cells section (3.4) of the Fuel Cell Technologies Program Multi-Year Research for Fuel Cells, Development and Demonstration Plan:

(A) Durability (of cathode catalyst supports)
(C) Performance (of supported cathode catalyst)

Technical Targets

This project is directed at conducting durability and activity studies of Pt on various supports, with the objective of meeting the DOE life time criteria.

Membrane electrode assembly (MEA) tests are in progress for lead supports, and have shown 2X improvement in stability over baseline vulcan carbon/ XC72 supports (Table 1). Alternative supports such as CNTs have shown no degradation after 100 hours, thus providing a synergistic opportunity for metal oxide modification of CNTs. Rotating disc electrode (RDE) tests have also shown significant improvement in durability over baseline.

ESA – electrochemically active surface area; TBD – to be determined

Accomplishments

• Optimum ITO content in graphene found to maximize activity and durability:
  – Activity and durability are 1.5X and 1.7X of baseline.
  – Pt distributed uniformly at ITO/graphene interface as predicted by density functional theory (DFT) model.

• Demonstrated Pt/CNT stability of >2X over Pt/XC72.
• Demonstrated 2X durability of Pt/OGMC over Pt/XC72.
• Demonstrated 3X durability of Pt/ITO non-carbon support over baseline.
• Obtained consistency between RDE and MEA test results.
• Validated DFT prediction for higher Pt/WC activity and higher Pt/VC stability.

**Introduction**

Conventional cathode catalyst supports are susceptible to corrosion during high potential excursions, high temperature and under start-stop conditions [1]. Hence lack of cathode support durability is a major technical barrier with respect to commercialization of fuel cells for transportation [2]. Oxidation of support leads to detachment of Pt from support, while repeated oxidation and reduction of catalyst leads to dissolution and reprecipitation [3]. The dissolution of platinum is accompanied by penetration of Pt into the membrane or gas diffusion layer, while reprecipitation leads to agglomeration of Pt in the catalyst layer. These lead to an overall decrease in ESA along with non-uniform current density distribution, leading to sintering of Pt catalysts caused by localized heating.

In order to overcome these barriers and meet the DOE technical targets for durability and performance, we have developed new classes of alternative and durable cathode supports, based on modifying the carbon surface conductive metal oxides [4] such as ITO, TiO₂ and SnO₂. Alternate supports such as CNT, graphene sheets were also investigated to take advantage of their superior properties [5,6]. In addition, conductive metal oxides were also used as an alternative to carbon-based supports. The durability and performance have been enhanced due to the following advantages for our cathode supports:

- Formation of a protective barrier between carbon and Pt mitigates carbon corrosion.
- Bonding between Pt and metal oxide substrates enhances the stability of Pt particles.
- More uniform dispersion of Pt, allowing better performance at equivalent loading.
- Higher activity and durability of CNT, OGMC and graphene over XC72 provides potential for an order of magnitude improvement with metal oxide modification.
- DFT modeling indicates stable Pt/ITO/graphene interface.
- Carbon-free metal oxides (ITO) successfully identified as candidates for catalyst support.

**Approach**

New classes of carbon supports modified by CMOs have been developed to improve durability and performance of the cathode catalysts. In order to prevent alloy formation, electrocatalysts were synthesized by the ethylene glycol method [7]. Durability of various carbon supports such as XC72, carbon multi-walled nanotubes (CMWNT, also referred to as CNT in this report), ordered graphitized mesoporous carbon and graphene were compared. DFT modeling was performed to identify potential supports with better oxygen reduction reaction (ORR) activity and stability than Pt-XC72. DFT predictions were validated by experiments.

Carbon supports were modified with WC and various conductive metal oxides such as TiO₂, SnO₂, and ITO. The durability was investigated using an internally developed accelerated test protocol, with voltage stepped from 1.4-0.85 V vs. normal hydrogen electrode (NHE). An investigation of the effect of CMO modification of various supports such as CNT, graphene and OGMC was conducted. MEA tests were performed on various supports with and without metal oxide modification, with the fuel cell held at 1.2 V at 80°C, and measurement of ESA, ORR activity at 0.9 V and polarization curves performed every 20 hours.

**Results**

DFT predictions for high activity of Pt/WC was validated with experiments, while DFT prediction for high Pt/VC stability was also validated with Auger electron spectroscopy (AES). Optimum CMO composition for graphene supported catalyst was found, leading to 50-70% improvement in activity and durability over baseline. DFT modeling predicted a stable Pt/CMO/graphene interface, with Pt nanoparticles in contact with both CMO and graphene, with verification from transmission electron microscopy (TEM) images. Durability for OGMC and CNT-supported catalysts was found to be >2X of baseline. CMO supported catalysts, which were previously shown to be highly durable, have shown rapid improvement in ESA and activity using RDE tests. MEA formulation methods for non-carbon and conductive metal oxide modified supports are currently being optimized. MEA tests were conducted on alternative carbon supports such as CNTs, OGMC and graphene, with tests ongoing on CMO modified graphene and non-carbon supports.

DFT analysis had predicted the superior activity and stability of Pt on WC (0001) and superior stability of Pt on vanadium carbide (VC). In order to verify the activity enhancement of Pt/WC (0001) over Pt, the performance of Pt-WC synthesized by atomic layer deposition (ALD) was determined by cyclic voltammetry (CV), with results corresponding to 30 ALD cycles surpassing Pt foil performance significantly. In order to verify superior stability of Pt on VC in the presence of oxygen, Auger electron spectroscopy was carried out on Pt/V(110) and on Pt/VC before and after exposure.
to 3,000 L oxygen at 300 K. For the former, Pt signal decreased, accompanied by an increase in the V signal, while for Pt/VC, the Pt signal did not decrease upon exposure to oxygen. These results were also confirmed by high resolution electron energy loss spectroscopy (HREELS).

The lead cathode catalysts developed are shown in Figure 1, with Pt/VC as the baseline. CNT and OGMC were found to be very stable supports. TiO₂ modification of Vulcan carbon improved both ESA and stability. The dispersion of Pt on graphene was not uniform, with agglomeration of Pt particles present. Modification of graphene surface with ITO resulted in better distribution of Pt nanoparticles, resulting in improved activity and durability. The results for Pt/ITO was very encouraging, with excellent durability. Based on these results, Pt/OGMC, Pt/CNT, Pt/graphene, Pt/ITO/graphene and Pt/ITO were selected for MEA testing.

The consistency between RDE and MEA results are shown in Figure 2 from some commercial ETEK catalyst, Pt/VC baseline, and Pt/CNT. The trends for ESA and durability are the same for both types of measurements.

Metal oxides protect carbon substrate from oxidation. Figure 3 shows the polarization curves and CVs of carbon with/without metal oxide coating. The oxidation current densities (A/g carbon) were reduced for metal oxides coated graphene and carbon black, indicating that metal oxides protect carbon from oxidation. The CVs of metal oxide coated carbon are similar to that of pure carbon in the potential range of 0-1.4 V (proton exchange membrane fuel cell electrode

![FIGURE 1. ESA and Durability for Lead Cathode Catalysts - RDE Potential Step between 0.85 V (30 sec) to 1.4 V (150 sec) vs. NHE](image)

![FIGURE 2. Consistency between RDE and MEA Results](image)

![FIGURE 3. Polarization Curves and CVs of Carbon With/Without Metal Oxide Coating in Nitrogen-Saturated 0.5 M H₂SO₄](image)
potentials), which reveals that metal oxides (ITO, SnO$_2$, TiO$_2$) are stable.

ITO/graphene nanocomposites were synthesized in organic solvent by the hydrothermal method. Graphene, indium precursors and tin precursors were mixed in the organic solvent. Under the proper temperature and reaction time, ITO nanoparticles nucleate and grow on the surface of the graphene. Through this one-pot synthesis, uniform ITO nanoparticles were evenly dispersed on the graphene sheets. High activity was obtained for ITO/graphene substrates. Optimization of ITO content showed that at 75% ITO, the activity and durability were maximized as shown in Figures 4a and 4b. TEM images show the uniform dispersion of Pt using ITO mediated graphene (Figure 4d), while Pt agglomeration on graphene is seen without ITO (Figure 4c). Tests are ongoing to determine its effectiveness in an MEA.

Periodic DFT calculations were done to study the thermodynamic stability of Pt/ITO-graphene in both vacuum and oxygen atmosphere. The Pt/ITO/graphene system was found to be the most stable compared to Pt/ITO and ITO/graphene, with the highest interaction energy. The DFT model structure shows Pt at the interface of ITO/graphene (Figure 5a). Figure 5b shows the cross-section TEM for Pt/ITO/graphene, with Pt present at the interface of ITO/graphene, as predicted by the DFT calculations. A schematic showing Pt location in the Pt/ITO/graphene system is also shown (Figure 5c).

MEA tests were conducted on select catalysts, with degradation done by potential hold at 1.2 V at 80°C/7.4 psig/100% relative humidity, followed by measurement of ESA, activity and polarization curves. As seen in Figure 6, significantly higher durability was achieved for Pt/CNT and Pt/OGMC compared to baseline both in terms of ESA degradation and decrease in current at 0.6 V. During MEA formulation for graphene-based support, some vulcan carbon was added to the Pt/graphene catalyst (Pt/graphene + XC72) in order to increase the space between graphene sheets, and thus allow access of Nafion$^\text{a}$ to the inter-sheet space.

Conclusions and Future Directions

Significant progress has been made in improving supported cathode performance and durability:

- DFT modeling predictions for higher Pt/WC ORR activity was verified by ALD deposition of Pt on WC and measurement of activity.
- DFT modeling prediction for higher Pt/VC stability in the presence of oxygen was verified by AES and HREELS.
- Optimum ITO content was found to maximize activity and durability.

- Optimum ITO content was found to maximize activity and durability.

- ITO mediation enabled uniform Pt distribution in the Pt/ITO/graphene system. DFT prediction of stable Pt/ITO/graphene configuration with Pt at the edge of ITO/graphene was verified by TEM.
- Demonstrated > 2X stability of Pt/CNT over Pt/XC72.
- Demonstrated 2X durability of Pt/OGMC over Pt/XC72.
Demonstrated 3X durability of Pt/ITO over baseline.

Obtained consistency between RDE and MEA results.

Future work will involve improving the performance of non-carbon CMO supports by incorporating mesoporosity within the supports and improving MEA formulation for these novel supports. CMO modification of alternative carbon supports such as CNT and OGMC, which show 2X higher durability than baseline vulcan carbon, will also be conducted.

Project Start Date: January 1, 2007
Project End Date: December 31, 2010

Objectives

• Overall objective:
  - Develop a non-platinum cathode electrocatalyst for polymer electrolyte membrane fuel cells (PEMFCs) with the following attributes to meet DOE's technical targets for electrocatalyst activity, durability, and cost:
    - Promotes the direct four-electron reduction of oxygen with high electrocatalytic activity (0.44 A/mg Pt or 720 μA/cm² @ 0.9 V).
    - Chemically compatible with the acidic polymer electrolyte.
    - Stable at high potentials and to potential cycling (5,000 h @ 80°C, <40% electrochemical area loss).
    - Low cost ($5/kW).

• Specific objectives for Fiscal Year (FY) 2010:
  - Prepare/characterize model systems (bulk electrodes) and nano-particles of Pd-Mo, Pd-Re, Pd-Ta, and Pd-W binaries and Pd-Cu-Mo, Pd-Cu-W, Pd-Cu-Re, Pd-Cu-Ta, and Pd-Cu-Ni ternaries:
    - Varying Pd to base metal ratio, annealing temperature, and annealing atmosphere.
    - Characterizing oxygen reduction reaction (ORR) activity, surface composition, and electronic structure.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:
(A) Durability
(B) Cost
(C) Performance

Technical Targets

This project is addressing the following 2010 DOE technical targets for electrocatalysts:
• Activity: 0.44 A/mg Pt or 720 μA/cm² @ 0.9 V.
• Durability: 5,000 h @ 80°C, <40% electrochemical area loss.
• Cost: $5/kW, 0.3 mg platinum group metal (PGM)/cm².

Accomplishments

• Calculated the ORR energetics for Pd and Rh alloys and the effect of water solvent on these energetics.
• Calculated the effect of adsorbed oxygen on surface segregation energies of Pt and Pd alloys.
• Determined the effect of annealing temperature and atmosphere on the ORR activity of twenty-one bi-metallic and tri-metallic Pd bulk electrodes; highest ORR activity enhancement with alloying was 2.1x (Pd₃Mo).
• Synthesized and characterized the structure, oxidation state, particle size, and ORR activity of nano-particles in the Pd-W, Pd-Mo, Pd-Re, and Pd-Ni-Cu systems.
• Achieved a nano-particle ORR activity enhancement with alloying of 3.4x with an (ORR activity of 680 mA/mg Pd at 0.8 V and room temperature for a Pd₁₈Ni₁₈Cu₆₄ alloy).
• Determined valence band structure of highest activity bi-metallic Pd alloys (PdMo and PdCu).
Introduction

The platinum-based cathode electrocatalyst is a major contributor to the cost of PEMFC power systems [1,2]. The goal of this project is to develop active and stable non-platinum noble metal-base metal alloy ORR electrocatalysts to expand the availability of effective materials beyond Pt alloys and thereby reduce the cost of the cathode electrocatalyst.

Approach

Our approach to developing non-platinum noble metal PEMFC cathode electrocatalysts is to utilize noble metal-base metal alloys. The function of the base metal is to decrease the loading of the noble metal and to modify its valence band structure to make it more Pt-like in its bonding with ORR reactants, intermediates, and products. The choice of noble metal and base metal combinations are based on calculated valence band or “d-band center” shifts of the noble metal in noble metal-base metal alloys and on the tendency of the noble metal to segregate to the surface of the alloys [3-7].

Two project tasks guide the choice of alloy systems: (1) computational studies of preferred catalyst atomic structures, electronic structures, d-band centers, and preferred reaction pathways and activation energies and (2) model system (bulk electrode) fabrication and characterization. Favorable alloy systems are fabricated as high-surface-area-carbon-supported nano-particles using co-impregnation, colloidal, and strong-electrostatic adsorption techniques. The nano-particles are characterized by a variety of spectroscopic, microscopic, and electrochemical techniques to determine composition, phase structure, particle size, electronic structure, and ORR activity and stability.

Results

Computational Results

This year’s computational effort focused on the change in the energetics of the ORR on Pd and Rh with alloying, the effect of water solvent on these energetics, and the change in the alloys’ noble metal segregation energies in the presence of adsorbed O. The alloys studied, Pd,W, Pd,Mo, Pd,Re, Pd,Ta, Rh,Co, and Rh,Fe, were those with calculated d-band centers close to that of Pt and favorable energies for noble metal surface segregation, as detailed in last year’s report [8].

As shown in Figure 1, the ORR may proceed through various adsorbates and pathways. The binding energies of each of the potential ORR adsorbates and the activation energies of the reaction steps were determined using periodic quantum mechanic calculations on four-layer noble metal or noble metal-base metal alloy slabs. The trends determined from these calculations were:

- Alloying Pd decreases the binding energy of H, O, O₂, and H₂O₂ and increases the binding energy of OH, OOH, and H₂O.
- Alloying Rh increases the binding energy of OH.
- Alloying Pd decreases the barriers for H₂O formation and O hydration (two key steps in the ORR).
- Alloying Rh increases the barriers for H₂O formation and O hydration.

The presence of water solvent was found to alter the barriers for the ORR steps, thus modifying the preferred reaction pathway and overall reaction barrier. For Pd and Pd alloys the favored pathway in the gas phase is through OOH formation, OOH dissociation, O hydration, and HOH formation. In water solvent, the favored pathway is through the steps of O₂ dissociation, OH formation, and HOH formation. On Rh and Rh alloys the preferred steps in the gas phase are O₂ dissociation, O hydration, and HOH formation, whereas in the presence of water O₂ dissociation is followed by OH and HOH formation. The overall ORR barrier is reduced when alloying Rh with Co and increased when alloying with Fe. All Pd alloys showed lower overall barriers than Pd alone.

The computational studies of noble metal surface segregation energies for two Pt alloys (Pt,Co and Pt,Ni) and ten Pd alloys (Pd, Au, Pd,Cu, Pd, Ir, Pd, Mo, Pd, Os, Pd, Re, Pd, Rh, Pd, Ru, Pd, Ta, and Pd, W) showed that only Pd, Ir and Pd, Os segregate both in the absence and presence of adsorbed O. The alloys Pd,Mo, Pd, Re, Pd, Ta, and Pd, W were found to be extremely non-segregating in presence of adsorbed O, indicating that elimination of oxygen during the heat treatment/annealing step of alloy preparation is crucial and also a potential source of instability of the alloy materials during the ORR.

FIGURE 1. Potential Pathways for the Oxygen Reduction Reaction

- Alloying Pd decreases the binding energy of H, O, O₂, and H₂O₂ and increases the binding energy of OH, OOH, and H₂O.
- Alloying Rh increases the binding energy of OH.
- Alloying Pd decreases the barriers for H₂O formation and O hydration (two key steps in the ORR).
- Alloying Rh increases the barriers for H₂O formation and O hydration.
Experimental Results

This year’s experimental efforts focused on the synthesis and characterization of bulk alloys and nanoparticles of the Pd binary alloys Pd-Mo, Pd-W, Pd-Re, and Pd-Ta. These systems were identified last year as having favorable valence band energies, palladium surface segregation energies, and bonding characteristics with ORR reactants, intermediates, and products [7]. We also studied ternary systems based on the palladium-copper binary system to further enhance its activity and stability [8-10].

Model Systems

Ingots of 21 different compositions in six Pd alloy systems were fabricated by arc-melting. To promote surface segregation of Pd, the ingots were annealed at temperatures between 600 and 1,500°C in atmospheres of 3.5-3.7%H₂/He, 1% H₂/Ar, 100 ppm H₂/Ar, or Ar. The ingots’ ORR activity and the effect of annealing temperature and atmosphere on the activity were determined using cyclic voltammetry in a quiescent oxygen-saturated aqueous electrolyte. Using this method, the figure of merit for activity is the half-peak potential of the oxygen reduction current peak.

These studies showed that annealing Pd alloys promotes surface segregation of Pd, as evidenced by Pd-like voltammetry in deaerated electrolyte and positive shifts in the ORR half-peak potential (i.e., enhanced ORR activity). The degree of Pd segregation depended on the annealing environment and temperature, the oxophilicity of the base metal, and the Pd to base metal ratio. Of the 21 Pd alloy ingots tested, the Pd₇₂Mo₂₈ alloy showed the highest enhancement of ORR activity with an increment in ORR half-peak potential of 22 mV compared to Pd alone, but 28 mV lower than that of Pt. A 22 mV shift in half-peak potential translates to a 2.1x ORR activity enhancement assuming a Tafel slope of 68 mV/dec (Figure 2).

X-ray photoelectron characterization of the Pd₇₅Mo₂₅ alloy showed that Mo modifies the Pd valence band, extending the density of states (DOS) to higher binding energies as reflected in a d-band center shift of 0.38 eV (Figure 3). Compared to Pt, Pd₇₅Mo₂₅ lacks DOS near the Fermi energy and at >4 eV binding energy. These missing states may explain the lower ORR activity, however further studies are needed to determine the involvement of various states in the ORR.

Nano-Particles

High-surface-area carbon-supported nano-particles of Pd-W, Pd-Mo, Pd-Re, and Pd-Ni-Cu alloys were synthesized using colloidal and strong-electrostatic adsorption (Pd-W and Pd-Mo), co-impregnation (Pd-Re), and colloidal techniques (Pd-Ni-Cu). The atomic ratios of Pd to base metal of the various systems are listed in Table 1. X-ray diffraction confirmed the formation of alloys in all cases. In addition to the alloy, the Pd-Mo system also contained an additional molybdenum carbide.
phase was detected for the Pd-Mo system. Oxygen reduction reaction activity was determined using the rotating disk electrode (RDE) technique and aqueous acidic electrolyte. The highest ORR activities achieved for each system are summarized in Table 1. Of the systems studied, only Pd-Ni-Cu showed enhanced ORR mass activity. X-ray photoelectron spectroscopy analyses indicated that the inhibition of ORR activity for the binary alloy nano-particles may be due to the presence of base metal oxides on the nano-particle surfaces.

### TABLE 1. Summary of palladium alloy nano-particle catalysts synthesized this year and the highest mass (im) and area-specific (is) ORR activities achieved in each of the alloy systems. The atomic ratio of Pd to base metal and the post-deposition heat treatment resulting in the highest ORR activities are shown in parentheses.

### Conclusions and Future Directions

Computational studies of the energetics of the ORR on Pd, Rh, and base metal alloys of Pd and Rh indicated that alloying Pd with Mo, W, Ta, or Re should increase ORR activity. Alloying Rh with Fe should decrease ORR activity and alloying with Co should increase activity. Experimental studies of the ORR activity of Pd alloy ingots showed that alloying with Re, Cu, W, and Mo at a 3:1 atomic ratio of Pd to base metal does enhance the ORR activity of Pd. The ORR activity increased in the order: Pd-Re<Pd-Cu<Pd-W<Pd-Mo, with Pd-Mo showing an area-specific activity enhancement of 2.1x versus Pd alone. Valence band characterization of Pd-Mo showed that Mo modifies the valence band of Pd, extending the density of states to higher binding energies. Though the overall d-band center of Pd is shifted toward that of Pt upon alloying with Mo, the valence band of Pd-Mo lacks states near the Fermi energy and at higher binding energies (>4 eV). Future efforts will focus on alloying Pd with other binary and ternary combination of base metals to mimic Pt's density of states to further enhance the ORR activity of Pd.

Future work:

- Perform RDE studies on bi- and tri-metallic model systems (bulk electrode ingots) that showed the highest ORR activities in quiescent electrolyte experiments.
- Determine the surface composition and valence band structure as a function of annealing temperature and atmosphere, using X-ray photoelectron spectroscopy, for these model systems.
- Continue synthesis of nano-particles of most promising compositions identified in model system and computational studies, with goal of achieving base metal oxide-free surfaces.
- Expand surface segregation calculations to include other noble metal:base metal ratios, ternaries, and effect of annealing atmosphere.
- Study segregation effect for binary and ternary systems in the presence of different adsorbed species on the surface.
- Study ternary systems, such as Pd-Cu-Mo, Pd-Cu-W, Pd-Cu-Re, Pd-Cu-Ta, Pd-Cu-Ni with varying Pd to base metal ratios to enhance the activity and stability of highest activity binary system identified to date.
- Continue determining alloy electronic structures using DOS spectra and perform detailed analysis of how the electronic structures affect ORR activity.

Project Start Date: March 2007
Project End Date: 2011

Objectives

The main objective of this project is to:

• Develop oxygen reduction reaction (ORR) catalysts, alternative to pure Pt, capable of fulfilling cost, performance and durability requirements established by DOE for the polymer electrolyte fuel cell (PEFC) cathode; assure path to large-scale fabrication of successful compositions.

Individual objectives of this research are as follows:

• Design, synthesize and characterize new catalyst supports and electrode structures for new-generation ORR catalysts.

• Determine ORR mechanism on newly developed catalysts via extensive physicochemical characterization and electrochemical and fuel cell testing.

• Optimize electrodes with new catalysts and structures for maximum performance.

• Evaluate catalyst stability; minimize performance loss over time.

• Assure path forward for the fabrication and scale up of viable catalysts.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability (of catalysts and electrode layers)

(B) Cost (of catalysts and membrane electrode assemblies [MEAs])

(C) Performance (of electrodes, including (i) ORR overpotential and (ii) O₂ mass-transport rates)

Technical Targets

Non-platinum cathode catalyst research in this project focuses on DOE’s 2010 technical targets specified in Table 3.4.12 (Electrocatalysts for Transportation Applications) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan. The 2010 targets relevant to this research project together with the current status (where applicable) are shown in Table 1.

Accomplishments

• Significantly advanced knowledge of factors affecting ORR activity of the Pt monolayer-type catalysts (facet, shape, particle size, high coordination number).

• Specific and mass activity of ultra-low Pt-content core-shell catalysts significantly improved, up to 1,200 μA/cm² and 1.1 A/mgPGM (2.4 A/mgPt) at 0.90 V, respectively (rotating disk electrode [RDE] testing); DOE performance targets met and substantially exceeded.

• Excellent stability demonstrated with several platinum group metal (PGM) catalysts, including hollow-Pt nanoparticle catalyst (less than 17 mV performance loss at E½ after 20,000 scans) and Pt₅/Pd₂AuNi/C nanoparticles (ΔE½ limited to 6 mV after 10,000 potential cycles).

¹ Ptₓ/Pd/C catalyst from scaled-up synthesis by Cabot Fuel Cells, tested in 50-cm² single fuel cell at 80°C; cathode - 0.28 mg PGM/cm²; anode - 0.05 mg Pt/cm² Pt/C; MEA not optimized.
² Mass activity per mg PGM in Pt/Au/Pd/Co catalyst in RDE testing at 0.90 V.
³ Most catalysts tested using DOE electrocatalyst accelerated stress test protocol of cycling from 0.6 V to 1.0 V at 50 mV s⁻¹ for 30,000 cycles under N₂ gas flow.

- 2010 DOE activity target for non-PGM catalysts reached; open circuit voltage (OCV) of 1.04 V and volumetric ORR activity of 165 A/cm³ electrode (after mass-transport correction) achieved with cyanamide (CM)-Fe-C catalyst in fuel cell testing; rapid improvement in fuel cell performance of several other non-precious metal catalysts shown.
- High durability accomplished with polyaniline (PANI)-based catalysts to potential holding at OCV as well as to potential (RDE) and voltage (fuel cell) cycling, up to 30,000 cycles (DOE protocols followed).
- ORR activity of PANI-derived catalysts correlated to microporosity and Fe-N coordination; improved durability linked to graphene sheet formation (results of advanced spectroscopic and microscopic characterization).
- Synthesis of BNL’s Ptₓ/Pd/C core-shell catalyst scaled up to 20 g per batch.

Introduction

This multitask and multi-partner project focuses on the development of new oxygen reduction catalysts and electrode structures for the PEFC cathode, with either greatly reduced precious-metal content relative to that presently used by stack developers, or entirely precious-metal-free. The main objective of this effort is to lower the catalyst cost in the fuel cell power system through improvements in ORR performance in terms of both electrocatalysis and oxygen transport to the reaction site.

Approach

The primary research goal of this project is the development of new oxygen reduction catalysts, in two different classes: (i) catalysts with ultra-low platinum content (stable metals or alloys as cores; non-precious-metal core catalysts; mixed metal shells for higher ORR activity) and (ii) non-precious metal catalysts obtained by high-temperature treatment of various precursors of carbon, nitrogen and transition metals. Understanding of the key factors impacting ORR activity and performance durability of catalysts in both classes is pursued through a major characterization effort including X-ray absorption spectroscopy (XAS), X-ray photoelectron spectroscopy (XPS), and high-resolution transmission electron microscopy (TEM), among other techniques.

Development of new catalysts is closely tied to novel electrode structures, tailored to maximize either catalyst utilization in the case of precious metal-based ORR catalysts (e.g. core-shell Pt-based catalysts) or the loading of non-precious metal catalysts with intrinsically lower than platinum volumetric ORR activity. The electrode-structure component of the effort concentrates on two groups of materials: (i) carbon- and non-carbon-based nanostructures for efficient mass transport, improved durability, and maximum catalyst utilization, and (ii) open-frame catalyst structures obtained using microemulsion/reverse emulsion techniques.

In addition to short-term testing and initial performance assessment, catalysts, supports, electrode structures, and membrane-electrode assemblies developed in this project are subject to long-term performance (durability) testing. Performance degradation mechanisms are being identified and, if possible, addressed. Fabrication and scale up of viable catalysts and supports is also being tackled through collaboration between partners in this project.

Results

Catalysts with Ultra-Low Pt Content — A variety of strategies were implemented in the past year to generate PGM-containing catalysts with high activity and stability. Three major ideas were applied:
(1) inducing proper degree of lattice contraction in the Pt surface layer to increase ORR activity, (2) removing low-coordination surface atoms that decrease activity and durability, and (3) partially substituting PGM with non-precious metals into the cores of the catalysts. A more flexible synthesis approach using Prussian blue analogs for the latter type of catalyst was also developed. Scale-up efforts on the more mature PtPd/C catalyst were also continued.

Several catalysts based on applying Pt monolayers to Pd cores were prepared. In general, depositing Pt onto Pd results in higher ORR activity because of the Pt lattice contraction (Figure 1a) and beneficial electronic interaction. The addition of an Ir layer onto the Pd core followed by annealing to bring Pd to the surface generates a contracted Pd layer. When the Pt monolayer is deposited, the additional lattice contraction due to the presence of subsurface Ir results in even higher ORR activity – \( \text{PtML-PdIr/C specific ORR activity: } 938 \, \mu\text{A/cm}^2 \) (3× that of Pt/C); mass activity: \( 2.17 \, \text{A/mgPt} \) (more than \( 20\times \) that of Pt/C) (Figures 1b and 1c). Pt\(_{80}\)Ir\(_{20}\)/Pd/C showed good fuel cell performance (0.55 A/mgPt), and the \( E_\circ \) of Pt\(_{ML}\)/Pd/C gained 27 mV (to 0.903 V) after a Br\(^{-}\) treatment that removed low coordination atoms.

The catalytic activity per gram of precious metal was further increased in this class of catalysts by mixing Ni into the Pd core, removing reactive Ni atoms with exposure to Au, and finally depositing a Pt monolayer (Figure 2). The obtained Pt/Au/PdxNi catalyst shows remarkable activity (by RDE testing) far exceeding the DOE target specified above – \( 1.10 \, \text{A/mgPGM} \) (2.41 A/mgPt). A synthesis involving Prussian blue analogs was developed allowing for surfactant-free synthesis of multi-metallic aggregates that include non-precious metals in the core (possibly convenient for further nanoparticle engineering). Using this approach, an active and durable Pt\(_{ML}\)/Pd\(_{x}\)Au\(_{y}\)Ni\(_{z}\) catalyst was prepared (\( E_\circ = 0.865 \, \text{V} \)). The catalyst loses only 6 mV in \( E_\circ \) after 10,000 potential cycles.

In an alternative approach, a Pt/Ni core shell catalyst was synthesized and the Ni was subsequently removed, resulting in a hollow Pt sphere with 1.2% Pt lattice contraction (Figures 3a and 3b). The hollow-sphere catalyst exhibits good durability, losing only 17 mV in \( E_\circ \) after 10,000 potential cycles and 10,000 potential pulse sequences (see figure caption for details) and maintaining a high activity of 0.62 A/mgPGM (Figure 3d).

**Scale-Up Synthesis of Catalysts with Ultra-Low Pt Content** — The synthesis of the Pt\(_{ML}\)/Pd\(_{x}\) catalyst was scaled up further to 20 g by Cabot Fuel Cells using a spray-pyrolysis approach. The catalyst delivered very good performance in fuel cell testing, matching mass-
activity of previous smaller batches (0.55 A/mg_{Pt} and 0.12 A/mg_{PGM} at 0.90 V).

Precious Metal-Free Catalysts — The focus of research in this catalyst category continued to be on materials obtained by heat-treating carbon supported precursors in the presence of transition metal salts (Fe and Co), with the scope now limited to CM-derived and PANI-derived catalysts. The ORR activity of both types of catalyst greatly increased over the Fiscal Year (FY) 2009 versions as shown in Table 2, with a nine-fold

Average electrode density assumed as 0.4 g/cm^{3} (Neyerlin et al., J. Electrochem. Soc. 153, A1955, 2006; Lefèvre et al., Science 324, 71, 2009)
increase observed for CM-type catalysts and a five-fold increase observed for PANI-derived catalysts.

The activity of CM-derived catalyst was enhanced by (1) the use of a different carbon support, and (2) the addition of a second sulfur-containing precursor. With these changes, the activity of the catalyst was determined to be 165 A cm\(^{-3}\) (per electrode volume) at 0.80 V in fuel cell testing, using extrapolation to compensate for mass-transport losses (see Figure 4b). This value is comparable to the DOE 2010 performance target (see targets table above).

The PANI-derived catalysts were improved through the design of a two-step synthesis that was intended to maximize the benefits of using both Co and Fe precursors. Based on our previous results, Co has been shown to increase the presence of graphene-type structures (perhaps connected to durability) and pyridinic nitrogen content, whereas Fe has been shown to generate more active catalysts and perhaps to form more bonds with nitrogen. Introducing the metals in two separate steps indeed increases the catalytic activity as shown in Figure 5a with \(E_{\text{red}} = 0.82\) V, gaining 20 mV versus PANI-Fe-C and 40 mV versus PANI-FeCo(3:1)-C. The latter catalyst showed the best combination of activity
A comprehensive characterization effort has continued with a special focus on PANI-Fe-C catalysts prepared at different heat-treatment temperatures and having very different ORR activities. These samples have been thoroughly analyzed ex situ using spectroscopic and structural methods to gain insight into the nature of the active site. XAS, XPS, and pore-distribution results have been combined using the principal component analysis (PCA) method as shown in Figure 7 in an attempt to identify the strongest correlations between observations and catalyst activity. Fe-N-type coordination, as identified by XAS and XPS, remains strongly associated with oxygen reduction activity in ORR-active samples (900°C, 850°C, 800°C), and thus continues to be a primary candidate for the active site.

The most active, 900°C catalyst has the highest Brunauer-Emmett-Teller (BET) surface and microporous surface area (in agreement with Dodelet group results), a bimodal pore distribution, and high initial contents of Fe carbide, Fe in oxide-like coordination, and Fe in phthalocyanine-like coordination.

**Conclusions and Future Directions**

- Core-shell and core-less catalysts with greatly reduced Pt loading have been developed that offer much better ORR performance in aqueous electrolytes and in hydrogen-air fuel cells than standard carbon-supported Pt catalysts; based on measured RDE activity in FY 2010, the best of these catalysts can lose up to a factor of 3 activity (see Table 1) upon incorporation into stacks and still meet 2010 DOE stack performance targets, provided de-alloying and catalyst agglomeration can be avoided; FY 2010 RDE durability data

**FIGURE 6.** PANI-Fe-C catalysts prepared with different support materials: (a) 500-hour fuel cell life tests; (b) TEM images showing the presence of graphene-sheet “bubbles” in PANI-Fe-MWNT; “bubbles” (→) are co-located with the FeSx regions/particles (→); MWNTs are still present (→) after catalyst preparation.
Susceptibility of carbon-rich non-precious metal catalysts to flooding continues to be a major performance issue for non-precious catalysts, especially at high current densities; based on FY 2010 results, apparent durability is also impacted by water management in the electrodes; future research efforts must focus on designing electrode structures that allow for more efficient water management than traditional MEA designs.

Contract Number:  DE-EE0000456

Subcontractors and Federally Funded Research
and Development Centers:
• Dalhousie University, Halifax, Nova Scotia, Canada
• Oak Ridge National Laboratory, Oak Ridge, TN

Project Start Date:  August 1, 2009
Projected End Date:  July 31, 2013

Objectives

• Develop catalysts that will enable proton exchange
membrane (PEM) fuel cell systems to weather the
damaging conditions in the fuel cell at voltages
beyond the thermodynamic stability of water during
the transient periods of start-up/shut-down and fuel
starvation.
• Demonstrate that these catalysts will not
substantially interfere with the performance of nor
add much to the cost of the existing catalysts.

Technical Barriers

This project addresses the following technical
barriers from the Fuel Cells section of the Fuel
Cell Technologies Program Multi-Year Research,
Development and Demonstration Plan:

(A) Durability
(G) Start-up and Shut-down Time and Energy/Transient
Operation

Technical Targets

While the number of start-up and shut-down cycles
for an automotive fuel cell has been estimated to be over
50,000, the number of these events when the cathode
electrochemical potential exceeds 1.23 V has not been
assessed.  In agreement with DOE, the technical targets
for the first year of the project have been defined as
follows:

• Develop cathode catalyst that can withstand currents
of 1 mA/cm² at potential of <1.45 V and 10 mA/cm²
at potential of <1.50 V with added oxygen evolution
reaction (OER) catalyst of no more than 2 µg/cm² of
platinum group metals (PGM).

Accomplishments

• Produced OER catalysts with 2 µg/cm² PGM that
achieved the first year milestone for OER activity of
1 mA/cm² at 1.45 V.
• Developed integrated OER/oxygen reduction
reaction (ORR) catalysts with only 2 µg/cm²
(Ru + Ir) showing no loss of ORR activity relative to
the baseline ORR catalyst.
• Canvassed the space around the components (Ru,
Ir, Ti) of the model OER durable catalyst in the real
PEM fuel cell environment.
• Established that Ru is the most active OER catalyst,
Ir is the most stable and that combinations of
Ru + Ir retain some of the properties of the two.
• Modified the anode catalyst to inhibit ORR while
preserving the same activity towards hydrogen
oxidation reaction (HOR).

Introduction

The project addresses a key issue of importance
for successful transition of PEM fuel cell technology
from development to pre-commercial phase (2010 -
2015).  This issue is the failure of the catalyst and the
other thermodynamically unstable membrane electrode assembly (MEA) components during start-up/shut-down and local fuel starvation at the anode, commonly referred to as transient conditions. During these periods the electrodes can reach potentials up to 1.5 V. One way to minimize the damage from such transient events is to minimize the potential seen by the electrodes. At lower positive potentials, increased stability of the catalysts themselves and reduced degradation of the other MEA components is expected. This project aims to develop catalysts that will reduce the potentials experienced during transient conditions. In order to achieve the above goal we are working on two major concepts:

- Cathode catalysts with high activity towards oxygen evolution from water
- Anode catalysts with low oxygen reduction reaction activity

**Approach**

This project will try to alleviate the damaging effects during transient conditions from within the fuel cells, via improvements to the existing catalyst materials. We will modify both the anode and the cathode catalysts to favor the oxidation of water over carbon corrosion by maintaining the cathode potential close to the thermodynamic potential for water oxidation. The absence of hydrogen and simultaneous presence of oxygen in separate regions of the anode is necessary to provoke and maintain cathode potential >1.23 V. Oxygen in these regions of the anode gets reduced. The protons for the reduction of oxygen are supplied from the cathode side via either carbon or water oxidation. The presence of a highly active OER catalyst on the cathode reduces the overpotential for a given current demand thus reducing the driving force for carbon and platinum dissolution. In addition, inhibition of the ORR on the anode side lowers the OER current through reduced proton demand which in turn decreases the OER current on the cathode resulting in reduced cathode potential.

Key requirements for both concepts are:

- **On the cathode**: implement the OER catalyst with negligible inhibition of the ORR on the existing cathode catalyst and with minimal addition of PGM, i.e. to deposit the OER catalyst as a separate, discontinuous phase - as nanoparticles.
- **On the anode**: implement the ORR inhibiting component with negligible inhibition of the HOR, either as a mixed or a separate phase.

**Results**

**Task 1. Efficient Oxygen Evolution Reaction Catalysts**

Most of the activity during the first year of the project was related to this task. The catalysts prepared were based around the model catalyst containing ruthenium, iridium, and titanium [1]. Since the oxides of ruthenium and iridium are known to have the best catalytic properties for OER in aqueous solutions, some of the catalyst syntheses were performed in the presence of oxygen [2,3].

In order to be able to properly examine the inherent activity of the OER catalyst, one needs a substrate with minimal interference from the underlying ORR catalyst. The unique features of 3M’s nanostructured thin film (NSTF) catalyst such as the lack of carbon that can corrode and the durability at high potential made it a logical choice as a support for the added OER catalyst. In addition, the NSTF fabrication process of physical vapor deposition via sputtering in vacuum allows for a wide range of materials in variety of compositions to be synthesized [4,5].

The OER catalysts synthesized and characterized can be grouped in four major categories, ranging from single elements up to a quaternary system.

1. **The Single Elements**

   To our knowledge, the most comprehensive study to date of the behavior of Ru, Ir and Ti in the real PEM fuel cell environment was completed during the first year of this project. In addition to testing samples with only 2 µg/cm² PGM, as required by the year one milestone, we have produced and tested samples with 10 µg/cm² PGM to enhance the impact of the presence of ruthenium and iridium on the cathode ORR catalysts. The OER activity was assessed by quasi-steady state measurements where polarization curves for oxygen evolution were recorded at 2 mV/s. Three consecutive potential sweeps were performed up to each of the voltages set for the year one milestones, 1.45 V and 1.5 V, as well as 1.55 V, 1.6 V and 1.65 V. The first sweep allowed us to assess the intrinsic activity. The second and the third sweep provided insights into the stability of the OER catalysts. The impact of the added OER catalyst on ORR activity was assessed through standard fuel cell performance testing before and after the OER test.

   In Figure 1 the OER polarization curves with 10 µg/cm² of either Ru (1A) or 10 µg/cm² of Ir (1B) over 0.15 mg/cm² Pt on NSTF are presented. The difference between the two OER catalysts is that Ru is initially more active than Ir, however, Ir preserves its activity even after excursions to very high potentials whereas Ru loses activity. It is worth noting that the OER activity of the platinum itself as well as Pt coated with 10 µg/cm²
Ti is extremely small, ~0.5 mA/cm² at 1.65 V. The likely cause for the loss of OER activity of the ruthenium catalyst during OER testing can be determined from the cyclic voltammograms before OER, and after exposure to 1.45 V and 1.65 V (Figure 1C). Initially, the cyclic voltammograms are dominated by the presence of ruthenium which is manifested in large capacitive current in the platinum double layer region and by the suppression of the characteristic peaks for hydrogen underpotential deposition (Hupd) and Pt oxide formation and reduction. After exposure to 1.45 V the features from the presence of ruthenium are substantially, but not completely diminished. The cyclic voltammograms only become platinum-like (as if ruthenium were completely removed) after reaching 1.65 V: well pronounced Hupd peaks, proper double layer and Pt-oxide formation/reduction. Thus, loss of Ru from the Pt ORR catalyst causes the loss of OER activity. In contrast, the cyclic voltammograms for Ir over Pt on NSTF are practically unchanged even after the exposure to 1.65 V.

The behavior of catalysts with only 2 µg/cm² additional PGM followed the same pattern as samples with 10 µg/cm² additional PGM. At the year one milestone potentials for both Ir and Ru catalysts are above the milestone OER activity of 1 mA/cm² at 1.45 V. However, only Ir catalysts exhibit activity above the milestone of 10 mA/cm² for 2 µg/cm² additional PGM at 1.5 V.

As indicated already, integration of the OER catalysts with the existing cathode catalyst, Pt in this study, was examined via 50-cm² MEAs (Figure 2). Within the reproducibility of the fuel cell testing, the integrated catalysts fall in two groups:

- No impact – no loss of ORR activity: Ir with 2 and 10 µg/cm² and Ru with 2 µg/cm².
- Negative impact – significant loss of ORR activity: high Ru content (10 µg/cm²) before OER testing and Ti.

Loss of Ru during OER testing allowed the 10 µg/cm² Ru cells to move from the negative impact group to the no impact group after OER testing. ORR activities measured at 0.9 V according to the DOE protocol follow the same pattern as the fuel cell polarization curves.

In order to get insights into the composition of the OER catalysts, X-ray photoemission spectroscopy (XPS) and electrochemical surface area measurements (via Hupd) were completed on all samples. For all samples assessed, the OER catalysts were deposited over 0.15...
mg/cm² Pt on NSTF. The atomic concentrations and ratios of Ti, Ir and Ru coatings vs. Pt reveal that Ti covers more of the Pt surface than the other elements. The fraction of the platinum surface covered by the deposited elements is higher than would be expected for pure elements because of the oxidation state of the deposits. Even though no deliberate oxygen was introduced in the vacuum deposition chamber, O/Ti ratios indicate that Ti is present as TiO₂. Ir is also present as IrO₂ in the thinner coating, 2 µg/cm², while metallic Ir dominates in the 10 µg/cm² samples. Because of overlapping of binding energies for carbon and ruthenium, deconvolution of the Ru high resolution spectra is very complex. Nonetheless, because of the key role that ruthenium plays as an OER catalyst component, a rigorous in-depth methodology was developed to determine the real surface concentration of ruthenium and its valence state. Based on the atomic concentrations of Ru, O, and oxidized C, we believe that Ru may be present as organo-metallic compounds through Ru-O-C bonds for both 2 and 10 µg/cm² on Pt-NSTF.

2. Ti – Ir OER Catalyst

The purpose of this series was to explore the influence of the combination of one OER-active (Ir, 1 - 2 µg/cm²) and one supportive, OER-inactive component (Ti, 2 - 4 µg/cm²). The results obtained suggested that the properties of these two elements are additive. OER activity improves with the Ir content. The OER activity improves further when the catalyst is made in the presence of oxygen. This improvement is more prominent at higher potentials. However, both the polarization curves as well as the intrinsic ORR activity are lower due to the Ti coverage of the ORR catalyst (Pt).

Transmission electron microscopy (TEM) results from Oak Ridge National Laboratory reveals that both Ti and Ir are clearly observed on the Pt surface as a thin layer. A Ti/Ir “nanocrystalline” layer is observed on the surface of Pt “cap” and ~50 nm down the sides of the Pt/NSTF ORR catalyst. The Ti/Ir layer is ~4-5 nm thick. In high resolution XPS, these samples show an unusual Ir spectral feature that appears only when Ti and Ir are deposited on the same catalyst. This feature will be a subject of further investigation.

3. Ti – Ir – Ru – Ox OER Catalyst

The purpose of this series was to explore the combination of the model catalysts where all the components are present. The primary variable here was the flux of oxygen during the sputter deposition. The most interesting finding in this series was that the presence of oxygen during deposition correlates with changes in fuel cell performance rather than with the OER activity or stability. Based on XPS, the presence of oxygen during the catalyst deposition decreases the amount of sputtered Ti, most probably due to the oxide buildup on the surface of the Ti target.

TEM imaging showed a thin, continuous layer of Ti, Ru and Ir was present on the surface of the Pt/NSTF “cap” and on the surface of the Pt coating along the sides of the coated NSTF whiskers. However, no individual particles were seen. The ~2 nm thick layer is crystalline, contains Ti, Ir, and Ru and is primarily on the “cap” surface. The amount of Ru in the surface layer is greater than either Ti or Ir, in agreement with XPS data for the same samples. Oxygen was also detected, indicating the possible presence of oxides.

4. Ir – Ru – Ox OER Catalyst

Based on the evaluation of the single component OER catalysts as well as the negative impact of Ti on the fuel cell performance, further effort on the project...
focused on the binary composition of Ir and Ru. The ratio of Ru:Ir was varied from 3:1 to 1:3 w/w (85–38 Ru at%), keeping the total OER added PGM loading at 2 µg/cm², the level defined by the milestone for year one. In addition, the same catalysts were deposited in the presence of oxygen. All catalysts achieved the milestone OER activity at 1.45 V and some at 1.5 V (Figure 3). Samples prepared with oxygen during the deposition process behaved the same way. As such the binary Ru–Ir catalyst composition has been chosen for future studies aimed at achieving different morphologies.

Task 2: Anode Catalysts with Low Oxygen Reduction Reaction Activity

This task is based on the notion that HOR as a facile reaction can proceed with practically unchanged rate when a Pt catalyst gets passivated by additives such as tantalum [6]. The rate of the ORR, a much more demanding reaction, on the other hand, decreases much more rapidly [7]. The effort in this task is still in the beginning phase. A series of Pt₁₋ₓ(Ta₂O₅)ₓ coatings on NSTF whiskers grown on glassy carbon disks for HOR was prepared. A series of Pt₁₋ₓ(Ta₂O₅)ₓ catalysts deposited on NSTF-whiskers grown on glassy carbon disks for HOR was produced. As expected, the presence of significant amounts of Ta₂O₅ decreases the exchange current densities for HOR decrease by only a small amount (Figure 4).

Conclusions and Future Directions

- Integrated OER/ORR catalyst systems with 2 µg/cm² of additional PGM achieved the first year milestone for OER activity of 1 mA/cm² at 1.45 V, with no impact on the ORR.
- Exploring the space around the components (Ru, Ir, Ti) of the model OER durable catalyst in real PEM fuel cell environment provided a direction for the future synthetic efforts which will be based around combinations of Ru + Ir.
- Having established the inherent activities of the OER catalyst, future catalyst evaluation protocols will focus on more realistic startup–shutdown test conditions, including cell reversal.

Project Start Date: July 20, 2009
Project End Date: 2013

Objectives
• Produce novel catalysts based on extended Pt surfaces with increased activity and durability.
• Further increase mass activity of extended surface catalysts.
• Effectively incorporate extended Pt catalysts into more traditional dispersed electrodes for improved mass transport/water management.
• Demonstrate and validate models for catalysts and electrodes based on extended surfaces.

Technical Barriers
This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:
(A) Durability (of catalysts and membrane electrode assemblies)
(B) Cost (of catalysts and membrane electrode assemblies)
(C) Performance (of catalysts and membrane electrode assemblies)
(D) Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets
This project is synthesizing novel extended surface Pt catalysts and will be incorporating these catalysts into thick, dispersed electrodes. The project has targets outlined in the Multi-Year Research, Development and Demonstration Plan for both electrocatalysts for transportation applications (Table 3.4.12) and membrane electrode assemblies (MEAs) (Table 3.4.13). A summary of these targets is presented in Table 1.

Accomplishments
• Synthesized novel extended surface Pt catalysts using Cu nanowires and spontaneous galvanic
displacement (SGD). These materials advance our team’s earlier work in the area of Ag and Se nanowires as templates [1]. Cu-based systems offer potential advantages as Pt-Cu alloys have been found to yield materials with greatly enhanced specific activity [2]. Preliminary results have shown significantly enhanced specific activity of these structures compared to traditional Pt catalysts.

- Demonstrated for the first time continuous, conformal coating of Pt on carbon nanotubes (CNTs). CNTs offer the potential of high conductivity and low corrosion compared to other support materials. Demonstrated control of Pt layer thickness by deposition time.
- Investigated vertically aligned CNTs growth and Pt deposition by several techniques. Optimized growth parameters to allow a wide range of tube lengths and packing densities providing tunable substrates for deposition.

Introduction

Pt remains a primary limitation for the widespread commercialization of fuel cell vehicles. To date, approaches looking to replace Pt with a non-PGM have met with limited success. “Thrifting” of Pt (i.e., ultralow Pt loadings) seems to be the most likely (near-term) option for meeting cost, performance and durability targets. Typical Pt catalysts for fuel cell applications are small nanoparticles (such as cubo-octahedron) that have high surface areas, and therefore significant fractions of Pt atoms are surface accessible. This makes sense as one would want as many Pt atoms on the surface as possible. However, catalytic activity and durability of extended surfaces can outweigh the surface area advantages of smaller particles, particularly if these advantages can be maintained at thin wall thickness, as highlighted by the promising work done on nanostructured thin film catalysts based on Pt or Pt alloys at 3M [3] and Pt and Pt alloy nanotubes UC Riverside [1]. The synthesis of catalysts with high mass activity and the effective implementation of these catalysts in high-performance, durable and robust MEAs will help enable fuel cell commercialization on a significant scale.

Approach

Our approach involves synthesizing novel catalyst particles using either a nanostructured support material such as CNTs, metal oxide nanoparticles, or perylene red nanowhiskers; or a sacrificial metal template. Pt is deposited on these materials either through vapor deposition (including sputtering and atomic layer deposition [ALD]) or solution deposition (including galvanic displacement). Our goal is to produce nanostructures with thin, continuous films of Pt as similar structures have shown high catalytic activity and durability. The materials synthesized are characterized by several techniques with a strong focus on microscopy and electrochemistry. To date, extended surface catalysts have been demonstrated in traditional, thick catalyst layers that include Nafton® and have been shown to exhibit good tolerance to a wide range of operating conditions including cold-start. The novel catalysts produced in this project will be implemented in thick, dispersed electrodes to investigate the production of high-performance, robust electrodes from these materials. Modeling will be used in support of our catalyst synthesis studies and our electrode studies, extending established models involving wetting of Pt on supports, simulating electrode architecture, and evaluating criteria that impact electrode performance.

Results

We have investigated a number of substrates for their potential application as supports for extended surface Pt hosts. Our results with CNTs have focused on two approaches: CNT mats, where mats are drop cast onto substrates prior to Pt deposition; and vertically aligned CNTs. Based on the high surface tension of Pt and the tendency of numerous Pt/CNT catalysts reported to form isolated particles, we expected difficulty in getting CNTs to conformally coat with Pt. Our early studies resulted in the first reported continuously coated CNTs. These materials, an example of which is shown in Figure 1, obtained from Pt-sputtered CNT mats, demonstrated the potential of CNTs as hosts for continuous thin films of Pt and resulted in an early project milestone being accomplished. Through systematic studies of deposition time we were able to obtain target Pt thickness of ~2 nm, such as that estimated from Figure 1 from comparisons of coated regions of CNTs to uncoated regions highlighted by the measurements within Figure 1.

Vertically aligned CNTs were investigated as they resulted in an increased materials yield on a geometric area basis compared to the drop cast CNT mats. As part of this project vertically aligned CNTs were for the first time synthesized at NREL. In the area of vertically aligned CNT synthesis, we performed tests to investigate reproducibility of our methods both from sample to sample and within a sample. These studies focused on Fe-catalyst deposition for vertically aligned carbon nanotubes (VACNTs) and involved sputtering, ALD, and electrochemical deposition. We also modified synthesis conditions to include water assisted deposition. We now have a wider materials set for study and a better appreciation for the variables controlling VACNT formation. We also isolated that it is largely reproducibility of the Fe-based catalyst used for VACNT growth that is the principal step leading to
reproducibility issues between samples. The use of ALD allows for better reproducibility than what was obtained using other techniques. Figure 2 and Table 2 summarize the impact of temperature on the growth conditions presented and give examples of the different VACNTs that we have synthesized and how by controlling specific parameters (in this case temperature) we produce materials with specific properties.

In the area of Pt deposition, our studies have shown that VACNTs have very heterogeneous coatings of Pt regardless of deposition technique, although ALD provides slightly better uniformity than sputtering in most cases. Because ALD is a step-by-step process that offers the potential for very thin, conformal coatings we had hoped for much more uniform coatings using ALD. Of particular issue is the slow nucleation process of Pt on CNTs, as reflected in Figure 3a, which shows the Pt composition at the bottom, middle and top of 20 micron VACNTs. Pt deposition on the surface takes over 100 cycles before significant nucleation takes place. The resultant particles either tend to have exceptionally thick coatings or discrete particles using the approaches we have investigated and are strongly dependent on their location along the CNTs. In order to investigate the nucleation process we have performed a number of pretreatments to the CNTs including oxygen plasma, Ar plasma, and trimethylaluminum (TMA). Of these three pretreatments, only the TMA pretreatment showed an enhancement in nucleation rate. Even with this increased nucleation, the sample still showed a strong dependence on position Figure 3b. With further increases in nucleation rate it is possible that ALD will yield the target structures we are striving for, so continued effort will be placed on investigation of nucleation rates using ALD.

In the area of metal template synthesis and SGD, we have focused on Cu nanowires followed by subsequent displacement by Pt. There are only a few reports of Cu nanowire synthesis in the literature and the reported procedures have taken many hours with limited yields. We have developed a microwave-assisted wet chemical approach that takes only 15 minutes and greatly increases our yield of materials, examples of the materials generated are shown in Figure 4. These nanowires add to the Ag and Se nanowires that have already been demonstrated as templates for spontaneous galvanic displacement by our project subcontractor UC Riverside [1]. Cu offers potential advantages over Ag and Se because it has been shown to lead to improved activity when used in alloys with Pt [2]. We have examined a limited materials set after galvanic displacement and have found improvements in specific activity when compared to traditional materials (~6x improvement). Our studies in this area are in the preliminary stages and will continue with a focus on mass activity and durability.

**Conclusions and Future Directions**

We have demonstrated for the first time conformal Pt coatings on CNTs, and Pt nanostructures from Cu nanowires. We have performed controlled growth of CNTs. We have investigated Pt ALD, sputtering, SGD and other solution based routes as Pt deposition techniques. Future work, broken down by topical area, includes:

- **Templates/Cores**
  - Further advancement of Cu-based nano-templates.
  - Development of short, less dense VACNTs that are analogous to the 3M nano-structured thin-film whiskers.
  - Investigation of metal oxide supports.

- **Pt Deposition**
  - Continued investigation of sputtering onto CNT mats in order to increase heterogeneity and yield.
  - ALD studies investigating the effect of adhesion layers and processing conditions on Pt nucleation and growth.
  - Optimization of SGD displacement process, resultant structures/composition, and electrochemical performance and durability.

- **Electrode Studies**
  - Electrochemical screening (specific and mass activity) of novel catalysts.
  - Incorporation of highest performing catalysts into electrode studies.
  - MEA fabrication and fuel cell testing of novel catalysts.
• Modeling
  – Advancement of models and correlation of experimental data with models involving Pt wetting on surfaces, electrode structure and performance.

Project Start Date:  September 2009
Project End Date:  September 2012

Objectives

- Fundamental understanding of the oxygen reduction reaction on multimetallic PtM (M = Co, Ni, Fe, Mn, Cr, V, and Ti) and PtM1N2 (M1 = Co or Ni; N2 = Fe, Mn, Cr, V, and Ti) materials.
- Develop highly-efficient, durable, nanosegregated Pt-skin PtM and PtM1N2 catalysts with ultra low Pt content.
- Find relationships between activity/stability of well-characterized bulk alloys and real nanoparticles (NPs).
- Develop novel chemical and physical methods for synthesis of monodispersed PtM and PtM1N2 alloy NPs and thin metal films.
- Resolve electronic/atomic structure and segregation profile of PtM and PtM,N2 systems.
- Resolve composition effects of PtM and PtM1,N2 systems.
- Demonstrate mass activity and stability improvement of PtM and PtM1,N2 alloy NPs.
- Use computational methods as the basis to form any predictive ability for tailoring binary and ternary systems to have desirable reactivity and durability properties.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(B) Cost
- Reduce precious metal loading of catalysts.
- Increase the specific and mass activities of catalysts.
- Increase the durability/stability of catalysts with cycling.
- Test and characterize catalysts.

Technical Targets

This project is conducting fundamental studies of the oxygen reduction reaction on Pt-based PtM binary and PtM1,N2 catalysts. Insights gained from these studies will be applied toward the design and synthesis of highly-efficient, durable, nanosegregated Pt-skin catalysts with ultra low Pt content that meet or exceed the following DOE 2015 targets:

- Specific activity @0.9 V Ir-free: 720 mA/cm²
- Mass activity @0.9 V: 0.44 A/mgPt
- Platinum group metal total content: 0.2 g/kW
- Total loading: 0.2 mg/cm²
- Catalyst support loss: <30%
- Durability with cycling (80°C): 5,000 hrs

Accomplishments

- Synthesized wide range of bi/multi-metallic NPs with controlled size and composition by colloidal organic solvo-thermal approach.
- Resolved particle size effect for bimetallic NPs: optimal size is found to be 5 nm with activity (1.5 A/mgPt) that exceeds the DOE 2015 targets.
- Established post-synthesis routes for altering surface/adsorption and catalytic properties:
  - Acid treatment for removal of non-precious metal atoms and optimal annealing temperature to create the most active (1.4 A/mgPt) segregation profiles for bimetallic PtM NPs.
  - Performed composition optimization of bimetallic PtM catalysts.
  - Established activity (stability) trends for bimetallic NPs.
- Confirmed that ternary alloys could provide additional tunability towards activity and stability.
Introduction

In the quest to make the proton exchange membrane fuel cell (PEMFC) a competitive force, one of the major limitations is to reduce the significant overpotential for the oxygen reduction reaction (ORR) and minimize dissolution of the cathode catalysts. Here, we report a progress for Fiscal Year (FY) 2010 in experimental and theoretical studies to addressing the importance of alloying Pt with 3d elements (M= Ni, Co, Fe etc.) in order to form catalytically active materials with so-called nanosegregated profile [1] and to minimize the amount of Pt. We have demonstrated that the nanosegregated surfaces are superior in both: exceptional catalytic activity for the ORR and higher stability of Pt surface atoms.

Approach

To address the challenges that are listed as the DOE targets for the Fuel Cells sub-program we rely on our materials-by-design approach [2,3]. This involves four major steps: (i) advanced synthesis of novel nanoscale materials, which enables control of their size and composition; (ii) characterization of atomic and electronic properties by ex situ and in situ surface characterization techniques and theoretical methods; (iii) resolving the surface electronic and crystal structures at atomic/molecular level that govern efficient kinetics of the ORR; and (iv) synthesis/fabrication of the highly efficient nanoscale materials, which are guided by the fundamental understanding of structure-function relationships.

Results

The Crystallite Size Effect for Pt₃M Catalysts: The crystallite/particle size effect is the variation in reaction rate or selectivity with characteristic dimension of metallic catalysts, while the structure sensitivity refers to the dependence of reaction rate or selectivity on the geometry of the surface. Hence a structure sensitive reaction is expected to exhibit a crystallite size effect. This has been confirmed for the ORR on Pt, i.e., the ORR is strongly affected by the particle size of Pt NPs supported on carbon [4]. In order to systematically explore this effect for Pt alloys we have established novel colloidal organic solvo-thermal routes for synthesis of monodisperse Pt₃M NPs with controlled size ranging from 3 to 9 nm in diameter. We have found that the particle size effect also applies for the ORR on Pt₃M NPs [5]. As summarized in Figure 1 for 3-9 nm Pt₃Co NPs, while specific activity increases with the particle size, i.e., from 2-4 mA/cm², respectively, the optimal mass activity is obtained for ~5 nm NPs. Both the specific activity (3 mA/cm²) as well as the mass activity (1.6 A/mgₚt) of the ORR on 5 nm Pt₃Co NPs significantly exceeds the DOE targets of 0.72 mA/cm² and 0.44 A/mgₚt.

Temperature-Induced Segregation towards the Nanosegregated Materials: The term nanosegregated materials has been coined to describe the formation of oscillatory concentration profile with 100% Pt in the first layer, counterbalanced by depletion of Pt in the second layer, which is followed by enrichment of Pt in the third layer [1]. Surface segregation was confirmed experimentally and theoretically for the bulk Pt₃M single and polycrystalline surfaces, but not for corresponding NPs. Given that the highest activity that has ever been observed on cathode catalyst was obtained on
Pt<sub>3</sub>Ni(111) electrode, with a specific activity 90-fold higher than the state-of-the-art Pt/C catalysts [1], it has been of paramount importance to develop preparation method that would allow the design of the PtM NPs with nanosegregated-like catalytic properties.

For that reason the temperature annealing effect on Pt-alloy NPs was explored. The results are summarized in Figure 2 for the monodisperse and homogeneous 4.5 nm Pt<sub>3</sub>Co/carbon catalyst synthesized by solvo-thermal route and then treated at various temperatures, ranging from 300 to 800°C. No obvious size or morphology change was observed for the catalysts annealed up to 400-500°C (Figure 2a). Particle sintering appeared for the catalyst annealed at the temperatures higher than 500°C, which is evident at 800°C (Figure 2b). The X-ray diffraction (XRD) analysis showed single crystal phase for all thermally annealed NPs, confirming the homogeneous alloy composition. This exclusion allowed exploration of the intrinsic effect of thermal annealing on the catalytic performance of the catalyst. Figure 2e and ref. [6] show that, without significant particle sintering, the specific activity increase of almost 1 mA/cm<sup>2</sup> was obtained for the nanoparticles pre-treated at 400°C. If compared to the state-of-the-art Pt/carbon catalyst, 3-fold activity enhancement for the ORR is reached on this catalyst. In turn, this may imply that the surface segregation may have happened with Pt<sub>3</sub>M NPs even at the moderate 400-500°C temperatures.

Due to experimental limitations in resolving the concentration profile of the very first atomic layers for nanoscale materials, we used Monte Carlo simulations to probe formation of the Pt-skin for 5 nm Pt<sub>3</sub>Co NP at the optimal temperature. Figures 2c and 2d reveal that the resultant Pt concentrations are 99 at% in the outermost surface layer, 44 at% in the second sub-surface layer, and 92 at% in the third sub-surface layer, suggesting that 400°C would induce formation of the nanosegregated structure. As shown in Figure 2e, the descending trend in specific surface area for different annealing temperatures is followed by ascending trend in specific activities. In turn, volcano-like shape is observed for mass activity vs. annealing temperature. It is important to point out that the activities presented here are much higher than those reported in the literature for PtCo alloy catalysts prepared by conventional co-precipitation or impregnation methods [7]. This suggests that the solvo-thermal synthesis brings high level of control of the crucial parameters such as homogenous distribution of particle size and composition profiles, which indeed lead to formation of nanosegregated-like properties.

Composition Effects—Tailoring of Nanosegregated Layers: Having established the optimal particle size of Pt<sub>3</sub>M NPs and the most favorable annealing temperature for the formation of nanosegregated-like materials, the next step was to establish the most favorable composition of PtM NPs. To unravel this complex issue we relied on the advanced solvo-thermal methods to synthesize Pt<sub>x</sub>Ni<sub>y</sub> NPs with altered 3:1, 1:1, 1:2 and 1:3 atomic ratios. In order to avoid the particle size effect, the size of all NPs was controlled to be 5 nm. Due to surface chemistry of the 3d elements under PEMFC-related conditions, the NPs were pretreated in acid solution to remove surface Ni atoms and to form the so-called skeleton-like surface structure (Figure 3). As summarized in ref. [8], the highest specific (4.0 mA/cm<sup>2</sup>) and mass (1.5 A/mgPt) activities for the ORR are observed on NPs having 1:1 Pt to Ni atomic ratio. This result differs from the most active concentration profile (3:1 Pt/Ni atomic ratio) previously observed on the extended Pt<sub>3</sub>M surfaces [8]. The resolution of this disparity is obtained by utilizing energy-dispersive X-ray (EDX) spectroscopy; i.e, EDX
showed that acid pretreatment transforms PtNi NPs into Pt skeleton structure with ca. 25% Ni.

Further modification and altering of the activity and stability of PtNi NPs was obtained by subsequent annealing at 400°C. This treatment allowed relaxation of low-coordinated surface atoms and the formation of the core (PtNi)/shell (2 atomic Pt layers) structure depicted in Figure 3. The XRD analyses revealed that the core/shell-like NPs are homogenous having a face-centered cubic pattern with the decrease of lattice constant due to the alloying of Pt with Ni. The core/shell PtNi NPs have unique activity for the ORR, i.e., 1 mA/cm² at 0.95 V (!) as well as a promising stability (PtNi/Pt NPs do not suffer from the decay in activity or surface area after 30,000 cycles between 0.5 to 1.1 V).

Electrocatalytic Trends for Ternary Systems:
Organic colloidal solvo-thermal approach was developed to synthesize Pt-based PtM₁N₂ (NM = Fe, Co, and/or Ni) ternary alloys in order to understand fundamental differences between bimetallic and ternary systems, Figure 4. It is expected that addition of the third 3d element would induce additional level in altering of the catalytic activity for binary systems. Currently, there is no fundamental correlation between the addition of two 3d elements and induced change of electronic/adsorption/catalytic properties of the nanosegregated materials. The preliminary results (summarized in Figures 4a-d) are encouraging, given that PtCoNi NPs show specific (5 mA/cm²) and mass (2 A/mg) activity that exceed the corresponding bimetallic systems and the DOE 2015 targets. In turn, this indicates that ternary alloys could provide additional tunability towards the activity and stability of Pt-based alloys. We strongly believe, therefore, that our material-by-design approach will enable further enhancement of the catalytic properties with breakthrough performance for the cathode catalysts in PEMFCs.

Conclusions and Future Directions
- PtM and PtM₁N₂ NP cathode catalysts obtained from the organic solvo-thermal synthesis exhibit superior activity and stability than those prepared by the conventional methods. The optimal particle size, annealing temperature, and alloy composition of the PtM NPs are determined.
Significant mass activity and durability improvements are obtained for PtM and PtM,N₂ NPs. Advanced theoretical modeling (density functional theory, Monte Carlo) methods are developed for resolving nanosegregated structures. Understanding of the ternary alloy catalysts is yet to be addressed.

In collaboration with industrial partners, fabrication and testing in a membrane electrode assembly of the most promising catalysts is planned as well as patenting of the novel synthetic routes developed in this project.

Objectives

Developing high-performance fuel cell electrocatalysts for the oxygen reduction reaction (ORR) comprising contiguous Pt monolayer (ML) on stable, inexpensive metal or alloy:

- Nanoparticles (NP)
- Nanorods
- Nanowires
- Carbon nanotubes (CNT)

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Durability
- Cost
- Performance

Introduction

The last decade has seen considerable advances made in fuel cell electrocatalysis yielding improved electrocatalysts, and increasing our understanding of the kinetics of the ORR along with affording significant advances in theoretical treatments. However, some technological difficulties that hamper the automotive applications of fuel cells have not been removed. It is generally accepted that there is an optimal size for the...
ORR where the balance between the effects of increasing the surface area and the adverse effect of small particles oxidation are met.

**Approach**

The awareness of a complex influence of the nanoparticle size and shape on the catalyst’s activity has been growing, but a clear description was not available. We examined the effects the thickness of the Pt shell, lattice mismatch, and particle size on specific and mass activities from the changes in effective surface area and activity for oxygen reduction induced by stepwise Pt ML depositions on Pd and Pd₃Co nanoparticle. We find significant weakening of binding energy of oxygen (BE-O) on the (111) facet compared to the extended surface due to nanoscale induced in-plane lattice contraction. Because the ORR rate on Pt is desorption limited, lowering BE-O enhances the ORR activity. Thus, the high coordination (111) facets are most conducive to the ORR on nanoparticles. In addition, they are less prone to dissolution than low-coordinated edges, defects, and less close-packed facets.

Therefore, smooth, lattice contracted (111) like surface structures are needed to achieve durable high ORR activity. Based on our understanding of the effect of shape, size and composition of nanoparticles on the kinetics of the ORR, we have studied Pt monolayers on surfaces having predominantly highly coordinated atoms that exist on nanorods, nanowires, smooth nanoparticles, hollow Pd spheres, single crystalline nanoparticles with predominantly (111) facets. We have studied hollow Pt electrocatalyst to optimize the nature and size of templates, deposition process and the size of hollow with respect to activity and stability. We will also study design and synthesis of, what we call, the second generation core-shell catalysts particularly using a sub-surface core modification.

**Results**

**Pd Nanorods, Nanowires as Supports**

The structural sensitivity of the ORR on Pt is now established for nanoparticles catalysts. The activity decreases in the sequence for the (111) > (100) > (110) oriented facets. The nanorods and nanowires with smooth surfaces present attractive option because they can be tailored to increase surface fraction of atoms of the most ORR active facets and decrease low coordination sites. Syntheses of nanorods and nanowires were carried out using chemical and electrochemical deposition. In both cases enhanced reaction kinetics was observed. This is the first report on electrochemical deposition of nanowires. The results will be reported soon. They are quite promising; given the better Pd utilization and a direct formation at the carbon surfaces that provides electrolyte access to a major part of the catalysts' surface and thus its the best utilization. Figure 1 shows the scanning transmission electron microscope (STEM) image of carbon supported Pd nanowires synthesized using a chemical procedure and polarization curves for a Pt₉/Pd/C catalysts. Their specific and mass activities for Pt monolayers on Pd nanorods are given in Table 1, while for nanowires are 641 μA/cm² and 1.01 A/cm², respectively. The results are preliminary, and indicate broad possibilities for improvements.

**Smooth, or Smooth and Hollow, Pd Nanoparticles**

Smooth Pd nanoparticles can be obtained by removing the low coordination support atoms (at edge and kink sites), which are places where OH strongly adsorbs and the dissolution first occurs can increase the catalyst's stability and activity without particle size growth. Several cycles of bromide adsorption and subsequent reductive desorption removes the low-
coordination atoms from Pd surfaces. The morphologies of the Pd nanoparticles before and after the bromide treatment show that the sharp edges appearing in most of the particles in the Pd/C can be hardly observed after the bromide treatment, resulting into a rounded-shape nanoparticles, much more uniform particle size distribution. The latter indicates a pronounced Ostwald ripening effect. The effect of the Br- treatment of a Pd surface causes an increased activity and stability of a Pt/Pd/C catalyst having \( \text{i}_{\text{on}} = 1.21 \, \text{A/mg Pt} \) and \( \text{i}_{\text{p}} = 0.78 \, \text{mA/cm}^2 \) that surpasses commercial Pt/C catalysts by 5 times in mass activity. A negligible change in \( \text{E}_{\text{1/2}} \) after 10,000 potential cycles indicates a high stability of a Pt monolayer on a smooth Pd surface.

**Hollow Pt Nanoparticle Catalysts**

We explored whether hollow can induce a needed lattice contraction as a no-cost, trouble-free core. Using Ni nanoparticles as dissoluble template, we produced compact Pt hollow nanospheres. Excellent durability was found: no loss after 10,000 potential sweep cycles between 0.65-1.05 V, and in severe pulse potential cycle test, 30 s alternatively at 0.65 and 1.05 V, sustainable Pt mass activity of 0.58 mA g\(^{-1}\) was achieved, exceeding the DOE target of 0.44 mA g\(^{-1}\) for platinum group metals. In another test, no further loss was confirmed after additional 7,000 potential cycles that last more than 200 hours. The enhancement over solid Pt nanoparticles (45% Pt/C, 3.2 nm) is six-fold after 100-hour durability test.

As shown in the STEM images (Figure 2), compact single grain nanospheres with 3-12 nm in diameter and 1-2 nm in shell thickness were found after durability test. Electron and X-ray diffraction measurements revealed up to 2% average lattice contraction compared to Pt lattice constant of 0.3923 nm. The density functional theory (DFT) calculation for solid and hollow Pt nanoparticles manifests a trend that the lattice contraction with a subsequent weakening of oxygen binding energies relative to that of Pt(111) is greater for hollow than for solid nanoparticles, independent of particle size. In addition to lattice contraction, we found significantly smoother surface on hollow particles. Both effects led to high sustainable ORR activity not achieved previously.

**Conclusions and Future Directions**

- Smooth surfaces, with highly-coordinated atoms, are suitable to support a Pt ML that yield very active catalysts.
- Pd nanowires were synthesized. Their thickness needs to be reduced and removal of surfactants simplified to obtain an excellent catalyst with a Pt ML.
- Sub-surface ML modification of cores is very promising; it opens up numerous possibilities for design of catalysts.
- Hollow Pd and Pt nanoparticles are very attractive for further studies.
- Initial difficulties with refractory metal alloys and metallization of CNTs are being resolved; the results are encouraging (not shown here).

Future studies will focus on:

1. Improve synthesis of Pd nanorods, nanowires, and Pd hollow NPs. (BNL, MIT, JMFC)
2. Improve metallization and catalysation of CNTs, oxides, nitrides. (JMFC, MIT, BNL)
3. Pd-Nb alloy NPs; start the work on Pd-W NPs and Pd-V. (BNL, MIT)
4. Scale-up of selected catalysts up to 20 grams. (JMFC, BNL)
5. MEA fabrication and tests.

**Special Recognitions & Awards/Patents Issued**

3. Three patents issued in 2010
   - 7,704,919 Electro catalysts having gold monolayers on platinum nanoparticle cores, and uses thereof
   - 7,704,918 Synthesis of metal-metal oxide catalysts and electrocatalysts using a metal cation adsorption/reduction and adatom replacement by more noble ones
   - 7,691,780 Platinum- and platinum alloy-coated palladium and palladium alloy particles and uses thereof

4. Three patent applications in 2010
   - 20100177462 Platinum-Based Electro catalysts Synthesized by Depositing Contiguous Adlayers on Carbon Nanostructures
   - 20100099012 Electrocatalyst Synthesized by Depositing a Contiguous Metal Adlayer on Transition Metal Nanostructures
   - 20100097742 Electrodes Synthesized from Carbon Nanostructures Coated with a Smooth and Conformal Metal Adlayer

Project Start Date:  October, 2009
Project End Date:  October, 2014

Objectives

• Development of durable, high mass activity platinum group metal (PGM) cathode catalysts enabling lower cost fuel cells.
• Elucidation of the fundamental relationships between PGM catalyst shape, particle size and activity to help design better catalysts.
• Optimization of the cathode electrode layer to maximize the performance of PGM catalysts – improving fuel cell performance and lowering cost.
• Understanding the performance degradation mechanisms of high mass activity cathode catalysts – provide insights to better catalyst design.
• Development and testing of fuel cells using ultra-low loading high-activity PGM catalysts – validation of advanced concepts.

Technical Barriers

This project addresses the following technical barriers from Section 3.4 of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability: PGM catalysts durability goals have not been achieved for transportation and stationary systems.
(B) Cost: The amount of expensive PGM catalyst currently required in fuel cell stacks does not meet cost targets for transportation and stationary systems.
(C) Performance: The performance of PGM catalysts at required loadings to meet cost targets does not meet the current targets.

The technical targets for catalyst loading are indicated in Table 1. These targets were formulated with the assumption that fuel cell durability and impurity tolerance would not be impacted by the decreased Pt loadings used in the fuel cells.

Technical Targets

Table 1. Technical Targets: Electrocatalysts for Transportation Applications (Extracted from Table 3.4.12. Technical Plan April 27, 2007)

Accomplishments

• New nanowires supports for low PGM catalysts developed.
• Polypyrrole nanowire supports developed using electrosynthesis.
• Ultra-low loading Pt layers successfully deposited by radio frequency magnetron sputtering.
• Pt dispersion onto differing supports studied by scanning electron microscopy (SEM) and X-ray diffraction.
• Theoretical density functional theory modeling commenced.
• Single-cell fuel cell testing of new low-PGM catalysts commenced.

Introduction

Minimizing the quantity of Pt group metals used in proton exchange membrane fuel cells is
one of the remaining grand challenges for fuel cell commercialization. Tremendous progress has been achieved over the last two decades in decreasing the Pt loading required for efficient fuel cell performance. Prior work at Los Alamos has led to a twenty-fold reduction in the amount of Pt required for good fuel cell performance at acceptable power densities. Unfortunately, the fluctuations in the price of Pt represent a substantial barrier to the economics of widespread fuel cell use. Durability and impurity tolerance are also challenges that are tightly coupled to fuel cell Pt electrode loading. Traditional approaches to decreasing the amount of Pt required for good performance include:

- Increasing mass activity by decreasing Pt particle size by supporting on carbon.
- Alloy formulation Pt-Co, Pt-Cr alloys to improve mass activity.
- Increasing Pt utilization by optimization of electronic and ionic contact of the Pt particles.
- Improving conductivity of the electronic and ionic conducting constituents of the membrane electrode assembly.
- Improving reactant to and product mass transport away from the electroactive sites. Recent novel approaches include the nanoengineering of core shell catalysts and Pt particles of unusual geometries such as nanowires/whiskers.

The success of the aforementioned approaches has been great; however further advances using such approaches may be reaching a number of limitations. In the case of decreasing particle size, a peak in mass activity is observed around 2.5 nm Pt particle size due to a steady decrease in the area specific catalytic activity for oxygen reduction when the quasi-spherical particle size decreases below threshold bulk values in the ~10 nm range. The mass activity continues to improve due to an inverse linear relationship between particle surface area and particle volume (mass). The decrease in area specific activity overwhelms the increase in surface area for a given mass for Pt particle sizes between 2 and 3 nm. Durability also suffers as the difference in positive free energy between the nanoparticle and a bulk crystal also increases with decreasing particle size. The energetic destabilization of the Pt particles with decreasing size makes them more susceptible to oxidation, dissolution/re-precipitation and grain growth via Oswald ripening processes. Long-term fuel cell durability testing, cyclic voltammetry and thermodynamic measurements confirm this behavior.

**Approach**

Our approach to new PGM catalyst design is multi-tiered. We are designing new low platinum loading catalysts on novel support materials to improve fuel cell performance. Novel PGM shapes; nanoparticles, nanotubes and nanowires are being synthesized in a variety of sizes. We are using contemporary theoretical modeling and advanced computational methods to understand and engineer the new catalysts. We are also modeling and designing appropriate catalyst architectures to maximize the performance of our novel catalysts. Catalyst-support interactions and their effects on durability and mass activity are also investigated. We study and test the performance of the catalysts in electrochemical cells, single-cell fuel cells and fuel cell stacks. The new catalysts are extensively characterized before and after fuel cell operation.

**Results**

**Activation of Pyrograf and Bulk Chemical Deposition of Polypyrrole with Light and Heavy Deposits**

Low-cost Pyrograf III carbon nanofibers (Applied Sciences Inc.) were “activated” with concentrated nitric acid to impart surface functionality. The hydrophilic surface moieties provided relatively stable aqueous suspensions and purportedly improved the adhesion and uniformity of polypyrrole depositions. For bulk chemical depositions of polypyrrole, appropriate amounts of pyrrole were added to roughly 2 mg/cm² aqueous Pyrograf suspensions and stirred briskly. After at least 10 minutes, ammonium persulfate was then added to catalyze the polymerization. The suspensions quickly flocculated to a degree commensurate with the pyrrole addition. The PPy-coated nanofiber products were filter rinsed with deionized water.

**Activated Pyrograf with Ti and Pt Depositions**

To form thin and uniform carbon nanofiber films, dilute aqueous suspensions of activated Pyrograf were filter cast onto hydrophilic microporous filter membranes (Millipore HVLP). The hydrophilic nature of the filter was crucial for achieving an equal flow throughout and hence an even amount of material accumulation. After thorough drying, the thin film coated filters were loaded into a multi-target sputtering system (Model 2400, High Tech Services, Inc.) equipped with 15 cm titanium and platinum targets. The Ti target was first sputter cleaned for 15 min with 500 W radio frequency power under 8 mTorr of argon and then the filter samples were sputter coated with the Ti for 12 min at 50 W. The Ti-coated samples were removed from the sputtering chamber for analysis and to allow air-induced formation of oxides to avoid possible alloying with the subsequent Pt deposition. Later, the samples were reintroduced into the sputtering system. After sputter cleaning for 10 min at 300 W radio frequency power, Pt was deposited on the samples for 3 min at 50 W in
8 mTorr argon for a target deposition of 0.05 mg Pt/cm². Subsequent analyses with X-ray fluorescence (XRF) were used to verify platinum loadings. The Pt-catalyzed Ti-coated Pyrograf films were applied to vacuum-table-dried Nafion® NRE212 membranes by hot-pressing the nanofiber coated filters under high-pressure (15 MPa) at 130°C for 3 min. Despite the pressure, the full depth of the film did not always transfer. In this example, XRF indicated that a nanofiber layer corresponding to 0.042 of the original 0.05 mg Pt/cm² adhered to the membrane. The 5 cm² active area fuel cell was completed with the use of an ELAT® SSE 2.22 carbon cloth gas diffusion layer (GDL) backing the nanofiber cathode and a Nafion®-impregnated Pt catalyzed carbon cloth ELAT® electrode on the anode side (ELAT® materials originally supplied by E-Tek). The cloths and catalyzed membrane were assembled loose, cell compression was relied upon to provide the necessary interfacial continuity.

Activated Multi-Walled Carbon Nanotubes (MWCNTs) and Pt Deposition

MWCNTs (Nanostructured and Amorphous Materials Inc.) were activated in a similar manner as the Pyrograf, although the MWCNTs were not as easily suspended. Well-dispersed aqueous suspensions could only be obtained using high dilutions and the direct insertion of a high-power ultrasonic horn (Branson Sonifier 450) into the mixture to break up agglomerates. When filter cast, these suspensions provided highly uniform thin films. Platinum deposition, catalyzed membrane preparation and the remaining fuel cell components were similar to the above Pt/Ti/Pyrograf cell, except that an even higher pressure (20 MPa) was used to obtain a similar transfer effectiveness corresponding to a loading of 0.044 mg Pt/cm².

Fibron Carbon Supports and Pt Deposition

An aqueous nanofiber polypyrrole dispersion (PPC-10-1-01 from Fibron Technologies, Inc.) was further diluted and filter cast as above to form a uniform thin film. Pt was sputter coated for loadings of 0.05 mg Pt/cm². Even though the catalyzed nanofiber polypyrrole Fibron film was hot-pressed to the membrane at the higher pressure (20 MPa), only 0.035 equivalents of the 0.05 mg Pt/cm² Fibron film transferred to the membrane. The remaining fuel cell aspects of this particular Fibron-based cell were the same as above. An improved fuel cell environment for the nanofiber catalyst layer and a simpler cell fabrication process was achieved by eliminating the problematic step of hot-pressing the nanofiber film to the membrane. This was accomplished by directly filter casting the nanofiber suspension onto the GDL. Since the surface of a carbon cloth GDL varies substantially in topography and porosity around the weaves, much more uniform microporous layer-coated carbon paper GDL materials were used instead. In the filter casting process, the Nafion®-coated GDL was first soaked with methanol to promote wetting of the full structure before the aqueous suspension was introduced. An SGL 30 DC carbon paper gas diffusion layer was first coated with 0.18 mg Nafion®/cm². A dilute suspension of Fibron nanofiber polypyrrole was filter cast onto the GDL. After drying, the nanofiber-coated GDL was sputter coated with 0.05 mg Pt/cm². For the remaining fuel cell components, SGL 30 DC was painted with a 2:1 Pt/C:Nafion® ink with a 0.05 mg Pt/cm² loading to serve as the anode and Nafion® NRE 212 was used for the membrane. The fuel cell was assembled with loose components. In this configuration, the cathode interfaces superficially consisted of Nafion® membrane/Pt-coated polypyrrole/Nafion® recast/GDLmicroporous layer. After compression, significant intermingling of these layers probably occurred.

Fuel Cell Testing

The 5 cm² fuel cells were tested at 80°C with hydrogen/air pressures of 30/30 psig (285/285 kPa) and reactant humidifiers operating at 80°C. High air-flow stoichiometries (up to 4 x stoichiometry at 1 A/cm²) and/or sub-saturated air humidification conditions were required to obtain stable operation of the flooding-prone cathode nanofiber structures. Elevated cell resistances in the polarization curves occurred due to the relatively dry operating conditions and the corresponding improvements in performance and high-frequency resistance on the return (upward) voltage scan. Due to the precarious balance between excessively dry and flooding, performance of these nanofiber-based fuel cells are much more sensitive to operating conditions than conventional electrodes. High charge transfer resistances were also observed due to the lack of ionomer penetration into the nano-composite electrodes.

Electrochemical Synthesis of Polypyrrole Nanowires

Our alternative support material studies include the development of low Pt loading catalysts on polypyrrole nanowires [1-4]. Using electrochemical synthesis methods, we were able to grow polypyrrole nanowires on a carbon paper GDL using template molecules such as heparin and starch. With this new approach we can achieve a high surface area structure that may lead to a higher oxygen reduction reaction catalytic activity with lower Pt loadings.

Electrochemical synthesis was carried out in an aqueous solution containing 0.2 M pyrrole, 0.40 wt% heparin sodium salt and 0.07 M LiClO₄ by applying potential square waves between 0.300 V (2 s) and 0.850 V (8 s) for 1,200 s at room temperature. Potentials
measured vs. Ag/AgCl (3.5 M KCl) reference electrode. Without the use of templating agents, a low surface area dendritic structure results (Figure 1).

In order to increase the surface area in the polypyrrole film, we first used heparin as a template molecule during the polypyrrole electropolymerization process on a glassy-carbon electrode while applying cyclic multipotential steps. As shown in Figure 2, the presence of heparin results in polypyrrole/heparin nanowires with a much higher surface area than the polypyrrole dendrite structure. After the use of heparin as a template molecule proved to be effective for the formation of a nanowire structure, we obtained a similar result on a carbon paper GDL, so it could be used as a new high surface area gas diffusion electrode (GDE) in a fuel cell configuration. By studying different variables such as pyrrole/heparin ratio and deposition time, the electropolymerization process was optimized so we one can control the diameter and length of the nanowires as desired.

While heparin worked very well as a proof of concept template molecule we immediately searched for a low-cost replacement since heparin is an expensive prescription drug used as a blood thinner. As a result of our search for an alternative template molecule, we found that starch is a very good candidate as is shown in Figure 3. Additionally, starch has the advantage of being inexpensive, easy to find and environmentally benign. Moreover, as in the case of heparin, we found that the tuning of different variables such as pyrrole/starch ratio and deposition time allows controlling the diameter and length of the nanowires.

We are currently investigating Pt deposition by RF magnetron sputtering and by electrochemical deposition. After the optimization of the electrochemical synthesis of the Pt coated polypyrrole/starch nanowires is completed, fuel cell test studies will be carried out in order to obtain performance and stability data for the new GDE. Additionally, the structure will be also prepared on a glassy carbon disk electrode and rotating ring disk electrode studies will be performed to determine the catalytic activity of the Pt coated polypyrrole/starch nanowires.

Conclusions and Future Directions

- Pt catalysts can be deposited uniformly on a variety of nanowire supports using radio frequency magnetron sputtering.
• New oriented polypyrrole nanowire catalyst supports were developed for fuel cell cathode use.
• Novel supported Pt catalysts require optimization of the electrode layer.
• Oxygen reduction activity as a function of loading will be probed by rotating disk electrode electrochemical methods.
• Support stability will be studied using cyclic voltammetry and post testing materials characterization.
• Mechanism of the nucleation and growth of PGM on the supports will also be studied.

V.E.11 Molecular-Scale, Three-Dimensional Non-Platinum Group Metal Electrodes for Catalysis of Fuel Cell Reactions

Objectives

1. Demonstrate that non-platinum group metal catalysts can be used for oxygen reduction in polymer-coated electrode structures based on polyelectrolyte membranes. (Year 1)

2. Incorporate catalysts into polymer binders of composite electrodes for the construction of membrane electrode assemblies (MEAs) to demonstrate that this is an effective matrix for testing of new catalysts. (Year 2)

3. Demonstrate that the three-dimensional structure of polymer-coated electrocatalyst layers can offset slower kinetics of the catalyst centers when compared with two-dimensional platinum or non-platinum catalysts. (Year 3)

4. Demonstrate that significant stability of the matrix is possible. (Year 3)

5. Demonstrate the design, synthesis and scale up of new catalysts capable of performance that is superior to platinum group metals. (Year 4)

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

(C) Performance
(E) System Thermal and Water Management
(B) Cost
(A) Durability

Technical Targets

- Non-Pt catalyst activity per volume of supported catalyst – 300 A/cm³
- Cost <$3/kW
- Durability >5,000 hours (>120°C)
- Electrochemical area loss <40%
- Electrochemical support loss <30 mV after 100 hrs @ 1.2 V

Accomplishments

- Developed electrochemical screening methods for new catalysts using classical electrochemical methods.
- Developed synthetic methods to prepare new catalysts.
- Developed modeling procedures for prediction of catalyst activity on a molecular level.
- Modified polymer synthesis methods to provide attachment of catalysts to polymers.
- Undertaken preliminary study of polymer ink formulation for non-Nafion® binders for composite electrode fabrication for MEAs.

Introduction.

Although proton exchange membrane (PEM) fuel cells are relatively efficient energy conversion devices
(−50%), there still remains considerable interest in improving the performance while reducing the cost. An area of study that can lead to greater efficiencies while reducing costs is that of the electrocatalysts and particularly the catalysts used for oxygen reduction where the sluggish kinetics leads to inefficient conversion of the energy to heat rather than electricity. The heat generation imposes extra costs due to system complexity to handle both heat and water management. The use of platinum and other platinum group metal catalysts adds further expense. There therefore is considerable interest in developing alternative catalysts that are less expensive and also more efficient. Gasteiger and co-workers [1] have provided a very thorough review of the benchmark activities required for Pt, Pt-alloy and non-Pt catalysts for oxygen reduction and describes in detail different approaches to catalysis of this important reaction.

Methods have been reported to prepare non-precious metal catalysts that involve a curious procedure whereby a rather complicated molecule such as a metal porphyrin or a complex such as iron phanethroline is adsorbed on carbon and then heated to over 800°C to form the catalyst [2-5]. In some cases the carbon support is treated with nitrogenous compounds at high temperature followed by addition of metal ions such as Fe or Co. Although the resulting electrodes are often highly porous with very high surface areas the resulting catalyst layers on the electrode surface are two-dimensional in nature. With these non-platinum catalyst structures the kinetics of oxygen reduction are much less rapid than commercially available platinum on carbon electrode. It is thought that the density of the non-platinum catalytic sites is insufficient to sustain the desired reaction. With the porphyrin catalysts, for example, their poor solubility results in strong adsorption on to the carbon support and insufficient loading of catalyst as well as possible deactivation of the metal center. Since it has been shown by Heller [6], for example, that the copper laccase enzyme obtained from biological sources is capable of supporting current densities for oxygen reduction of 0.5 mA/cm² at a planar carbon electrode with a polarization of only 70 mV, it appears that nature has evolved a catalyst that can outperform platinum. Electrode structures are desired which can allow incorporation of such catalytic species into MEAs, which increase in the surface concentration of the electrocatalysts and which allow the activity of the catalyst to be retained while it is incorporated into the PEM fuel cell engineering platform.

Approach

Homogeneous redox catalysis has been the center of considerable academic attention for several decades now. A recent review by Saveant [7] provides an extensive overview of the topic and includes methods of tethering catalysts close to the electrode surface. These methods suggest ways to incorporate into fuel cell MEAs electrocatalysts that mimic the enzyme catalyst centers and may lead to better performance at reduced cost. Figure 1(a) shows a schematic of a gas diffusion electrode structure typically used in a PEM fuel cell. The electrode usually consists of catalyst nanoparticles (e.g. Pt) dispersed on carbon support particles bound together by a polymeric ionomer material (e.g. Nafton®) on a current collector such as a gas diffusion layer (GDL) which is electronically conductive. The polymer therefore acts as a binder to hold the electrode together and as an electrolyte to transport hydrogen ions to and from the electrode surface. This structure has been designed to optimize the transport of electrons, hydrogen ions, substrate and product to and from the catalyst surface and generally the overall thickness of the electrode layer is about 10 μm. A thicker electrode introduces mass transport limitations that degrade performance. The right hand side of Figure 1(a) shows a schematic blow up of the surface of the electrode where the polymer binder layer is used to bind homogeneous catalysts close to but not right on the surface. This structure allows the use of a variety of catalysts some of which are listed in Figure 1(a) and could be used to tether even an enzyme catalyst such as the copper laccase structure shown in Figure 1(b) or an oxygen binding catalyst such that shown in Figure 1(c). It has been shown (see reference [7] and references therein) that the optimum thickness of the polymer layer can be up to 500 nm thick which would be equivalent to about 100 monolayers of the catalyst on the electrode surface. This thickness of the polymer layer on the electrode particle surface represents little if any increase of the overall thickness of the gas diffusion electrode and hence it is possible to greatly increase the areal density of catalysts on the electrode without increasing the electrode thickness, a concern that was well described by Gasteiger et al. [1].

The operation of the polymer-tethered catalyst layer can appear puzzling to some and the reader is referred to reference [7] for further details. Suffice to say here is that the electrons are transferred from the surface of the current collector by means of an electron hopping mechanism between redox centers as well as by movement of the polymer tethered catalyst back and forth towards the electrode. Therefore the polymer in addition to binding the catalyst must also provide the means to transport protons and ions which can neutralize the charging of the polymer layer. This charging process may indeed be a rate determining step but so also may be the rate of diffusion of the oxygen into the layer or the actual rate of reaction of the catalyst with the substrate and the subsequent dissociation rate of the catalyst and product. In this the catalyst is no different from a metal surface catalyst. What is very different about this approach is that the catalyst center
is effectively a homogeneous catalyst and it may be approached from all directions by the substrate. This provides a geometric advantage for the catalyst center over a surface bound center and can provide an increase in catalytic activity of an order of magnitude or more. This effect combined with the multilayer effect can provide up to three orders of magnitude increase purely due to geometric effects on a molecular scale that hold the potential to make up for the large catalyst area and potentially slower intrinsic kinetics.

The third and most important advantage of the approach is that the catalyst functions essentially as a homogeneous catalyst that can be thoroughly characterized in solution. This makes design and synthesis of the catalysts much more straightforward since the can be studied without resort to surface analysis techniques and to the invocation of surface effects that are poorly understood. Thus, catalysts can be designed from first-principles based on well-known chemistry and physics. The structures of the catalytic centers are understood since the catalysts are synthesized and characterized by classical electrochemical methods in solution thereby avoiding some of the difficulties that have arisen from surface bound catalysts. The catalysts are then incorporated into polymers for coating on electrode surfaces and again the behavior can be characterized by simple electrochemical methods prior to incorporating the polymer-bound catalysts into composite electrodes for MEAs. This last step is critical for the project and represents the Go/No-Go decision point that allows the flow of more efficient catalysts into the PEM fuel cell platform for practical use.

Results

Figure 2 illustrates the process of catalyst screening and incorporation into polymers using classical cyclic voltammetry techniques. Figure 2(a) shows the voltammetric response of a representative iron porphyrin complex (Fe(III)/TMPyP) which is soluble in aqueous perchloric acid solution due to the quaternized pyridinium groups. The Fe(III)/Fe(II) redox couple is shown to be a chemically and electrochemically reversible couple under nitrogen (blue line) indicating fast electron transfer between the carbon electrode and the iron complex. Upon saturation of the solution with oxygen the red curve is observed which shows the increase of reduction current due to reaction of the Fe(II) complex with oxygen. The extent of the increase in current is dependent upon the relative concentration of catalyst and substrate and the sweep rate used to perform
the experiment. From measurements such as these it is possible to actually determine the rate constants of the catalytic reactions [7]. The corresponding copper complex was also active for catalysis of the oxygen reduction reaction (ORR). A point to note here is that these complexes show some stability in acid at least kinetically. Many complexes are immediately decomposed by acid and these results show that the instability can be mitigated. Whether this will be long enough to be useful in a fuel cell remains to be seen.

Figure 2(b) shows the voltammery of a catalyst which has been attached to a polymer and the polymer layer coated on a carbon electrode. In this case the catalyst is a rhodium Cp* organometallic complex which has carbon-metal bonds that are not susceptible to acid cleavage. The left hand voltammograms show the response of the catalyst in two cases. One is with a thin layer of polymer (B) and the other is with a thick layer (A). Integration of the current peaks gives the charge due to the catalyst and hence one can calculate the density of catalyst sites on the electrode. The peak shapes are symmetrical and characteristic of a thin layer of reactant on the electrode surface. These shapes vary with the sweep rate and from such experiments it is possible to estimate the rate of polymer charging [8] as well as diffusion rates through the polymer layer. The voltammogram on the right hand side of Figure 2(b) shows the effect of the addition of a substrate molecule which is reduced by the catalyst. One can see in this case a small increase in the reduction current and a reduction in the height of the oxidation current peak which indicates a reaction occurs between catalyst and substrate but the small increase in reduction current indicates a slow reaction. In this case comparison with the behavior of the catalyst in solution shows that the activity of the catalyst is reduced and this was attributed to low availability of hydrogen ions for the reaction in the polymer matrix that was used. This illustrates the importance of the polymer properties in providing for transport of protons to the site of the reaction. The polymer used in this case was not a polyelectrolyte with no ion transport functionalities. For future work in this project it will be important to choose polymer matrices with this capability and for this use will be made of
polymers from the high temperature membrane project funded by the Department of Energy [9].

These initial results from simple electrochemical experiments demonstrate the importance of the polymer structure that is used to tether the catalysts to the electrode. Preparation of Pt-catalyst MEA electrodes with polymers other than Nafion® is shown in Figure 3 to illustrate this point. The break-in current of a Nafion® electrode is compared with that of an electrode prepared with a polyether polysulfone binder electrolyte. The cartoons on the right hand side of Figure 3(a) represent what is thought to be happening. During break-in the Nafion® polymer is mobile enough to move close to the surface and provide adequate contact. The polyether polysulfone is a stiff polymer and is unable to move close to the electrode surface and hence the break-in is very poor. Figure 3(b) shows polarization curves for three different polymer binders. Once again there is a distinct correlation between the flexibility of the polymer backbone or side chain and the performance in an MEA. These results emphasize the importance of polymer structure on the ability to fabricate a workable MEA electrode and hence attention to polymer structure and properties is critical to the success of this project. In order to demonstrate the feasibility of MEA fabrication readily available catalysts will be selected for incorporation into the polymers. The presence of the catalysts will alter the properties of the polymers and hence considerable experimentation will be required to determine the best formulations and fabrication procedures. This is best done with easily obtainable catalytic centers.

Figure 4 illustrates some syntheses of copper complexes which will be examined for catalytic activity using the classical electrochemical procedures. These are related to complexes already described by Gewirth et al. [10]. In addition to synthesis and characterization experimentally these complexes will also be modeled by molecular calculation to compare theory and experiment. Validation of the modeling procedure by such experiments will allow new catalysts to be

![Figure 3](image-url)

**FIGURE 3.** Effect of Polymer Structure on MEA Performance  (a) Comparison of break-in of MEA electrodes prepared with Nafion® and polyether polysulfone; (b) Comparison of polarization curves of MEAs prepared with different polymer binders in the gas diffusion electrode.
Future Directions

- Increase screening rates of available catalysts to select promising candidates that are stable to acid.
- Develop quantitative measurements of catalytic activity in solution and in polymer-solvent mixtures that are representative of an MEA electrode environment.
- Develop synthetic procedures for attachment of catalysts to polymer binders.
- Continue to explore the properties required of polymer binders to facilitate fabrication of MEAs and study how the presence of catalytic centers changes these properties.
- Design and prepare new catalysts.
- Develop and validate molecular modeling techniques.

Conclusions

Conclusions

- Classical electrochemical methods can be used to characterize the catalytic activity of homogeneous ORR catalysts.
- The structure of the polymer matrix must be designed to provide adequate charge and mass transport to the catalyst centers.
- The polymer binder properties are critical for MEA fabrication.

Conclusions and Future Directions

Subcontractors:
• W.L. Gore & Associates, Elkton, MD
• SGL Carbon, Meitingen, Germany
• University of Delaware, Newark, DE

Project Start Date: July 1, 2007
Project End Date: June 30, 2010

Objectives

The objective of the CIRRUS project is to advance the state-of-the-art in fuel cell operability under subfreezing conditions, consistent with requirements for applications involving such conditions (e.g. automotive, forklifts, backup power systems, and auxiliary power units) and DOE targets, specifically to:

- Demonstrate repeatable achievement of 50% rated power in less than 30 seconds from a -20°C start condition, using less than 5 MJ auxiliary energy.
- Demonstrate unassisted start capability from an initial temperature of -40°C.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(D) Water Transport within the Stack
(G) Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets

Nuvera is demonstrating the ability to meet DOE’s 2010 targets in a full format, subscale stack assembly operating in a simulated but fully realistic ambient environment, using system-compatible operating protocols. The hardware platform initially used in this work was Nuvera’s Andromeda™ fuel cell, designed in 2005, with an active area of 360 cm² and a rating current density of 1.0 A/cm². In the previous reporting period it was shown that Andromeda is capable of starting from -20°C in 30 sec to 50% of its rated power respecting an energy budget of 5 MJ. This report presents the progress obtained in proving the reliability of the startup procedure identified and the durability of a stack subjected to such protocol.

Though the work on Andromeda has been successful at -20°C, the intrinsically high thermal mass of the stack limits the ability to lower even further the starting temperature and it imposes the removal of the coolant during freeze operation even at -20°C.

Thus a stack redesign was required to study startability from extreme temperatures (-40°C) and allow operations at -20°C with resident coolant that dramatically simplify the fuel cell balance of plant.

This new stack, Orion™ (active area 250 cm², rating current density 2 A/cm²), became available last year, and it has been used as the stack platform for this project since the third quarter of 2009.

Accomplishments

- The reliability of the selected startup procedure (from -20°C) was proven through 200 freeze starts performed on Andromeda.
- The diagnostic run on samples subjected to 200 freeze starts did not show significant degradation of fuel cell materials.
- Orion prototypes demonstrated performance (0.6 V @ 2 A/cm²) matching design expectations.
- The Orion stack was successfully started from -20°C with resident coolant, achieving the DOE targets of time to 50% power within the energy budget.
Introduction

For fuel cells to be commercially viable as powerplants in automotive applications, the ability to survive and start reliably in cold climates (as low as -40°C) is a must. Since fuel cells are water-based energy systems, this requirement is a significant technical challenge.

Water transport studies are imperative for achieving DOE targets for fuel cell startup time from subfreezing conditions. Stack components must be selected that endure thermal and humidity cycling over the operating range, and operating strategies must be devised that enable the fuel cell to start, i.e. generate power and heat up sufficiently before ice extinguishes the galvanic reactions, and afford evacuation of a sufficient amount of water, using a limited amount of auxiliary power, at shutdown.

Approach

Nuvera has structured the project into four different phases: investigation, selection, qualification and validation. In the Investigation phase (third and fourth quarters of 2007, completed) Nuvera surveyed the status of the art on the topic and set up the enabling tools (test infrastructure and modeling capabilities). In the Selection phase (2008, completed) Nuvera used these tools to select a proper freeze start strategy to meet the DOE requirements and a set of materials to enable the successful execution of the test. In the Qualification phase (2009, completed) Nuvera assessed performance stability of the combined material set and operating methods in a durability test campaign. The results of this campaign, supported by the interaction with the partners of the project (W.L Gore, SGL and University of Delaware) drove the identification of improvements of materials, strategy and stack architecture. Finally, the effectiveness of these actions is being verified in the Validation phase (first and second quarters of 2010) in which the most advanced configuration is tested to quantify the improvements achieved.

Results

In 2009 Nuvera set up a test campaign that consisted of repeating the same startup protocol 200 times on an Andromeda stack. As stated before, the objectives were to prove the reliability of the procedure and measure the degradation of the materials to understand the main area of improvement and development. The test was made possible through the automation of a test stand with integrated climatic chamber (performed in 2008) that allowed five startups per day, significantly accelerating the testing process. The results proved the robustness of the protocol as it can be seen in Figure 1. In fact, all the startups were successful and even though in some cases the stack didn’t reach exactly the 50% of rated power after 30 sec (50% of 0.664 W/cm²), overall the performance was above the 50% target with no decreasing trend over time. Some voltage degradation was noticed along the course of the test but the measurement of the stack resistance proved the decrease in voltage over time can be almost entirely attributed to a progressive loss of compressive load. This issue has been addressed in the Orion stack by implementing a compression system that provides a better control of the compressive load.

In two different situations (after 100 and 200 cycles) the stack was opened and material samples were extracted for analysis at Gore and SGL labs. The investigation was focused on detecting the typical freeze related decay mechanisms identified during the Freeze Workshop held at Nuvera in early 2009. Even though some evidence of degradation occurred, none of these could be related directly to freezing. This finding indicates that the combination of the procedures applied and the materials used did not experience accelerated degradation with respect normal operation of the fuel cell, at least after 200 repetitions. A summary table describing the decay modes investigated, the diagnostic techniques used and the results found is reported in Figure 2 with some pictures illustrating the findings.

Over the course of the year several prototypes of the Orion stack have been assembled to stabilize the hardware and achieve the performance targets. The
The proven high power density of the stack helps to reduce its thermal mass because it decreases the number of cells that are needed to obtain the rated power. Furthermore, the stack hardware is lighter, which leads to a lower intrinsic thermal mass, and the cooling compartment is smaller, which results in lower overall mass of coolant that is resident during the startup phase. The tests run on Orion highlighted the effectiveness of the design actions described above. A dedicated coolant loop was built to supply an Orion stack with an anti-freezing cooling fluid (mixture of water and ethylene glycol) and such loop was installed on a portable rack that allowed freezing the stack and the coolant system as a whole. The startup performed on this setup was successful as shown in Figure 4 where the Orion stack was able to start from -20°C and in 28 seconds it reached the 50% of rated power (50% of 1.2 W/cm²). The total energy spent to purge the stack during the shutdown phase and the subsequent startup was calculated at 2.937 MJ, which is less that the DOE target of 5 MJ.

**Conclusions and Future Directions**

Nuvera will focus the remaining months of the project on exploring the capability of Orion to start from
extreme temperatures approaching -40°C. Preliminary tests conducted at -30°C seem to confirm the advantage of a reduced thermal mass but more investigation is needed.

For the future Nuvera recognizes the need to study the impact of different pre-conditions on the ability to start from sub-freezing temperature. For this purpose Nuvera implemented a technique to monitor the high frequency resistance of the stack during operation, which is recognized by the fuel cell community as a good indicator of the state of hydration of the membrane, the effectiveness of the purging procedure applied, and the likelihood of a successful startup.

Finally the work done in CIRRUS has proven that the temperature over the surface of the membrane electrode assembly is far from being uniform during the startup and the knowledge of the temperature gradients as a function of time might be an interesting area of study to drive the optimization of materials and procedures.

V.G.1 Development and Demonstration of a New-Generation High Efficiency 10-kW Stationary Fuel Cell System

Technical Targets

Work under the project is aimed at developing novel fuel processing, polymer electrolyte membrane (PEM) fuel cell technologies and integration strategies in order to make progress toward achieving DOE targets for stationary PEM fuel cell power systems for year 2011. These targets and project progress are shown in Table 1.

2 Percentage presented as per 1,000 hours given that total test data are less than lifetime target.
3 Equivalent to <10% after 40,000 hours durability target.

Other challenges being addressed under the project are:
• Cost reduction by the simplification of balance-of-plant (BOP) components and development of an adsorption enhanced reforming fuel processor.
• Reduced startup time by improved thermal management design.

Accomplishments
• Successful commissioning of an integrated prototype in a laboratory setting.
Automated fuel processor combustor startup and safety shutdowns implemented.
Continuous (24 hours/day) test operation capability established.
53.4% gross electrical efficiency on integrated fuel cell subsystem.
32.6% electrical efficiency demonstrated on integrated CHP prototype system.
9.3 kW of waste heat recovered.
Continuous production of ~95% purity hydrogen on separate bench-scale adsorption enhanced reforming test rig:
- No materials degradation indicated
- >10,000 regeneration cycles achieved
Over 7,000 hours on separate test fuel cell stack with ~6% performance degradation:
- ~3x improvement from previous year
Operational hours on integrated CHP prototype system detailed in Table 2.

Introduction

The development of highly efficient and cost-effective clean energy solutions is not without challenge. Hydrogen fuel cell technologies are expected to become a significant player in reducing our dependence on imported fossil fuels and curb the further accumulation of greenhouse gases and criteria pollutants. Fuel cells can be used in many applications, including but not limited to stationary primary and backup power, portable power and motive power (automobiles, motorcycles, aircraft, etc.).

This project is focused on the design, fabrication and field demonstration of a stationary CHP system that will provide multi-dwelling residential and light commercial end-users with on-site generated electrical and heating needs. The proposed technology addresses DOE targets by using PEM fuel cell stacks as they have been proven to achieve high efficiency, greater durability and lower costs than competing fuel cell technologies.

An integrated hydrogen generator employs an optimized steam methane reformer (SMR) to achieve high fuel to hydrogen output, along with the recovery and utilization of heat from waste streams to address DOE's combined efficiency (electricity plus useful heat) target of greater than 80%.

In parallel to the development of an SMR-based fuel processor, IE has collaborated with California State Polytechnic University, Pomona to research an alternate hydrogen generation method called adsorption enhanced reforming (AER). According to process simulations done at Sandia National Laboratories in 2008, AER promises up to 40% CHP system electrical efficiency when integrated into the as-designed, open-architecture (pure hydrogen interface between the fuel cell and hydrogen generator) prototype unit now operating in our laboratory.

Approach

The approach to achieving the project’s 40% electrical efficiency target is incremental and based on, (1) optimization of the SMR plus fuel cell architecture and (2) the development of an 80% or greater thermally efficient AER hydrogen generator that can “plug and play” into the same SMR plus fuel cell hydrogen feed interface. The SMR plus fuel cell optimization work will rely on allowing slightly less than 100% hydrogen to enter the fuel cell (99%, balance inert) which will translate into only a small efficiency penalty to the fuel cell, but has the advantage of increased hydrogen recovery from the hydrogen generation process whereby its thermal efficiency can be boosted from 70% up to as much as 73%. Preliminary process simulations indicate that this approach can increase the overall CHP system electrical efficiency from its current status of 32.6% to approximately 36%.

An AER hydrogen generator produces a fuel cell feed stream similar to the optimized SMR plus fuel cell system approach but requires operation at 500°C versus 900°C. This means less energy is required for hydrocarbon conversion by the AER approach making the technology more thermally efficient than SMR. Predictive models have indicated that hydrogen generation efficiencies of up to 85% can be achieved with the AER technology compared to 70%-73% attainable by SMR. The multiplier between the AER hydrogen generator and the fuel cell efficiencies, less 12% for the parasitic power requirements to run the CHP system (0.85 x 0.55 -0.12), would result in an electrical efficiency of approximately 41%. Furthermore, since with AER, hydrocarbon reforming and carbon dioxide adsorption occur simultaneously, an additional purification step is eliminated thereby reducing system complexity and costs.
Results

During Fiscal Year (FY) 2009, the integrated CHP system was designed. This last year (FY 2010) marked the construction and testing of the CHP prototype comprised of 23 modular subsystems including water delivery and recovery, fuel delivery, controller and power management, air delivery, safety, chassis, purification, reformer, fuel cell and enabling sub-subsystems. Each subsystem underwent independent bench testing and validation prior to being installed on the overall CHP system. After all subsystems were installed onto the CHP unit, the system went through a cold commissioning phase to check the functionality of electrical components, pressure test vessels and piping and validate the controller system under cold-gas flow conditions. Subsequently, the unit was hot commissioned over a one month period where combustor startup and reforming behaviors were initiated and observed. The pre-commissioning prototype is shown in Figure 1.

After commissioning, the unit was operated first during normal day shifts until the controller safety shutdown sequence and test facility alarms were automated. In March, the unit ran unattended 24 hours/day and achieved its longest continuous run of 31 days while operating in some combination of hot-idle, reforming, pure hydrogen production or electrical production mode(s). A comprehensive set of tests were conducted to evaluate system load versus hydrocarbon conversion in the reformer, fuel cell gross and net efficiency, peak system efficiency and useful heat recovery as a function of cooling water inlet temperature. Conversion ranged from 77%-89% depending on conditions. A summary of other test results are presented in Table 3.

</table>
As represented by check marks in Table 3, four initial performance milestones were achieved during functional validation testing. These data were collected from a sub-optimized prototype. The highest recorded electrical efficiency was 32.6% (natural gas compression parasitic power demand not factored in) with a combined CHP efficiency of 60.8%. Optimization steps, including but not limited to, returning pressure swing adsorption (PSA) exhaust gas to the reformer combustor, replacement of an existing flue heat exchanger with a larger one, improved insulation and operating the reformer at higher temperatures will be carried out in the coming months. Performance estimates for an optimized SMR plus fuel cell system architecture based on the aforementioned steps are shown in the far right column of Table 3. These estimates are lower than DOE targets due largely to the input energy requirement of reforming at ~900°C and associated heat losses. To address this gap, IE continues to develop strategies to advance AER and AER fuel cell/FC interface technologies that could meet these targets in a real commercial system.

The prototype startup times from stone cold (20°C) to full electrical production, referred to as “cold start” ranged from 4-6 hours. The hot start time defined as the period from which the fuel processor was in “hot-idle” (combustor fired only maintaining the reactor without reforming near 700°C) to full electrical production was approximately one hour. To date, the CHP prototype has undergone 29 cold starts/ stops, and nine hot starts/stops without degradation in mechanical integrity and/ or catastrophic failure such as a sudden loss of pressure while operating.

Work on AER was conducted in collaboration with California State Polytechnic University, Pomona under the direction of Professor Dr. Mingheng Li. A four-tube (2” diameter by 48” long each) reactor was designed, constructed and tested from the middle of last year through March of 2010. The experimental rig produced hydrogen continuously by reforming in one tube for 30 seconds and then switching to an adjacent tube that would reform for the next 30 seconds. As there were four tubes in total, each tube, while not reforming would undergo 90 seconds of regeneration (desorption of undesired reaction products in preparation for the next 30 second reforming step). Tests were done using ethanol, liquefied petroleum gas (LPG) and methane as the feed. Regeneration was done with a simulated fuel cell cathode exhaust gas (oxygen reduced air with water vapor) to emulate process conditions that the AER fuel processor would see when fully integrated into a CHP system. The reactor beds were packed with a mixture of Ceria impregnated hydrocarbon reforming catalyst and potassium-promoted hydrotalcite carbon monoxide/ dioxide adsorption pellets. Experimental conditions are shown in Table 4.

</tbody>
</table>

During the testing phase, more than 350 hours of hydrogen production were logged with each reactor tube having been subjected to roughly 10,000 reforming-regeneration cycles. We did not observe any decrease in hydrocarbon conversion (80-90% depending on process settings) or materials degradation as commonly found throughout the literature regarding prior art.

The sample data represented in Figure 2 show a steady flow of product gas (~96% H₂, ~4% balance being a mixture of CO, CO₂, N₂ and CH₄). Of the ~4% balance, CO which is known to poison PEM fuel cells exists at the sub-100 parts per million (PPM) level. While this amount is too much for use in these fuel cells, a passive device can be used in conjunction with AER to convert this CO back to CH₄ prior to entering the stack; CH₄ is harmless to the stack. The CO₂ in the stream is also at the sub-100 PPM level.

In parallel to the design, construction and testing of the AER rig, process models were developed using HYSYS software. With inputs setting the operating temperature at 500°C, pressure at 60 psig and steam to carbon ratio of 2:1, the model predicted a reformer gas outlet equilibrium concentration of 2.56% CH₄, 79.2% H₂ and 18.15% H₂O. After condensing out the water downstream of the reformer, the concentration becomes...
3.24% CH₄ and 96.76% H₂. These modeled predictions are consistent with the experimental data.

**Conclusions and Future Directions**

Progress during project year three was marked by the construction and validation testing of a CHP prototype in IE’s laboratory. Over 350 hours of electrical production were logged whereby 32.6% system electrical efficiency was achieved. More than 2,100 hot hours and 29 start/stop thermal cycles were carried out.

Continuous production of near fuel cell grade hydrogen has been achieved with a bench-scale AER rig. Over 10,000 process cycles were logged without signs of materials (reforming and adsorbent pellets) degradation.

The coming year will focus on PSA retrofit engineering, system-wide optimization and field demonstration.

Major tasks/direction going forward:

- PSA retrofit engineering.
- System repackaging, pre-deployment testing and optimization.
- Six-month field demonstration in the United Kingdom (Chalvey, Slough).

**FY 2010 Publications/Presentations**

V.G.2 Development of a Low Cost 3-10 kW Tubular SOFC Power System

Objectives

The goal of the project is to develop a low cost 3-10 kW solid oxide fuel cell (SOFC) power generator capable of meeting multiple market applications. This is accomplished by:

- Improving cell power and stability.
- Cost reduction of cell manufacturing.
- Increase stack and system efficiency.
- Prototype testing to meet system efficiency and stability goals.
- Integration to remote and micro-CHP (mCHP) platforms to allow short and longer term market penetrations.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost
(C) Performance

Technical Targets

This project is directed toward achieving the stationary generation goals of the DOE fuel cell power systems. This project will work on cost reduction of the desired product while also demonstrating required life and efficiency targets through multi-level testing.

Accomplishments

- Passed “Go/No-Go” test by achieving 0.7%/1,000 hr degradation (goal <2%) over 1,500 hr testing.
- Have demonstrated a 24% increase in power density enabling 33% reduction in stack volume and 15% reduction in stack weight.
- Operated over 5,000 hrs at an ambient temperature of over 45°C.
- Have received $1.1M in Italian government funding to match DOE development funds for mCHP units.

Introduction

Achieving combined heat and power goals of over 40% net electrical efficiency and over 85% total energy efficiency are goals of the DOE and present administration to reduce our dependence on foreign energy and reduce the emission of greenhouse gases. SOFCs, with their ability to use the present U.S. fuel infrastructure and high grade waste heat are ideal candidates for this challenge. To date, the limitation on making this goal a reality has been the reliability and cost of such systems.

This project is designed to address these limitations and bring this promising technology to the market place. This is being achieved by working on all aspects of the SOFC power generator including: (1) improving cell power and stability, (2) cost reducing cell manufacture, (3) increasing stack and system efficiency,
(4) prototype system testing, and (5) integration into a mCHP platform. This phase of the project will make a major drive toward the DOE’s goals set forth for 2012 stationary power generators.

Approach

To achieve the project objectives, the approach has been to perfect the individual system pieces followed by optimizing their integration through:

- **Cell Technology**: Improving power and stability of the cell building block.
- **Cell Manufacturing**: Improving processing yield and productivity while decreasing material consumption.
- **Stack Technology**: Refining stack assembly and improve heat removal and integrity while cost reducing individual component costs.
- **System Performance**: Developing simplified controls and balance-of-plant components to allow for a reliable, highly efficient unit.

Results

In the past year, significant progress was achieved in improving the power of each individual tube. Figure 1 shows that power progression since the 2009 yearly review. During 2009 the average of all cells tested operating at 800°C was a little over 200 mW/cm². In early 2010 that value was increased to approximately 550 mW/cm² or over 150% at the same operating temperature of 800°C. The operating temperature of the cell was then lowered by 50°C and the peak power was just below 500 mW/cm², again a greater than 100% improvement. Later in the fiscal year further enhancements were made in the cathode layer and the manufacturing process to apply that layer allowing a peak power of 615 mW/cm² at 750°C. Further testing is ongoing and the anticipation is that these same powers will be achievable at 700°C. The advantages of these power enhancements is straightforward as to less tubes resulting in less cost but the reduction in temperature further exacerbates the improvements by allowing for less insulation which is less cost and size of the overall unit.

Gains were not only realized in peak power per tube but also power per tube at normal operating points. Figure 2 shows the power density at 0.7 V operating voltage which is more near the average operating point of a generator. As can be seen, at the start of the DOE program each tube could only achieve 72 mW/cm² while prior to last years annual merit review the value had increased to 339 mW/cm². Since the 2009 review the power at 0.7 V operation has further been enhanced to 421 mW/cm² or an additional 24%. This achievement allows for a reduction in almost a quarter of the cell count which represents a sizable overall cost of the unit while maintaining an efficiency of a generator at or above 40% (net power/lower heating value). This also represents a sizable volume and weight reduction which can not be overlooked when considering shipping costs and installation difficulties for these smaller units by field personnel.

Power enhancements and size and weight reductions themselves are not enough to make for a commercially viable product. A sizable determination of the long-term acceptance of this product is its performance stability resulting in a lower overall cost of electricity and cost of ownership. Recognizing this to be the case Acumentrics worked with the DOE to develop a mid-project “Go/No-Go” milestone to demonstrate that the stability of the stack can achieve a goal of less than 2%/1,000 hr degradation. Figure 3 shows the results of that test over the first 1,500 hrs of its operation. The 1 kW unit was nominally operated near 600 W and achieved 0.7%/1,000 hr degradation passing the milestone with less than half the allowable limit. This unit was also tested for over 5,000 hr total operation showing comparable stability numbers which have proven its viability to be placed in a number of remote power applications. These applications will be further tested in the coming year and may prove to be viable test sites and a starting point for a market transformation project.

In addition to cell power and stability enhancements, there have been...
a number of improvements in the generator performance and cost reduction. One of the most significant generator cost reductions has come with improvements in the high-temperature recuperator used to pre-heat the incoming air utilizing the exhaust gas from the fuel cell stack. The goal of this device is to be as small, least expensive, and as efficient as possible while having a low pressure drop and lifetime that matches or exceeds that of the stack. Figure 4 shows the advancement in that device over the last year of development. The initial device was 300 in$^3$ in volume and nearly 18 lbs in weight. The latest generation has been reduced to a third of the volume or 100 in$^3$ and less than 4 lbs in total weight. Long term this results in less cost since the weight reduction has primarily come from the utilization of less metal and thereby reducing the material cost component of the overall device. Novell brazing techniques allowing for manufacture of the device with these thinner materials while maintaining the quality needed for the product.

**Conclusions and Future Directions**

Significant strides have been made in achieving the goals set forth for stationary fuel cell generators under the DOE multi-year plan.

- Passed “Go/No-Go” test by achieving $0.7\% / 1,000$ hr degradation (goal $<2\%$) over $1,500$ hr testing.
- Have demonstrated a $24\%$ increase in power density enabling $33\%$ reduction in stack volume and $15\%$ reduction in stack weight.
- Operated over $5,000$ hrs at an ambient temperature of over $45°C$.
- Have received $1.1$M in Italian government funding to match DOE development funds for mCHP units.

Moving forward, the advances made in cell power will be tested for longer durations to assure the achievability of lifetime goals. Further testing will demonstrate not only stability at steady-state operation but also consider thermal cycling for product platforms with less stringent operating hour requirements but more stringent cyclic duty. Work will also continue into resolving thermal management issues now that significantly higher power is being achieved in a smaller volume. Further work into the reduction of weight and cost of the metallic recuperator will be performed to meet the long-term product goals.
FY 2010 Publications/Presentations

Objectives

- To design and produce an advanced prototype proton exchange membrane (PEM) fuel cell system with the following features:
  - 5 kW net electric output.
  - Flexible-fuel capable—liquefied petroleum gas (LPG), natural gas, ethanol.
  - Reduce material and production cost and increase system and stack durability.
  - Increase electrical efficiency over the existing GenSys 5U48 design.
  - Increase total system efficiency by incorporating combined heat and power (CHP) capability.

- To show a path to meet long-term DOE objectives:
  - 40% system electrical efficiency.
  - 40,000-hour system/fuel cell stack life.
  - $750/kW integrated system cost (with reformer).
  - $400/kW fuel cell stack cost (direct hydrogen).

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(C) Performance  
(B) Cost  
(A) Durability

Technical Targets

Integrated Stationary PEM Fuel Cell Power Systems (5-250 kW) Operating on Reformate

This project conducted fundamental analysis and demonstration of fuel flexible (ethanol/LPG) CHP integrated system. Results of the system design have shown the ability to meet the following DOE 2011 targets:

- Survivability (min and max ambient temperature)  
  -35 to +40°C  
  - Successful system operation shown from -40 to +46°C

- Noise < 55 dB(A) @ 10 m  
  - Measured noise emissions of <60 dB(A) at 3 m at rated power at nominal ambient conditions which when applying the inverse square law equals 49.5 dB(A) at 10 m.

Learning gained from work activities of this project will be applied toward the design and manufacture of a system that is on a path to meet the following DOE 2011 targets:

- Durability at <10% rated power degradation: 40,000 hours
- Cost at 2,000 units/year: $750/kWe
- Performance (target values adjusted to account for LPG-fueled system)  
  - Electrical efficiency at rated power: 38.5%  
  - CHP efficiency at rated power: 78.5%

Accomplishments

- Completed the analytical and design work necessary for the prototype system, received a “go” decision from DOE for the next phase of the project.
- Completed the fabrication and assembly of the prototype system and began system integration testing.
- Achieved system material cost reduction of 53 percent (in production quantities) when compared to prior year’s system material cost roll-up.

Introduction

Long-term commercial acceptance of PEM-based fuel cell systems is contingent on reducing the material and operating costs and improving the durability of the
system and its components. The current technologies employed for PEM fuel cell stacks and the uniqueness of other system components contribute significantly to the material cost of the system.

This project is not only advancing the state-of-the-art of PEM fuel cell technologies, but also established an integrated, low-cost, flexible-fuel reformer for on-site fuel cell power generation. These achievements, in turn, helped to enable commercialization of the technology by improving economic feasibility and providing multiple fuel options for a variety of commercial applications. This project included the design, manufacture, test and field demonstration of a CHP, grid-connected fuel cell system. The resulting system advanced the state-of-the-art toward the DOE's program objectives of increased durability, reduced cost and improved efficiency.

Approach

- Concept Development (100% complete)
  - Go/No-Go: Concept design review
- System Definition (100% complete)
  - Go/No-Go: System interface review
- System Integration (100% complete)
  - Go/No-Go: Field readiness review
- Prototype Field Demonstration (85% complete)
  - Construction Engineering Research Laboratory unit demonstration rolled into 7A project using commercial GenSys unit.
  - Demonstration currently being conducted at Union College Beuth House, Schenectady, NY, using commercial GenSys unit.
- Project Closeout (90% complete)

Results

Demonstration

Plug Power installed a GenSys Blue high-temperature PEM fuel cell system at Union College Beuth House in Schenectady, NY. This includes field readiness design, build, shipping, installation, commissioning, demonstration, decommissioning, site restoration and public/end user education. The system continues to run, logging 1,436 hours since commissioning, and is continually evaluated.

Stack Sourcing

The original project intent was to leverage Plug Power’s supply chain and knowledge gained during Topic 3.1 work activities at Warner Robins Air Force Base (which led to development of the “Rev 3” membrane electrode assembly, MEA), and expand to a fuel cell stack solution capable of meeting both DOE objectives and those required for productization.

Based on preliminary work on the TeleCOOP project, Plug Power and Ballard proceeded to collaborate. However, stack integration complications occurred with the commercially available Ballard MK-1500 series stack design and DOE goals were not met. These complications included: high pressure drop posing issues finding applicable balance-of-plant components, high differential pressure posing issues in controllability of the system, and system efficiency and turndown capability being negatively impacted by the stack design.

Improvements made by 3M in durability and cost, and leveraging the production design MEA, confirmed the viability of a Plug Power/3M stack solution from a material cost and superior system design perspective.

Stack Sourcing Pressure Drop

The commercially available stack had up to 3.5x the pressure drop of the Plug Power stack design. The higher pressure drop required for the water management method led to lower system efficiency and difficulty finding components to supply the required reactants. Low power efficiency was also affected due to “differential pressure floor.”

Stack Sourcing Efficiency Impacts

The efficiency impact of the commercially available stack negated any potential gains it had in cost and durability. The GenSys 6U48 product advantage over incumbent technology is based on superior efficiency leading to op-ex savings. The commercially available stack was not a viable solution for a GenSys product and did not show a path to meeting DOE objectives.

Low-Temperature PEM for CHP Applications

Using a low-temperature PEM system in a CHP application has been studied for both the maximum heat recovery and maximum output temperature based on the existing design. 8,200 W (28,250 BTU/hr) are available at a temperature of 65°C (150°F) and the maximum outlet temperature of 77°C (170°F) is possible with 5,050 W available. Further improvements in quality of heat are possible at the expense of electrical efficiency and Plug Power is investigating the viability of a low-temperature CHP system based on the GenSys system architecture.

System Material Cost

Material cost of the GenSys system has been reduced by 63 percent due to design activities related to this project. Fuel cell stack material costs were reduced 59 percent and an additional 15 percent cost reduction is expected once the design is fully tooled.
Reliability Improvements Startup Sequencing

In an effort to combat carbon corrosion on the MEA during H2/air front propagation at start-up, various system controls approaches were studied. Results of these tests proved that a controls and isolation solution existed that was much less costly than an MEA materials solution. This allowed reduction in MEA loading, leading to a lower overall cost.

Reliability Improvements Cathode Humidification

Several different types of cathode humidifiers were studied with the goal of reducing part cost while maintaining a high cathode saturation for increased stack life. The outcome from these tests resulted in qualification of a part that was approximately 50 percent of the cost of the incumbent, with improved levels of humidification across the operating range.

Conclusions and Future Directions

The Union College unit will be decommissioned in the summer of 2011. Due to significant system advancements, DOE has agreed to close out the 7C project and roll the Construction Engineering Research Laboratory contract obligations into the 7A project. Under the 7A project Plug Power will provide data to the Construction Engineering Research Laboratory from one of the 20 systems to be installed at Warner Robins Air Force Base in Georgia.

Contract Number: DE-FC36-04G014303

Subcontractors:
• The Toro Company, Bloomington, MN
• University of California, Davis, CA (UC Davis)

Project Start Date: August, 2007
Project End Date: September, 2011

Objectives

• Develop a proton exchange membrane (PEM) fuel cell system to operate in off-road applications.
• Established comprehensive set of PEM fuel cell system requirements for turf and grounds maintenance vehicles.
• Evaluate air-filtration technologies for off-road applications.
• Shock and vibration testing in the lab and field.
• Fully integrate prototype PEM fuel cell system in a Toro® Workman® e2065 – series utility vehicle for field trials.
• Fully integrate second generation PEM fuel cell system in a Toro® Mid-Duty Electric (MDE) light-duty maintenance truck.
• Conduct field trials utilizing two vehicles at various venues.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

Accomplishments

• Measured the shock and vibration spectrum for golf course maintenance vehicles.
• Gathered information on the air contaminants that may have an effect on fuel cell operation and developed an air filter for fuel cell systems.
• Developed the Workman® Model e2065 lawn tractor equipped to operate on direct current (DC) voltages, had accelerometers installed and evaluated shock and vibration.
• Measured the power load profiles on two golf courses.
• Designed and installed an IdaTech Liquid Fueled Fuel Cell System in a Toro® Workman® Model e2065 light-duty maintenance truck.
• Installed a 2nd generation IdaTech Liquid Fueled Fuel Cell System in a Toro® Workman® model MDE light-duty maintenance truck.
• Completed field trials with two vehicles.

Introduction

Nearly no practical work has been performed by the fuel cell industry, its suppliers and trade associations on the subject of off-road fuel cell operation. The environments encountered in off-road applications could adversely affect fuel cell performance and life, requiring re-designing for the harsher environment.

One of the recognized challenges in fuel cell systems air purification is in providing a highly efficient particulate and chemical filter with minimal pressure drop. PEM integrators do not want additional parasitic loads added to the system as compensation for a highly efficient yet highly restrictive filter. Additionally, there is challenge in integrating multiple functions into a single air intake module tasked with efficiently and effectively filtering high dust loads, diesel soot, pesticides, ammonia, high frequency noise, and other anticipated off-road contaminants.

It is one key project objective to develop a strategy, and through it a solution, for achieving clean cathode inlet air. Other off-road concerns are related to fuel cell power requirements and the effect of shock and vibration.
Approach

- Measure the air quality for off-road application and develop an air filter.
- Measure the shock and vibration spectrum for off-road vehicles, and then subject an IdaTech fuel cell system to the spectrum.

Results

An IdaTech Liquid Fueled Fuel Cell System was assembled, tested at IdaTech, delivered to UC Davis and demonstrated at UC Davis. Initial shock and vibration testing was completed at UC Davis followed by field trials at River's Edge golf course and The High Desert Museum, Wildlife and Living History. Accelerometers were mounted in the rear compartment next to the fuel cell system for all shock and vibration testing. The field trial results indicate the rear of the vehicle sustains higher shock g-forces than the front with the maximum recorded shock of 117 g-forces. The vibration results show that the terrain provides input vibrations in the range of 1 to 20 Hz at 2 to 3 g-forces and that the vehicle does not sustain any vibration amplitudes greater than 1 g-force.

Toro® determined that the IdaTech FCS 3000 fuel cell system matched the operational requirements of the Workman® Model e2065. As a result, a Toro® Workman® Model e2065 light-duty maintenance truck was received and retrofitted to house an IdaTech FCS 3000 fuel cell system. The model e2065 unit was designated test vehicle-one (TV-1).

Three fuel cell systems were assembled and all three passed operational testing. One fuel cell system, while sitting next to the vehicle, was used to charge the batteries. After successfully demonstrating that the fuel cell system could charge the batteries, the fuel cell system was reconfigured and installed into the vehicle. The vehicle has accumulated 63.5 hours of off-road operation at the River’s Edge Golf Course. A photo of TV-1 on the golf course is shown in Figure 1. During the summer of 2008, TV-1 accumulated 62 hours of maintenance duties. During the winter an upgrade was performed on the fuel cell system. Wiring connections were reduced, a smaller, lighter DC-to-DC converter on studier sheet metal support and onboard data acquisition were incorporated. Every ten seconds data is stored on a replaceable memory card. The installed upgraded fuel cell system is shown in Figure 2. TV-1 has accumulated the following statistics:

- System run time = 318 hrs
- Total fuel feed = 474 liters

A second vehicle, designated TV-2, was procured from Toro® which Toro® has designated an MDE model (Mid-Duty Electric). The new vehicle design incorporates front wheel shocks and an accessible area under the front hood. An upgraded fuel cell system was installed in the vehicle. The batteries were placed in front and two in the rear compartment. This eliminated the “saddle bag” batteries external to the rear compartment in the first vehicle. The vehicle rear compartment was modified to provide ease of removal of the whole system for maintenance. Onboard data acquisition was added with data collection every 10 seconds on a memory card. The fuel cell system installed in TV-2 is shown in Figure 3. The second vehicle was deployed at The High Desert Museum (HDM) Wildlife and Living History south of Bend, Oregon. This field trial differed in that the terrain was flatter, the operators more educated and the vehicle accumulated more operating hours. The vehicle is
shown in front of the HDM in Figure 4. TV-2 has accumulated the following statistics:

System run time = 368 hrs
Total fuel feed = 315 liters
Total energy = 149 kW-hrs
Total thermal cycles = 63

The present systems have four generic printed circuit boards installed. Many of the functions on the boards are not used with the present system. Many wires could be eliminated by consolidating the four boards onto one board. We have contacted the Etrix Group Inc., a local electronic design company, to consolidate the needed functions onto one board.

Conclusions and Future Directions

Overall the prototype vehicle project was a great success making significant progress toward manufacturing of a green vehicle for golf course and parks and recreation maintenance vehicles with potential for liquid fuelled fuel cell powered vehicles in industrial settings. Operation at two test venues was successful, however, improved reliability is required. Some example of faults and corrections:

- System over heated on very hot day – added cooling fan.
- Thermocouple shorted – added restraint.
- Wires fell off coolant switch – restrained wires.
- Fuel pump slowed down, dirt was cause – sealed pump gearbox opening.
- Fuel line dry – removed tank dip tube and place exit at tank bottom.
- Inverter not ramping up – installed improved inverter and improved firm ware.
- Troubleshooting faults takes too much time – added onboard data acquisition.
- Multiple printed circuit boards with unused capability and extra connectors increase wiring breakage – consolidation of board recommended.

The two test units have completed filed trials and are in the process of being disposed.

Work on air filtration (Task 3) has been restarted due to Donaldson’s decision to cease fuel cell filter production and support. The objective is to evaluate commercially available air filters for off-road applications. The work has just commenced with UC Davis.
Objectives

- Understand the role of cathode electrocatalyst degradation in the long-term loss of polymer electrolyte membrane fuel cell (PEMFC) performance,
- Establish dominant catalyst and electrode degradation mechanisms,
- Identify key properties of catalysts and catalyst supports that influence and determine their degradation rates,
- Quantify the effect of cell operating conditions, load profiles, and type of electrocatalyst on the performance degradation, and
- Determine operating conditions and catalyst types/structures that will mitigate performance loss and allow PEMFC systems to achieve the DOE lifetime targets.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Durability
- (B) Cost
- (C) Performance

Technical Targets

This project is conducting fundamental studies of platinum-based PEMFC cathode electrocatalyst degradation mechanisms. Insights gained from these studies can be applied toward the definition of operating conditions to extend PEMFC lifetimes and to the development of cathode electrocatalyst materials that meet the following DOE 2015 electrocatalyst durability targets with voltage cycling:

- 5,000 hours (<80°C) and 2,000 hours (>80°C),
- <40% loss of initial catalytic mass activity, and
- <30 mV loss at 0.8 A/cm²

Accomplishments

- Prepared Ketjen carbon-supported Pt nano-particle electrocatalysts (Pt/C) of varying particle size and incorporated these electrocatalysts into the cathodes of membrane-electrode assemblies (MEAs).
- Quantified Pt/C catalyst oxygen reduction reaction (ORR) activity, electrochemically-active surface area (ECA), and performance losses in a fuel cell as a function of initial Pt particle size and cell parameters (relative humidity, temperature, upper potential limit, and cycling protocol).
- Developed a kinetic Monte Carlo (KMC) code to predict Pt nano-particle evolution under fuel cell conditions.
- Determined Pt particle size and particle size distribution evolution during potential cycling as a function of initial Pt particle size (1.9, 3.2, 5.7, and 9.1 nm) during potential cycling in an aqueous environment, using anomalous small-angle X-ray scattering.

Introduction

One of the primary challenges facing the development of PEMFCs for automotive and stationary power applications is the durability of the fuel cell materials. Though significant progress has been made toward achieving the technical target of 5,000 operating hours, particularly for non-conventional catalysts...
architectures, the durability status for conventional stacks is considerably shorter than 5,000 hours [1-3]. Typical degradation rates for constant load conditions are 25-40 µV/h and can be an order of magnitude higher when operating under non-steady-state conditions prevalent in the automotive application, including load and start-stop cycling and extended time at open circuit [3]. The observed degradation under these conditions has reversible and irreversible components with one of the most dominant contributors to irreversible degradation being loss of cathode oxygen reduction reaction activity. The subjects of this project are the irreversible losses in PEMFC performance, as these are the most challenging in terms of mitigation strategies. Specifically, this project focuses on cathode catalyst degradation, because the degradation of this component has the most profound impact on cell performance. The project’s primary focus is elucidation of the effects of catalyst and support physicochemical properties and cell operating conditions on the rates and mechanisms of cathode catalyst degradation, with a secondary focus on the impact of catalyst degradation on the transport properties of the cathode.

Approach

The project approach is to perform systematic cell degradation tests, in situ and ex situ structural characterization of the catalysts, fundamental out-of-cell studies, and theoretical modeling to identify the degradation modes and factors contributing to cathode catalyst degradation. The catalysts to be studied are benchmark Pt on carbon supports with varying properties, Pt alloys with varying oxophilicity, and three classes of Pt catalysts having the highest reported oxygen reduction activity. Specifically, our approach is to utilize accelerated stress tests of MEAs containing various catalysts and supports and in situ and ex situ dissolution, microscopic, structural, and chemical characterization of these catalysts. To elucidate the effect of particle size, we will systematically vary the particle size of Pt and one Pt alloy on a standard support. To elucidate the effect of catalyst type and catalyst oxophilicity, we will study four classes of catalysts: Pt, Pt alloys, acid-leached alloys, and core-shell catalysts with approximately the same particle size and particle size distributions. To elucidate support effects, we will study Pt on carbon supports with systematically varied surface area, pore size, and relative proportions of micro- and mesopores. In addition, to study the role of carbon degradation in ECA loss we will assess the effect of surface area of carbon exposed to the electrolyte and Pt contact area with the carbon using a series of Pt/C catalysts with differing Pt loading. We will also determine the effects of catalyst precursor impurities on degradation rates by post-synthesis doping of a Pt/C catalyst with varying levels of precursor impurities (e.g., Cl, Na, K, and F).

The results of the experimental efforts will feed into coupled models at various levels of complexity from atomic-level, ab initio oxidation and dissolution calculations, to catalyst degradation models, to cell kinetic and transport models. The modeling effort will also define the experiments necessary to complete the cell model. The project can be categorized into three broad and coupled tasks: (1) MEA studies utilizing accelerated stress test protocols, on-line electrochemical diagnostics, and post-test microscopic and X-ray scattering characterization, (2) mechanistic and physicochemical property studies using aqueous electrochemistry, X-ray spectroscopy/scattering, transmission electron microscopy (TEM), scanning transmission electron microscopy (STEM), and in situ TEM, and quartz crystal microbalance measurements, and (3) model development, verification, and implementation. All of these techniques have been demonstrated to provide important and complementary information regarding catalyst degradation mechanisms.

Results

To establish the background for studies of advanced classes of catalysts, our initial studies have focused on determining the effects of cell operating parameters and initial Pt particle size on cell performance and performance degradation. Catalysts were prepared containing 40 wt% Pt nano-particles with a mean diameter of 1.9 nm on high-surface-area Ketjen black carbon support (Pt/C). This material was heat treated to form catalysts with mean particle sizes of 3.2, 7.1, and 12.7 nm, respectively. These catalysts were studied in an aqueous electrochemical environment (0.1 M HClO₄ electrolyte) using anomalous small angle X-ray scattering, to determine the evolution of Pt particle size and particle size distribution as a function of potential cycling using the DOE cycling protocol (0.6 V to 1.0 V triangle wave; 50 mV/s). These catalysts were also incorporated into the cathodes of MEAs and subjected to the DOE cycling protocol in the fuel cell environment. Cell diagnostics of cathode catalyst ECA, ORR mass activity, and air and oxygen polarization curves were performed after 1,000, 3,000, 5,000, and 10,000 voltage cycles. Studies were also performed on the effect of various fuel cell operating parameters (relative humidity [RH], temperature, cycling profile, and upper potential limit) on the degradation of the cathode electrocatalyst performance on membrane-electrode assemblies containing the 3.2 nm Pt/C as the cathode catalyst. The results of these initial studies are summarized below.

Summary of MEA and aqueous cell particle size study results:

- Cycling to 1.0 V has minimal impact on ECA and oxygen reduction reaction mass activity of catalysts
with large initial particle size (7.1 and 12.7 nm; see Figure 1).

- Cycling to 1.0 V degrades the ORR mass activity of catalysts with small initial particle size (1.9 and 3.2 nm) toward that of larger particles (7.1 and 12.7 nm).
- Beginning of life fuel cell performance of MEAs with smaller cathode catalyst particle size (1.9 nm and 3.2 nm) is highest, but voltage cycling degrades performance to below that of MEAs with larger initial particle size (7.1 nm and 12.7 nm).
- MEAs with larger cathode catalyst particles (7.1 nm and 12.7 nm) show minimal performance degradation over 10,000 voltage cycles.
- Particles of \( \sim 3 \) nm show growth and narrowing of distribution over 1,750 potential cycles in aqueous electrolyte (Figure 2-top).
- Particles of \( \sim 12 \) nm show no growth or change in distribution over 1,750 potential cycles in aqueous environment (Figure 2-bottom).
- Anomalous small angle X-ray scattering shows that the mean particle diameter of \( \sim 3 \) nm catalyst grows by \( \sim 0.1 \) nm over 1,750 cycles, with the majority of particle growth occurring during the first 900 cycles in aqueous environment.
- Potential cycling causes Pt catalysts of 2.4 to 5.7 nm initial size to evolve to identical specific surface areas, independent of initial particle size.

Summary of MEA parametric study results (Figure 3):

- Increasing the upper limit of voltage cycling from 0.95 V to 1.05 V increases cathode catalyst ECA loss and ORR mass activity loss.
In addition to causing a loss of ECA, cycling to high potentials (1.05 V) increases cathode transport losses.

- Low anode/cathode inlet RH decreases cathode catalyst degradation (30% RH versus 100% RH).
- Increased cell temperature increases cathode catalyst degradation (90ºC versus 80ºC).

These studies on Pt/C provide the background for ongoing studies of platinum alloy (e.g., Pt₃Co/C) cathode electrocatalyst degradation modes.

In the modeling tasks of the project, a KMC model has been developed that can predict Pt nano-particle evolution under fuel cell conditions. As a first step of the validity of this tool, the evolution of a 3.1 nm Pt particle from a spherical particle with random atomic orientation to its thermodynamic equilibrium structure in vacuum at 300 K was determined. As shown in Figure 4, the KMC tool correctly predicts the evolution of the particle to a cubo-octahedra structure, as observed experimentally. This model is being further developed to follow the shape and structure evolution of Pt alloy nano-particles and the changes in the nano-particles in the fuel cell environment due to various processes, such as dissolution and surface migration of atoms. This KMC tool will enable the identification of the causes of the stability/instability of nano-particle alloys in the fuel cell environment and to identify properties and mechanisms that control degradation.

**Conclusions and Future Directions**

The following interim conclusions can be made from our initial studies of the degradation of baseline Pt/C electrocatalysts:

- Initial fuel cell performance increases with decreasing cathode electrocatalyst mean Pt particle size, however degradation of performance with potential cycling increases with decreasing particle size.

- Potential cycling (0.4 to 1.0 V; 50 mV/s) causes Pt catalysts of <∼4 nm initial mean diameter to evolve to specific surface areas comparable to those of 7-12 nm particles (20-30 m²/g).

- Performance degradation with potential cycling can be attributed to increased rates and extent of ECA loss with decreasing Pt particle size for electrocatalysts with mean Pt particle sizes <∼4 nm.

- Extent of loss of ∼3 nm Pt nano-particle cathode electrocatalyst performance, caused by loss of ECA, increases with increasing cell temperature, increasing RH, and increasing upper limit of potential cycling.

The immediate future direction of the experimental portion of the project is to complete characterization of the Pt/C class of catalysts, including acquiring additional data needed for the nano-particle degradation modeling effort, such as Pt dissolution rates and extent of oxidation as a function of potential. Immediate future work on advanced catalysts will focus on characterization of platinum-cobalt alloy nano-particles of varying initial particle size.

**Future Directions**

- Characterize Pt dissolution as a function of particle size for Pt and Pt₃Co.

- Determine effect of temperature on Pt dissolution rates for “benchmark” Pt/C catalyst (3.2 nm mean diameter).

- Determine ORR activity of Pt₃Co/C catalysts of varying particle size and evolution of activity with potential cycling.

- Quantify Pt₃Co catalyst performance loss in a fuel cell as a function of initial particle size and cell parameters.

- Extend KMC code development to alloy nano-particles.

- Model aqueous cell and MEA mean particle size and particle size distribution evolution with cycling.
• Develop model for Pt nano-particle voltammetry, including states of oxide as a function of potential to predict Pt dissolution rates.
• Synthesize and characterize nano-particles of advanced Pt alloy electrocatalysts (e.g., Pt₃Sc and Pt₃Y).

Start Date: October 2009
Project End Date: 2013

Objectives

- Identification and delineation of individual component degradation mechanisms.
- Explore Nafion® structure and correlate different electrode structure to fuel cell tests:
  - Understand impact of structure electrode on durability and performance.
  - Define different production methods (especially solvents) on electrode structure.
- Quantify influence of operating environment on different component degradation.
- Make degradation measurements of components and component interfaces.
- Elucidation of component interactions, interfaces, operating conditions on cell degradation.
- Develop individual degradation models of all fuel cell components.
- Development and public dissemination of an integrated model of cell degradation.
- Development of advanced in situ and ex situ characterization techniques for analysis of fuel cell component degradation.
- Develop methods to mitigate degradation of components.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:
(A) Durability
(B) Cost

Technical Targets

- Transportation Durability: 5,000 hours (with cycling)
  - Estimated start/stop cycles: 17,000
  - Estimated frozen cycles: 1,650
  - Estimated load cycles: 1,200,000
- Stationary Durability: 40,000 hours
  - Survivability: Stationary -35°C to 40°C
- Cost ($25/kWe)

Accomplishments

- Characterization of particle size growth after freeze operation and comparison to drive cycle operation data.
- Measurements of effect of catalytic ink solvent on electrode layer durability:
  - Comparison of electrochemical surface area (ECSA) and mass activity on performance durability.
  - Measurement of mass transport changes in electrode.
  - Characterization of polymer dispersion and electrode structure by small angle neutron scattering (SANS) and nuclear magnetic resonance (NMR).
- Measured water profile changes after severe catalyst corrosion.
- In situ carbon corrosion measurements separating catalyst support, gas diffusion layer (GDL), microporous layer (MPL), and GDL substrate.

**Introduction**

The durability of polymer electrolyte membrane (PEM) fuel cells is a major barrier to the commercialization of these systems for stationary and transportation power applications. Although there has been recent progress in improving durability, further improvements are needed to meet the commercialization targets. Past improvements have largely been made possible because of the fundamental understanding of the underlying degradation mechanisms. By investigating component and cell degradation modes, defining the fundamental degradation mechanisms of components and component interactions, new materials can be designed to improve durability. Various factors have been shown to affect the useful life of PEM fuel cells [1-4]. Other issues arise from component optimization. Operational conditions (such as impurities in either the fuel and oxidant streams), cell environment, temperature (including subfreezing exposure), pressure, current, voltage, etc., or transient versus continuous operation, including start-up and shutdown procedures), represent other factors that can affect cell performance and durability.

To achieve a deeper understanding of PEM fuel cell durability and component degradation mechanisms, we have assembled a multi-institutional and multi-disciplinary team with significant experience investigating these phenomena. This team is headed by LANL and includes three other national laboratories (Argonne National Laboratory, Lawrence Berkeley National Laboratory and Oak Ridge National Laboratory), a university (University of New Mexico), a membrane/ionomer supplier (Ion Power), and a stack integrator (Ballard Power Systems).

**Approach**

Our approach to understanding durability and degradation mechanisms within fuel cells is structured in three areas: fuel cell testing (life testing, accelerated stress tests [ASTs], ex situ aging), characterization of component properties, and modeling (component aging and integrated degradation modeling). These areas have aspects that can be considered free-standing, but each benefit greatly from work performed in the other areas. The modeling studies tie together what is learned during component characterization and allow better interpretation of the fuel cell studies. This approach and our team give us the greatest chance to increase the understanding of fuel cell degradation and to develop and employ materials that will overcome durability limitations in fuel cell systems. This work is also being coordinated with other funded projects examining durability through a DOE Durability Working Group, and through a US Fuel Cell Council task force on durability.

**Results**

One of the major degradation issues involves the electrocatalyst, and has been studied in some detail [1] yet is not completely understood, nor have the durability issues been fully solved. The cost of the noble metal used in the catalyst makes this a crucial area that requires improvement in durability. For example, Pt particle size has been observed to increase especially during power cycling. Post-characterization of the cathode catalyst by techniques such as transmission electron microscopy (TEM) and X-ray diffraction (XRD) show particle size growth and particle agglomeration. An example of the change in platinum particle size distribution is shown in Figure 1a for operation with the US06 drive cycle.

Similarly, other types of operation show similar Pt particle degradation such as operation at freezing temperatures as shown in Figure 1b. This analysis shows that cathode catalyst coarsening observed over 2,000 hours of drive cycle operation is similar to a short period of operation with freeze cycles. The catalyst particle size is observed to rapidly increase compared with life testing at a constant potential. Also, the degree of particle size growth is dependent upon the amount of water in the system, with operation at 100% relative humidity (RH) showing a higher degree of particle growth (5.0 nm) compared to operation at 50% RH (4.2 nm), compared with an initial average particle size of 2.2 nm. This particle growth is attributed to dissolution and re-precipitation. In addition to the particle size growth, a change in the particle size distribution is occurring, as evidenced by the bi-modal shape observed especially with the 100% RH testing, observed at ~8 nm. This is evidence of particle coalescence, as particle growth by dissolution and re-precipitation should not show a change in the shape in the distribution. A short period of operation with freeze cycles shows a similar cathode catalyst coarsening (see Figure 1b). During freeze operation, significant coarsening of Pt on cathode was observed (from ~2.2 nm to ~4.2 nm) for both tested cells, no difference was observed in the Pt sizes and distributions between the two cells, however this Pt particle growth occurred in only a few hundred hours of operation but with the sub-freezing operation. Figure 2 shows TEM of how the electrocatalyst and the catalyst layer changes during
Movement of Pt is observed from cathode to the cathode/membrane interface. Increased Pt agglomeration is observed near interface (0.2-0.4 µm). Pt-particles are observed across the remaining 47 µm to anode side however, no Pt particles are observed within 3 µm of cathode. Pt particles are also found in the center of the membrane, noting that Pt particles are observed continuously/homogeneously across the membrane starting ~3 µm from cathode, with a nominal Pt particle size ~15 nm diameter. Pt particles are found across membrane up to anode/membrane interface, where the Pt “plates” the anode surface.

The main metrics for analysis of electrocatalyst durability have been ECSA, mass activity, and performance as measured by polarization curves. Post characterization by TEM and XRD has been most widely used to determine the particle size growth. Comparing mass activity and ECSA as a function of particle size can show a good correlation [1,5,6]. This correlation appears to be true for catalysts in certain types of MEAs. However in other types, the correlation can be poor, or even non-existent. An excellent example of this is shown by the polarization performance curves as a function of potential cycles in Figures 3a and 3b and the corresponding ECSA shown in Figures 4a and 4b. This work done by Christina Johnston and Yu Seung Kim at LANL explores the effect of different solvents on the electrode structure performance and durability. Electrodes made from water-based catalytic inks show rapid performance degradation, whereas electrodes made from catalytic inks based on glycerol, show virtually no performance loss. This examination was for identical cathode catalysts.

However, the lack of performance loss appears to not be associated with the catalytic surface area, as in Figure 4a vs. Figure 4b, the loss in catalyst surface area is essentially identical. For the case of electrodes made from a glycerol-based catalytic ink, there is essentially no
To meet commercialization targets, improvements in durability are still required. Catalyst and electrode durability remains a primary degradation mode; catalyst particle growth occurs with potential cycling and with freeze testing/cycling. ASTs are used to rapidly evaluate component degradation, however the results such as ECSA and mass activity are sometimes easy to correlate, and sometimes difficult to correlate. Correlation of the results appears to depend upon the electrode layer structure, and the fabrication process used to produce the electrode. Tests which were developed to accelerate single components also affect the performance in other areas. Examples of this are tests to examine losses due to catalyst degradation and kinetics losses and also lead to losses in mass transport.

**Conclusions**

Future Directions

- Fuel Cell Durability Testing and Performance Evaluation
  - Elucidation of single component degradation mechanisms:
    - Electrocatalyst, catalyst support, membrane, ionomer, MEA, GDL, metal bipolar plate, carbon bipolar plate, and seals.
  - Elucidation of multi-component degradation mechanisms.
  - Parametric aging studies:
    - Temperature, RH, transients (potential cycling), and shut-down/start-up,
  - Fuel cell testing on mixed MEAs:
    - Mixed Nafion®/hydrocarbon membranes and ionomer.
    - Characterization of Nafion® within aged electrode films.
  - Evaluation of water/Nafion® dispersions tendency to create weaker electrode structures.
- Fuel Cell Component Characterization
- SANS of electrode layers.
- XRD and TEM: higher crystallinity in aged electrodes.
- Neutron reflectivity measurements of swelling of Nafion® films on carbon substrates.
- NMR characterization of aged fuel cell components (membrane, catalyst and GDL).
- Development of in situ analytical techniques:
  - In situ Raman and infrared.
  - Effect of film-forming properties on the electrode/membrane interface by X-ray tomography and scanning electron microscopy.

Fuel Cell Degradation Modeling
- Development of models for alternating current impedance data; heliox and 100% O2 experiments.
- Model membrane degradation:
  - Effect of mechanical loads on chemical degradation.
  - Effect of chemical degradation on mechanical properties.
  - Mechanical failure of the membrane due to RH cycling.
- Model corrosion of the graphite and metallic bipolar plate.
- Improve model for electrocatalyst degradation and catalyst support carbon corrosion:
  - Account for Pt band formation.
  - Model Pt agglomeration due to carbon corrosion.
  - Carbon oxidation due to potential cycling, startup/shutdown, and fuel starvation.
  - Effect of support loss on ECSA.
- Model effect of GDL/MPL degradation:
  - Improve transport model to account for measurable properties such as surface energies, internal contact angles, pore size distributions.
  - Model effects of sealants and gaskets including impact of degradation products.

V.H.3 Durability of Low Platinum Fuel Cells Operating at High Power Density

Objectives

- The objective of this project is to study and identify strategies to assure durability of fuel cells designed to meet DOE 2015 cost targets.
- Develop a practical understanding of the degradation mechanisms impacting durability of fuel cells with low platinum loading (≤0.2 mg/cm²) operating at high power density (≥1.0 W/cm²).
- Develop approaches for improving the durability of low-loaded, high-power stack designs.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost

Technical Targets

¹ Cost assessment of Nuvera's architecture by Directed Technologies, Inc. based on their DOE-sponsored Design for Manufacturing and Assembly model [1] and comparing the results to an updated “Industry” estimate. 0.60 V/cell @2.0 A/cm² were obtained at 0.5 mg/cm² platinum loading on Orion stack by Nuvera.
² Demonstrated under power profile specific-to-fork truck applications in material handling market at total platinum loading of 0.5 mg/cm².
³ Demonstrated in 360-cm² stack by Nuvera in New European Driving Cycle power profile at platinum loading of 0.50 mg/cm².
⁴ Demonstrated in 250 cm² stack by Nuvera - 0.60 V/cell @ 2.0 A/cm².

Accomplishments

- Nuvera completed system analysis specific to high-power operation and its impact on the process conditions throughout the active area of the fuel cell stack. The results informed the experimental design for the combined test cycles, or new stress tests (NSTs), based on rated current density (RCD) of 1, 2 and 3 A/cm² and respective constant power turn down.
- New single-cell, open flowfield hardware capable of high RCD was developed and validated over the planned range of experimental operating conditions.
- Catalyst-coated membranes (CCMs) with two levels of platinum loadings (0.45 and 0.2 mg/cm²) were selected and the higher loaded material was procured and characterized at the beginning of life (BOL) in Nuvera 360-cm² cells and LANL 50-cm² hardware throughout the range of operating conditions. The CCM proved promising to allow increased operating temperature with sub-saturated inlet gasses at appropriate gas stoichiometries as targeted by the automotive system map presented by ANL [2]. An accelerated stress test (AST) campaign on the selected material set has started at LANL.
- ANL performance model was calibrated for the open flowfield, and the resulting modeling polarization curves matched Nuvera experimental BOL data, completing the ground work for further development of the durability model.
Introduction

Understanding and improving the durability of cost-competitive fuel cell stacks is imperative to successful deployment of the technology. Stacks will need to operate well beyond today's state-of-the-art rated power density with very low platinum loading in order to achieve the cost targets set forth by DOE ($15/kW) and ultimately be competitive with incumbent technologies. Little-to-no study of durability factors has been carried out in this area of design and operation. The industry today is focusing mostly on reduced platinum loading as it heads for the DOE target point of 0.2 mg/cm² platinum and 1.0 W/cm² power density. As demonstrated through DOE-sponsored cost modeling, this point falls short of the corresponding $15/kW stack cost target for 2015.

Approach

Nuvera proposes an accelerated cost-reduction path focused on substantially increasing power density to address non-platinum group metal material costs as well as platinum. Understanding the largely unstudied factors affecting stack durability under these high power conditions is the focus of the present project. Of specific interest is the impact of combining low platinum loading with high power density operation, as this offers the best chance of achieving long-term cost targets. The team effort will be divided into two activities: modeling and experiments.

Results

Development efforts were focused on the detailed design, procurement and validation of single cell with open flowfield (SCOF) hardware. Nuvera’s patent pending design, shown in Figure 1, allows operation at high current density, flexible selection of the flowfield design, simulation of stack-level temperature gradients as well as an isothermal profile, control and uniformity of compression over the active area apart from sealing, and current distribution measurement.

Material sets A and B were selected for the project in standard and custom platinum loadings with advice from leading CCM developer W.L. Gore. Anode electrode 584.05 loaded at 0.05 mg/cm², membrane M815 at 15 microns thickness, and cathode electrode C580.4 loaded at 0.4 mgPt/cm² comprise the benchmark CCM A. Custom cathode electrode C580.15 is being procured by W.L. Gore for the CCM B, preserving the same anode electrode structure and membrane as in CCM A and resulting in total platinum loading of 0.2 mg/cm² in material set B. All cells are assembled with gas diffusion media produced by W.L. Gore.

Material set A was received in 50-cm² format for the ASTs and in 360-cm² format for the NSTs and characterized for the BOL polarization curve, sensitivities to relative humidity, temperature, and cathode stoichiometry. Data obtained both at Nuvera and Gore demonstrated capabilities of M815 to increase the window of operating temperatures using sub-saturated inputs to the cell provided specific stack operating conditions are maintained. Electrochemical impedance spectroscopy and other diagnostic data obtained on material A both at LANL and Nuvera showed expected cell low initial resistivity and other metrics to be monitored in the test campaign.

In the experimental campaign we focused only on those ASTs which provide direct input to the durability model and can be compared to the fuel cell tests under load protocols (NSTs). ASTs will focus on the electrocatalyst stability at cycling potential defined in B1 protocol by the DOE. Additional AST B1* will be conducted with a lower range of cycling potential than B1 to correspond to the cell voltage achieved in Nuvera large-area cell at 2.0 A/cm². We will also focus on the membrane mechanical stability defined in the B4 protocol by the DOE.

The NST protocols focused on the combined power cycles at the different current densities were proposed, discussed and agreed among Nuvera, LANL and ANL. Three groups of NSTs are defined as following: N1 is the group of sensitivity tests aimed at evaluating the addition of electrical current on the ASTs, N2 is a group of combined humidity and load cycles derived from the protocol recommended by the Fuel Cell Technical Team (FCTT), and N3 is a group of combined city/highway drive cycles accounting for system conditions and implications.
The test plan is designed along three parameter vectors: total Pt loading, current density and the flowfield architecture (graphite single cell with land and channel, SCOF and stack). The latter parameter doesn’t represent a quantified metric, however, is chosen to maximize applicability of the test results across the industry. The schematics of the experimental design space is shown in Figure 2.

N3A-X protocols were evaluated in Nuvera 360-cm² cell stacks for performance and stability over several hundred hours. On-going N3A-2 durability test on material set A in an eight-cell stack is currently passing 600 hours with the cell voltage decay stabilizing below 10 μV/hr/cell at 1 and 2 A/cm² current density, shown in Figure 3.

A two-dimensional fuel cell performance model was established at ANL and initial assessment against

the BOL data was completed. The model accounts for:

a) a seven-layer cell architecture, including both anode
and cathode flowfields, gas diffusion and catalyst layers;

b) temperature, current, potential, relative humidity,
and species distribution; and

c) anode/cathode counter-flow, cathode/coolant co-flow. Modeling results were
calibrated with the polarization curves from 360- and
250-cm² area cell stacks.

Polarization curves resulting from modeling effort
are plotted in Figure 4 overlaying experimental data at
BOL on 360-cm² area cells with 18-micron membrane
and 0.5 mg/cm² total Pt loading electrodes, representing
Nuvera’s internal benchmark MEAs.

Conclusions and Future Directions

The work completed in the first nine months of
the project has concluded the preparatory phase of the
experimental and modeling scope. All partners agreed
to the detailed experimental test plan of ASTs and NSTs
going forward. Preliminary qualification of CCM A in

Nuvera 360-cm² area stacks proved the feasibility of
using this material set for the project and helped establish
essential aging parameters towards understanding
degradation mechanisms and durability model
development. In the next period work will focus on:

• Delivery to and validation of SCOF at LANL.

• Completing ASTs on CCMs A and B and analysis of
test results by the partners.

• Analysis of the ANL model’s sensitivities to metrics
recorded in the ASTs.

• Beginning the NST campaign on SCOF both at
LANL and Nuvera.

• Continuing the NST campaign in the large-format
cells in short stacks and benchmarking the results
between SCOF and large area cells.

• Publishing the degradation model framework and
further model validation.

**V.H.4 Improved Accelerated Stress Tests Based on Fuel Cell Vehicle Data**

**Objectives**

- Correlate real-world operating conditions to cell degradation.
- Correlate existing DOE accelerated stress tests (ASTs) to degradation.
- Assess degradation modes between real-world operating conditions and existing DOE ASTs.
- Recommend modified ASTs that more accurately gauge in situ component behavior.
- Identify life-limiting mechanisms not addressed by current DOE ASTs and recommend new ASTs.

**Technical Barriers**

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

(C) Performance

**Accomplishments**

- Fleet performance and operating cycle analyses complete.
- Correlation of platinum decay in real-world operation and lab AST complete.
- Lab ASTs for platinum degradation complete.
- Lab ASTs for carbon support corrosion complete.
- Lab ASTs for membrane mechanical degradation complete.

**Project Approach**

UTC will lead a top-tier team of industry and national laboratory participants to update and improve DOE's ASTs for hydrogen fuel cells. This in-depth investigation will focus on critical fuel cell components (e.g., membrane electrode assemblies, MEAs) whose durability represents barriers for widespread commercialization of hydrogen fuel cell technology. UTC has access to MEA materials that have accrued significant load time under real-world conditions in a PureMotion® 120 power plant used in transit buses. These materials are referred to as end-of-life (EOL) components. Advanced characterization techniques are used to evaluate degradation mode progress using these critical cell components extracted from both bus power plants and corresponding materials tested using the DOE ASTs. These techniques will also be applied to samples at beginning-of-life (BOL) to serve as a baseline. These comparisons will advise the progress of the various failure modes that these critical components are subjected to, such as membrane degradation, catalyst support corrosion, platinum group metal dissolution, and others. Gaps in the existing ASTs to predict the degradation observed in the field in terms of these modes will be outlined. Using these gaps, new ASTs will be recommended and tested to better reflect the degradation modes seen in field operation. Also, BOL components will be degraded in a test vehicle at UTC designed to accelerate the bus field operation.

**Results**

**Fleet Durability Growth**

Before reviewing the progress on each of the individual tasks, some perspective on the role of the
DOE program in improving proton exchange membrane fuel cell durability is helpful. UTC’s approach to achieve the durability targets consists of three aspects. First, UTC is analyzing its fleet operation cycle for critical factors that accelerate performance decay and materials degradation. Second, sub-scale ASTs are performed at LANL using DOE protocols. Third, UTC is implementing its accelerated life test (ALT) article to simulate real-world degradation with selected accelerated conditions identified from the data analysis. Data collected from detailed teardown analyses of aged components from these three elements are incorporated in physics-based numerical models for materials and performance decay.

**Task 1.1 - Fleet Data Analysis**

The first aspect of this analysis is to characterize the performance decay among the various buses in the field. Figure 1 shows the stack performance decay observed in the various bus vehicles. The 2010 fleet leaders are currently still in service with over 6,000-7,000 hours of operation. The 2008 fleet leader failed after ~2,850 hours of field service as a result of hydrogen cross-over and exhibited an overall decay of ~5-6 µV/hr. The second aspect of the fleet data analysis is to identify the key components of the field operating cycle that can be correlated to the degradation of key components (e.g. MEAs). Figure 2 shows the fleet operating cycle that is typically seen in any given hour of operation. Such a cycle imposes ~100 load cycles per hour with about ~30% time spent at an idle condition. As seen in Figure 2, the required power draw (green trace) is instantly manifested in the fuel cell voltage response (blue trace). At a high level, this indicates that the fuel cell is exposed to the bus power draw directly, and that the hybridizing batteries on-board mainly serve to recover energy during braking. Thus, the imposed cycle on the fuel cell is aggressive and represents very realistic conditions from both a fleet and light-duty vehicle perspective.

**Task 1.2 – EOL Stack Diagnostic Testing**

For the current DOE project, since the 2010 fleet leaders are currently still in service and not yet available, the stacks from the 2008 fleet leader were chosen for detailed diagnostics and post-mortem analyses. Cells were extracted from the stack for comparison between BOL and EOL. Although characteristics associated with all four DOE ASTs with targeted mechanisms (namely, catalyst decay, carbon corrosion, membrane mechanical and membrane chemical decay) have been investigated, only the result pertinent to platinum group metal (PGM) decay is reported here. Results associated with other
mechanisms will be reported in future reports. Figure 3 shows performance decay of cells from the 2008 fleet leader stack. It can be seen that after ~2,850 hrs of field operation, the voltage decay is ~15 mV at 0.2 A/cm².

**Task 1.3 – EOL Stack Teardown Analysis**

The stacks were torn down and cells extracted for detailed analysis. Four areas of the cell (air inlet and outlet, fuel inlet and outlet) were subjected to detailed analysis using a variety of ex situ techniques that include cyclic voltammetry to study Pt electrochemical surface area (ECA), X-ray diffraction (XRD) and transmission electron microscopy (TEM) techniques for Pt particle size and distribution. ECA results obtained from the 2008 fleet leader cell using cyclic voltammetry (2,850 hrs) are shown in Figure 4, which also include baseline (BOL) ECA data. At BOL, both anode and cathode catalysts had ECA of ~80 m²/g. After 2,850 h, the average ECAs of anode and cathode are ~50 m²/g and ~28 m²/g, respectively. Assuming that only ~70% of Pt surface area is ionically contacted by cyclic voltammetry, the Pt particle sizes can be estimated based on Pt theoretical density which are also shown in Figure 4 (in red).

**Task 1.4 – High-Resolution TEM Analysis**

PGM catalyst decay was also investigated using TEM techniques. Analysis on BOL and EOL MEAs were performed at ORNL. Images obtained from baseline and 2008 fleet leader samples are shown in Figure 5.
is clear from these images that Pt particle coarsening has occurred. ECA measurements and TEM analysis of the catalyst at the air inlet are in qualitative agreement.

**Task 2 - Lab-World Degradation - DOE ASTs**

All lab DOE ASTs are performed at LANL on a BOL MEA used in a UTC 2008 fleet leader. Table 1 summarizes the status of all sub-scale AST testing.

### PGM Decay AST

Catalyst AST testing has been completed on the BOL MEA. The ECA and voltage loss are shown in Figure 6. It has been concluded that surface area, voltage and mass activity loss after 50,000 cycles at 0.6-1.0 V is ~37%, ~5 mV and ~20%, respectively. Comparison between these results and the DOE 2012 targets for catalyst is shown in Table 2. Post-mortem analyses on the AST-degraded electrodes are ongoing.

**Membrane Mechanical Degradation AST**

Lab DOE AST for membrane mechanical degradation has also been performed on the BOL MEA used in a UTC 2008 fleet leader. Tested under the DOE relative humidity cycling protocol, the membrane endured ~5,500 cycles before significant cross-over was observed. Cross-over current, shorting resistance, and teardown analysis on the degraded MEA are currently underway and will be reported in the future.
degradation will be performed in the third quarter in 2010.

- ALT: Test vehicle has been facilitated.
- Next Step: Correlate real-world degradation to lab tested degradation for carbon corrosion and membrane mechanical/chemical degradation. Complete testing BOL materials using ALT test vehicle.

Project Start Date: October 2009
Project End Date: 2013

Objectives

- Correlation of the component lifetimes measured in an accelerated stress test (AST) to “real-world” behavior of that component.
- Validation of existing component specific ASTs for electrocatalysts, catalyst supports and membranes (mechanical and chemical degradation).
- Development of new ASTs for gas diffusion layers (GDLs) and bipolar plates.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost

Technical Targets

Cost and durability are the major challenges to fuel cell commercialization. ASTs enable the rapid screening of fuel cell materials and are critical in meeting the long life times required for stationary and automotive environments. Moreover these ASTs can also help predict the lifetime of the various components in “real-world” applications.

- Transportation Durability: 5,000 hours (with cycling)
  - Estimated Start/Stop cycles: 17,000
  - Estimated Frozen cycles: 1650
  - Estimated Load cycles: 1,200,000
- Stationary Durability: 40,000 hours
  - Survivability: Stationary -35°C to 40°C
- Cost ($25/kWe)

Accomplishments

- Performed all four DOE Fuel Cell Tech Team recommended ASTs on baseline GORE™ membrane electrode assemblies (MEAs) at two different loadings and on two different membrane types
- Ballard manufactured and supplied LANL the MEAs that went into the P5 and HD6 bus stacks.
- ORNL manufactured and supplied metal nitrided bipolar pate materials for AST testing.
- Characterized Pt particle size in the catalyst layer before and after ASTs using X-ray diffraction.

Introduction

The durability of polymer electrolyte membrane (PEM) fuel cells is a major barrier to the commercialization of these systems for stationary and transportation power applications [1]. Commercial viability depends on improving the durability of fuel cell components to increase the system reliability and to reduce system lifetime costs by reducing the stack replacement frequency. The need for ASTs can be quickly understood given the target lives for fuel cell systems: 5,000 hours (~7 months) for automotive, and 40,000 hrs (~4.6 years) for stationary systems. Thus testing methods that enable more rapid screening of individual components to determine their durability characteristics, such as off-line environmental testing, are needed for evaluating new component durability in
a reasonable turn-around time. This allows proposed improvements in a component to be evaluated rapidly and independently, subsequently allowing rapid advancement in PEM fuel cell durability. These tests are also crucial to developers in order to make sure that they do not sacrifice durability while making improvements in costs (e.g. lower platinum group metal loading) and performance (e.g. thinner membrane or a GDL with better water management properties).

DOE has suggested AST protocols for use in evaluating materials, but only for the catalyst layer (electrocatalyst and support), and for the membrane [2,3]. The USFCC has also suggested AST protocols for the same materials [4]. While these protocols have concentrated on the catalyst, catalyst support and membrane materials, to date, no accelerated degradation protocols have been suggested for GDL materials or MPL layers, bipolar plates or seals. In spite of recent advances in AST development, a main portion, which is deficient, is the quantitative correlation between the results of a given fuel cell AST and the degradation rate or life in an operating fuel cell.

**Approach**

A main desired outcome of this task is the correlation of the component lifetimes measured in an AST to in situ behavior of that component in “real-world” situations. This requires testing of components via ASTs and in operating fuel cells, and delineating the various component contributions to the overall cell degradation. This will primarily be performed by using a simplified one-dimensional model that takes into account the different component contributions like membrane ionic conductivity, cathode catalyst layer kinetic losses and mass transport losses (catalyst layer and GDL) to the overall losses observed in operating cells [5]. This project will then attempt to correlate the performance losses observed due to a particular component in “real-world” situations with the degradation in AST metrics of that component. The correlation between AST and life data if state-of-the-art materials are used, in essence gives one data point. Thus, for a reasonable correlation to be made, materials with different life spans will be utilized. This relies on the expertise of the suppliers as partners in the project. This work is also being coordinated with other funded projects examining durability through a DOE Durability Working Group, and through a USFCC task force on durability.

**Results**

GORE™ Primea® MEAs sandwiched between two SGL SigracetTM 24BC GDLs were used as the baseline MEAs for AST testing in a single serpentine flow field. The testing was performed in accordance with the published Fuel Cell Tech Team protocols [6]. The results from the potential cycling AST are illustrated in Figure 1, which shows the degradation in electrochemical surface area (ECSA) and performance as a function of the number of potential cycles. There is reasonable agreement in the ECSA and performance loss targets with the lower loaded (0.2 mg-Pt/cm²@ cathode) MEA showing a 40% loss in ECSA after 12,500 cycles and a 30 mV loss in performance after 15,500 cycles. Moreover, the higher loaded (0.4 mg-Pt/cm²@ cathode) MEA exhibited better durability with the 40% ECSA loss target occurring after 20,000 cycles. Figure 2 illustrates the impedance of an MEA before and after the potential cycling test. The Nyquist plot clearly shows two semi-circles with the low frequency semi-circle corresponding to mass transport losses and the high frequency semi-circle corresponding to kinetic losses. It is seen that the potential cycling not only introduces a significant increase in the charge transfer resistance, but it also results in an increase in the mass transport losses. This result indicates that the upper potential for the cycling that is presently 1.0 V may need to be lowered in order to avoid any carbon corrosion and make this test truly representative of the electro-catalyst alone.

Performance degradation due to catalyst support corrosion during a 1.2 V constant potential hold is
illustrated in Figure 3. It is seen that two identical MEAs showed very similar performance losses indicating the excellent reproducibility of the tests. Figure 3a shows that by doubling the cathode catalyst loading to 0.4 mg-Pt/cm², the loss of ECSA can be delayed significantly. The target 40% ECSA loss is reached after 61 hours instead of 29 hours. Figure 3b confirms that this translates to a slower loss of performance at 1.5 A/cm². However, the 30 mV target for this metric is still passed within the first ≈12 hours. This illustrates that there is significant loss in performance due to mass transport losses that is not captured in the ECSA measurements and therefore the ECSA metric may not be very relevant for this constant potential hold AST.

The main metrics for analysis of electrocatalyst durability have been ECSA, mass activity, and performance as measured by the kinetic region of polarization curves. Post characterization by transmission electron microscopy and X-ray diffraction (XRD) has been most widely used to determine the particle size growth. As shown in Figure 4, comparing mass activity (MA) and ECSA as a function of particle size (determined by XRD) can show a good correlation. Here, the fresh cathode catalyst had a spherical particle size of 2.7 nm that grew to ≈6.5 nm after 30,000 potential cycles and to ≈10 nm after 200 hours of 1.2 V potential hold. Although the mechanism of Pt particle growth is expected to be completely different in these two tests, it is important to note that the average Pt particle size can be used as an excellent marker to track performance loss in both “real-world” and AST testing of PEM fuel cells.

Conclusions and Future Directions

The ASTs performed on baseline GORE™ materials showed excellent repeatability for both the catalyst layer...
and membrane. Potential cycling led to an increase in the Pt particle size at the cathode that correlated well with catalyst MA and ECSA loss. The catalyst cycling was however found to cause some mass transport losses that may be associated with carbon corrosion. Constant potential holds led to a dramatic increase in catalyst particle size and an associated thinning of the catalyst layer that were consistent with both mass transport and kinetic losses observed in fuel cell performance. The GORE™ 510 catalyst layer had reasonably good Pt catalyst stability but poor carbon corrosion resistance. The durability of the catalyst and the support increased with increasing loading. The GORE-SELECT™ 720 and N212 membranes had excellent mechanical stability and met the DOE AST targets. The following work will be carried out in the coming years of this project in order to validate existing ASTs and recommend new ASTs.

- **AST Testing**
  - Perform ASTs on the Ballard-supplied materials.
  - Perform ASTs on materials with differing durability supplied by Ion Power.
  - Develop ASTs for ORNL supplied bipolar plate materials.
  - Develop ASTs for GDLs/microporous layers.

- **“Real-World” Testing**
  - Perform simulated automotive drive cycle testing on selected materials with differing durability.
  - Study effect of operating conditions (stressors) like temperature, pressure and relative humidity on drive cycle testing.
  - Analyze the performance data from two different Ballard bus stacks.

- **Characterization of Materials**
  - In situ characterization of catalyst activity, membrane crossover and shorting resistance, and mass transport limitations as a function of AST and “real-world” testing.
  - Ex situ characterization of catalyst particle size distribution, layer thickness, membrane thickness, and GDL hydrophobicity as a function of AST and “real-world” testing.

- Correlation of AST to “Real-World” Data
  - Modeling of fuel cell performance data to provide component specific degradation rates.
  - Statistical correlation of performance degradation with physical properties in both AST and “Real-world” data.

Contract Number: DE-EE0000466

Subcontractors:
- Georgia Institute of Technology, Atlanta, GA (S.S. Yang)
- Los Alamos National Laboratory, Los Alamos, NM (R. Borup)
- Michigan Technological University, Houghton, MI (J. Allen)
- Queen’s University, Kingston, Ontario, Canada (K. Karan, J. Pharoah)
- University of New Mexico, Albuquerque, NM (P. Atanassov)

Project Start Date: January 1, 2010
Project End Date: March 31, 2013

Objectives

- Identify/verify catalyst degradation mechanisms:
  - Pt dissolution, transport/plating.
  - Carbon-support oxidation and corrosion.
  - Ionomeric thinning and conductivity loss.
  - Mechanism coupling, feedback, and acceleration.
- Correlate catalyst performance/catalyst structural change as a function of:
  - Unit cell operational conditions.
  - Catalyst layer morphology and composition.
  - Gas diffusion layer (GDL) properties.

- Develop kinetic and material models for catalyst layer aging:
  - Macro-level unit cell degradation model.
  - Micro-scale catalyst layer degradation model.
  - Molecular dynamics degradation model of the platinum/carbon/ionomer interface.
- Develop mitigation strategies for catalyst degradation through modification of:
  - Operational conditions.
  - Component structural morphologies/compositions.

Technical Barriers

This project addresses the following technical barriers of the DOE Fuel Cell Technologies Program Multi-year Research, Development, and Demonstration Plan. This plan can be accessed at http://www.eere.energy.gov/hydrogenandfuelcells/mypp/.

(A) Durability
- Pt catalyst and Pt catalyst layers degradation:
  - Effect of structure and composition
  - Effect of operational conditions

(B) Performance:
- Effect of cathode catalyst structure and composition

(C) Cost (indirectly)

Technical Targets

This project is conducting fundamental studies of Pt/carbon catalyst degradation mechanisms and degradation rates which will be correlated with unit cell operational conditions and catalyst layer structure and composition. Furthermore, forward predictive micro- and macro- models for cathode performance and degradation will be developed. Design curves that will be generated both through model simulations and experimental work will enable membrane electrode assembly (MEA) designers to optimize performance, durability, and indirectly cost towards the 2015 stack targets for fuel cell commercialization [1]:

- Durability: 5,000/40,000 hrs (2015 transportation/2011 stationary application target)
  - Electrocatalyst support loss <30 mV after 100 hrs @ 1.2 V
  - Electrochemically active surface area (ECSA) loss <40%
• Cost: $15/kWₑ
  – Platinum group metal total loading: 0.2 mg

**Approach**

A dual path approach is taken in this project:

1. Development of models at the molecular, micro-structural, and macro homogeneous scales that include the degradation effects related to platinum dissolution/transport/plating, carbon surface oxidation/corrosion, and ionomer thickening/conductivity loss. These models will provide the ability to study the effects of composition, the morphological design, and the operational window on catalyst degradation via simulated accelerated stress testing (AST). The design curves generated in each scale of the modeling work will enable the development of mitigation strategies through trade-off analysis.

2. Development of key operational and catalyst/catalyst layer structural degradation design curves through AST coupled with ‘state-of-the-art’ in situ/ex situ characterizations techniques. This allows the correlation of performance loss with structural changes measured within the MEA. The experimentally collected design curves will enable the identification of mitigation strategies through MEA property trade-off analysis; as well it will provide validation data for the various levels of degradation models described above.

**Accomplishments**

The following was accomplished during the first two quarters:

• The Discrete Macro-model was further developed to include a description of catalyst layer composition and structure (Agglomerate Model) with inputs for platinum loading, the catalyst compositional weight ratios, platinum particle size, utilization (or ECSA), material densities, and layer thickness. A comparison of Discrete and Agglomerate Model simulations showed that predicted performance is very sensitive to the choice of the catalyst model. The Agglomerate Model, which at the present time does not include liquid water, is able to capture mass transport losses at high current density suggesting that both the presence of liquid water and the catalyst structure have an effect on mass transport losses (Figure 1).

• Simulated design curves of the effect of performance on ionomer cathode loading reveals optimal performance at ~30% for the baseline MEA in agreement with experimental results (Figure 2).

• The methodology and diagnostic techniques for MEA characterization have been down-selected in order to establish an efficient and extensive characterization protocol.

• Key operational and structural stressors have been identified and prioritized for AST based on their effect on the degradation rates.

• The DOE catalyst AST and the Ballard Standard AST protocols were evaluated using a reference MEA in order to understand and compare their impact on catalyst layer degradation. The major differences between the two protocols are the cathode environment, cycle profile and frequency, and the upper potential voltage limit shown in Table 1. The performance losses from the two different protocols at the end of the test (Figures 3 and 4) are very similar and consistent with
predominately kinetic changes for both ASTs as shown by the voltage loss, EPSA and mass activity changes. At high current density the performance losses increase indicating some contribution of non-kinetic related losses that is somewhat larger for the BPS AST. The post-mortem analysis revealed that both the membrane and cathode thicknesses did not change under both protocols, while differences were observed in the average Pt crystallite size and Pt migration into the membrane. A larger average Pt crystallite size was observed in the MEA subjected to the DOE protocol due to re-deposition of Pt at the catalyst layer/membrane interface under N₂ conditions at the cathode. Under a simulated air cathode environment, a Pt band was observed in the membrane which does not form when N₂ is used.

**Future Directions**

The 2010/2011 anticipated work and accomplishments are expected to be:

- Expanded macro-level model that captures the compositional-based effects with an extended range of the validation data (both operationally and compositionally).
- Modeled molecular features/characteristics of the Pt/C/ionomer interface.
- Expanded Micro-structural and Macro-homogenous Models that include a liquid water description.
- Measured performance degradation rates for different carbon supports, ionomer content, and Pt/C ratios.
- Measured performance degradation rates as a function of upper potential limit for Pt supported on a mid-range and low surface area carbon black.

V.I.1 Diesel-Fueled SOFC System for Class 7/Class 8 On-Highway Truck Auxiliary Power

Objectives

Design, develop, and demonstrate a practically sized, diesel-fueled solid oxide fuel cell (SOFC) auxiliary power unit (APU) configured to provide electrical power for sleeper cab auxiliary loads of on-highway trucks to meet the requirements for cost, size, weight, fuel efficiency, and operation on diesel fuel.

• Develop ultra-low sulfur diesel (ULSD) fuel processor.
• Develop fuel cell that operates on ULSD catalytic partial oxidation (CPOX) reformate.
• Design, build and test APU under real-world conditions.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost
(C) Performance

Technical Targets

This project is to develop APU systems for heavy truck applications to reduce idling of the main engine. The following lists the current DOE 2010 auxiliary power units and truck refrigeration unit targets and the actual 2006 proposal targets in ( )s:

• Cost: $400/kWe (1,500 $/kW)
• Specific power: 100 W/kg (17 W/kg)
• Power density: 100 W/L (8 W/L)
• Efficiency @ rated power: 35% (25%) (lower heating value basis)
• Cycle capability: 150 cycles (10 cycles)
• Durability: 20,000 hours (1,500 hours)
• Start-up time: 15-30 min (60 min)

Accomplishments

Developed:

• Low-cost balance-of-plant (BOP) concepts and compatible systems designs.
• Identified low-cost, high-volume components for BOP systems.
• Demonstrated efficient SOFC output power conditioning.
• Demonstrated SOFC control strategies and tuning methods.

Demonstrated:

• Operation meeting SOFC APU requirements on commercial ULSD fuel.
• SOFC system operations on dry CPOX reformate.
• Successful start-up and shut-down of SOFC APU system without inert gas purge.

The SOFC APU demonstration was carried out at the Cummins Power Generation (CPG) facility in Minneapolis, Minnesota on February 26, 2010. The demonstration was successfully completed on February 27, 2010 including the necessary steady-state, transient, and peak power operation tests. Table 1 lists the results against project objectives.

DC - direct current; AC - alternating current

Introduction

With the onset of anti-idling legislation and the rising cost of fuel one potential early adopter for SOFC fuel cell technology is the on-highway truck APU application. First, an SOFC APU could provide the same electrical source as a conventional internal combustion engine-based APU. Second, it has the potential to improve exhaust emissions, fuel efficiency, reduced transmitted noise and vibration, and provide heating for both cabin and engine.

This project was directed at designing, building and demonstrating a ULSD-fueled SOFC APU installed in an on-highway truck to supply AC power for cabin loads, engine heating, and battery charging during rest periods.

Approach

The plan to complete the objectives of the project included identifying the overall truck system performance, power electronics, heating, battery, fuel cell system, and fuel cell hot zone requirements.

The APU design used a novel dry CPOX reformer that requires no water. The APU is a modular design, based on four ~600 W (gross) modules, yielding ~2 kW net DC power. The scale up of fuel cell modules to 600 W and the development of the diesel CPOX reformer was to have been accomplished by modifications to a pre-existing 250 W SOFC module. CPG was responsible for project management, system design, packaging, all cold BOP equipment including air and fuel supply and metering, vibration isolation, power electronics and controls. Protonex built the hot modules, including stacks, reformers, heat exchangers, tail-gas combustors and insulation packages.

Results

Since last year’s report, we fabricated and tested two generations of complete SOFC modules and operated those modules on both hydrogen/nitrogen mixtures and on reformed liquid fuels. In addition to tests of full-scale stacks and modules, we also tested sub-scale modules and fuel processor components.

Each module in the APU was a complete, independent hot zone containing a tightly-integrated stack, fuel processor, recuperative heat exchanger and tail-gas combustor inside an insulation package. The stacks used 66 tubes, each Ø10x135 mm. The first round of modules were delivered to CPG in the third quarter of Fiscal Year (FY) 2009, the second round used for the demonstration in the first quarter of FY 2010.

In FY 2009, Protonex began testing subscale stacks on liquid fuels to determine proper set-points for the fuel processor and cathode air flow to enable reliable startup and shutdown of stacks on liquid fuels. These tests included operation on both ULSD and low-sulfur kerosene fuels. Each thermal cycle was between 180°C and 720°C with heating and cooling times of approximately 40 minutes each. The power was very stable over these cycles, with less than 1% power loss over 10 thermal cycles.

CPG completed the BOP air delivery system fabrication for the four module fuel cell system. The system includes one cathode air blower, one CPOX air boost blower, four cathode flow control valves, four anode control valves, eight air mass flow sensors. The system achieved the required flow characteristics for the modules. CPG utilized low-cost automotive components in this fuel cell development application to prove a reduced cost bill of materials.

CPG revised the power electronics topology to eliminate the DC-DC boost. The revised topology was simpler and provided an overall efficiency improvement of 3-4%.

Identified and tested a group of inexpensive waste heat recovery exchanger designs that provide the required cab heating with an effectiveness of ≥95% and pressure drop of <2” water over the required range of operating conditions. From a previous study it is known that the cab requires about 5 kW of heat during a peak winter event. The heat exchanger is capable of transferring the required amount of heat at a very high effectiveness at all flow conditions.

The final demonstration occurred on February 26th, 2010 (Figure 1) with the results shown in Table 1. The key performance parameters are:
1. Operation meeting SOFC APU requirements on commercial ULSD fuel.
2. SOFC systems operating on dry CPOX reformate.
3. Successful start-up and shut-down of SOFC APU system without inert gas purge.
4. AC power output sufficient to operate 12,000 BTU air conditioning system.

The test consisted of heating each module individually for convenient monitoring, and allowing the entire system to achieve a steady state. Note that the system is capable of starting all modules simultaneously if desired. The steady-state DC power production was 1,500 W gross with approximately 580 W of parasitic losses for a net production of 1,120 W. A peak power loading of 1,680 W with a net output of 1,225 W was recorded for 10 minutes higher peak loading of the modules is possible, the peak loading was not limited by inherent module capability, rather it was limited by the thermal balance. Future systems could be designed for higher firing rates and power production with moderate design modifications to the heat exchangers, fuel feed system and thermal insulation package.

After the peak loading, the system continued in steady-state DC power operation for 10 hours, simulating the rest period over which a Class 7/8 APU would operate. At the end of this time the power output was 1,490 W gross and 1,110 W net.

The system was then transitioned to AC loading for 1.5 hours. The AC loading required the modules to be connected in series electrically; thus forcing the same current through all modules and reducing total power by 5%. The larger change in parasitic losses was due to the inverter efficiency of ~85%. The power produced during this period is shown in Figure 2, 1,460 W gross and 820 W net at the end of the test. This allowed the air conditioning, lighting and additional DC loading thus simulating a truck “hotel” load to all operate simultaneously from power generated by the SOFC sub-system.

Conclusions and Future Directions

Summary

- During FY 2010 the project fabricated and delivered the second generation of SOFC modules with significantly improved performance and stability. These modules were demonstrated and characterized on both hydrogen and reformed liquid fuels.
- Demonstrated the viability of a dry CPOX approach at the stack and module level.
- Built and tested two complete 4-module sets for testing.
- Completed conceptual design of higher-power (~1 kWe) module.
- Completed SOFC APU unit fabrication and demonstration.
- Project work completed in the second quarter of FY 2010

Discussion

At the conclusion of the SOFC APU project the technology may be seen to be approaching the necessary requirements for creating successful commercial implementation(s) in mobile power markets in the five-to ten-year range.
Key technical obstacles for commercial implementation were addressed in this project:

- Diesel fuel reforming without water (including sulfur handling): The Protonex module demonstrated short-term operation on commercial ULSD without supplementary water or water recycling under controlled oxygen-to-carbon ratio conditions.
- Cost: The implementation of low-cost automotive control components was demonstrated through novel adaptations to achieve required accuracy and resolution. Stereolithography components demonstrated potential for cost-effective integration of multiple functions in tooled components.
- Performance: The APU power unit demonstrated the potential to produce required mission levels of power generation from a package envelope comparable to current production APU products.

Durability and efficiency are two areas that require additional development to reach commercial requirements. Observed levels of stack degradation during this project are recognized to be inadequate to support a commercial product and are the object of ongoing development at Protonex.

Observed system efficiency, while comparable to small diesel gensets operating at light-load conditions, needs improvement to maximize economic benefits. Observed efficiency was negatively impacted in three areas:

1. Tubular stack elements performed below expectations, especially at higher levels of fuel utilization. Projections were based on performance of the previous smaller tubes.
2. Carbon-free operation of the CPOX reformer required higher than expected O/C ratios, lowering effective reformer efficiencies.
3. The BOP was sized to the projected stack power. Operation at the lower power levels demonstrated by the prototype stacks resulted in an effectively oversized BOP.

After some experience in control of full SOFC fuel cell systems it is apparent that proper mechanical system design allows utilization of low-cost sub-system components and reduces parts count.

• PACCAR, Inc., Mt. Vernon, WA

Project Start Date:  September 1, 2004  
Project End Date:  April 30, 2010

Objectives

To demonstrate a solid oxide fuel cell (SOFC) auxiliary power unit (APU) capable of operating on low sulfur diesel fuel, in a laboratory environment, for the commercial trucking industry.

• Design and develop a SOFC APU that will increase fuel and overall system efficiency of Class 8 long haul trucks.
• System and subsystem shock and vibration limits will be studied and recommendations made in the final report, which will address methods of isolation of the APU system to these parameters.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells – Portable Power/APUs/Off-Road Applications section of the Fuel Cell Technologies (FCT) Program Multi-Year Research, Development and Demonstration (RD&D) Plan:

(A) Durability  
(B) Cost  
(C) Performance  
(G) Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets

This project is directed at the development and demonstration of a SOFC APU for heavy-duty truck (Class 8) applications to reduce idling of the main engine. If successful, the project will address the following DOE technical targets as outlined in the FCT Multi-Year RD&D Plan (see Table 1). Upon completion of the project the attached technical targets verses actuals table was developed and presented to the DOE on June 22, 2010 (see Table 2).

*Electrical efficiency only – does not include any efficiency aspects of the heating or cooling likely being provided.

*Cost based on high-volume manufacturing quantities (100,000 units per year).

*From Table 3.4.8 (page 3.4-19) of the DOE Hydrogen, Fuel Cells & Infrastructure Technologies Program - Multi Year Research, Development and Demonstration Plan.

Based on reported data to DOE Solid State Energy Conversion Alliance Phase I deliverables for a Natural Gas Based SOFC System. LHV - lower heating value

Accomplishments

• Design and development of the next generation enhanced DPS3000D APU.
• Full-scale component modeling and build.
• Use of next generation stack design.
Completion of specialized test stands for testing the
DPS 3000D.
Initial testing of the APU system and subsystems in
accordance with test plan.
Initial vibration and durability testing (see Figure 1).
Fifteen-hour continuous test and demonstration of
a diesel-fueled SOFC APU mounted on a Class 8
Peterbuilt Model 386 truck with loads.

**Introduction**

Delphi Corporation (Delphi) has teamed with
heavy-duty truck original equipment manufacturers
PACCAR Incorporated (PACCAR), and Volvo
Trucks North America (VTNA) to define system level
requirements and develop an SOFC-based APU. The
Delphi team has enlisted Electricore, Inc. to serve as
administrative manager for the project.

The project defines system level requirements, and
subsequently designs and implements an optimized
system architecture using an SOFC APU to demonstrate
and validate that the APU will meet system level goals.
The primary focus is on APUs in the range of 3-5 kW
peak for truck idling reduction. Fuels utilized will be
low-sulfur diesel fuel.

**Approach**

Delphi has been developing SOFC systems since
1999. After demonstrating its first generation SOFC
power system in 2001, Delphi has partnered with Volvo
Trucks and PACCAR Inc., to develop and demonstrate
an SOFC-based APU for heavy truck applications.

Delphi utilized a staged approach to develop a
modular SOFC system for low-sulfur diesel fuel and
Class 8 truck applications. First, Delphi gathered APU
requirements from heavy-duty truck manufacturers
including VTNA and PACCAR to develop specific
technical requirements for the APU. Following
this, Delphi continued the development and testing
of major subsystems and individual components as
building blocks for the APU. The major subsystems
and individual components were then integrated into
a “close-coupled” architecture for integrated bench
testing. Delphi took additional steps to refine the overall
APU and each of its components. Specialized test
stands were designed and developed to test the APU
enhancements and system functionality.

**FIGURE 1.** DPS3000A System on Shaker Table
**Status**

In the past year Delphi focused on refining and enhancing the overall APU system design and performing detailed system and subsystem testing. Specifically, work was focused on the SOFC APU hardware design and build; subsystem test fixture hardware build; and subsystem testing and development iterations.

The work this period included Tasks 2.6, 2.8, 2.10, 2.11, 3.1, 3.2, and 3.3. These tasks focus on the SOFC APU hardware design and build; subsystem testing and development iterations; system module testing and development; and bench testing of the APU. The testing was completed on time and under budget.

Tests were completed on the enclosure flow under different configurations. The original design had only one inlet, while a revised design had two inlets in various configurations. Comparative testing indicated significant flow improvement by going to the two inlet design. Figure 2 shows the flow velocity at various process air blower (PAB) rates. The dark blue line (bottom) is the flow rate for the one inlet design while the other rates are for the two inlet design under different configurations.

The development of APU hardware and test stands to validate subsystems was initiated and completed in 2010. Delphi engineers noted improvements that can be made to the stand in order to attain the most accurate data from the tests. The system vibration test stand (Figure 1) was successfully designed and fabricated with capability of the following:

- 24/7 unmanned operation
- Hot system running with diesel fuel
- Rapid thermal cycle testing
- Continues load testing
- Three-axis vibration

Positive results were gathered from the vibration testing indicating the robustness of the design for on-road application of the SOFC as an APU.

Additional full APU system development and testing was conducting including:

- Thermal cycling tests of the complete system
- Hardware development
- Software development
- Load cycling of only thermal stacks
- Usage of anode tail gas simulation to generate recycle

During this phase Delphi performed 22 full thermal cycles on ultra-low sulfur diesel (ULSD), and 160 total hours of operation. Delphi successfully demonstrated complete system “Turn-Key” starts, warm-ups, and repeated cool-downs.

Delphi also successfully performed full simulated load cycles using the DPS3000D set 3 with EC stacks, pulled power during cycle testing, monitored stack cell

![FIGURE 2. Enclosure Flow Test](image-url)
voltages, performed five ULSD starts and two additional full thermal cycles. Furthermore an initial natural frequency sweep was performed. The SOFC system was also tested for noise generation and electromagnetic compatibility at Delphi Packard Division.

Delphi has finished the final review for the completion of reports and documentation required for the final oral/visual presentation. The final presentation was completed June 22nd, 2010. The presentation was presented to DOE staff and members of the Delphi development team.

The project was completed on time and to budget.

  Laboratory (JPL), Pasadena, CA

Project Start Date:  July 20, 2009
Project End Date:  September 30, 2011

Objectives

Our objective is to improve the catalytic activity and
durability of PtRu for the methanol oxidation reaction
(MOR) via optimized catalyst-support interactions.

•
  Determine the effect of ion implantation on the catalyst activity and stability of PtRu catalyst nanoparticles deposited on highly-oriented pyrolytic graphite (HOPG) supports. Implantation will cause n- or p- doping via incorporation of various species, initially focusing on nitrogen.

•
  Determine the effect of doping level and dopants type (n or p) on the catalytic activity and durability of the PtRu/HOPG model catalyst system that improve catalyst-substrate interaction resulting in an improved catalyst material for the methanol oxidation reaction.

•
  Apply this dopant-engineering approach to high surface area carbon supports. The goal is to improve catalyst utilization, activity, and durability for membrane electrode assemblies.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program’s Multi-Year Research, Development and Demonstration Plan (section 3.4.4):

(A) Durability
(B) Cost
(C) Performance

Technical Targets

This project aims to improve the catalytic activity and durability of PtRu for the MOR via optimized catalyst-support interactions. Insights gained from these studies will be applied toward the development and demonstration of DMFC anode catalyst systems that meet or exceed the following DOE 2010 Consumer Electronics targets:

•
  Cost:  $3/W
•
  Specific Power:  100 W/kg
•
  Power Density: 100 W/L
•
  Lifetime:  5,000 hours

Accomplishments

(1) Established an optimal N-implantation parameter set for HOPG, which resulted in enhanced PtRu catalytic activity for MOR.
(2) Obtained experimental results demonstrating an increase in durability on N-doped samples.
(3) Sputter deposited PtRu alloy with controlled composition, phase, and orientation from a single PtRu alloy target.
(4) Built a chamber that allows for ion-implantation and sputter deposition of powders.
(5) Established protocol for deposition of uniform PtRu catalyst particles on commercial and chemical vapor deposition synthesized B-doped and N-doped powders.

Introduction

High material cost and insufficient catalytic activity and durability are key barriers to the commercial deployment of DMFCs – the most advanced fuel cell technology for consumer electronics application. DMFCs
are attractive for portable commercial and military applications because they offer extremely high theoretical energy density (~10x better than Li-ion batteries).

To accelerate the commercialization of DMFCs for consumer electronics applications, next generation materials based on leap-frog technology are needed. In DMFCs, the MOR on the anode limits the performance and durability. Breakthroughs in DMFC anode catalysis with respect to performance, cost and durability will help enable and accelerate the commercialization of DMFCs.

**Approach**

This project focuses on improving the catalytic and durability of the anode catalyst for the MOR. Our approach is to modify and improve catalyst-support interactions in order to substantially increase activity, selectivity, and durability of PtRu catalytic systems. The team systematically investigated the effects of ion-implantation on HOPG, as a model support analogue [1-3], on PtRu catalysts. These well-defined systems allowed us to assess dopant effects and provide a test-bed for exploring new dopant/catalyst combinations. These doped and undoped carbon substrates are decorated with PtRu using both aqueous solution and physical vapor methods. The catalysts are characterized with various techniques such as microscopy, X-ray diffraction, X-ray photoelectron spectroscopy (XPS) and electrochemistry to determine the catalyst particle size, dispersion, composition, structure, degree of alloying, MOR activity and electrochemical durability. The catalyst synthesis process and materials are down-selected based on best performance and transferred to high surface area carbon studies for further study. The highest performing materials will be used in DMFC testing.

**Results**

We demonstrated enhanced PtRu catalytic activity for methanol oxidation by achieving smaller particle size and more uniform dispersion of PtRu on N-doped HOPG. For the N-implantation conditions investigated, we determined 45 seconds as optimal for N-doping. Nitrogen was found to incorporate into the carbon network, resulting in the formation of sp3-sp2 bonding disrupting the graphitic structure of the undoped HOPG. Various oxygen groups, including C-O, C=O and N-C=O, were also observed after implantation. Ion implantation of N2 longer than 45 seconds resulted in no additional surface structural disorder. The relative amount of nitrogen (7%, determined by XPS) introduced into the carbon substrate also saturated after 30-45 seconds. Electrochemical data obtained by project partner, JPL, confirmed NREL results. (Argon implanted HOPG was used to establish benchmark performance caused by structural defects.)

Figure 1 shows examples of PtRu deposited on various HOPG samples. It is apparent from Figure 1 that the most uniform and smallest particles of PtRu catalyst were obtained using N-doped HOPG samples. Ar-doping improved the dispersion compared to undoped HOPG but resulted in a more pronounced agglomeration of catalyst particles as compared to N-doping. Similar samples to those shown in Figure 1 at higher PtRu loadings were used to measure methanol oxidation activity. Table 1 shows that nitrogen doping resulted in the highest MOR activity and highest surface roughness factor as compared to undoped and Ar-doped HOPG. Table 1 also shows that our microwave deposition of Pt and Ru onto N-HOPG gave comparable activity to commercial PtRu catalysts on a per metal surface area basis.
We developed a novel method to deposit Pt\(_{1-x}\)Ru\(_x\) alloy or amorphous films/particles by sputtering from a single, alloyed PtRu target. We were able to control the PtRu composition with sputtering power and chamber oxygen concentration. We can also demonstrate a dependence of the orientation and phases (hexagonal close packed/face centered cubic) of Pt\(_{1-x}\)Ru\(_x\) with overall chamber pressure. Finally, we designed and built a new chamber for ion implantation and sputter deposition of catalyst on high surface area carbon materials (Figure 2). Preliminary experiments were performed and the resultant materials are being characterized.

**Conclusions and Future Direction**

- Demonstrated that nitrogen implantation on HOPG enhanced MOR activity.
- Established different PtRu deposition methodologies.
- Established optimized N-doping level on HOPG via ion implantation.
- Initiated a preliminary study of the effect of different dopants.
- Developed a processing system for ion implantation of high surface area carbon materials, and initiated study of high surface area carbon.
- We will conduct studies of other dopants on HOPG (B, S, I).
- We will investigate different methods to dope high surface area carbon (in situ and ex situ) (e.g., ion implantation, chemical vapor deposition, and pyrolysis).
- We will characterize and measure methanol oxidation performance of PtRu/doped high surface area carbon.
- We will optimize materials and measure DMFC performance and durability of optimized catalysts.

References

Objectives

- Develop ultra-thin membranes having extremely low methanol crossover, high conductivity, durability, and low cost.
- Develop cathode catalysts that can operate with considerably reduced platinum loading and improved methanol tolerance.
- Produce a membrane electrode assembly (MEA) combining these two innovations that has a performance of at least 150 mW/cm² at 0.4 V and a cost of less than $0.80/W for the membrane and cathode catalyst.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost
(C) Performance

Technical Targets

This project is conducting focused research on next generation membrane and cathode catalyst materials for direct methanol fuel cells. Insights gained from these studies will be applied toward the design of a MEA for portable power applications that meet the DOE 2010 targets:

- **Performance**:
  - Specific Power (100 W/kg),
  - Power Density (100 W/L), and Energy Density (1,000 Wh/L)
- **Cost**: $3/W
- **Lifetime**: 5,000 hours

In translating DOE-published targets, we have defined the following goals for the membrane, cathode catalyst, and MEA performance based on our modeling efforts in Table 1.

V.J.2 Novel Materials for High Efficiency Direct Methanol Fuel Cells

Arkema and IIT are developing a new generation of thin membranes with very low methanol cross-over and high conductivity. The membranes are formed from blends of polyvinylidene fluoride with a variety of highly sulfonated polyelectrolytes, technology that was developed in two previous projects. A number of variables can be easily adjusted in the blending process to tailor the membrane properties. The key to obtaining the desired properties resides in control of composition, architecture, and morphology of the membrane components. These are controlled on a practical level through polyelectrolyte chemistry, membrane composition, processing, and additives, which
will be systematically investigated and correlated with properties.

QSI will develop a new series of cathode catalysts with improved mass activity obtained by suppressing methanol oxidation. These cathode materials will be palladium-based nanocatalysts mixed with platinum carbon with considerably reduced platinum loadings. These catalysts are prepared using gas phase condensation, which allows for control of particle size, alloy ratio, and core-shell structure.

**Accomplishments**

The award contract for this project was signed on June 30th. Work is in progress on the preparation of initial membrane and catalyst compositions for property screening. Methods are also being established for MEA preparation, conditioning, and testing. While new membrane and catalyst materials are being prepared, tests are being run on MEAs constructed from currently available Arkema and QSI materials as a baseline for the project. Without any modifications to the cathode catalyst and membrane, significant improvement in 10 M methanol is already observed over a 7 mil perfluorosulfonic acid membrane-based MEA (Figure 1).

**Future Directions FY 2010-2011**

- Prepare and screen a library of membrane samples to identify compositions that produce the lowest methanol crossover, while maintaining adequate conductivity.
- Synthesize and screen the properties of a series of Pd-based catalysts, including palladium and palladium-metal alloys. Reactor operating parameters (pre-alloy conditions, gas flow, voltage) will be optimized for the preparation of 3-10 nm particles.
- Continue efforts to establish procedures for MEA conditioning and testing.

**FY 2010 Publications/Presentations**

Project Start Date: January 1, 2010
Project End Date: June 30, 2012

Objectives

Optimize the functionality and internal water recovery features of the UNF passive water recovery membrane electrode assembly (MEA) to facilitate overall system simplicity, thereby increasing power and energy density and lowering the cost at the system level to address DOE's fuel cell target goals for consumer electronics applications.

• Optimize the UNF MEA design:
  – Improve durability and reliability.
  – Increase power and energy density.
  – Lower the cost.

• Develop commercial production capabilities:
  – Scale up the process to commercial batch operation level.
  - Improve performance and lower reproducibility.
  - Lower cost.

• Increase catalyst stability and lower loading:
  – Increase the anode catalyst stability.
  – Lower MEA cost.

Technical Barriers

This project addresses the following technical barriers for consumer based electronic applications of less than 50 W from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost
(C) Performance

- Beginning of life, 30°C, sea level, 50% relative humidity, excluding hybrid battery, power module alone
- Normalized from DP3 data from 150 ml cartridge to either 100 ml or 200 ml for comparison purposes
- Lifetime measured to 80% of rated power

Approach

The passive water recovery MEA (Figures 1 and 2) has been specifically designed for operation in the UNF system. This design incorporates the novel passive water recycling features of the MEA. The water recycling features enable significant simplification and miniaturization of the fuel cell at the system level, thus optimizing the resulting power and energy density. This approach optimizes the key attributes of the MEA and improves the system performance and durability. The scaling up of the manufacturing process for the MEA layers enhances both performance and reliability and reduces the overall cost. Our approach to improve
the anode catalyst structure to enhance the stability of the ruthenium improves the overall durability in direct methanol fuel cell (DMFC) applications. With our partners we will optimize the manufacturing process for preparing the passive water MEAs. We will move beyond the prototype operation by developing a batch manufacturing process which will improve the MEA-to-MEA reproducibility, increase the durability, and reduce the cost of the overall MEA. Our approach includes an evaluation of the MEA produced at both the single cell and the system level against system operating conditions required for a small compact DMFC system developed

in a related project at UNF. This process will include controlled warm-up and shut-down, standard operation and storage, and some anticipated out-of-operating specification conditions.

**Accomplishments**

The project was initiated in January 2010. Major accomplishments to date:

- Designed baseline MEA to produce passive water recovery under system operating conditions designed to optimize the overall system performance.
- Developed a Pt₈Ru₈Au on carbon catalyst that looks promising for improved ruthenium stability, with 99% of the surface area retention after long-term chronoamperometry compared to 88% retention of the surface area for a commercially available reference sample.

**Future Directions**

- Continue catalyst development and characterization:
  - Optimize and scale up of the anode catalyst with improved ruthenium stability.
  - Integrate improved catalyst into the passive water recovery MEA design.
  - Increase testing of high stability anode catalysts under system operating conditions, including long-term catalyst durability testing under operating and storage conditions.

- Improve manufacturing techniques for the liquid barrier layer:
  - Optimize steps to improve manufacturing process and lower sample to sample variation.
  - Test process variability and the effects on the MEA reproducibility and durability.

- Optimize MEA structure:
  - Develop optimized MEA coating and fabrication to produce lower sample to sample variability and improve performance.
  - Incorporate improved catalyst and liquid barrier layers to optimize performance and durability.

- Single cell and stack testing:
  - Measure performance and durability under system type operating conditions including start up, shut down, and storage conditions.
V.K.1 Development of Thermal and Water Management System for PEM Fuel Cell

Objectives

- Develop an advanced heat exchanger (radiator) that can efficiently reject heat with a relatively small difference between fuel cell stack operating temperature and ambient air temperature.
- Test humidification systems to meet fuel cell inlet air humidity requirements. The moisture from the fuel cell outlet air is transferred to inlet air, thus eliminating the need for an outside water source.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Multi-year Research, Development and Demonstration Plan:

Develop an advanced cooling system to meet the fuel cell cooling requirements. The heat generated by the fuel cell stack is a low-quality (lower temperature) heat that needs to be dissipated to the ambient air. To minimize size, weight, and cost of the radiator, advanced fin configurations were evaluated.

Evaluate air humidification systems which can meet the fuel cell stack inlet air humidity requirements. Two humidification devices were down-selected, one based on membrane and the other based on rotating enthalpy wheel. The sub-scale units for both of these devices have been successfully tested by the suppliers.

**Approach**

To develop a high-performance radiator for a fuel cell automobile, various advanced surfaces were evaluated, including: foam; advanced, offset, and slit louver fins; and microchannel with various fin densities. A value function was developed to evaluate and compare the cost of various fin geometry radiators. The value function is based on the cooling system weight, performance, parasitic power, and initial cost. Two fin geometries -- 18 fpi louver and 40 fpi microchannel -- were down-selected. The full-scale radiators were built and tested. The results were presented in last year’s annual progress report as well as final test report submitted last year.

A full-scale Nafion® membrane module and enthalpy wheel was designed, built and is being tested to validate the performance. A test stand was designed and built, to test the selected humidification devices where fuel cell stack operating conditions are simulated. The test results at ambient conditions are summarized here. The testing of the planer membrane module is scheduled for the third quarter of 2010. The select humidifier with optimum performance will be tested at sub-ambient conditions to simulate winter operating conditions.

**Results**

The testing of the full-scale and sub-scale Nafion® membrane module was successfully completed.

The humidity of the inlet stream (secondary flow) and outlet stream (primary in) for the full-scale module is plotted against average flow rates to humidifier inlet and outlet flow streams in Figure 1. Due to instrumentation and test stand limitations, the humidity of the humidifier inlet stream was limited to about 80 percent. The data scatter cannot be explained; each test point was taken when the system reached the steady-state condition.

The secondary inlet stream humidity data are adjusted higher (close to 100 percent), which resulted in higher humidity for the primary flow. Even after the adjustment, the primary flow is still lower than the 60 percent required for the PEM fuel cell, particularly at higher flow rates.

The sub-scale humidifier was also tested and the results are shown in Figure 2. The water transfer efficiency of the subscale humidifier was lower than full-scale by more than 10 percentage points.

**Conclusions and Future Directions**

The testing of full- and sub-scale membrane modules was successfully completed. The humidity of the fuel cell inlet air stream will be short of required 60% based on membrane module test results.

The testing of the enthalpy wheel is also completed the test data is being analysed. A full-scale planer-based
membrane module has been acquired and the testing is planned for the 3rd quarter of this year. The rectangular configuration of the planer module and the use of membrane sheets rather than fibers will result in ease of installation as well lower cost. This full-scale unit will be tested in the existing test stand.

The humidification device down-selected from the three under consideration will be tested at sub-ambient conditions. The completion of this testing will conclude the water management portion of this project at the end of Fiscal Year (FY) 2010 and the final report will be submitted in first quarter of 2011.

This testing project is conducted with close cooperation with Argonne National Laboratory, and the test data is provided to them for their PEM fuel cell system model.

**FY 2010 Publications/Presentations**

Objectives

- Demonstrate a durable, high-performance water transport membrane.
- Build and test a compact, low-cost, membrane-based module utilizing that membrane for use in an automotive stationary and/or portable fuel cell water transport exchangers.
- Model and show high volume costs associated with membrane and module.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan in Task 7, “Develop balance of plant components”:

(B) Cost
(E) System Thermal and Water Management
(A) Durability
(C) Performance

Accomplishments

- Contacts with various original equipment manufacturers (OEMs) have been initiated, and some preliminary feedback on humidifier operating conditions has been obtained for automotive and stationary conditions.
- Initial investigation of a number of membranes and processes has begun.
- A permeance testing system has been redesigned, and initial testing between 60° and 95°C, 70% relative humidity (RH) for several GORE™ humidification membranes has commenced.
- An alternate room temperature water vapor transport test protocol has been developed for rapid screening of new materials.

Introduction

Today it is essential to humidify the gases supplied to the fuel cell inlets for automotive and many stationary fuel cell stack designs. In this work, we propose to provide a new, inexpensive, composite membrane capable of very high water vapor transport and low air cross-over. The composite structure has been designed to allow lower total cost while still meeting automotive and stationary humidifier water transport and durability targets.

Because the transport rates of these new materials are so high, current planar membrane humidifier designs are not capable of fully utilizing the high rates. Therefore, the project will use an innovative, low-cost humidifier module with customized channel geometries that can take advantage of the high water transport rates. By having a materials development effort integrated with a humidifier module-system design and build program, we will be able to effectively exploit the improved material properties in an actual device.

Approach

Perfluorosulfonic acid (PFSA) membranes fulfill most of the requirements for the water transport media at the heart of the planar membrane water exchanger. They fall short primarily on cost, and secondarily on durability, especially when they are made thin to increase performance and lower cost. W. L. Gore and Associates, Inc. (Gore) has developed a composite water vapor transport membrane that has overcome both of these limitations. The basic composite structure
consists of a very thin ionomer layer sandwiched between two microporous polymer layers. The ionomer layer provides the active water transport and provides an impermeable layer to prevent gas cross-over. The water transport rate can be engineered to be very high either through the use of a material that has very high inherent water transport rates (e.g., PFSA), or by making it extremely thin (e.g., <5 µm). Of course, both can be used for the highest possible rate. The ionomer composition can be either a PFSA, or any other ionomer, for example a hydrocarbon. The microporous layer provides three critical features: first it protects the thin ionomer layer from mechanical damage during handling; second, it confers strength to the thin layer allowing it to be more durable during use. Third, it offers a strong, protective support layer for placement of a macroporous gas diffusion layer. The composition of the microporous layer is not restricted, although we believe that the high strength offered by expanded polytetrafluoroethylene is desirable. The initial tasks of the project are preparation and optimization of the various high performance water transport membrane, and characterization of the permeance and durability of the membranes. This will lead to a down selection to appropriate materials based on the performance criteria, coupled with cost modeling.

Although the basic structure described above has already been developed by Gore [1], the material has not yet been optimized for automotive or stationary humidifier applications. In particular, there is a trade-off between using a relatively expensive ionomer (e.g., PFSA) in a thicker ionomer layer, versus using a less expensive hydrocarbon ionomer in a thinner layer. Depending on thickness, each of these could have the same water vapor transport rate, yet may have very different durability at temperature, not to mention different costs. Furthermore, the microporous layer is expected to impact the durability and performance. A more open, weaker (and presumably less expensive) microporous layer would offer less resistance to water transport, but also offer less strength so could adversely impact durability. Finally, the effect of the macroporous gas diffusion layer has not been examined. Its composition, properties and attachment (loose-laid or laminated) have yet to be explored.

Our subcontractor, dPoint, has developed an innovative pleated planar membrane humidifier that is able to achieve automotive OEM water transport and pressure drop requirements. It has the advantages of low-cost materials and manufacturability, compact size, high pressure tolerance, a replaceable membrane cartridge and the flexibility to design for specific membrane characteristics. The pleated design utilizes existing low-cost, high-volume pleating equipment that is used to manufacture air filters for automotive and heating, ventilation and air conditioning applications. A flat sheet permeable membrane is folded and separated with a plastic injection molded flow field insert. The flow field inserts have an open channel design that allows excellent flow distribution, maximum membrane active area and very low pressure drop. The membrane cartridge has a potted elastomeric seal around the perimeter to prevent leakage at high-pressure conditions. The membrane cartridge is placed in a clamshell housing that has been designed to withstand automotive pressures and temperatures. The pleated humidifier is a proven technology that dPoint has been developing in cooperation with several major automotive OEMs. Further improvement in humidifier size, cost and performance is possible through the use of the Gore membrane and optimizing the flow field channel design to take full advantage of this new membrane.

### Results

At the time of writing of this report, results are very limited because we have just completed the first quarter of a two-year project. To date, a high-temperature permeance measurement system has been designed, built and tested. The design is similar to those used previously for similar measurements [2,3]. Based upon input from automotive and stationary OEMs, appropriate test conditions for measurements have been chosen as 70% RH air on the membrane wet-side, dry air on the membrane dry-side, with test temperatures between 60 and 95°C. Initial testing has commenced on various controls, as well as several variations of newly prepared materials. These initial results of various materials that have been prepared (Table 1) indicate very high permeance rates for some variants of the developed materials. One exciting material is shown in Figure 1, where the ionomer layer in the composite is ~1 micron.

thick. This composite is air-impermeable, and should have high permeance because of the very thin ionomer layer. The permeance testing of this material is underway.

One issue related to testing is the time required to measure permeance, upwards of 4 days per sample. Therefore, an alternate room temperature water vapor transport test protocol is under development for rapid screening. This new test protocol is based upon a modified version of the International Organization for Standardization Standard 15496, Measurement of Water Vapor Permeability of Textiles for Purpose of Quality Control. The initial testing indicates reasonable correlation with higher temperature permeance test results. Further analysis and testing is required to establish whether this approach is truly viable, either as a quality control tool, or for new material screening.

Conclusions and Future Directions

- Water transport rates through GORE™ humidification membranes can be very high, especially for the fluorinated ionomer-based materials.
- Transport measurements of these high-rate materials are a challenge.
- A range of alternate materials have been prepared and water permeance and air-impermeability will be measured shortly.
- Cost modeling of potential membranes, coupled with air-impermeability and water permeance data, will be used as inputs to a Go/No-Go decision to occur within the next nine months.
- A new test protocol for quick room screening water permeance has been developed. Future work will establish whether this is a correlation with results this new test and higher temperature permeance measurements that more closely model actual use conditions.

TABLE 1. Status of key technical targets relevant for metallic bipolar plates (DOE tentative revised targets). Data shown for archival nitrided Fe-20Cr-4V foil coupons from the successful 1,000 h cyclic single-cell fuel cell stamped foil test set [1-3]. Results for a benchmark untreated stainless steel, 904L, are also shown as measured corrosion current density values are sensitive to test cell setup in the pH3 sulfuric acid solutions specified by the DOE targets.

Objectives

- Develop and optimize stainless steel alloys amenable to formation of a protective Cr-nitride surface by gas nitridation, at a sufficiently low cost to meet DOE targets and with sufficient ductility to permit manufacture by stamping.
- Demonstrate capability of nitridation to yield high-quality stainless steel bipolar plates from thin stamped alloy foils (no significant stamped foil warping or embrittlement).
- Demonstrate single-cell fuel cell performance of stamped and nitrided alloy foils equivalent to that of machined graphite plates of the same flow-field design (~750-1,000 h, cyclic conditions, to include quantification of metal ion contamination of the membrane electrode assembly and contact resistance increase attributable to the bipolar plates).
- Demonstrate potential for adoption in automotive fuel cell stacks.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost
(C) Performance
Accomplishments

- Promising preliminary results with quartz lamp technology to reduce nitriding cycle time from 1-2 hours to <10 minutes to reduce processing costs.
- Promising preliminary automotive flow field stamping assessment of ORNL Fe-20Cr-4V alloy.

Introduction

Thin stamped metallic bipolar plates offer the potential for (1) significantly lower cost than currently-used machined graphite bipolar plates, (2) reduced weight/volume, and (3) better performance and amenability to high-volume manufacture than developmental polymer/carbon fiber and graphite composite bipolar plates. However, most metals exhibit inadequate corrosion resistance in proton exchange membrane fuel cell (PEMFC) environments. This leads to high electrical resistance due to the formation of surface oxides and/or contamination of the MEA by metallic ions, both of which can significantly degrade fuel cell performance. Metal nitrides offer electrical conductivities up to an order of magnitude greater than that of graphite and are highly corrosion resistant. Unfortunately, most conventional coating methods (for metal nitrides) are too expensive for PEMFC stack commercialization or tend to leave pinhole defects, which result in accelerated local corrosion and unacceptable performance.

Approach

The goal of this effort is to scale up and demonstrate the technological and economic viability of thin (≤0.1 mm) stamped metallic bipolar plates protected by a thermal (gas) nitrided surface. Proper selection of bipolar plate alloy composition and nitridation conditions can yield a pin-hole-free, electrically conductive and corrosion resistant nitride-based protective surface layer. Proof-of-principle was established via nitridation of model Ni-Cr base alloys to form thermally grown Cr-nitride base surfaces that exhibited excellent corrosion resistance and maintained low interfacial contact resistance (ICR) in PEMFC environments [4]. Unfortunately, Ni-base alloys are too expensive for automotive PEMFC bipolar plate applications. Iron-base stainless steel alloys can potentially meet the DOE cost targets. However, they exhibit high permeabilities to nitrogen, which results in internal Cr-nitride precipitation and poor corrosion resistance on nitriding instead of the desired continuous, protective Cr-nitride surface layer.

Efforts led by ORNL and NREL [4-6] have identified an approach to bypass the high nitrogen permeability of Fe-Cr base stainless steels to permit protective nitride surface layer formation. It is based on pre-oxidation to form a Cr-V-rich oxide surface, followed by nitridation of the oxide layer to form a mixed nitride/oxide surface structure [1-4]. The developed alloys contain small additions of V, up to 4 wt%, to aid in conversion of the initially formed surface oxide to nitride. For the low-cost Fe-20Cr-4V wt% alloy developed by ORNL, using short nitriding cycle times (1-2 h) to reduce nitriding cost, a mixed nitride/oxide surface consisting of “through oxide-thickness” V-rich nitride particles dispersed in Cr-rich oxide, is formed [1-3]. The Cr-base oxide and the V-nitride surface provide for corrosion resistance and the V-nitride particles provide low ICR with electrical connectivity from the surface through the oxide to the underlying metal.

Results

Single-cell fuel cell testing of pre-oxidized/ nitrided Fe-20Cr-4V foil stampings (referred to as “nitrided” in the remainder of the paper for simplicity), 904L (Fe-22Cr-24Ni-4Mo wt% base) stampings (no surface treatment), and machined graphite plates were completed in Fiscal Year (FY) 2009 [1-3]. A test cycle of open-circuit voltage for 1 min, 0.60 V for 30 min, 0.70 V for 20 min, and 0.50 V for 20 min was used, with 1,000 hours (h) of durability testing evaluated for each material. All three materials showed good durability with no significant degradation in cell power output. Post-test analysis indicated no metal ion contamination of the MEAs occurred with the nitrided Fe-20Cr-4V or graphite plates, and only a minor amount of contamination was detected with the 904L plates (1.1 µg/cm² Fe and 0.18 µg/cm² Cr). The 904L was used as a benchmark material in addition to graphite because its high Cr, Mo, and Ni content result in excellent corrosion resistance in PEMFC environments. However, as shown in Table 1, the ICR value of 904L, similar to other untreated stainless steels, exceeds DOE targets by over an order of magnitude. In FY 2010, untreated stampings of type 321 stainless steel (type 316 Fe-18Cr-12 Ni stainless with 0.3-0.7 wt% Ti) were also evaluated in order to assess the aggressiveness of the aforementioned single-cell test cycle for a lower alloy content, conventional grade austenitic stainless steel. Extensive corrosion of the 321 test plates was observed after only 120 h of operation, indicating that the cyclic test conditions employed were aggressive.

Efforts in FY 2010 were directed to three primary tasks: 1) single-cell fuel cell evaluation of repeat nitrided Fe-20Cr-4V stampings treated over a range of conditions to assess robustness to variable nitridation reaction conditions, 2) assessment of the potential for reduced nitriding cost and improved performance using rapid nitriding cycles with quartz/plasma lamps, and 3) amenability assessment of the developed ferritic Fe-Cr V
alloys for stamping of state-of-the-art automotive bipolar plate flow-fields.

Figure 1 shows initial single-cell fuel cell polarization curves (<150-200 h total cycle testing) for a series of ~15 cm² active area stamped and nitrided Fe-20Cr-4V foils using a Nafion® 212 MEA. Nitridation peak temperature hold times were performed at 1, 1.5, and 2 h at 1,000°C to intentionally yield a wide range of nitrogen/oxygen mass uptakes and surface structures to simulate the degree of variability that may be encountered in mass production. For comparative purposes, results obtained with the Nafion® 212 MEA for the nitrided (1 h at 1,000°C) Fe-20Cr-4V stampings that previously accumulated ~1,500 h of total fuel cell operation (marked aged 1,500 h in Figure 1) as part of the FY 2009 durability assessment are included in Figure 1 [1-3]. The voltage-current (V-I) curves for these materials were remarkably similar, with the 1- and 1.5-h nitrided plates essentially the same as the 1,500 h aged stampings. The 2-h nitrided stampings, which were intentionally overnitrided, showed slightly higher performance V-I curves, possibly due to a higher volume fraction of conductive nitride phase.

One-thousand h durability evaluation is underway for the 1.5- and 2-h nitrided plates. After ~600 h of evaluation, the V-I curves for the 2-h nitrided material show excellent behavior with no evidence of performance degradation. However, performance degradation was observed after ~600 h for the 1.5-h nitrided material, which, based on N and O mass uptake on nitridation, was expected to exhibit good performance. Visual examination of the 1.5-h nitrided plates confirmed signs of corrosion attack. Surface chemistry and cross-section analysis are planned to identify the reasons for the unexpected susceptibility to corrosion of this material. Although preliminary, the apparent degradation of the 1.5-h nitrided stamping during the durability assessment repeat tests is a concern for scale up of the current Fe-20Cr-4V alloy and nitriding cycle to commercial production. It is possible that the steps taken to reduce bipolar plate cost, relatively low alloy Cr and V content and use of short, 1-2 h conventional furnace peak temperature holds for nitriding may result in excessive variability in corrosion resistance of the nitrided surface. Longer nitriding cycles may solve this issue, but would also result in increased production cost. Two routes to addressing this potential issue without cost increase are being pursued: 1) use of rapid thermal cycle quartz lamp technology for nitriding of Fe-20Cr-4V and 2) evaluation of a more Cr-rich alloy foil (Fe-23Cr-4V), which is expected to exhibit a more robust nitrided surface structure, but must first demonstrate sufficient amenability to stamping. The increase in Cr level from 20 wt% to 23 wt% is not expected to significantly increase alloy cost, but may decrease alloy ductility and amenability to stamping.

Initial single-cell fuel cell polarization curves for stamped Fe-20Cr-4V foil nitrided at 1,000°C for 10 minutes using quartz lamp technology for heating are also shown in Figure 1. Despite the very short nitriding cycle, V-I performance behavior superior to the conventional furnace nitrided Fe-20Cr-4V foils was observed. Figure 2 shows X-ray photoelectron spectroscopy (XPS) of the as-nitrided surface. Strong enrichment of V and N are evident, suggesting a high volume fraction of V,N phase particles in the (Cr,V)2O3 surface, consistent with the excellent single-cell V-I polarization curves obtained with this material (Figure 1). Of particular importance with regards to potential durability performance, no Fe was detected in the surface regions of the quartz lamp nitrided material. Nitridation of Fe-20Cr-4V foil using conventional furnaces typically results in a small amount of Fe retained in the surface (a few atomic percent), which may result in a lower degree of corrosion resistance. The rapid thermal cycle of the quartz lamp, which involves heating to peak temperatures in minutes rather than the hours for the conventional furnace, is speculated to minimize transient formation of Fe-rich oxidation.
and/or nitridation products compared to conventional heating technology. Further exploration of quartz lamp nitriding is underway, with cyclic single cell fuel cell durability assessment of quartz furnace treated stampings planned.

As a prelude to automotive bipolar plate evaluation of nitrided Fe-20Cr-4V foil, a preliminary stamping assessment of the Fe-20Cr-4V foil for suitability to automotive fuel cell bipolar plate flow field designs was conducted in conjunction with General Motors (GM). Figure 3 shows results of the automotive stamping screening of the Fe-20Cr-4V alloy foil relative to austenitic 316L stainless steel foil. Comparable flow-field structures were obtained, which suggests that the mechanical properties of the Fe-Cr-V alloys may be sufficient for manufacture of stamped automotive flow-field designs.

**Conclusions and Future Directions**

Although some concerns still exist regarding repeatability and robustness of the nitrided surface formed on stamped Fe-Cr-V alloy foils using short, low-cost cycle times, results obtained to date have indicated sufficient promise to warrant evaluation for scale up by industrial end users. A cost-shared subcontract was placed with GM in summer 2010 to perform an in-depth manufacturing evaluation of Fe-Cr-V alloys, including stamping and laser joining of bipolar plate cooling channels. GM will also pursue single-cell fuel cell evaluation of bipolar plates made by GM from Fe-Cr-V alloy foils after nitridation at ORNL. Both conventional furnace nitriding and quartz lamp nitriding will be evaluated. The project will conclude with completion of the GM evaluation effort.

**Special Recognitions & Awards/Patents Issued**

1. Claims for the patent disclosure “Iron-Based Alloy and Nitridation Treatment for PEM Fuel Cell Bipolar Plates” were allowed by the United State Patent Office in July 2010 (patent number not yet issued at the time of this report). Two previous patents were issued for the nitrided bipolar plate technology, #7,247,403 “Surface modified stainless steels for PEM fuel cell bipolar plates” and # 7,211,346 “Corrosion resistant metallic bipolar plate”

V.L.2 Low-Cost PEM Fuel Cell Metal Bipolar Plates

Objectives

- Reduce or eliminate the small amount of gold used in TreadStone’s current corrosion-resistant metal plate technology for proton exchange membrane (PEM) fuel cell applications.
- Develop the low-cost metal bipolar plates using commercially available low-cost carbon steel or aluminum as the substrate materials.
- Optimize the fabrication process for large-scale manufacture.
- Demonstrate TreadStone’s low-cost metal plate technology in the applications of portable, stationary and automobile fuel cell systems.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cell section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

(b) Cost

(c) Performance

Technical Targets

The focus of this project is to further develop TreadStone’s proprietary corrosion-resistant metal plate technology reducing the metal plate cost to <$3/kW, while still meeting the performance requirements. There are a number of performance requirements to PEM fuel cell bipolar plates. The most challenging requirements for metal bipolar plates are summarized in Table 1. TreadStone’s existing (2009) technology can meet DOE’s 2010 target. This project is aimed to meet DOE’s 2015 target.

d Includes contact resistance (on as-received and after potentiostatic experiment) measured.

Accomplishments

- Completed the low-cost conductive vias development. Demonstrated the processing technologies for Pd/Au composite vias, carbon nanotubes and conductive carbides as the conductive vias. The corrosion current of metal plates with these vias are below 1 µA/cm² in pH 3 H₂SO₄ + 0.1 ppm hydrofluorhydric acid (HF) solution under 0.8V normal hydrogen electrode (NHE) at 80°C.
- Developed the processing technology and the identified the coating materials for low-cost carbon steel substrate for PEM fuel cell applications.
Demonstrate our current metal plates in portable, stationary applications, operating at ambient pressure conditions, with short stack having 30 cm$^2$ and 267 cm$^2$ active area, respectively.

Demonstrated a 300 cm$^2$ active area, 10-cell, 2.5 kW short stack under utilizing durability testing cycle (including the Federal Test Procedure [FTP] cycle along with others) to mimic the automobile real world driving conditions. The stack has finished 800 hours stable operation, and continues to operate at Ford Motor Company.

Introduction

It has been reported that using metal bipolar separate plates can reduce the PEM fuel cell stack weight and volume by 40-50%, comparing with current graphite-based bipolar plates [1]. The major barrier to use metal bipolar plates in PEM fuel cells is the severe corrosion condition during stack operation. Most metals do not have the adequate corrosion resistance in the PEM fuel cell environment, which results in rapid performance degradation due to the formation of electrically resistive surface oxide scale, and potential contamination of the membrane electrode assembly (MEA) by the dissolved ions from the metal plates. Various corrosion protection techniques have been investigated to prevent metal plate corrosion in PEM fuel cell environments [2-7]. Some of these technologies have developed corrosion-resistant metal plates that can meet performance requirements. However, it is still a challenge to have a metal bipolar plate that can meet both the performance and cost requirements. The focus of TreadStone’s project is to develop the corrosion-resistant metal bipolar plates at the low cost to meet DOE’s 2015 targets.

Approach

Most people working on metal bipolar plates have been tried to cover the whole plate surface with an electronically conductive and corrosion-resistant material to protect the metal from corrosion and maintain the electrical conductance of the metal. The challenge of this approach is that there is only limited low-cost materials that could meet electrically conductive and corrosion-resistive requirements for PEM fuel cell applications, and the processing to apply these materials on metal substrate is either difficult or at high cost.

TreadStone takes a different approach to develop the metal bipolar plates for PEM fuel cell applications. It was found that it is unnecessary to have the whole surface electrically conductive to ensure the low contact resistance (interfacial contact resistance <10 mΩ.cm$^2$) between bipolar plates and the gas diffusion layer (GDL). TreadStone’s approach is based on this principle, as shown in Figure 1.

The majority of the metal surface area is covered with the low-cost corrosion-resistant but non- (or poor) conductive material (green layer in Figure 1). A corrosion-resistant and highly electrically conductive material (such as Au) forms the paths for electron transport, in the form of small conductive vias (yellow bars) penetrating through the non-conductive layer. Electrons generated from the anode reaction will flow through the GDL to the conductive vias (not the whole land area) pass the metal plate to the other side for the cathode reaction on the cathode of the adjacent cell. The conductive vias have a dimension as small as several micrometers, are distributed on the metal surface. The average distance between the conductive vias is 20-70 µm. The dense distribution of conductive vias ensures a uniform current distribution between the GDL and metal bipolar plates.

TreadStone’s approach is unique by using a small portion (<1-2%) of the plate surface for electrical contact. It was found that it could have more than 500,000 via/in$^2$ on the metal plate surface as the electrical contact point of metal plate with GDL, when small (<5 µm) conductive vias are used. It is because of the high amount of the contact points that ensure the low contact resistance of metal plates.

Results

TreadStone’s current metal bipolar plate uses small amount of gold as the electrical contacting material in the form of conductive vias, and stainless steel as the substrate material. In this project, we plan to develop the lower cost material to reduce the gold usage, or replace gold as the contact material. We have finished the process development to use palladium/gold composite as the contact materials. We also developed
the process to use carbon nanotubes and conductive carbides as the conduct material.

The palladium/gold composite uses the palladium particle as the base material, and the very small amount of gold plated on the palladium surface to ensure low contact resistance of the metal plate with GDL. The gold is in the form of 10-20 nm thick on the palladium particle surface. The corrosion experiments and the electrical contact resistance measurements indicate that stainless steel with the palladium/gold composite conductive vias can meet the PEM fuel cell application. Because palladium is about 30% cheaper than gold, this approach could reduce the gold via cost.

Using carbon nanotube and carbides as the conductive via materials can eliminate the gold on the metal bipolar plates. We have developed the processing technology to deposit carbon nanotube and carbide particles on metal plates. Figure 2 shows the microscopic pictures of carbon nanotube and chromium carbide on 304 stainless steel surface. Figure 3 shows the potentiostatic corrosion test of 304 stainless steel with carbon nanotubes on the surface in pH3 H2SO4 + 0.1 ppm HF solution under 0.8 V NHE at 80°C. The contact resistance of the stainless steel plates with carbon nanotube before and after 100 hours corrosion tests is below 10 mΩ.cm². The corrosion test of stainless steel with chromium carbides on the surface shows the similar performance that indicates these metal plates have the potential to be used in PEM fuel cells.

Stainless steel substrate cost is the major cost item (accounting for 50-60%) in the metal bipolar plate, even using the commercially available lower cost 304 stainless steel foil. We plan to develop lower cost carbon steel or aluminum-based substrate material for PEM fuel cell applications. In the first year of the project, we have developed the processing technology to apply a corrosion-resistant, non-conductive coating material and gold or palladium conductive vias to prevent the substrate material corrosion while maintain the desired electrical conductance requirement.

Short stacks using TreadStone’s metal plates have been designed, and assembled for portable, stationary and automobile applications. The portable power stack has 30 cm² active area on each cell. The designated power is 200 W with open cathode for air cooling. The stationary stack has 263 cm² active area on each cell. The designated power is 1 kW with liquid cooling. The initial short stacks have been assembled, and their performance has been evaluated. The experiments are continuing to demonstrate the long-term stability of the stack using Treadstone’s metal bipolar plates.

A 10-cell, 2.5 kW short stack for automobile application has also been assembled and tested at Ford Motor Company. Figure 4 shows the picture of the stack in the testing station. The stack has 300 cm² active area on each cell, and operates under high pressure. The stack is being tested for durability (which includes the FTP cycle along with others) mimicking real-world
driving conditions. It has finished 800 hours of stable operation, and continues to operate.

Conclusions and Future Directions

Treadstone’s unique corrosion-resistant metal bipolar plates have demonstrated stable operation for PEM fuel cells in portable, stationary and automobile applications. The processes to use lower cost materials have been demonstrated to further reduce the metal plate cost to meet DOE 2015 targets. Further development will be focused on:

- Scale up the lower cost conductive vias processing technique for the large scale production.
- Demonstrate the low-cost carbon steel and aluminum plates based bipolar plates.
- Demonstrate the long-term operation stability of the TreadStone’s low-cost metal plates in PEM fuel cell applications.

V.L.3 Metallic Bipolar Plates with Composite Coatings

Objectives

Develop a fluoropolymer-inorganic filler composite coating that is electrically conductive and provides a physical barrier to corrosive species within the fuel cell.

- Apply the composite coating to aluminum alloy substrates using an established high-volume manufacturing process.
- Synthesize titanium diboride (TiB$_2$) and calcium hexaboride (CaB$_6$) powders using a low-cost process.
- Measure the H$_2$ permeation flux, corrosion resistance, and area specific resistance of the composite coated aluminum plates.
- Demonstrate the ability to make the surface of the coatings hydrophilic.
- Create a flow field design for a plate with an active area $>$50 cm$^2$, make stamping dies for the design, and demonstrate the ability to stamp aluminum sheets.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

(B) Cost

(D) Water Transport within the Stack

Technical Targets

The goal of this work is to develop an aluminum-based bipolar plate that meets all of the DOE technical targets for bipolar plates shown in Table 1 [1]. This goal will be met by applying a composite coating that is both electrically conductive and corrosion-resistant to the aluminum plate using an established high-volume manufacturing process.

Accomplishments

- TiB$_2$ and CaB$_6$ powders have been synthesized using a low-cost process that is scalable. An invention disclosure is being filed for the CaB$_6$ synthesis procedure.
- High aspect ratio metal boride powder synthesis has been demonstrated.
- The stability of TiB$_2$ and CaB$_6$ has been tested at 80°C in sulfuric acid solutions.
- Composite coatings have been applied to aluminum substrates using electrostatic spraying and wet spraying; both are high volume manufacturing processes.
- Corrosion resistance that exceeds the DOE targets has been measured for composite-coated aluminum plates under both anodic and cathodic conditions for 24 hours.
- Hydrophilic coating surface properties were achieved using a simple two-step process.
• A flow field design and the corresponding stamping dies were created and used to stamp 75 pieces of aluminum alloy.
• The H₂ permeation flux of the stamped aluminum plates was measured under the conditions specified in the DOE target and no hydrogen permeation was detected.
• Baseline single cell tests were performed on the uncoated, stamped aluminum bipolar plates for 300 hours.

Introduction

Aluminum bipolar plates offer a potential weight reduction of up to 65% over stainless steel, while still having the desired mechanical properties that a metal offers. Furthermore, untreated aluminum can meet all of the DOE bipolar plate targets except for corrosion resistance. To overcome this one weakness, we have been applying a composite coating consisting of a matrix of an acid-resistant fluoropolymer and a filler material that is electrically conductive and acid-resistant. Metal borides and carbon-based materials, such as graphite, carbon black, and carbon fibers, were identified as candidate filler materials. Composite-coated aluminum bipolar plates can be fabricated using techniques, such as stamping, welding, and spraying, that are currently used for high-volume manufacturing of many consumer goods. In the first year of the project, we have focused on the H₂ permeation, corrosion, and electrical properties targets.

Approach

In order to meet the cost target using metal boride filler materials, it was necessary to develop a low-cost metal boride synthesis process. Furthermore, the use of high aspect ratio filler powders would allow for a reduction in the volume fraction of the filler (for lower costs), so synthesis procedures to obtain such filler powders were also developed. We have worked on identifying the combination of fluoropolymer and filler that will provide the desired electrical conductivity in a composite coating. We have made free-standing composite films and sprayed fluoropolymer (ethylene-tetrafluoroethylene, ETFE or polychlorotrifluoroethylene, PCTFE) mixed with either graphite or carbon fibers onto non-conductive substrates, and we have measured the surface conductivity/resistivity of these samples. We have varied the type of graphite, the type of fluoropolymer, and the ratio of filler to fluoropolymer in an effort to increase the electrical conductivity of the coatings. Other subtasks include corrosion testing of coated aluminum panels, flow field design and stamping of aluminum plates, and hydrogen permeation measurements. We have also developed a treatment procedure for making the coating surface hydrophilic to ease water transport within the stack.

Results

Of the metal borides, TiB₂ and CaB₆ were chosen because they have the desired combination of reported electrical conductivity [2], density, and corrosion resistance [3]. Low-cost processes were developed and used to synthesize TiB₂ [4] and CaB₆. Inexpensive Ti, Ca, and B precursors were used in the 3-step synthesis procedures, which used processing temperatures of up to 1,600°C. Powder X-ray diffraction (XRD) results showed only the desired metal boride product and, in the case of TiB₂, a small amount of excess carbon. Analysis by transmission electron microscopy (TEM) showed that particle sizes were, on average, sub-micrometer in diameter, Figure 1a. By adding a small amount of a seed element, elongated grains could be grown, Figure 1b.

It is reported that the environment inside a proton exchange membrane (PEM) fuel cell is acidic due to the presence of the Nafion® membrane and Nafion® ionomer in the electrodes combined with the humidity [5]. Acid stability tests were conducted on commercially purchased and SIUC-synthesized TiB₂ and CaB₆ at 80°C under 3.5% H₂ in helium with reflux. Two sulfuric acid solutions were used in the tests: 1) 0.5 M H₂SO₄ (pH=1) with 2 ppm NaF and 2) 0.001 M H₂SO₄ (pH=5) with 0.1 ppm NaF. The results of the tests are shown in Table 2. The values shown in the “% Sample Remaining” column were calculated from the measured change in weight of the samples. Neither of the borides was found to be completely resistant to the acid, but CaB₆ performed better than TiB₂.

Electrochemical corrosion experiments were also conducted on the CaB₆ and TiB₂ powders to corroborate the findings of the acid stability tests. Powders of TiB₂ (Cerac, -200 mesh) and CaB₆ (Alfa Aesar, -325 mesh) were ball-milled in ethanol and then mixed with Nafion®. A thin film of the mixture was applied to a rotating disk electrode and electrochemically tested in both O₂-saturated and O₂-free (i.e., Ar purged) 0.1 M H₂SO₄. Potential holds at several potentials and potential scans that are relevant to the bipolar plate application were run. The measured corrosion currents were higher than the DOE target of 1 x 10⁻⁶ A/cm², indicating that both CaB₆ and TiB₂ would not be stable in the PEM fuel cell environment.

Surface electrical conductivity/resistivity measurements of free-standing composite samples were measured using a four-point probe (Jandel) driven by a potentiostat. The free-standing samples were made by mixing the appropriate amounts of PCTFE and the
desired filler powders, and then uniaxially pressing them at 235°C to sinter the fluoropolymer and form a solid disk. Selected conductivity results are shown in Table 3 for samples that had 60 vol% electrically conductive filler with 40 vol% PCTFE. The measured electrical conductivities of the composites were significantly lower than the published bulk conductivities of the fillers. This is likely due to contact resistance between the filler particles. Furthermore, the PCFTE may act to separate the filler particles as it flows between the particles during sintering. Also, in the case of CaB₆, it is suspected that the published bulk value is erroneously high [6,7].

Based on the results in Table 3 and the acid stability tests showing that the borides are unstable, we proceeded to investigate composite coatings that had graphite-based fillers. Slurries were made by ball milling the desired amounts of graphite and fluoropolymer with solvents. They were then sprayed onto a non-conductive ceramic substrates and the resistivity/conductivity was measured using the 4-point probe. A composition that was 40% flake graphite, 20% spheroidized graphite, and 40% EFTE was found to have the best resistivity of 0.03 Ω·cm.

Having a hydrophilic surface on the bipolar plate aids with water management in the electrodes, so we have invented a method for changing the PCFTE surface from hydrophobic to hydrophilic by applying two solutions, sequentially, and heating the film up to 135-150°C for 5 minutes after each application. This method was demonstrated on a 60% graphite-filled PCTFE film, as shown in Figure 2, and on similar coatings that were sprayed onto aluminum. Contact angle measurements made using a First Ten Ångstroms system yielded contact angles of 108° for the untreated sample (Figure 2, left) and 65° for the treated sample (Figure 2, right).

Corrosion resistance measurements of coated aluminum samples using electrochemical methods [10] were conducted to evaluate the ability of the coatings to provide a physical barrier between the aluminum substrate and the corrosive media in a fuel cell. In these experiments, the electrolyte was 0.001 M sulfuric acid (pH=3) with 0.1 ppm NaF. For cathodic corrosion tests, air was bubbled continuously through the acid solution and 0.6 V vs. Ag/AgCl (or 0.8 V vs. normal hydrogen electrode, NHE) was applied for 24 hours. For anodic corrosion tests, argon was continuously bubbled through the acid solution and -0.4 V vs. Ag/AgCl (or -0.2 V vs. NHE) was applied for 24 hours. The results for aluminum plates with a coating of 20 vol% carbon fiber/80 vol% EFTE applied by electrostatic spraying at Orion Industries are shown in Figure 3. The current densities fall below the DOE corrosion target, showing that the coatings provide a stable barrier.

A total of 75 uncoated aluminum bipolar plates with flow fields have been stamped with a 60 cm² active area. The design is based on a GTI patented trapezoid flow field structure for PEM fuel cells with very low pressure drop. The hydrogen permeability of the formed plates was tested and there was no hydrogen pass-through detected at 50 psig (3.4 atm), meeting the DOE target. In addition, the bipolar plate design was proven during fuel cell testing which demonstrated that the stacks can be well sealed against fuel, oxidant, and cooling water leaks. During fuel cell lifetime testing using the bare, uncoated aluminum bipolar plates, it was found that the use of aluminum leads to high electrical resistance, which increases with time. These baseline data will be used for comparison against the coated aluminum plates.

Conclusions and Future Directions

- TiB₂ and CaB₆ are not sufficiently acid resistant for use in PEM fuel cell stacks.
- Composites made with flake graphite as the filler have the highest electrical conductivities.

Special Recognitions & Awards/Patents Issued

References

Objectives

- Develop a working material specification to guide the development of proton exchange membrane fuel cell (PEMFC) seal materials.
- Synthesize and compound materials that meet the requirements of the materials specification.
- Evaluate candidate materials through accelerated ex situ testing to predict whether the material will meet durability objectives given in Table 1.
- Validate the performance of the best performing material candidate through in-cell testing.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

Technical Targets

The aim of this project is to develop and evaluate new non-silicone liquid injection moldable (LIM) and dispensable materials to improve durability for both transportation and stationary applications while maintaining or improving on the cost benefits of LIM silicone materials.

\* DOE Transportation/Stationary targets.
\*\* Real-time out-of-cell testing at 90°C.
\*\*\* Based on high volume production (500,000 transportation systems per year/2,000 stationary units per year).

Note: A cost target for seals is not currently carried in the Fuel Cell Technologies Program Multi-Year Research, Development, and Demonstration Plan. See footnote (d) below for an explanation of how this target was derived.

\*\*\* Suggested cost target range for transportation applications derived from Reference 1 ($3.77/kW), Reference 2 ($2.10/kW) and conversations with the Fuel Cell Tech Team ($2.00/kW). Based on Reference 1, a reasonable suggested target for stationary applications may be $5.87/kW.

Accomplishments

- Completed more than 10,000 hours of compressive stress relaxation (CSR) testing at 90°C.
- Completed more than 4,500 hours of CSR testing at 120°C.
- Completed more than 10,000 hours of aging in air at 120°C.
- Developed materials that meet all minimum beginning of life (BOL) targets and most desired project goals.
- Developed additional candidate with greater measured BOL tear and tensile strength.
- Developed materials shown to be more stable than one tested silicone and a few tested ethylene propylene diene monomers (EPDMs).
- Accumulated 1,700 hours of in-cell testing.

Introduction

Seal durability is critical to achieving the 2010 DOE operational life goals for both stationary and transportation PEMFC stacks. The seal material must be chemically and mechanically stable in an environment consisting of aggressive operating temperatures, humidified gases, and acidic membranes.
The seal must also be producible at low cost. Currently used seal materials do not meet all these requirements.

High consistency hydrocarbon rubber compounds (rubbers that are solid or semi-solid prior to curing) that show promise for compatibility with the PEMFC environment are difficult to process in a way that leads to low-cost PEMFC production. Silicone-based LIM rubber compounds which are easy to process in ways leading to low-cost production are highly gas permeable and have been shown to be unstable in PEMFC applications. To produce PEMFC stacks which are both highly durable and low in cost, a seal material with the stability of high consistency hydrocarbon rubber and the processing ease of a LIM silicone is sought.

**Approach**

To accomplish the objectives of this project, the approach is to develop and evaluate non-silicone LIM seal materials that can meet the specialized mechanical, compatibility, and cost requirements inherent to the design and operation of PEMFCs. To guide material development, a working material specification was developed. Materials developed to this specification by Henkel are evaluated through out-of-cell testing at Virginia Tech, Henkel and UTC Power in simulated environments. Using an appropriate set of accelerated testing techniques, an initial lifetime estimate will be made for the candidate materials. The best candidate or candidates will be selected for in-cell testing to validate the performance of the material in a PEMFC environment. Specimens for out-of-cell testing and full size prototypes for in-cell testing are produced by Freudenberg-NOK General Partnership.

The outcome of the project will benefit the PEMFC industry by providing a seal material specification, a material that satisfies it, and verification that the specification and the material enable a low-cost and durable seal.

**Results**

The work over the last year has been focused on four tasks:
- Material Development
- The Completion of Out-Of-Cell Testing
- Molding of Prototype Components for In-Cell Testing
- In-Cell Validation Testing

Additional experimental material development was carried out over the last year. The work has yielded FCS3, the final material candidate to be developed as a part of the project. It is a one-part material with the same cure characteristics and thermal stability as FCS2, but with increased strength, modulus, and elongation.

This brings the total of material candidates introduced to four. In Table 2, some key properties of the four are compared to each other and to the materials specification. All four meet the minimum requirements in the material specification with one exception. The viscosity of FCS3 is higher than originally desired. However, initial molding trials indicate that the higher viscosity should be acceptable. While seal components suitable for use in PEMFC applications could be produced from any of the four, the higher strength and elongation of FCS3 broadens the range of design options available.

A variety of out-of-cell tests were used in the evaluation of the materials developed for this project such as mass uptake, environmental aging and stress relaxation. The aim was to evaluate the beginning of life properties and to evaluate how those properties changed with time when subjected to combinations of temperatures and chemical environments typical of PEMFC operation.

One of the most important measures for determining the durability of seals is CSR. This is a measure of decay in sealing force with time. During the past year, over 9,000 hours of CSR testing at 90°C in air was completed on FCS2 using a sub-scale molded O-ring seal (SMORS) – a seal over-molded around the perimeter of a porous substrate. The result is summarized in Figure 1. The result agrees with results achieved previously when testing FCS0 CSR plugs in 90°C air, dionized water, and a 50/50 etylene glycol/water solution for 10,000 hours. The key result is that after 9,000 hours, less than 20% load decay was measured. This result is important. Significantly greater values are typically seen in silicones and even some EPDM materials after less than half this time. While these higher values can typically be accounted for in the design of sealing systems, lower values translate directly into increased durability and greater design flexibility.

As mentioned above, CSR testing had previously been conducted on the FCS0 material. This testing used the test specimen configuration specified in ASTM D 6147 Section 7.1.1. Because this geometry is very different than that used to produce a functional fuel cell seal, the CSR testing was repeated with SMORS in all the environments tested previously and also in a 0.1 M H₂SO₄ solution. Testing was completed this year and results are shown in Figure 2. In this case, after more than 4,000 hours, load decay for three aqueous test environments was approximately 20%. It should also be noted that the behavior in the three environments is substantially the same. This indicates, for instance, that the material is resistant to a sulfuric acid solution having a pH of approximately 1.0. This in turn suggests that the material could be directly over-molded onto poly(fluorosulfonic acid) membranes.

It is important to recall that the materials developed on this project are hydrocarbon-based elastomers. Given this fact, it is expected that one of the most significant threats to the stability of the candidate materials is oxidation. To evaluate this threat, a comparison of the oxidative stability to some other materials which have been considered for PEMFC applications was carried out. A key result of this work is provided in Figure 3. In this figure, relative change in mass with time is tracked for testing at 120°C. The inlaid figure provides results for 150°C testing completed previously. In this figure, the candidate material is being compared to three EPDM-based materials. Significant changes in the rate of either weight gain or loss can be correlated to significant degradation in mechanical properties. The result indicates that the candidate material has greater oxidative stability than the EPDM-based materials tested.

In addition to out-of-cell testing, two types of prototype seals were molded this year. The first was a seal over-molded onto a plastic sub-gasket. This seal was used for in-cell validation testing, and 1,700 operating hours were accumulated. Post-test evaluation remains to be completed. The second full-size prototype seal produced was of an integrated molded seal configuration. The purpose of this molding activity was to test the effect of different parameters and materials, such as gas diffusion media type, on mold-flow when producing parts with the integrated molded seal configuration. Learning from this activity was used to form the development of a final full-size prototype component.
Conclusions and Future Directions

Based on the work performed to date for the project, the following can be concluded:

- The material development strategy (synthesis and compounding) is sound.
- Based on all testing completed, the materials developed have a high probability of success for meeting the 2010 DOE goals for use in automotive PEMFC applications and are likely to meet the needs of longer lifetime applications as well.
- Activities for the remainder of the project will include the following:
  - Evaluation of a high volume capable injection molding technique for over-molding seals around the perimeter of full-size MEAs.
  - Additional full-size in-cell testing to further validate out-of-cell test results.
  - Complete evaluation of material and processing costs to assess likelihood of meeting suggested cost target at high volume.

References

Objectives

- Advance the state-of-the-art in technology for air-cooled proton exchange membrane (PEM) fuel cell stacks and related GenDrive™ material handling application fuel cell systems.
- Demonstrate FCvelocity™ 1020ACS stack durability of 5,000 hours (2.5x nominal durability) through enhanced system operational strategies or utilization of advanced fuel cell stack materials.
- Determine a stack/system concept that is suitable for sub-zero operation down to -30°C.
- Determine a stack/system concept that achieves a total cost that is competitive with incumbent materials handling fuel cell technology solutions.
- Develop, evaluate and trade-off the stack and system to meet materials handling requirements for freeze and cost.
- Develop an understanding around integrating air-cooled stack technology into a dynamic materials handling system.
- Perform life-cycle cost analyses for freeze tolerance strategies.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability (with respect to start-up, freezing and low relative humidity operation)
(B) Cost (with respect to stack and balance-of-plant [BOP] trade-off)
(C) Performance (with respect to voltage degradation, low relative humidity and sub-zero performance)

Technical Targets

- Stack/system concept that is suitable for sub-zero operation down to -30°C.
- Durability for an air-cooled fuel cell stack ≥5,000 hours operating under material handling conditions including start-stop cycles.
- GenDrive™ product cost reduction of 25% or greater using air-cooled stack design over baseline liquid-cooled GenDrive™ product.

Accomplishments

- Through detailed stack failure analysis the key stack failure modes were identified to be platinum loss and platinum crystal growth during start-stop and membrane leak induced cathode carbon corrosion. In extreme freeze events cathode catalyst fragmentation was also seen. Materials and operating strategies were selected to mitigate these failures.
- Advanced system operating strategies for the Mk1020 air-cooled stack have demonstrated 5,000 hours of operation to date (2.5 times initial durability), testing is still ongoing. These operating strategies focus on reducing cathode catalyst dissolution and corrosion and chemical and mechanical stress on the membrane.
- Advanced Mk1020 air-cooled stack membrane electrode assembly (MEA) concepts have demonstrated an improvement in both operating hours and start-stop cycles; 2,500 start-stops have been achieved and testing is on going. Advanced MEAs contain a membrane of lower ionic resistance and higher chemical stability as well as a better dissolution-resistant cathode catalyst.
- Stack-system modeling has been used to guide balance-of-plant design to achieve freeze targets. Validation of model output is ongoing.
Although over 100 freeze-starts were demonstrated on the FCvelocity™ 1020ACS stack the variability in performance start-to-start was high and would still contribute to the dominant degradation mode of platinum dissolutions and agglomeration. To achieve the performance and durability targets for materials handling the system will be designed to provide the stack with optimal conditions where possible (within realistic BOP cost restrictions).

Introduction

To be competitive with incumbent materials handling technologies there is a need to reduce the overall cost of the materials handling stack/system. The fuel cell stack incumbent technology is the liquid-cooled GenDrive™ system. The air-cooled stack offers a chance to reduce the cost of the system by eliminating the need for a humidifier and coolant loop. In order to be a viable option for materials handling applications the air-cooled stack must also demonstrate increased durability and freeze function.

Plug Power’s objective is to advance the state of the art in technology for air-cooled fuel cell stacks and related GenDrive™ material handling application fuel cell systems. This will be accomplished through a collaborative work plan to improve freeze tolerance and mitigate freeze-thaw effect failure modes within innovative material handling equipment fuel cell systems designed for use in freezer forklift applications.

The fuel cell system, derived from Plug Power’s commercially available GenDrive™ platforms, is providing battery replacement for equipment in the material handling industry. The fuel cell stacks are Ballard’s commercially available FCvelocity™ 9SSL (9SSL) liquid-cooled PEM fuel cell stack and FCvelocity™ 1020ACS air-cooled PEM fuel cell stack. Stack modifications to the FCvelocity™ 1020ACS will be explored. Plug Power will lead design-build-test and design-of-experiment efforts for GenDrive™ systems with support from Ballard Power Systems for the fuel cell stack and stack integration.

Approach

In this project the fuel cell stack, system and fuel cell stack operation will be designed together in order to trade off stack durability and freeze function with overall stack/system cost. Both stack and system level mitigation of freeze failure modes will be explored.

The project will develop an understanding of market needs, system requirements, stack-system limitations, historical data, models and small-scale testing to define stack/system operating strategies that achieve required freeze function and durability.

Multiple design, build, test cycles will be employed to increase learning through each iteration. Stacks and systems will be operated to failure under material handling freezer conditions, failure analysis will be performed to understand the root cause, stacks and systems will be designed to mitigate the failure modes, then built and tested, and trade-off analysis will be used to determine the design solutions that are built and tested.

Results

The Mk1020 air-cooled stack must first demonstrate performance and durability targets to be considered a viable GenDrive™ product solution. Specifically, the Mk1020 must demonstrate 5,000 hours running a representative load profile including start-stop cycles. The Mk1020 stack offers system simplicity by eliminating the liquid cooling system; this is achieved through an “open cathode” design where cooling and reactants are supplied by a single fan. As a result the MEA operates very dry, all start-ups are air-air start-ups and, under freeze conditions, the cooling power of the air stream is high making low current density operation difficult. All of these conditions increase the stack degradation and make freeze function a challenge.

The failure modes of the baseline Mk1020 stack were identified by running a stack through the standard Mk1020 ACS duty cycle and removing MEAs every 250 cycles for degradation analysis. The dominant voltage degradation modes were identified as catalyst dissolution, followed by membrane transfers (internal leaks). Results show that at the onset of internal membrane leaks the catalyst failure mechanism begins to include corrosion as well as dissolution as seen by a catalyst layer thickness reduction once the stacks begins to leak; this is thought to be due to air leaking to the anode during operation and on shutdown. Wet-dry cycling as well as operating at high potentials accelerate the membrane degradation, see Figure 1. To improve the durability by way of design changes, a more dissolution resistant cathode catalyst and leak-resistant membrane were explored.

In this report advanced stack concepts are represented by the following code: Ax Mx Cx, where A represents the anode, M represents the membrane and C represents the cathode. The baseline MEA is A1 M1 C1.

Advanced MEA concept durability is shown in Figure 2. The durability of the membrane, as seen by leak rate, has been significantly improved from the baseline (M1), both M2 and M3 have longer times to leak initiation. The voltage degradation rate is improved with the advanced catalyst design C3. The stack concept that provides a low degradation rate will be considered as the primary candidate.
Failure analysis of advanced concepts shows improvements can be made to the failure propagation of the catalyst and membrane. Results indicate lower crystallite growth, lower cathode catalyst thickness loss, and lower platinum dissolution. It was also noted that more durable membranes (M2 and M3) can lower...
the impact of cathode catalyst corrosion compared to the baseline. This further supports the link between localized transfers in the membrane and catalyst corrosion.

Based on the baseline stack durability testing and failure analysis the system can impact stack durability by controlling stack-critical parameters for performance and durability, including: stack temperature, relative humidity cycles, time at open circuit voltage, cathode potential, cathode potential cycles and mixed anode potentials.

System strategies designed to mitigate the known stressors and improve stack life were evaluated via screening tests and the best strategies were downselected for long-term durability testing. Each system strategy was designed to control one or more of the above critical parameters. Figure 3 illustrates cell voltage degradation as a function of hours for the baseline system and two advanced operating strategies.

Air-cooled stack durability and start-stop cycles have been improved over the original design air-cooled stack when operating under material handling conditions via successful implementation of operating system architecture strategies. Stack life has been demonstrated at 2.5 times the original design; going from 2,500 hours to 6,300 hours. Air-Air starts have been improved by 1.6 times the original design; going from 1,000 to 1,600.

Performance test results for the baseline Mk1020 stack indicate a lower performing polarization curve at the extreme temperatures, 40°C and -10°C. This was a result of fan turn-down limitations resulting in non-optimal stack temperatures during the polarization. Stacks that run above the optimum temperature tend to experience drier conditions, while stacks that run below optimum temperature tend to run wetter; both situations can lead to performance loss. Although the freeze-start capability of the baseline ACS stack was variable from test to test, over 100 freeze-start cycles were completed. The end cells of the stack were particularly sensitive, failure analysis of the most sensitive cells showed typical freeze failure damage; i.e. catalyst cracking and fragmentation.

Based on previous Ballard design work, a MEA/stack solution for freeze and durability can significantly increase the cost of the stack. Therefore, the primary approach is to explore system options and operating strategies in order to manage a sub-zero environment with extended durability.

A stack thermal computational fluid dynamics model that combines fluid flow and heat transfer in a single air channel was developed to explore several stack-system related freeze function strategies related to increasing the rate of stack heating. The baseline operating strategy, heater use, fan turn-down and cathode recirculation were explored to determine the
Failure analysis will be performed on stacks and systems to understand the freeze failure modes.

Freeze prevention and mitigation design step following failure analysis and the best solution(s) will be down-selected using trade-off analysis.

A product life cycle cost analysis will be used to evaluate the commercial viability of using an air-cooled fuel cell stack versus a liquid-cooled stack. The key parameters for the product life cycle cost analysis are the capital, maintenance, and operational costs. A GenDrive product with an air-cooled fuel cell stack must demonstrate a 25% lower capital cost and life cycle cost when compared to the 2009 end-of-year GenDrive with a liquid-cooled fuel cell stack.

A Go/No-Go project decision review will be held with the DOE to evaluate the metric of a 25% GenDrive™ product cost reduction using an air-cooled fuel cell stack versus a liquid-cooled fuel cell stack.

Air-cooled fuel cell stacks and systems will be built with freeze mitigation design strategies and re-tested to evaluate the improvements under material handling freezer conditions.

**Conclusions and Future Directions**

- Both stack and system test data are tracking to show advanced MEA concepts and/or advanced system strategies can achieve the requisite stack-system durability.
- The baseline freeze function of the stack is not sufficient to meet the materials handling requirements. Stack-system solutions are being explored.
- Stack/system testing under material handling freezer application conditions has not been completed and is needed to understand the commercial viability of the air-cooled stack.
- Models have been developed for stack and system operation in freezer conditions and used as input for the concept air-cooled fuel cell system architecture.
- Concept air-cooled fuel cell systems will be built and tested under material handling freezer conditions.

V.M.2 Fuel Cell Fundamentals at Low and Subzero Temperatures

**Objectives**

- Fundamentally understand transport phenomena and water and thermal management at low and subzero temperatures.
- Examine water (liquid and ice) management with nano-structured thin-film (NSTF) catalyst layers.
- Enable operational and material optimization strategies to be developed to overcome observed performance bottlenecks.
- Characterize and measure critical transport properties for operation with liquid water.
- Elucidate the associated degradation mechanisms due to subzero operation and enable mitigation strategies to be developed.

**Technical Barriers**

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (C) Performance
- (A) Durability
- (D) Water Transport within the Stack
- (E) System Thermal and Water Management
- (G) Start-up and Shut-down Time and Energy/Transient Operation

**Technical Targets**

This project is conducting fundamental investigations into fuel cell operation at low and subzero temperatures. The knowledge gained will enable various metrics to be met or exceeded. These include those related to durability, performance, and cost. Specially,

- **Durability**
  - 5,000 hr (automotive) and 40,000 hr (stationary)
  - Thermal cycling ability with liquid water

- **Performance**
  - Unassisted start from -40°C
  - Cold-start to 50% power in 30 seconds and with 5 MJ or less energy
  - Efficiency of 65 and 55% for 25% and 100% rated power, respectively
  - Stack power density of 2 kW/kg
  - Precious group metal (PGM) loading of 0.2 g/kW
  - Cost: $15/kWₑ

**Accomplishments**

- Project initiated.
- Completed the water movement during shutdown mathematical model including cell-position effects.
- Developed capabilities and experimental protocols for measuring capillary-pressure – saturation relationships for both gas diffusion layers (GDLs) and microporous layers (MPLs). Demonstrated that this relationship is critical and can be used to explain water transport throughout the material. Also designed a test fixture for measuring water distributions using X-ray tomography.
- Used dynamic scanning calorimetry to measure freeze kinetics and thermodynamics inside GDLs.
- Preliminary baseline cell studies finished including isothermal starts.

**Introduction**

Polymer electrolyte fuel cells experience a range of different operating conditions. As part of that range, they are expected to be able to survive and start at low and subzero temperatures. Under these conditions, there is a large amount of liquid and perhaps frozen water due to the low vapor pressure of water. Thus, water and thermal management become critical to...
understanding and eventually optimizing operation at these conditions. Similarly, durability aspects due to freeze and low temperatures are somewhat unknown and need further study in order to identify mechanisms and mitigation strategies. In addition, it is known that thin-film catalyst layers such as NSTF developed by 3M have issues with large amounts of liquid water due to their thinness. These layers provide routes towards meeting the DOE cost targets due to their high catalytic activities. This project directly focuses on the above aspects with the goal that improved understanding will allow for the DOE targets to be met with regard to cold-start, survivability, performance and cost.

**Approach**

The overall approach is to use a synergistic combination of cell, stack, and component diagnostic studies with advanced mathematical modeling at various locations (national laboratories, industry, and academia). Figure 1 shows the approach of the project. As can be seen, ex situ diagnostics will be used to quantify transport properties and to delineate phenomena that are used in the modeling. The multiscale modeling will account for stack position through boundary conditions that are fed to a pseudo three-dimensional or one- plus two-dimensional cell model. This model will be used during shutdown to predict the water profile during the subsequent cold-start. The model will be validated by comparison of measured in situ cell performance in both stacks and single cells. Durability will be probed by doing cycling and other stress tests as well as taking failed cells from the in situ testing and duplicating their failure ex situ. To understand controlling phenomena and the impact of various layers, a systematic investigation at the component scale will be accomplished. After initial baseline cell assemblies have been tested and explored, various components will be switched to understand the impact of each one on both performance and durability.

**Results**

As fuel cells operate at low and subzero conditions, liquid water and water management become more important. Thus, there is a need to study properties of the porous fuel cell layers in the presence of liquid water. This year, the focus was on the development of such diagnostic measurements. It is believed that one the key measurements for diffusion media is the capillary pressure – saturation relationship. We have developed an experimental methodology to measure such curves [1]. The results are shown in Figure 2 for both a standard SGL Group (SGL) GDL and a MPL. The MPL curve was obtained using a special layer provided by SGL in which a GDL was fully impregnated with an MP (as shown in the micrograph). The relationships clearly show that the MPL has a more hydrophobic signature, due both to its smaller pores and higher poly-tetrafluoroethylene (PTFE) weight fraction. What is interesting is that the MPL still exhibits the same intermediate wettability, where water is neither spontaneously imbibed or drained. These curves are now being used in modeling studies and going forward we aim to use this methodology to understand water distributions and the functioning of the MPL during operation [2].

Other diagnostics are aimed at determining what happens when water freezes in the various fuel cell layers. Figure 3 demonstrates measurements done with various GDLs using dynamic scanning calorimetry. For all GDLs, the crystallization temperature decreases as the PTFE content increases. Note that the SGL 24 and Toray (SGL) series GDLs follow a similar line, whereas water in the Toray (Fuel Cell Energy, FCE) GDL freezes at a higher temperature. One possible explanation is that the SGL 24 and Toray (SGL deposition) series GDLs have the same method of PTFE deposition, whereas the Toray (FCE) has a different method of PTFE deposition. This observation suggests that the method of PTFE deposition influences the crystallization...
temperature. We hypothesize that addition of PTFE to the porous network changes the average internal ice/substrate wettability (i.e., contact angle), as well as the attainable level of water saturation, causing the decrease in crystallization temperature.

A plot of crystallization temperature and saturation versus PTFE content is shown for the Toray (FCE) series in Figure 3(b). For PTFE contents between 0 and 40 wt%, crystallization temperature decreases slightly with the addition of PTFE. Above 40 wt% PTFE, the crystallization temperature decreases more steeply. Between 0 and 40 wt% PTFE, water saturation remains relatively constant (within experimental error). However, those GDLs containing 50 and 60 wt% PTFE become increasingly difficult to saturate with water due to the need for increased capillary pressure. Consequently, saturation decreases abruptly. This suggests that at low enough fractions of PTFE, the saturation is constant and the average internal ice/substrate surface energy changes, while at larger fractions of PTFE, the attainable level of saturation also contributes to the decrease in crystallization temperature.

Ice formation in traditional catalyst layers was probed using a technique in which cyclic voltammetry is done under subzero conditions after isothermal starts reach zero volts. At very low temperature and current densities, the produced ice freezes immediately upon production, and this can be used to obtain a relationship
as shown in the line in Figure 4. Then, the charge passed during isothermal starts can be plotted as shown in Figure 4. The figure shows the amount of the water produced that is in the ice phase versus liquid water. Thus, as the temperature is increased or the current density lowered, more product water can move away from the reaction site and does not freeze between the ionomer and catalyst particle. Knowing the amount of water in each phase will enable operation of the NSTF while meeting the DOE targets for survivability and cold start.

Conclusions and Future Directions

This project was initiated this year. Initial results are promising in guiding future directions and most of the year was spent on doing necessary diagnostic measurements and model development. The shutdown model clearly shows the redistribution of the water that occurs during long times and this can affect cell startup. Several novel experimental diagnostics for catalyst-layer ice, GDL freeze, and GDL liquid-related properties were developed and allow for better understanding of operation at low and subzero temperatures. In terms of future work, this can be summarized as:

- Cell performance:
  - Further testing of baseline and non-baseline assemblies.
  - Isothermal and adiabatic starts including cycling studies for tracking durability.

- Component characterization:
  - Consolidate/measure membrane properties at subzero conditions.
  - Diffusion media:
    - Neutron imaging of shutdown and water redistribution.
    - Capillary pressure – saturation relationships:
      - Impact of flowrate, temperature, injection sites (MPL analogs), materials
      - X-ray tomography for the water distribution
    - Measure effective gas diffusion coefficient and relative permeability versus saturation.
    - Measure and model freeze rate and ice-front propagation as a function of saturation.

- Modeling of shutdown, cold start, and isothermal start
- Stack studies for temperature distribution and performance characterization
- Understand and increase the operating window with thin-film catalyst layers

FY 2010 Publications/Presentations

References

Objectives

- Develop and validate a two-phase, three-dimensional transport model for simulating proton exchange membrane (PEM) fuel cell performance under a wide range of operating conditions.
- Apply the validated PEM fuel cell model to improve fundamental understanding of key phenomena involved and to identify performance-limiting processes and develop recommendations for improvements.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(C) Performance
(D) Water transport within the Stack

Technical Targets

Since the validated PEM fuel cell model developed in this project can be employed to improve and optimize the design and operation of PEM fuel cells, insights gained from applying the model will help meet the following technical targets:

- Performance: 650 W/L or 50% energy efficiency for automotive applications; 40% electrical energy efficiency for stationary applications.
- Cost: $30/kW for automotive applications and $750/kW for stationary applications.
- Durability: 5,000 hours for automotive and 40,000 hours for stationary applications.

Accomplishments

- Developed a single-phase, three-dimensional (3-D), single-cell model and made significant progress toward meeting the milestone of developing a 3-D, partially two-phase, single-cell PEM fuel cell model.
- Coupled the present PEM fuel cell model with DAKOTA (which is a toolkit for design, optimization, and uncertainty quantification developed by Sandia National Labs).
- Demonstrated the capabilities of the present PEM fuel cell model in case studies.
- Demonstrated utilities of the coupled PEM fuel cell model/DAKOTA capability in case studies.
- Implemented a sub-model for simulating cathode microporous layer (MPL) effect.
- Simulated performance of a PEM fuel cell with zigzag flowfield using the present model.
- Investigated water transport through cathode MPL-gas diffusion layer (GDL) using a pore-network model.
- Developed and demonstrated a sub-model for predicting membrane interfacial resistance.
- Measured pore size distributions of various GDLs with and without MPL.
- Obtained experimental polarization curves for different temperatures, relative humidity (RH), and cell segments.
- Measured axial and radial thermal conductivities of GDLs with various poly-tetrafluoroethylene contents.
- Measured liquid water profiles across GDL-MEA regions using neutron imaging for four different GDLs and two different relative humidities.
- Measured along-channel current and temperature profiles in a 12 kW PEM fuel cell stack.

Introduction

As PEM fuel cell technology matures and enters the stage of commercialization such that the industry strives
to achieve desired performance and durability and reduce costs, process design and optimization become increasingly important and indeed critical. Modeling and simulation can provide guidance in PEM fuel cell design and optimization and thus help accelerate the commercialization of PEM fuel cell technology. Despite tremendous research efforts and a large number of models published in the literature (see Chen et al. [1] and references therein), a comprehensive, multi-physics computer model suitable for practical use by PEM fuel cell engineers and designers, particularly in transportation and stationary applications, remains absent. This mainly is due to the many challenges involved in modeling the PEM fuel cell operation: multiple components and phases, multi-dimensionality, and complex physics with highly coupled transport phenomena and electrochemical reactions. The significantly disparate length scales in transport and the presence of liquid water within the PEM fuel cell when operating under practical current loads, relatively high inlet RH or moderate cell temperature, further add to the modeling challenges.

The objectives of this project are twofold: 1) to develop and validate a two-phase, three-dimensional transport model for simulating PEM fuel cell performance under a wide range of operating conditions; and 2) to apply the validated PEM fuel cell model to identify performance-limiting phenomena or processes and develop recommendations for improvements so as to accelerate the commercialization of fuel cell technology. To achieve these two objectives, a multi-institutional and interdisciplinary team with significant experience in modeling PEM fuel cells and in measuring model-input parameters and model-validation data has been assembled. This team is led by Sandia National Laboratories; and it includes two other national laboratories (Los Alamos National Laboratory and Lawrence Berkeley National Laboratory), a university (The Pennsylvania State University), and two PEM fuel cell manufacturers (Ford Motor Company and Ballard Power Systems). In addition to developing and validating a two-phase, 3-D PEM fuel cell model, we are also coupling the PEM fuel cell model with DAKOTA [2] (which is a toolkit for design, optimization, and uncertainty quantification developed by Sandia National Labs) in order to create a computational capability that can be employed for PEM fuel cell design and optimization. This report documents technical progress made in this project during the first nine months of Fiscal Year (FY) 2010.

Approach

Our approach is both computational and experimental. We first develop a two-phase, 3-D, transport model for simulating PEM fuel cell performance under a wide range of operating conditions by integrating the detailed component sub-models; FLUENT (a commercial computational fluid dynamics code) is employed as the basic computational platform. We then validate our PEM fuel cell model in a staged approach using experimental data available from the literature and those generated by team members. Lastly, we plan to apply the validated PEM fuel cell model to identify performance-limiting phenomena or processes and develop recommendations for improvements. As mentioned previously, we have assembled a team of leading experts in PEM fuel cell modeling as well as in physical, electrochemical and transport property characterization, and cell diagnostics via segmented cell measurements and neutron imaging — this means that our project team is highly qualified and in an excellent position to carry out the project.

Results

To illustrate the utility of the present PEM fuel cell model, polarization curves for three cell temperatures, RHs at the cathode inlet, cathode back-pressures, and cathode stoichiometric flow ratios, were computed in case studies. Due to space limitation, only the effect of cell temperature on cell voltage is shown here in Figure 1. A schematic of the PEM fuel cell used in these case studies and the geometrical parameters, material properties, and operating conditions are available elsewhere (see Chen et al. [1], Chen [3]). As shown in Figure 1, cell voltage increases with cell temperature. Figures 2a, 2b, and 2c display, respectively, computed 3-D contours of temperature, H2 concentration in anode flow channel, GDL and catalyst layer, and O2 concentration in cathode flow channel, GDL and catalyst layer, and O2.

![FIGURE 1. Effect of Cell Operating Temperature on Cell Voltage (RH\textsubscript{anode}=RH\textsubscript{cathode}=80%)](image)
concentration in cathode flow channel, GDL and catalyst layer. It should be noted that H₂ and air flow in a counter-flow fashion: H₂ flows from right to left whereas air from left to right in Figure 2.

To further illustrate its capability, the present PEM fuel cell model was employed to simulate the performance of a PEM fuel cell having a zigzag and trapezoid-cross-sectional flow field. Similar flow field design has already been adopted in practice [4]. Figure 3a shows the computed temperature contours. Figures 3b and 3c display the contours of H₂ and O₂ concentrations at the mid-plane of the anode and cathode catalyst layer, respectively. Though not shown due to space limitation, water content and current density distribution at the mid-plane of the membrane were also computed. In computed results shown in Figure 3, the cell was taken to operate at 200 kPa, 80°C, 1.0A/cm², 81% RH, 1.4 anode stoichiometry and 1.8 cathode stoichiometry. The simulated unit cell has an active area of 1.573 cm². The gas channels have a trapezoid cross-sectional area of 0.285 mm². The zigzag unit length and amplitude are 50 mm and 1.0 mm, respectively.

In addition to developing a baseline PEM fuel cell model, we've also implemented a sub-model of the MPL in order to investigate its effect on cell performance, particularly on water transport. It is known in industrial practices that MPL results in effective water management and improved cell performance. The present MPL sub-model is formulated based on the continuity of capillary pressure and water flux at the catalyst-layer (CL)/MPL and MPL/GDL interfaces. This allows the use of different realistic material parameters for different layers, thus automatically enabling the PEM fuel cell model to handle water transport across different porous layers. Figure 4 shows computed liquid-water saturation profile across the CL-MPL-GDL regions from a case study. Also plotted is liquid saturation for the case when MPL is absent. Clearly from Figure 4, MPL effectively reduces water saturation in the cathode MPL-GDL regions. It should be noted that in the present work, the MPL submodel was implemented in the cathode side only.

**Summary and Conclusions**

- A single-phase, 3-D, single-cell model for simulating PEM fuel cell performance was developed and the milestone of developing a 3-D, partially two-phase, single-cell PEM fuel cell model is expected to be met by the end of this FY.
- The present PEM fuel cell model was coupled with DAKOTA and this coupled computational

![FIGURE 2. Computed 3-D contours: a) temperature; b) H₂ concentration contours in anode channel, GDL and catalyst layer; and c) O₂ concentration contours in cathode channel, GDL and catalyst layer.](image)

![FIGURE 3. Computed contours of a PEM fuel cell with zigzag flowfield: a) temperature; b) H₂ concentration contours in anode catalyst layer; and c) O₂ concentration contours in cathode catalyst layer.](image)
capability will be useful in PEM fuel cell design and optimization.

- A MPL sub-model was implemented for the cathode side and results computed from a case study indicates that MPL effectively reduces water saturation in the cathode MPL-GDL regions.
- The present model was capable of simulating performance of a PEM fuel cell with complex zigzag flowfield having trapezoid cross-section.

**Future Directions**

- Complete development of a 3-D, partially two-phase, single-cell PEM fuel cell model.
- Complete measurements of model-input parameters and model-validation data in the single-phase operating regime; perform measurements in the partially two-phase operating regime.
- Perform validation of the 3-D, partially two-phase, single-cell PEM fuel cell model.
- Develop a 3-D, fully two-phase, single-cell PEM fuel cell model.
- Develop a sub-model for specifying boundary conditions at the GDL/channel interface.
- Couple PEM fuel cell model with DAKOTA for parameter estimation and uncertainty quantification.

• Lawrence Berkeley National Laboratory (LBNL), Berkeley, California
• Pennsylvania State University (PSU), State College, Pennsylvania

Project Start Date: July 1, 2009
Project End Date: September 30, 2012

Objectives

The objective of this project is to optimize the efficiency (electric potential at rated current) of a stack technology that meets DOE cost targets – the specific technical goal is to demonstrate stable and repeatable high performance on a full-format fuel cell stack, namely 7.5 W/mg-Pt. As cost reduction is of central importance in commercialization, the objective of this project addresses all applications.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(B) Cost

(C) Performance

(E) System Thermal and Water Management

Technical Targets

The key deliverable of this project is a performance model validated over a range of stack architectures operating at high power. Validation will be performed using a new, gradient-preserving test fixture that will enable high power density operation. The test campaign will consider: loadings from 0.5 mg/cm² to less than 0.2 mg/cm², current densities from 1.0 to 3.0 A/cm², and two flowfield architectures (land-channel and open). Results from these parametric studies will be used to inform and calibrate an electrode sub-model and a thermo-fluidic transport model. The integrated models will be used to investigate design and process aspects limiting performance. Throughout this project cell element designs will be refined and operating protocols will be adjusted accordingly. The operating map of the most promising architecture will be optimized in full-format testing. As mentioned earlier the experimental target consists of running a fuel cell stack at 7.5 W/mgPt and achieving a performance greater than 0.6 V at a power density greater than 1 W/cm².

Accomplishments

• System and cost analyses were conducted in collaboration with external partners. Data collected confirmed the value of studying high power density operation and increasing efficiency.

• Results collected on existing single cell hardware confirmed the need for an optimized fixture for this project.

• Initial tests on full active area hardware (Andromeda™) demonstrated 2.2 W/mgPt using a membrane electrode assembly (MEA) with 0.3 mgPt/cm² loading.

• A roadmap was defined by JM to describe the necessary steps of material development that are needed to achieve the goal of the project.

• A fuel cell performance model was built by PSU to represent both the channel/land and the open flowfield architectures.

Introduction

Hydrogen fuel cells are recognized as one of the most viable solutions for mobility in the 21st century, however there are technical challenges that must be addressed before the technology can become available for mass production. One of the most demanding aspects is the cost of present-day fuel cells which are prohibitively high for the majority of envisioned markets. The fuel cell community recognizes two major drivers to effective cost reduction: (1) decreasing the noble metal content, and (2) increasing the power density in order to reduce the number of cells needed to achieve a specified power level. Nuvera’s technology exhibits great promise for increasing power density on account of its proven ability to operate stably at high current densities (>1.5 A/cm²). However doing so compromises efficiency because it entails an increase of heat rejection duty and is thus more demanding on the cooling system. These competing aspects are being assessed in order to identify the proper trade-off, and ensure the modeling and experimental activities of the AURORA Program with respect to system-level constraints for automotive applications.

Approach

Nuvera structured the activities in the scope of the project to orbit around a focal point consisting of the fuel cell predictive model. Cost and system analyses are being performed in order to define the boundaries of the design space that the model should represent. This analytical work will inform the experimental tests on a new single-cell fixture to illuminate the physics and the parameters composing the backbone of the fuel cell model. The predictions generated by the model will drive both the process of optimization of the fuel cell operating conditions and the material development. The combined results of these two activities will be verified on single-cell fixtures as well as on full active area hardware, and the experimental data obtained will be used to validate and calibrate the model through multiple iterations.

Results

In Fiscal Year (FY) 2010 Nuvera worked with Directed Technologies, Inc. (DTI) to understand the impact of high power density on stack cost. The analysis was performed while minimizing the discrepancies between the most promising technical solutions identified respectively by DTI and Nuvera. This allowed for full leverage of DTI assumptions and experience in the cost analysis field. The results of this activity are shown in Figure 1 where the stack efficiency is benchmarked against the stack cost for different fuel cells characterized by increased level of performances. The advantage of high power density is clear. Depending on the achievable performance and the acceptable efficiency, this advantage translates into saving between $300 and $840/vehicle (with respect to DTI case). On the other hand Nuvera used a detailed vehicle model to predict heat rejection and radiator size for a spectrum of driving conditions and car types. This analysis showed the heat management is particularly challenging for large-size fuel cells vehicles (like sport utility vehicles) at any power density while it becomes a milder issue for small to medium-size cars.

PSU ran preliminary tests on existing single-cell fixtures consisting of a parallel channel/land flowfield with an active area of 14.6 cm² and 25 cm². In both cases, the polarization curves collected show the inability of the hardware to reach very high current densities. As shown in Figure 2, the mass transfer limitation for the 14.6 cm² cell becomes evident beyond 1 A/cm². In order to explore a broader range of current densities, Nuvera will provide PSU with a new fixture, that is equipped with Nuvera’s open flowfield and enables such characterization. A prototype of the fixture is represented in Figure 2.

Nuvera and JM performed a first test on a full active area, and 8-cell Andromeda stack with low loading MEAs (0.3 mgPt/cm²). This test represented the first attempt at running with Pt content below 0.5 mgPt/cm² and neither the stack architecture nor the materials used were optimized for the purpose. The performance recorded was quite low (0.33 V @ 2 A/cm²) but it was stable at all the current densities and the stack was capable of reaching 2.2 W/mgPt that is far from meeting the target but confirmed the feasibility of operating low loading materials at high current densities.

Based on the targets for this project JM crafted a roadmap to delineate the actions needed to achieve the project performance goals. This roadmap will be refined as more information becomes available through the model predictions, but for the time being it is
articulated into two major areas of research: (1) JM will develop a membrane optimized in terms of thickness and equivalent weight (to help lower the resistivity of the membrane and accordingly boost the performance in the ohmic region), and (2) JM will tune the catalyst layer to perform with a Pt loading approaching 0.2 mgPt/cm². Tuning will involve several steps including reducing Pt content of the existing catalyst structures, developing new catalyst structure that will enable lower loading, and using a gradient of Pt over the layer surface to optimize the local use.

PSU and Nuvera selected a model approach suitable to represent both channel/land and open flowfield stack architectures. In order to minimize the computational effort a two-dimensional (2-D)+1 geometry was preferred to a three-dimensional (3-D) one. The fuel cell is ideally divided in N control volumes in the Y direction (see Figure 3). The Y direction parameters (such as temperature, pressure, etc.) do not vary inside the control volume therefore each volume can be treated as a surface that can be represented by a 2-D model. This model is built with a fine mesh that is capable of properly capturing the phenomena in the XZ plane for the specific control volume. However, species concentrations and temperature are allowed to vary in Y direction along different control volumes (based on the equations describing mass conservation and heat transfer). Therefore each 2-D model simulating the corresponding control volume (or better surface) is inferred by the respective discrete variations along Y and is then solved for in the XZ plane.

PSU started the construction of the model (“Aurora model”) developing the convergence algorithm, implementing the equations that describe the variations.
in the Y direction, and using their pre-existing 2-D model (“PSU model”) as a first representation of the XZ plane. The Aurora model was adjusted to simulate Nuvera’s open flowfield and the predictions generated were compared to those corresponding with the Nuvera internal model. This benchmark offered a first level of confidence in the approach and it will also be pursued in the next phase of development when PSU integrates the LBNL membrane and catalyst sub-models into the Aurora model.

Conclusions and Future Directions

Nuvera will deliver the new single-cell fixture to PSU in order to start exploring the design space and to provide feedback to the model predictions. At the same time Nuvera will use the fixture internally to test new components with specific focus to high current density operation.

JM will pursue their material development roadmap and in 2010 the first generation of low-resistivity, low-Pt loading MEAs (0.2 mgPt/cm²) will be available for testing in both single-cell fixtures and full active area hardware.

LBNL will build the first version of the membrane and electrode sub-model while incorporating parameters to be provided by JM. The sub-model will then be embedded into the Aurora model and the predictions will be verified and tuned through the comparison of the Nuvera internal model and the experimental results collected.

• University of South Carolina, Columbia, SC

Project Start Date:  October 5, 2009
Project End Date:  October 4, 2012

Objectives

- Design of fuel cell components targeting specific transport properties:
  - Synthesis of block copolymers.
  - Design of flow fields and gas diffusion layers (GDLs).
- Determination of bulk membrane properties:
  - Water uptake and diffusivity.
  - Gas permeability.
  - Electro-osmotic drag.
- Transient, 3-dimensional modeling of fuel cell operation

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

Objectives

- (C) Performance
- (D) Water Transport within the Stack
- (E) System Thermal and Water Management
- (G) Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets

The goals of this project are not to reach specific technical targets put forth by the DOE (i.e., target catalyst loading, target cost per kilowatt). Instead, this project aims to develop fuel cell components (i.e., membranes, GDLs, bipolar plates and flow fields) that possess specific properties (i.e., water transport and conductivity). A computational fluid dynamics model will then be developed to elucidate the effect of certain parameters on these specific properties (i.e., the effect of membrane type and thickness on membrane water transport). Ultimately, the model will be used to determine sensitivity of fuel cell performance to component properties to determine limiting components and guide research.

Accomplishments

- Specified first iteration of GDL:
  - 150-190 μm thick.
  - One with no wet-proofing, one with 10 wt% Teflon® – poly-tetrafluoroethylene.
  - Target 77–80% porosity.
- Developed test station to measure diffusion coefficient of water through membrane. Test station measures diffusivity by contacting membrane with water vapor at different percent relative humidity (RH) on each side at nearly identical total pressures (i.e., by controlling ~10% RH difference between both sides of the membrane).
- Developed first iteration of fuel cell flow fields to achieve specific water transport and thermal management targets.
- Designed segmented cell to quantify fuel cell voltage vs. current at different points along the active area. Segmented cell will be used to identify regions of varying water transport and thermal management properties.
- Preliminary development of proton exchange membrane.

Diamonds:
**Introduction**

Many fuel cell component properties that influence water transport and thermal management are not well-understood [1,2]. A better understanding of how water transport and thermal management can be controlled would represent a significant step forward in meeting the DOE's stated 2015 targets. This project aims for a better understanding of water transport and thermal management by tailoring fuel cell components to exhibit specific transport properties. These transport properties will then be modeled, which will enable the prediction of the effect of changing component parameters on transport properties.

**Approach**

This project seeks to develop fuel cell components possessing specific transport properties. Membranes will be developed to achieve certain water transport and conductivity. Bulk membrane properties (i.e., diffusivity, water uptake, conductivity) will be evaluated and modeled. GDLs and bipolar plates and flow fields will be developed, also tailored to achieve specific water transport and thermal management targets. The fuel cell performance will be evaluated using these components. The model will be used to predict the effect of changing component parameters (i.e., changing membrane type and thickness, changing flow field configuration) on component transport properties and fuel cell performance.

**Results**

The first iteration of GDLs has been developed by the University of South Carolina and Engineered Fibers Technology, a subcontractor that has recently been replaced by Ballard Material Products. The GDLs are carbon-paper based and tailored to specific water transport properties. Engineered Fibers Technology is no longer able to supply customer-designed GDL materials; the subcontract has recently been moved to Ballard Material Products who can supply GDL materials possessing properties that are specified.

A test station designed to measure water diffusion in membranes has been developed, the schematic of which is shown in Figure 1. The test station consists of two sets of fuel cell hardware. One set serves as a membrane saturator, while the second set is the diffusion cell. Liquid water is kept on one side of the membrane saturator while the water vapor RH on the other side is controlled by a proportional valve. This is the water vapor in contact with one side of the membrane in the diffusion cell. The other side of the diffusion cell is in contact with water vapor at a lower RH, also controlled by a proportional valve. The flow rate of water through

![Diffusivity Test Station](image1)

**Figure 1. Diffusivity Test Station**

![Preliminary Diffusion Coefficient Data for Nafion® 212 at 80°C](image2)

**Figure 2. Preliminary Diffusion Coefficient Data for Nafion® 212 at 80°C**
the system is measured by a micro-flow meter. The diffusion coefficient is calculated by Fick’s law assuming steady state. Figure 2 presents preliminary data measured.

The first flow field has been designed by the University of South Carolina and will be manufactured by Tech-Etch. A schematic of the design is shown in Figure 3. Virginia Tech has been exploring options to design proton exchange membranes for this project. GES has designed a segmented cell to measure voltage and current density in separate regions of the active area, along with water transport and thermal management properties.

Conclusions and Future Directions

Continued determination of bulk membrane properties will be a main focus of this ongoing project. These properties will be included in future modeling activities.

• Continue to measure diffusivity.
• Develop water uptake/conductivity test station.
• Work with new subcontractor (Ballard Material Products) to design GDLs.
• Develop bipolar plates and flow fields for system design.
• Implement rigorous fuel cell testing protocol.
• Develop computational fluid dynamics model to predict water transport and thermal management.
• Extend model develop components possessing optimal transport properties.

Objectives

The objective of project is to advance reversible solid oxide fuel cell (RSOFC) technology in the areas of endurance and performance.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells and Production sections of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan [1]:

Fuel Cells

(A) Durability
(B) Cost
(C) Performance

Production

(G) Capital cost
(H) System efficiency
(I) Grid Electricity Emissions (for distributed)
(J) Renewable Electricity Generation Integration (for central)

Technical Targets

The project objectives are to meet the following performance and endurance targets in a kW-class RSOFC stack demonstration:

- RSOFC dual mode operation of 1,500 hours with more than 10 solid oxide fuel cell (SOFC)/solid oxide electrolysis cell (SOEC) transitions.
- Operating current density of more than 300 mA/cm² in both SOFC and SOEC modes.
- Overall decay rate of less than 4% per 1,000 hours of operation.

Meeting these performance and endurance technical targets will be key RSOFC technology development steps towards meeting DOE’s Technical Targets for Distributed Water Electrolysis Hydrogen Production by an RSOFC system.

Accomplishments

- Developed several candidate cell material systems meeting both performance (area specific resistance [ASR] less than 0.3 Ω-cm²) and endurance (degradation rate less than 4% per 1,000 hours) targets in both fuel cell and electrolysis modes.
- Validated cell material systems through long-term (1,000+ hours) tests, with two tests exceeding 8,400 and 6,400 hours exhibiting degradation rates under 3% per 1,000 hours.
- Conducted several RSOFC stack development tests in both SOFC and SOEC modes with SOEC/SOFC transients.

Introduction

RSOFCs are energy conversion devices. They are capable of operating in both power generation mode (SOFC) and electrolysis modes (SOEC). RSOFCs can integrate renewable production of electricity and hydrogen when power generation and steam electrolysis are coupled in a system, which can turn intermittent solar and wind energy into “firm power”. In order to address the technical and cost barriers, DOE funded a number of research projects over the past 10 years [2]. Although significant progress was made in those projects, further development is required especially in the areas of RSOFC performance and endurance. In this project, Versa Power Systems (VPS) is addressing performance and endurance issues for RSOFC cells and stacks.
Approach

VPS has identified four task areas in an effort to improve the performance and endurance of RSOFC systems: degradation mechanism study, cell material development, interconnect material development, and stack design and demonstration. In order to mitigate project risk, a stage-gate project management process is employed with a quantitative Go/No-Go decision point. The scope of the work has been carried out by:

- Building on VPS’ strong SOFC cell and stack baseline and leveraging cell and stack advancements from the DOE Solid State Energy Conversion Alliance (SECA) project.
- Carrying out parallel materials development activities and integrating them with cell production technology development.
- Conducting RSOFC stack and process designs to address durability, performance, and cost in both fuel cell and electrolysis operating modes.

Results

The development path for RSOFC cell material systems thus far can be summarized in Figure 1. Prior to the current project, three cell types—EC-1, EC-2, and EC-3—were developed based on VPS’ baseline TSC-2 cell. In the project, four RSOFC cell types were developed from the base of EC-1 and EC-2 cells. Most recently, two additional cell types—MAC-RSOFC-1 and MAC-RSOFC-5—were developed and tested. In total, 10 materials systems have now been evaluated for performance in SOFC and SOEC modes, some of which have already run for significant time periods under steady-state electrolysis conditions. Table 1 summarizes cell material systems’ ASR under both electrolysis and fuel cell conditions. It shows that several of these materials systems are now capable of meeting the ASR targets at 750°C.

Another key target is to achieve degradation rates under 4% per 1,000 hours of operation at more than 300 mA/cm² current density. Table 2 shows degradation rates in electrolysis mode at fixed operating conditions (750°C, 0.5 A/cm² and 50% steam utilization) in both mV and percent per 1,000 hours (percentages were calculated using a fixed voltage of 1.25 V). Figure 2 shows the steady-state operation of RSOFC-1 cell system in SOEC mode at 750°C and 0.5 A/cm². The degradation rate is about 2.7% per 1,000 hours for over 6,400 hours.

Interconnect material development has focused on testing in high steam and pure oxygen environments. Six different steel alloys (450, 434LN2, Sanergy, ZMG252, ZMG232L, and Haynes 230) have been tested in a high steam environment while three (434LN2, Sanergy, and Haynes 230) have undergone pure oxygen testing (one still in progress). 434LN2 had the best oxidation

behavior (least amount of weight gain) in a high steam environment. The pure oxygen testing was performed in a thermo-gravimetric analyzer at 800°C for over 800 hours while monitoring each test coupon’s weight gain. Thorough analyses of the surface oxide and oxide thickness in cross section were carried out by scanning electron microscope. The chemical compositions of the oxides were determined by energy dispersive spectroscopy and X-ray diffraction. The final alloy selection will be made for stack development once all tests and analyses are complete.

VPS has developed electrochemical modeling code that integrates with Fluent to allow fully coupled electrochemical, thermal, and flow modeling of an operating solid oxide stack. This tool is used extensively in stack design and operating condition selection. Figure 3 shows the temperature distribution across the cells in a 28-cell stack with 121 cm² active area cells (1.4 kW SOEC stack). Modeling results indicate that the total temperature range across all cells is 9°C, representing an almost ideal thermal environment for the operating stack in SOEC mode.

A preliminary stack test protocol was proposed and evaluated in a short stack test. A six-cell stack was built and tested to the protocol. As shown in Figure 4, it had completed 10 fuel cell-to-electrolysis cycles and a steady-state hold in SOEC mode. The electrochemical performance and degradation of the cells in stack are comparable to that of single cell test. Some degradation was observed over the 10 reversible cycles. In addition,
RSOFC-1 cells have been incorporated into two stack tests. Both tests focus on steady-state electrolysis at the six-cell (250 W) and 28-cell (1.4 kW) levels. These tests incorporated advances in contact design that had been developed by VPS under the DOE SECA program 550 cm² active area cells [3]. Some adjustment was made to fit the smaller 121 cm² cells used in this testing, and the results are promising. These advances will be rolled into future stack tests.

Conclusions and Future Directions

In the coming year, the project team will continue on the current development path. This includes:

- Testing of different conditions (temperature, current density, and utilization) for the chosen cell materials and reversible cyclic testing of cells in short stacks.
- Concluding the degradation mechanism study.
- Selecting final alloys following the completion of all tests.
- Continuing RSOFC stack development and testing.

**Objectives**

- Develop new anion exchange polymer electrolytes that have high hydroxyl conductivity and stability under alkaline conditions.
- Demonstrate an improved single-cell performance of solid-state alkaline fuel cells using the polymer electrolytes and non-precious metal catalysts.

**Technical Barriers**

(A) Durability: stability of fuel cells under highly basic conditions is not well understood. Strategies for mitigating performance loss over time are needed.

(B) Cost: material costs for platinum-based catalysts and membranes are the major barriers for fuel cell commercialization.

(C) Performance: anode and cathode performance depends on electrode structure and interactions between electrode materials.

**Technical Targets**

This project is conducting fundamental aspects of solid state alkaline fuel cells for practical use in transport applications. Insights gained from these studies will be applied toward next stage of development of alkaline fuel cell systems. Since there were no technical targets for solid state alkaline fuel cells provided by the current U.S. DOE Fuel Cell Technologies Program, we propose technical targets based on state-of-the-art alkaline fuel cells/materials in the original proposal. Key technical targets and current status are shown in Table 1.

Accomplishments

- Discovered that traditional aqueous quaternization produces incomplete amination due to undesirable alcohol formation while non-aqueous quaternization provides precise control of amination without forming alcohol.
- Prepared hydrocarbon-based guanidine base (HCGB) homopolymer which has extremely low water uptake (9%) with reasonable anion conductivity (35 mS/cm at 80°C) and stability (ca. 380 h in 0.5 M NaOH at 80°C).
- Prepared perfluorinated guanidine base (PFGB) polymer electrolyte. The anion conductivity of this material met the 2011 conductivity target (80 mS/cm at 80°C) but showed limited stability.
- Identified the degradation mechanism for PFGB polymer electrolytes and discovered that the electrolyte stability can be significantly improved by having an electron donating group next to the cation functional group.
- Prepared nano-structured whiskers for electrode supporting materials. This material will be used as a high surface area support for alkaline fuel cell electrodes.

**Introduction**

Recently, renewed interest has grown in the development of solid-state alkaline fuel cells, since the efficiency of oxygen reduction reaction of electro-catalysts in an alkaline environment is likely greater than...
in acidic conditions and therefore, expensive platinum-based catalysts can be replaced with inexpensive ones such as nickel, silver and carbon [1,2]. However, current quaternary ammonium-tethered anion exchange polymer electrolytes do not show enough stability under alkaline conditions due to the nucleophilic substitution reaction under highly basic conditions [3]. Furthermore, ionomer used in electrode layers have limited gas permeability that significantly reduces cell performance.

**Approach**

Our approach to achieve stable anion exchange polymer electrolytes is to use highly basic cation functional groups instead of traditional tetra-methyl ammonium group. Tetramethyl guanidine (TMG) has high basicity (i.e. pKa=13.6) and formed resonance structure which contributes further stabilization of cation through uniform electron distribution. In order to maximize the fuel cell performance, anion exchange membranes and ionomeric binders should be designed in a separate manner, as the requirements for each role are somewhat different. Another key approach is to prepare perfluorinated ionomer for electrode binding material that has significantly higher gas permeability. An alternative approach is to prepare nano-structured thin film electrodes which do not need an ionomeric binder which minimizes the limited gas permeability problem.

**Results**

One of the technical barriers for anion exchange polymer electrolytes is poor synthetic control of cationic functional groups [4]. We found that when quaternization was accomplished by soaking halogenated polymer electrolytes in aqueous trialkylamine, hydroxide ions can act as nucleophiles and compete with alkyl amines to produce primary alcohols in addition to alkylammonium salts. Once alcohols are formed in polymer chains, the ion exchange capacity of the polymer is reduced, and water sorption is increased which dilutes the concentration of cation functional groups and gives a significant impact on ion conductivity and water uptake. Figure 1 compares the water uptake and ion conductivity of aqueous quaternized and non-aqueous quaternized anion exchange polymer electrolytes. It is noted that much higher water uptake and lower proton conductivity was achieved with aqueous quaternized anion exchange polymer electrolytes. Non-aqueous quaternization improves hydroxyl conductivity significantly which is an encouraging result and the non-aqueous quaternization technique was used for our research.

Typically quaternary ammonium-tethered polymers are prepared from chloromethylated (or alkyl brominated) polymers and subsequent reaction with a tertiary amine to form the quaternary ammonium groups [5]. The amination step is typically performed by soaking a film of the halomethylated polymer in a solution of trimethylamine (TMA) such that the polymer remains in the solid state throughout the reaction (the heterogeneous method). Alternatively the amination can be done with the halomethylated polymer dissolved in a polar aprotic solvent such as N,N-dimethylacetamide (the homogeneous method). The heterogeneous method is somewhat simpler to perform in practice although it was our hypothesis that membranes prepared this way should have lower conductivities than their homogeneously-formed analogs due to lack of phase separation. Since the heterogeneous method involves casting films before the polymer has any attached ionic groups, the placement of those ionic groups should be random throughout the polymer matrix. By contrast,
in the homogeneous method the polymer is cast in its ionomeric form and the highly polar ammonium groups would have a chance to form highly-conductive microdomains within the membrane. We prepared anion exchange membranes from a halomethylated poly(phenylene) using both methods and were surprised to find that the membrane properties (particularly conductivity) were nearly independent from the amination method used. The presence or absence of water with the TMA (as discussed above) had a much greater impact on the membrane properties than the amination method did.

When tetramethyl guanidine is used instead of TMA, two vicinal chloromethyl groups can react to form hexamethylated guanidinium-containing polymers. Since two chloromethyl groups are involved in the reaction, the reaction ends up with gelation. In order to prevent the possible gelation, we synthesized guanidine functionalized polymers with TMG-fluorine reaction without the chloromethylation process. HCGB polymers were synthesized by reacting tetramethyl guanidine with polyarylene ether sulfone containing pendant 4-fluorophenyl sulfide groups and followed by methylation (Figure 2). PFGB polymers were prepared from perfluorosulfonic acid precursor using similar fluorine-TMG reaction. Fourier transform infrared (FTIR) analysis showed that after the methylation reaction, the C=N form of tetramethyl guanidine was changed to a resonance hybridization structure CN$_3$ form.

Anionic conductivity of OH$^-$ and CO$_3^{2-}$ form of HCGB and PFGB polymers was measured by an impedance analyzer. CO$_3^{2-}$ conductivity of both polymer electrolytes is about half of OH$^-$ conductivity. HCGB and PFGB anion exchange polymer electrolytes exhibited excellent hydroxyl conductivity in the range of 0.01-0.08 S/cm, depending on molecular structure and temperature. The conductivity of PFGB (0.08 S/cm) exceeded our target conductivity (0.05 S/cm) at 80°C. Figure 3 compares conductivity of various anion exchange polymer electrolytes as a function of water uptake. Water uptake of guanidine base polymers is extremely small compared to previously developed anion exchange membranes so effective anion conduction can be achieved at relatively low water uptake [6,7]. The stability was evaluated by immersion of the membrane into 0.5 M NaOH solution at 80°C. While HCGB showed reasonably high stability (~40% conductivity decrease for over 380 h), PFGB showed rapid degradation. Based on FTIR and solid state nuclear magnetic resonance data, nucleophilic attack to the center carbon molecule of the guanidine base was proposed as a main degradation mechanism as shown in Figure 4. The degradation via nucleophilic substitution produced two neutral species to lower ion exchange capacity and conductivity. Significantly different degradation rates between HCGB and PFGB suggested that electron-withdrawing and donating characteristics

![FIGURE 2. Synthesis of HCGB Base Polymer.](image-url)

![FIGURE 3. Hydroxyl conductivity of anion exchange polymer electrolytes as a function of water uptake.](image-url)
of the cation adjacent group is critically important and affects the nucleophilicity of the central carbon. We have therefore proposed to modify the polymer structure in order to mitigate cation degradation to achieve our stability target, which is our ongoing study.

Conclusions and Future Directions

- New highly conductive guanidine-based anion exchange polymer electrolytes were prepared using non-aqueous quaternization.
- Conductivity of anion exchange polymer electrolytes met or exceeded our internal target.
- Stability of anion exchange polymer electrolytes is strongly influenced by electron density of the adjacent cation group. Currently we are changing polymer structures to improve cation stability.
- We are planning to synthesize binary and ternary late-transition-metal (LTM) alloys based on Ni, Co, and Fe; and these LTM elements alloyed with the valve metals (Ti, Zr), in order to determine their performance for use as electrode materials in alkaline electrolytes.
- We are planning to fabricate a membrane electrode assembly for fuel cell performance evaluation as component materials are prepared.

Start Date:  September 2009
Project End Date:  2012

Objectives

- Develop a ceramic alternative to carbon material supports for a polymer electrolyte fuel cell cathode.
- Ceramic support replacement for carbon must:
  - Have enhanced resistance to corrosion and Pt coalescence.
  - Preserve positive attributes of carbon such as cost, surface area, and conductivity.
  - Be compatible with present membrane electrode assembly (MEA) architecture and preparation methods.
- Ceramic properties goals:
  - High surface area
  - High Pt utilization
  - Enhanced Pt-support interaction
  - Adequate electronic conductivity
  - Corrosion resistance
  - Synthetic methods amenable to scale-up
  - Reasonable synthesis costs

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability: Pt sintering, corrosion loss, effects from load-cycling and high potential.
(B) Cost: Better Pt utilization balanced by cost difference of new support vs. carbon.
(C) Performance: Pt sintering, corrosion loss, and loss of electroactive surface area.

Technical Targets

- Precious metal loading (0.2 mg/cm²)
- Cost (<$3/kW)
- Activity (0.44 A/mg Pt @ 0.9 V_{th,voc})
- Electrocatalysis support loss (<30 mV after 100 hrs @ 1.2 V)
- Electrochemical surface area loss (<40%)

Accomplishments

Synthesis of Non-Carbon Support Materials

- Ceramic materials with critical physical/chemical requirements for polymer electrolyte membrane fuel cell (PEMFC) catalyst support applications have been prepared.
- Utilized polymer-assisted deposition process to prepare conductive, cubic phase Mo₂N with surface area ca. 500 m²/g.
- Transmission electron microscope (TEM) analysis confirms highly crystalline structures less than 2 nm with carbonaceous material forming agglomerates.
- Prepared Pt/Mo₂N catalysts with Pt dispersed with an average Pt crystallite size as small as 36 Å.
- Synthesized black, conductive sub-stoichiometric titanium oxides (TiO₂-x, TiO) with surface areas up to 250 m²/g.
  - Oxygen deficient titanium oxide phases (TiO) exhibit average crystallite sizes as small as 40 Å.
- Accelerate Go/No-Go decision point for rare earth hexaboride materials.

Testing, Characterization and Evaluation

- Mo-N ceramics are electronically conductive and are stable in acid media (0.5M H₂SO₄).
- Performed initial cyclic voltammetry (CV) characterization using glassy carbon disk electrode showing Pt/C-like activity for both hydrogen redox and oxygen reduction reaction (ORR).
- ORNL TEM analysis of first samples of Mo₂N confirming small particle sizes.
Theory and Computation

- Completed density functional theory (DFT) calculations to optimize the structures of bulk molybdenum nitride polymorphs (α-MoN, β-MoN, γ-MoN). Experimental crystal structures are reproduced to within 3% confirming validity of approach.
- Started studies of platinum adhesion on selected molybdenum oxides surfaces. Platinum shown to be most stable in three-fold site of (001) surface of α-MoN.

Introduction

Catalyst support durability is currently a technical barrier for commercialization of PEMFCs, especially for transportation applications. Degradation and corrosion of the conventional carbon supports leads to losses in active catalyst surface area and, consequently, reduced performance. As a result, the major aim of this work is to develop support materials that interact strongly with Pt, yet sustain bulk-like catalytic activities with very highly dispersed particles. This latter aspect is key to attaining the 2015 DOE technical targets for platinum group metal (PGM) loadings (0.20 mg/cm²).

The benefits of the use of carbon-supported catalysts to drastically reduce Pt loadings from the early, conventional Pt-black technology [1–4] are well known. The supported platinum catalyzed membrane approach widely used today for fabrication of MEAs was developed shortly thereafter these early reports [5–7]. Of direct relevance to this present work, are the investigations into Pt particle growth in PEMFCs [8], and subsequent follow-on work showing evidence of Pt particles suspended free of the support within the catalyst layer [9]. Further, durability work has demonstrated the detrimental effects of potential cycling on carbon corrosion [10–14] and the link between electrochemical surface area and particle growth [15].

To avoid the issues with carbon degradation altogether, it has been proposed by numerous fuel cell research groups to replace carbon supports with conductive materials that are ceramic in nature [16, 17, and references therein]. Intrinsically, these many conductive oxides, carbides, and nitrides possess the prerequisite electronic conductivity required, and offer corrosion resistance in PEMFC environments; however, most reports indicate that obtaining sufficient surface area remains a significant barrier to obtaining desirable fuel cell performance. Ceramic materials that exhibit high electrical conductivity and necessary stability under fuel cell conditions must also exhibit high surface area as a necessary adjunct to obtaining high Pt dispersions and Pt utilization targets. Our goal in this work is to identify new synthesis approaches together with materials that will lead to ceramic supports with high surface areas and high Pt dispersions. Several strong candidates for use as PEMFC catalyst supports include: transition metal nitrides and sub-stoichiometric titanium oxides, which hitherto now have been prepared by other researcher groups with relatively low surface areas (ca. 1–50 m²/g typical [16–19]).

To achieve our goals of engineering high surface area, conductive ceramic support for utilization in PEMFCs, a multi-institutional and multi-disciplinary team with experience synthesizing and investigating these materials has been assembled. This team is headed by LANL and includes ORNL and the UNM. This report describes our Fiscal Year (FY) 2010 technical progress related to applying advanced synthetic methods towards the development of new ceramic supports for Pt catalysts for PEMFCs.

Approach

Our approach to preparing ceramic powders with prerequisite properties for use as a PEMFC Pt catalyst support is centered on the application of several novel materials synthesis methods. Initially, in this first year of work, the methods were conducted in parallel to insure the best possible results that ceramic support materials would be available with desirable physical characteristics for platinum disposition and subsequent electrochemical characterization for oxygen reduction activity. The first synthesis method used in this work is the aerosol through plasma (A-T-P) process. In this method, largely developed at LANL, a gas or liquid aerosol containing precursor species is passed through the hot zone (T >3,500 K) of plasma (virtually any gas including Ar, oxygen, nitrogen, air) with a residence time on the order of 0.1 second. The particles, modified by the plasma, then enter a zone of rapid cooling (10⁵ K/s or more) where nucleation and growth of new structures generally takes place. A particularly relevant example of the capability of the process was the production of supported metal particles. We are also employing a new materials synthesis process called polymer assisted deposition (PAD) that was developed at LANL. This is a solution method for the formation of materials ranging from oxides to nitrides and oxynitrides. In general we have employed this methodology to prepare conformal epitaxial films of metal oxides and nitrides. However, high surface area powder materials can also be obtained using an accelerated heating rate to generate low density, foam-like structures. The UNM component of the collaborative research project will focus on developing synthesis methods for high surface area, oxygen-reduction catalysts supported on conductive metal oxides. Their goal will be develop a new approach...
for Pt/NbO$_x$ electrocatalysts synthesis based on sol-gel synthesis of mesoporous niobia.

Computational methods will be used to complement the experimental effort. Although these techniques provide insight into fundamental processes occurring at the atomic level, our work will focus primarily in two areas, that of aiding the characterization and understanding of experimental data and providing additional direction to the experimental team in the preparation of new support materials with optimized properties. The theory and modeling work will focus on several areas of importance to the development and optimization of new electrode support materials. Initially, computational studies have been carried out to understand the structure and stability of the support materials in the absence of platinum particles. Following this, the parameters may then be used to study the nature of the platinum binding sites on the support and the platinum adhesion energy, the mobility of platinum on the support and the interplay between the electronic structure of the support and the platinum particle, which is reflected in the calculated density of states. Comparison of these values with bulk platinum can be used as a predictive tool for the optimization of the material.

Results

Alternative Support Materials

The use of the PAD process has immediately been successful at producing conductive ceramic materials with high surface areas. A milestone for this task has been accelerated such that the Go/No-Go decision in Q8 may be brought forward to early FY 2011. High surface area, conductive foams were successfully synthesized for molybdenum as Mo$_2$N. The materials have been accelerated such that the Go/No-Go decision in Q8 may be brought forward to early FY 2011. High surface area, conductive foams were successfully synthesized for molybdenum as Mo$_2$N. The materials have been accelerated such that the Go/No-Go decision in Q8 may be brought forward to early FY 2011.

A special insulated fixture of fixed volume has been fabricated and will be used in the near future to quantify the two-point resistance of ceramic supports in powder form under uniform compaction.

Figure 1 shows the X-ray diffraction (XRD) pattern obtained for Mo$_2$N sample final anneal temperature of 950°C in 6%H$_2$/Ar. The data have been fit to a cubic crystal structure (indices indicated) with a lattice parameter calculated to be 4.268 Å. Full profile fitting of the diffraction data indicates an average crystallite size of 1.6 nm. The Brunauer-Emmett-Teller (BET) surface area for this sample was approximately 500 m$^2$/g. This is an exceptionally high surface area for a transition metal nitride powder. TEM analysis performed by ORNL also indicate highly crystalline structures on the order of 2 nm with 0.2 to 2 μm agglomerates comprised of carbonaceous material holding together the smaller crystallites. Samples prepared using the PAD process typically show broad, amorphous diffraction characteristics ca. 26° two-theta and this would be explained by the presence of carbon. The exact weight percentage of carbon in these samples is presently being determined. Also to be determined is whether the residual carbon is only present in between Mo$_2$N particles or whether it is in solution with the moly-nitride. Mo$_2$N samples have also been prepared at 700°C with slightly higher surface area and a smaller average crystallite size on the order of 1 nm. A glassy carbon electrode (0.5 cm dia.) was prepared using a 1 mg/ml suspension of the as-synthesized Mo$_2$N (both 700 and 950°C preparation temperatures) after grinding the sample in an alumina mortar with isopropyl alcohol. Initial CV characterization (in 0.5 M H$_2$SO$_4$) showed no Faradic activity when the voltage was swept at a sweep rate of 100 mV/s from 0 to 1.2 V using a hydrogen electrode with 6% H$_2$ forming gas. The rotating disk electrode experiment (0.5 M H$_2$SO$_4$ saturated with O$_2$) did not show any oxygen reduction activity.

Figure 2 is the XRD pattern obtained after Pt disposition (20 wt%) onto the 700°C-prepared Mo$_2$N using incipient wetness approach and hexachloroplatinic acid post reduction. The Mo$_2$N sample prepared at 950°C was treated to a similar Pt disposition with the same loading with similar XRD but with slightly larger average Pt crystallite sizes. The dried samples were placed into a tube furnace and annealed at 70°C for 12 hours to reduce the platinum salt. Full profile analysis of these data indicates an average Pt crystallite size of 36 Å. Two new suspensions were prepared using the Pt/Mo$_2$N catalysts. The catalyst samples were applied to two glassy carbon electrodes (0.5 cm dia.) at
two different Pt loadings: 30.6 μg Pt/cm² for the sample prepared with the 950°C annealed Mo₂N and 20.4 μg Pt/cm² for the sample prepared with the 700°C annealed Mo₂N sample.

Figure 3 (a-top) shows the CVs of these catalyst samples. In both experiments, the conditions were identical: 0.5 M H₂SO₄ saturated with Ar with voltage scanned at a rate of 100 mV/S for 8 cycles each. The CVs shows hydrogen activity similar to Pt/XC-72 carbon with an apparent reversible oxidation peak at 0.45 V and reduction peak at 0.4 V. It is interesting that both CVs show similar activity despite different Pt loadings. This would tend to suggest that more work must be done to better optimize and utilize the Pt. Although the nature of the redox couple at potentials beyond the features well known to hydrogen redox reactions have not been explained, integration of the area under the anodic peak (up to 0.6 V) yields an electrochemical active surface area (EASA) values of 9.8 m²/gₚt and 20.8 m²/gₚt for the platinized Mo₂N prepared at 950 and 700°C, respectively. These particular values for EASA serve as a reference mark and an upper bound only. In our near-term future work, we will probe these features and calculate a more accurate EASA for these materials. The Ar was removed from the electrolyte and it was replaced with O₂. The disk electrode was rotated between 400 and 1600 rpm and the CV characterization was performed at a scan rate of 20 mV/s. Figure 3 (b-bottom) shows the results for oxygen reduction activity for the Mo₂N sample prepared at 950°C and at a loading of 30.6 μg Pt/cm². As with the hydrogen CVs, the Mo₂N sample prepared at the lower temperature, 700°C, and at a lower Pt loading, 20.4 μg Pt/cm², again shows comparable ORR current densities.

Sub-Stoichiometric Titanium Oxides

High surface area, conductive foams were successfully synthesized for titanium as both TiO and TiO₂ using a modified PAD process. As with the molybdenum nitride materials, the titanium oxide ceramics are prepared by first creating a water-based solution of the desired metal bound to a PEI polymer and EDTA. The solution is concentrated to a thick gel before being heated in a tube furnace to 950°C under forming gas. During the heating process, the polymer depolymerizes and EDTA decomposes to give gaseous products, which aid in foam formation. In the case of titanium oxide materials, the variation of the flow rate and purge time determine the extent of oxygen reduction. This important control parameter is presently being studied in greater detail and will be greatly expanded upon in future reports. As of preparation of this report, high surface area, black titanium oxide foams have
been prepared using the PAD approach. The black color is highly indicative TiO$_{2-x}$ with 0<\(x\)\leq 1. The two-point resistance of a typical piece of foam (ca. 1 cc in approximate volume) was similar to that of the Mo$_2$N foams; e.g. on the order of 10 ohms. The initial BET surface area measurements performed on the first samples of black titania powders confirm gas accessible surface areas similar to Vulcan XC-72 (e.g. 200–250 m$^2$/g). These surface areas are significantly higher than commercial, conductive Magnéli phase Ti$_2$O$_n$ synthesized through bulk synthesis and reduction (ca. 1-2 m$^2$/g) or even through hydrogen reduction of nano-crystalline anatase or rutile TiO$_2$ powders (ca. 25-50 m$^2$/g) [16,17]. We have started structural characterization of these recently prepared titania supports.

**Rare-Earth Hexaborides**

Lanthanum hexaboride solution was prepared using the PEI polymer and EDTA as a water solution. Preliminary experiments were conducted to create a crystalline mixed phase materials; however, further investigation is required to obtain a pure sample. Initial attempts to use A-T-P process or rare earth hexaborides including cations such as europium, barium, and lanthanum have proven to be unsuccessful at this point. Elemental analysis using XRF indicate the presence of rare earth component in the amorphous powders collected from the plasma torch exhaust however XRD data show the materials are devoid of any apparent long range structure. Subsequent annealing at high temperature (given very slow kinetics at moderate temperatures) initiates crystallization and grain growth but only at temperatures sufficiently high to cause enough grain growth to the extent that original purpose for applying the A-T-P process becomes moot. The remainder of FY 2010 will be used to further adjust and optimize synthesis conditions for this process.

**Computational Studies of Molybdenum Nitride Supports**

Computational studies of ceramic support candidates commenced in FY 2010 to provide theoretical input to experimental work. Periodic density functional calculations were carried out using the VASP software on three bulk molybdenum nitride polymorphs (tetragonal $\beta$-Mo$_2$N, orthorhombic $\delta$-Mo$_2$N, and cubic $\gamma$-Mo$_2$N). These calculations provide a calibration for the quantum chemical method used via a comparison of the experimental and calculated structural parameters. The calculations reproduce the structure data to within 4%, confirming the validity of the computational approach. The simplest surface structure was then selected as a model for the catalyst substrate (001 surface of $\delta$-Mo$_2$N) and a geometry optimization calculation was performed to examine the effects of surface relaxation compared to the bulk structure. Using this structure, the effects of surface adhesion of platinum were investigated. Three platinum binding sites on the MoN surface were considered: the on-top site, a bridging site and a three-fold binding site as shown in Figure 4. The calculated binding energies for each of the sites was found to decrease in the order: three-fold $\gg$ bridging $\gg$ on-top. The binding energy for the three-fold site is calculated to be comparable to that of a single platinum atom on a Pt(111) surface (approximately 550 kJ/mol$^{-1}$). The bulk structures of three Mo-N phases (tetragonal $\beta$, orthorhombic $\delta$, and cubic $\gamma$) were calculated with excellent agreement to literature data. The simplest surface structure ($\delta$-Mo$_2$N) was then selected, a model created, and the relative binding energies for the three possible Pt sites were calculated. The results were obtained using plane wave DFT with VASP software from calculations of the same class used to obtain the parent molybdenum nitride structures.

**Conclusions**

- Synthesis of high surface area ceramic nitride and oxide materials.
  - Mo$_2$N synthesized at 700 and 950°C using polymer-assisted deposition with BET surface area of 500 m$^2$/g.
  - Mo$_2$N samples are electronically conductive.
  - PAD procedure modified to prepare sub-stoichiometric TiO$_{2-x}$ and TiO with BET surface areas exceeding 200 m$^2$/g.
- Pt disposition onto Mo$_2$N support samples produced an active catalyst.
  - Initial CV and rotating disk electrode characterization performed.
  - Pt utilization and optimization required.

*FIGURE 4. Calculated binding sites for Pt on $\delta$-Mo$_2$N (001) surface showing onto p (A), bridging (B) and three-fold (C) sites.*
• TEM analysis confirms average crystallite sizes calculated from full profile fitting of the XRD data (e.g. <2 nm crystallites) and has found evidence of residual carbon remaining from the synthesis process.
• Plane wave DFT and VASP calculations reproduce the crystal structure data to within 4%, confirming the validity of the computational approach and the calculated binding energies for Pt nucleation on the surface of \( \partial \)-phase MoN.

Future Directions

• Finish rare earth hexaboride work – proceed to Go/No-Go decision early in FY 2011.
• Understand the nature and extent of carbon residual in materials prepared via PAD approach. Understand effect on durability and performance of PEMFC catalysts prepared using this approach.
• Better optimize the incipient wetness disposition/ utilization of Pt onto high surface area Mo\(_2\)N materials.
• Continue electrochemical characterization of the Pt/Mo\(_2\)N catalysts – increase number of potential cycles, study and determine the nature of the redox couple at 0.45 V.
• Continue computational studies of platinum thin films on molybdenum nitride surface and use the developed method to investigate titanium oxide phase as supports.
• Begin Pt disposition onto high surface area, sub-stoichiometric titania and perform electrochemical characterization.
• TEM characterize next round of Mo\(_2\)N and Pt/Mo\(_2\)N supports as well as perform initial characterization of sub-stoichiometric titania materials.

Accomplishments

Area I: Heat and Water Management

- Most Conductive Material: 2.5 wt% Akzo Nobel Ketjenblack EC-600 JD carbon black/65 wt% Asbury Carbons Thermocarb TC-300 synthetic graphite particles/6 wt% Hyperion carbon nanotubes/26.5 wt% Dow homopolymer polypropylene H7012-35RN:
  - Electrical conductivity: obtained 91 S/cm (DOE target is 100 S/cm) via compression molding and 38 S/cm via injection molding.
  - In-plane thermal conductivity: obtained 24 W/mK (DOE target is >20 W/mK) via compression molding and 18 W/mK via injection molding.

Area II: Development of New Electrode Materials

- Porous, machinable current collectors and mechanical supports.
- Pyrolysis of peroxyacetyl nitrate (PAN)-based foams in an oxygen-free environment at 1,200°C.
- Positive (cathodic) battery electrodes with a large macropore/mesopore space to hold electrochemically-active material.
- Supercapacitor battery anodes with a large accessible micropore surface area (i.e., >1,000 m²/g) for electric double layer charge storage.
- Carbon supports for fuel cell pseudomorphic overlayer anode catalyst(s) that promote dissociation of diatomic hydrogen into constituent protons and electrons.

Area III: Enabling Technologies for Membrane Synthesis

- Developed apparatus for continuous electrospinning of a single material fiber utilizing polymer solutions of a variety of types.
- Adapted the process to spin continuous fibers that are highly aligned utilizing a rotating electrode system.
- Developed a coaxial needle system to electrospin/electrospray core-shell fiber and particle of hybrid materials.
- Developed a novel pulsed direct current (DC) electrospray apparatus top allow better control over the particle size distribution and particle shell thickness.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:
(A) Durability
(B) Cost
(C) Performance
(D) Water Transport within the Stack
(E) Thermal System and Water Management

Introduction

In 2003, a National Academy of Sciences (NAS) report identified that several of the major stumbling blocks to the advent of practical fuel cells for application to transportation were associated with the lack of appropriate materials for the fuel cell construction. Specifically, they rely too heavily on precious metals, including platinum, to be affordable. The polymer electrolyte membrane, a key part of a fuel cell, needed to function better at high temperatures and better dissipate the main byproduct: water. Finally, virtually everything in the fuel cell needed to be lighter. The core projects for this DOE-sponsored Center at Michigan Tech have focused on several of the materials problems identified by the NAS. These include: new electrode materials, enhanced PEM materials, lighter and more effective bipolar plates, and improvement of the carbon used as a current carrier. Our research into these areas has been approached via seven different tasks.

Approach

This project will involve fundamental and applied research in the development and testing of lightweight and nanostructured materials to be used in fuel cell applications and for chemical synthesis. The advent of new classes of materials engineered at the nanometer level can produce materials that are lightweight and have unique physical and chemical properties. The grant will be used to obtain and improve the equipment infrastructure to support this research, and will also serve to fund seven research projects. These include:

1. Development of lightweight, thermally-conductive bipolar plates for improved thermal management in fuel cells;
2. Exploration of pseudomorphic nanoscale overlayer bimetallic catalysts for fuel cells;
3. Development of hybrid inorganic/organic polymer nanocomposites with improved ionic and electronic properties;
4. Development of oriented polymeric materials for membrane applications;
5. Preparation of a graphitic carbon foam current collectors;
6. The development of lightweight carbon electrodes using graphitic carbon foams for battery and fuel cell applications; and
7. Movement of water in fuel cell electrodes.

Results

Task 1 - Development of Lightweight, Thermally-Conductive Bipolar Plates for Improved Thermal Management in Fuel Cells (King, Keith)

Fundamental and applied research needs to be done to improve the potential for fuel cells to be used in stationary and transportation applications. The goal of this project is to develop lightweight composite materials to be used for bipolar plates within a fuel cell. Bipolar plates require high thermal and electrical conductivity. Dr. King’s research group extruded and molded into test specimens polypropylene (Dow H7012-35RN, a semi-crystalline thermoplastic homopolymer) based composites containing different carbon fillers (Akzo Nobel’s Ketjenblack EC-600 JD carbon black, Asbury Carbon’s Thermocarb TC-500 synthetic graphite particles, and Hyperion Catalysis International’s FIBRIL carbon nanotubes). Composites containing varying amounts of a single filler (maximum of 15 wt% carbon black, 15 wt% carbon nanotubes, and 80 wt% synthetic

FY 2010 Annual Progress Report 979 DOE Hydrogen Program
graphite particles) along with combinations of different fillers were fabricated and tested. Results indicate that the compression molded composite containing 2.5 wt% carbon black, 65 wt% synthetic graphite, and 6 wt% carbon nanotubes in polypropylene have an electrical conductivity of 91 S/cm and a thermal conductivity values of 6.6 W/m² K (through-plane) and 24 W/m² K (in-plane). These values are near the DOE conductivity targets of 100 S/cm and >20 W/m² K. Figure 1 shows a photomicrograph of this material.

**Task 2 - Exploration of Pseudomorphic Nanoscale Overlayer Bimetallic Catalysts for Fuel Cells (Holles)**

The reload synthesis technique has been used to prepare a series of bimetallic overlayer catalysts. Supported Re@Pd overlayers were found to have hydrogen heats of adsorption lower than that of pure components. Adsorption isotherms also support altered hydrogen adsorption on Pd in Re@Pd catalysts. Ethylene hydrogenation reactivity results support decreased binding of hydrogen. These reactivity results also suggest initial hydrogenation barrier stronger influence for apparent activation energy. All results consistent with first principles and single crystal studies of Pdₜₚ/Re. Ethylene hydrogenation activity can be correlated with computationally predicted shifts in the center of the d-band through heat of adsorption (Figure 2). These results are a strong indication that we can make catalysts that demonstrate the properties of pseudomorphic overlayer bimetallics.

**Task 3 - Development of Hybrid Inorganic/Organic Polymer Nanocomposites (Mullins)**

We studied the effects of pulse width, pulse amplitude, and pulse frequency on the particle’s shape, size, and size distribution systematically. We varied the pulse amplitude from 5 to 15 kV, pulse width from 15% to 95% and pulse frequency from 10 ms to 100 s; other parameters were kept constant. Particles were successfully fabricated using the pulsed-DC voltage. Results from this study were presented at the 2009 Materials Research Society Fall Meeting and were published in the 2009 Materials Research Society Fall Meeting Proceedings Volume 1239 Symposium VV. Part of the results was included in the January Quarter Report. We have continued our experiments with the coaxial electrospraying needle to produce hybrid composite particles. We have been working with polymeric shell materials including poly-l-lactic acid (PLLA) with cores containing aqueous metallic solutions, aqueous polymeric solutions, and normal hydrocarbons with metal acetyl acetonates. Our preliminary results from fluorescent microscopy and field-emission scanning electron microscopy showed that the fluorescein dye was successfully encapsulated in the PLLA. We are continuing to look for the best core-shell pair which would allow us to obtain the complete engulfing. Also, we believe that with the best choice of the processing parameters, we should be able to produce core-shell particles with controllable size in just a single-step process.

**Task 4 - Development of Oriented Polymeric Materials for Membrane Applications (Gilbert)**

Highly aligned PLLA electrospun fibers were fabricated using an electrospinning technique. Before electrospinning, a layer of PLLA film was cast onto coverslips to secure fiber position and alignment following electrospinning. The working conditions for electrospinning were the following: working voltage: 14 kV; working distance: 11 cm; flow rate: 2 ml/hr; using a 22 gauge sharp-tip needle. The fiber samples were coated with 5 nm gold, and the images were taken using a field emission scanning electron microscope.

**FIGURE 1.** Most Conductive Material: 2.5 wt% Akzo Nobel Ketjenblack EC-600 JD carbon black/65 wt% Asbury Carbons Thermocarb TC-300 synthetic graphite particles/6 wt% Hyperion carbon nanotubes/26.5 wt% Dow homopolymer polypropylene H7012-35RN.

**FIGURE 2.** Relationship between measured \( \Delta H_{\text{ads}} \) and turnover frequency (TOF) for ethylene hydrogenation. Heat of adsorption can also be predicted based on computationally predicted shifts in the d-band. Thus activity can be correlated with d-band predictions.

Under Task 5, investigators at Clemson University have synthesized PAN-based carbon foams that can function as mechanical supports for electrochemically-active material (e.g., nickel oxyhydroxide active mass) or catalytically-active metals. Because carbon foams are graphitic, they are excellent lightweight, porous current collectors for battery or fuel cell electrodes. Electrochemical deposition of nickel oxyhydroxide active mass has been used in Task 6 to demonstrate the use of carbon foams as scaffold materials in rechargeable positive (working) battery electrodes.

To test commercial foams (purchased from Poco Graphite and Koppers) and novel foams produced at Clemson University, we have examined the electrochemical performance of nickel electrodes by performing charge/discharge cycles in flooded and sealed cells. Significant progress has been made in optimizing active mass deposition in the working electrode of a nickel hydroxide battery cell as measured by efficiency of pore filling, accessibility to ion transport, and electrical contact with the carbon support. We have developed a flooded-cell protocol for depositing, forming, and cycling nickel-carbon foam working electrodes under positive-limiting conditions.

Using these electrodes, long-term cycling tests are being performed in asymmetric sealed cells (Figure 3), sometimes called an ultracapacitor configuration. In these cells, the nickel electrode serves as the positive, and up to three layers of a microporous carbon as the negative. The positive electrode stores and releases charge via a Faradaic (redox) mechanism, while the negative electrode uses an electrolytic mechanism, i.e., charge is stored in the electric double layer. Our negative electrode material is fabricated at Michigan Tech using Ketchen Black (manufactured by Akzo Nobel Corporation) and a Teflon® binder, and it has a measured capacitance of about 60 F/g. In sealed asymmetric cells that are negative electrode limited, we have achieved long-term performance in excess of 13,000 cycles before losing 20% of the initial cell’s discharge capacity.

In a related electrocatalytic application, we have conducted successful hydrogen dissociation experiments on an alumina support as a prelude to future deposition of a bimetallic overlayer fuel cell anode catalyst on a carbon foam support. Such a catalyst may be able to reduce or replace the current use of platinum for the catalytically-active sites.

Task 7 - Movement of Water in Fuel Cell Electrodes (Allen)

Technical accomplishments for the last year include a 2nd-level thermostat fabricated for environmental chamber; improved temperature control (including improved humidity control, potential hydrogen atmosphere). We addressed dependence of contact angles on drop size and improved algorithm for contact angle determination. A new drop deposition method was developed which injects water through GDL. The experimental phase of the work is complete and the funds expended. During the next month we will continue to compile the final reports and complete the data analysis.

Conclusions and Future Directions

The Center for Nanostructured and Lightweight Materials is funded until the end of June 2010. Data collection and analysis is complete; the final technical report will be finished by September 28, 2010.

FIGURE 3. Charge-discharge curves from an asymmetric cell (SW #63 as positive and carbon-filled Teflon® negative electrode) at 1.44 mA/cm² current density. The positive electrode was deposited in 1.8 M Ni(NO₃)₂ and 0.26 M Co(NO₃)₂ solution for 48 minutes. The current profile is in pink and the voltage profile is in blue. The cell shown achieved approximate 1,500 cycles.

Contract Number: DE-FG36-08GO8810

Subcontractors:
• Protonex Technology Corporation, Broomfield, CO
• Reaction Systems, LLC, Boulder, CO

Project Start Date: July 1, 2008
Project End Date: June 30, 2010
*Congressionally directed project

** Objectives **

- Develop solid oxide fuel cell (SOFC) materials for robust operation on renewable and logistics fuels.
- Identify optimal reforming strategies for renewable and logistics fuels.
- Create thermally stable fuel-reforming catalysts and supports.
- Employ system modeling to optimize auxiliary power unit (APU) configurations.
- Utilize model-predictive control to integrate system hardware.

** Technical Barriers **

- Durability: Broaden SOFC operating windows under logistics fuel streams.
- Performance: Increase efficiency through system optimization.
- Transient operation: Develop model-predictive control algorithms for use in dynamic control.

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(C) Performance
(G) Start-up and Shut-down Time and Energy/Transient Operation

** Technical Targets **

In this project, we conduct a range of studies to improve the durability, efficiency, and transient operation of SOFC auxiliary power units. Insights gained from these studies will be applied toward the design and synthesis of SOFC materials and systems to meet the DOE 2015 Technical Target for durability (35,000 hours), start-up time (15-30 minutes), and cycle capability (250 cycles).

** Accomplishments **

- Demonstrated expanded trouble-free operating windows of hydrocarbon-fueled tubular SOFCs through addition of barrier-layer architectures.
- Demonstrated stability of next-generation strontium-doped lanthanum titanate (Sr$_{0.8}$La$_{0.2}$TiO$_3$ - SLT) SOFC anode materials across all ceramic-processing conditions. These nickel-free perovskite anode materials have far greater resistance to re-oxidation and deposit-formation failure mechanisms than established nickel-yttria-stabilized zirconia (YSZ) anode materials.
- Demonstrated solid-state reaction sintering of barium-cerate-zirconate proton-conducting ceramics at 1/10th the current fabrication cost. Measurements of ionic conductivity of these materials exceed the highest previously reported levels.
- Established liquid-fuel processing strategies and experimentation.
- Utilized new experimentation to demonstrate catalytic partial oxidation (CPOX) of renewable liquid fuels, including ethanol and butanol.
- Evaluated SOFC performance under CPOXed butanol-reformate streams, with comparisons made to performance under hydrogen fuel.
- Developed hybrid computational fluid dynamics (CFD)-electrochemical modeling tools to examine heat transfer within 600-Watt tubular-SOFC stacks.
Utilized hybrid models to quantify effects of design changes on thermal and chemical non-uniformities within the stack.

Developed rapid, lower-order dynamic models to map response of slower, high-order physical models for use in dynamic system control.

Demonstrated fidelity of lower-order models in mapping system response across large changes in system operating conditions.

Established outreach to national and international scientists in the field of energy through the Distinguished Lecture Series.

Introduction

The objective of this project is to advance the current state of technology of SOFCs to improve performance when operating on renewable and logistics hydrocarbon fuel streams. While SOFCs can efficiently convert the chemical energy of hydrocarbon fuels into electrical energy, the conversion process can prove problematic if not carefully controlled, due to the risk of carbon-deposit formation, sulfur contamination, and deviations from design set points. In this project, we are developing new SOFC and catalyst materials to improve the robustness of system operation on hydrocarbon fuel streams. Additionally, modeling and experimentation is being conducted to examine and mitigate the formation of carbon deposits during fuel reforming and electrochemical-oxidation processes. Physically based models are being developed to examine SOFC-system operation and performance in auxiliary power unit (APU) applications, including control strategies for improving the dynamic response of such SOFC APU systems. Finally, outreach is being conducted through the Distinguished Lecturer Series, promoting collaboration between fuel cell researchers and scientists.

Approach

CSM has assembled a strong and diverse team of scientists and researchers with broad skill sets applicable to fuel cell development. Coordinated through the Colorado Fuel Cell Center, this team examines both the fundamental underpinnings and the key technical problems facing SOFC operation on renewable and logistics fuels. We develop new SOFC materials and architectures for use with renewable and logistics (i.e. liquid hydrocarbon) fuel streams, addressing the technical challenges and operating windows associated with carbon-deposit formation and sulfur poisoning. We develop catalyst materials and reforming strategies for optimal processing of liquid hydrocarbons and biomass-derived fuels for use in fuel cells. We develop system-integration strategies to create robust SOFC systems that utilize renewable and logistic fuels. Through advanced fuel cell modeling and simulation, we examine the fundamental underpinnings of the atomic-scale charge-transfer processes occurring during SOFC operation on renewable and logistic fuels, incorporating the effects of load following and system control. Finally, we promote outreach programs through the creation of a Distinguished Lecturer series at the CSM campus to bring fuel cell scientists from across the nation in an exchange of ideas with faculty and students.

Results

Task 1. Ceramic Materials and Architecture

Fuel cell reliability and performance can be greatly improved through development of new materials and architectures that promote robust SOFC operation on renewable and logistics fuels. In this task, we investigate new SOFC anode materials that promote tolerance to sulfur compounds and mitigate carbon-deposit formation. We are developing a perovskite-based nickel-free anode material for achieving sulfur tolerance and robust, deposit-free operation on renewable and logistics fuels. Today's SOFCs are widely designed around a composite nickel/YSZ anode formulation. While this anode material provides high electronic conductivity and good internal fuel-reforming characteristics, the cost of the nickel material can be high. Additionally, nickel suffers from problems during operation, including long-term sintering that decreases cell performance, intolerance to sulfur-containing fuel streams, and susceptibility to oxidation that can lead to cell fracture. Perovskite-based anodes can mitigate a number of these issues, as they have been shown to be more sulfur and redox tolerant than today's nickel anodes, while also achieving high power density in button-cell experiments.

The primary focus of our next-generation perovskite anode material is SLT. Within this project, we have fabricated SLT powders through solid-state powder-processing techniques, and confirmed the stability of the SLT with other SOFC materials (like the YSZ electrolyte material) throughout all high-temperature cell-fabrication processes. We have developed a host of experimental methods to quantify anode performance, including an electronic-conductivity test stand, and a unique separated anode experiment to compare gas transport and internal-reforming chemistry of next-generation anodes to that of traditional Ni-YSZ anodes. We have used this experimentation to confirm that the electronic conductivity of SLT is among the highest of perovskite-based ceramic materials, making it a leading material for replacing the nickel found in today's SOFCs. We are using these results to fabricate complete SLT-based tubular SOFCs, like those shown in the high-resolution micrographs of Figure 1. Note the high porosity of the SLT anode, the finer porosity of the...
SLT/YSZ anode functional layer, and the thin and dense YSZ electrolyte layer captured in these images.

We have also extended our development of a novel, inexpensive solid-state reactive-sintering (SSRS) technique from fabrication of BaZr$_{0.8}$Y$_{0.2}$O$_{3-\delta}$ to creation of BaZr$_{0.1}$Ce$_{0.7}$Y$_{0.1}$Yb$_{0.1}$O$_{3-\delta}$ (BZCY), two proton-conducting ceramics. As shown in Figure 2, we have demonstrated that the ionic conductivity of our SSRS-fabricated BZCY material is higher than any previously reported proton-conducting ceramic, while be fabricated at one tenth the cost of traditional fabrication methods.

**Task 2. Fuel Processing**

Robust operation of fuel cells on renewable and logistic fuel streams hinges on the emergence of fuel-reforming technology that is compatible with SOFC requirements. In this task, we develop reforming strategies for optimal processing of liquid hydrocarbons and biomass-derived liquid fuels for use in SOFCs. Within this task, CSM researchers work with subcontractor Reaction Systems, LLC to synthesize thermally stable catalysts and catalyst supports, and then measure their activity and stability for reforming of both renewable and logistics fuels. Novel catalyst supports have been fabricated, and the improvements in thermal stability demonstrated. Construction of a catalyst testing rig has been completed, and used to explore operating windows for catalytic partial oxidation of butanol, a high-energy-density biomass-derived liquid fuel. After establishing operating windows, the CPOX'ed butanol reformate has been fed to a conventional tubular SOFC fabricated by industrial partner CoorsTek, Inc, with cell-performance comparisons made to that under hydrogen fuel streams. As shown in Figure 3, cell performance under CPOX'ed butanol reformate fuel reached 60% of the pure-hydrogen performance level.

**Task 3. System Optimization and Control**

The system modeling and optimization effort centers on creating optimal SOFC-based APU system architectures, and is inclusive of an examination of dynamic component interactions during various operating modes. Modeling and analysis efforts are applied to the ongoing APU development efforts of Protonex Technology Corporation with the specific aims
of improving both system performance prediction under sensor uncertainty and heat-loss estimation methods.

Utilizing the commercially available Fluent CFD software, a hybrid CFD/electrochemistry model of the 600 W tubular Protonex stack has been established and utilized to examine heat transfer and oxygen usage within the stack tube bundle. Results are shown in Figure 4; imbalances in O₂ mole fraction are fairly modest. However, temperature variations from cell to cell can reach nearly 50°C, presenting significant degradation issues to tubular-stack developers. Alternative designs may enable a more-uniform temperature distribution within the stack.

The goal of the Fuel Cell System Control task is the design of a control system to regulate the operation of a complete SOFC system. The control system design is based on a dynamic model that can predict system behavior given perturbations in actuator settings, such as air and fuel flows and power loads. Ideally, these models are based on physical first principles; however, physically based models are often very complex, and take considerable computational resources to compute. When utilized for real-time control, computational complexity can become a limiting factor in the usefulness of the model, and it becomes necessary to capture the dominant behavior in a lower order models that can be run quickly. Our approach is to start with physically based models, and apply system-identification techniques to develop the required reduced-order models.

This project has focused on control of the fuel cell stack in isolation. We have implemented this reduced order model in MATLAB/Simulink, along with the state estimation and model-predictive control components. The state-estimation component uses the reduced-order model of the plant and measurements of the inputs and outputs to find the current internal state that best matches the observed behavior. Then, the model-predictive-control component calculates the future actuator commands that are needed to drive the system from the current state to the desired future behavior. This future behavior is specified in terms of either desired signal trajectories (e.g. current set-point) or desired signal bounds (e.g. minimum voltage or fuel utilization). We have utilized this model to demonstrate robust dynamic control of SOFC stack performance with a broad load variation. This control was established within the constraints of cell voltage and fuel utilization, validating the performance of the reduced-order models for capturing the response of the higher-order physical models.

Task 4. Outreach

In this task, CSM hosts a seminar series that brings prominent fuel cell researchers to the CSM campus for interaction with our students and our faculty. This exchange of ideas will promote national collaboration, further the development of fuel cells, and grow the CSM program. During the previous year, Prof. Robert Dibble of the University of California, Berkeley provided CSM Engineering Division students with a seminar entitled Recent “Developments in the Combustion Analysis Laboratory at the University of California at Berkeley”. Additionally, Dr. Marco Hartmann of the Karlsruhe Institute of Technology provided a talk entitled “Generation of Hydrogen and Synthesis Gas from Higher Hydrocarbon Fuels by Catalytic Partial Oxidation.” This talk was given as part of CSM’s Chemical Engineering Department Seminar Series.
**Future Directions**

**Task 1. Ceramic Materials and Architecture**
- Measure electrical conductivity and catalytic activity of novel anode compositions over a range of anode conditions.
- Establish fabrication protocols for perovskite-based tubular SOFCs.
- Evaluate the long-term stability of protonic conductors using thermogravimetric analysis, differential thermal analysis, and dilatometry.

**Task 2. Fuel Processing**
- Extend partial-oxidation experiments on butanol fuel.
- Develop process windows for deposit-free SOFC operation under butanol reformate.

**Task 3. System Optimization and Control**
- Extend tube-stack models to examine relationships between stack design and performance.
- Implement explicit form for model predictive control.

**FY 2010 Publications/Presentations**

V.O.3 Development of Kilowatt-Scale Coal-Based Fuel Cell Technology*

Objectives

Develop a kilowatt-scale coal-based solid oxide fuel cell (SOFC) technology. The outcome of this research effort will form the technological basis for developing megawatt-scale coal-based SOFC technology. Objectives for 2010 included the following:

- Determine the effect of CO and CO$_2$ on the performance of the coal-based fuel cell.
- Study the long-term electrochemical oxidation of coke.
- Investigate the integration of fuel cells in series and parallel for the coal-based fuel cell stack.
- Evaluate the operation conditions of a steel coal injection unit.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Multi-Year Research Development and Demonstration Plan:

(A) Durability
(B) Cost
(C) Performance

Technical Targets

This project is directed at the development of kilowatt-scale coal-based SOFC technology. This project will develop a technological basis for the scale up of power generation capability of a kW SOFC to megawatt scale. A current density of 100 mA/cm$^2$ at 0.4 V was the initial target for demonstration of a coal-based SOFC.

Accomplishments

Year 2010 focused on the following milestones:

- Studied the effect of CO and CO$_2$ on the activity of the anode catalyst and the performance of the coal-based fuel cell. Exposure of the Ni anode to CO was found to improve the fuel cell performance and decrease the fuel cell energy efficiency.
- Investigated the integration of fuel cells in series and parallel for the coal-based fuel cell stack. Integration of fuel cells in parallel was found to produce maximum current densities 30% higher than integration in series.
- Demonstrated the long-term electrochemical oxidation of coke.

Introduction

The direct use of coal in the SOFC to generate electricity is an innovative concept for electric power generation. The coal-based fuel cell could offer significant advantages: (i) minimization of NO$_x$ emission due to its operating temperature range of 700-1,000°C, (ii) high overall efficiency because of the direct conversion of coal to CO$_2$, (iii) the production of a nearly pure CO$_2$ exhaust stream for the direct CO$_2$ sequestration, and (iv) low investment and maintenance cost due to simplicity of the process. This technology also promises to provide low cost electricity by expanding utilization of U.S. coal supplies and relieving our dependence on foreign oil.

A small-scale coal fuel cell system including coal injection and fly ash removal parts will be fabricated. The main objectives of this project are (i) improving the anode catalyst structure and the interface between electrodes and electrolyte, (ii) developing and refining the coal fuel cell fabrication techniques, and (iii) testing a small-scale coal fuel cell system. Successful
development of this novel coal fuel cell technology will significantly enhance the energy security of the U.S. and bridge the gap between a fossil fuel-based economy and the future hydrogen-based economy.

Approach

Anode supported fuel cells were fabricated by the tape casting and screen printing approach, which involves: (i) generating a Ni-ytria-stabilized zirconia (YSZ) anode support layer (70 wt% Ni), a Ni-YSZ interlayer (50 wt% Ni), and a high purity YSZ electrolyte layer, (ii) cutting the layers in the shape of a 2 cm diameter disc and co-firing at 1,400°C, and (iii) screen printing and firing at 1,200°C a lanthanum strontium manganese (LSM)-YSZ cathode layer. The cells were tested in a steel reactor comprising a gas inlet port, a coke feeding mechanism, and a gas exhaust outlet port connected to a mass spectrometer (Pfeiffer Omnistar) and a gas chromatographer (SRI 8610 C). Ag paste was coated along the perimeter of the anode electrode to enhance the contact between the anode and the steel reactor serving as anode current collector; Ag mesh and Ag paste current collectors were attached to the cathode electrode. The fuel cell performance and energy efficiency was evaluated by introducing the fuel (H2, coke and coal) and monitoring the current produced at different voltage loads.

The microstructure of the fuel cell electrodes was characterized before and after the testing experiments by X-ray fluorescence, scanning electrode microscopy, and energy dispersive X-ray spectroscopy, with the purpose of monitoring the reducibility of the fuel cells fabricated in-house. The performance and energy efficiency of the fuel cell was tested in coke, a carbonaceous fuel produced by the pyrolytic reaction of coal at high temperature (800-950 °C). The effect of CO2 product on the anode catalyst activity and performance was investigated. Fuel cell efficiencies were calculated by considering the power produced by the cell and the heat of combustion of the fuel consumed during the electrochemical reaction. Once sufficient understanding was gained for (i) the reaction mechanism of electrochemical oxidation of coal-based fuel on the anode electrode, (ii) the effect of CO2 on the performance of the fuel cell, (iii) the microstructure of the anode electrode (porosity, tortuosity, and stability), and (iv) the coal feeding approach, efforts were expanded to the development of new anode catalysts, fuel cell fabrication methods, and current collection assemblies for stack fabrication.

Results

The effect of CO on the performance of the fuel cell was studied by testing of the cell in coke and different concentrations of CO, monitoring the power produced and the composition of the gases at the fuel cell exhaust. Figure 1(a) shows testing of the fuel cell in 5.0 g of coke and He (200 sccm) under open circuit voltage (OCV) conditions and at a load of 0.4 V produced a maximum current of 190 mA, and the formation of CO and CO2 product. The concentration of the CO and CO2 products were determined from the mass spectrometer profiles and gas chromatograph analysis of the exhaust stream. The thermodynamic efficiency (εT) of the fuel cell during operation in coke was determined to be 49.4% from the data of Figure 1(b), by relating the electric power produced by the fuel cell at the operating voltage, Wf, and the enthalpy change of the carbon oxidation reaction, DH. Wf was estimated from Figure 1(b) by integrating the highlighted area under the current vs time curve. The enthalpy change of reaction, DH, was estimated considering the amount of carbon consumed during the electrochemical oxidation reaction and the low heating value of coke. The amount of coke consumed was determined by combination of the increase of CO and CO2 concentration in the outlet stream when changing the operating conditions from OCV to 0.40 V, as summarized below

\[
\eta = \frac{W_f}{\Delta H} = \frac{U}{\eta} = \frac{0.4 \cdot 144.75}{355,200 \cdot 0.0915 \cdot 1 \cdot 1} = 49.4\%
\]

LHV=lower heating value of carbon (J/mol)

\( (CO+CO_2)_{\text{exhaust}} - (CO+CO_2)_{\text{inlet}} \) = increase in the concentration of CO and CO2 (mol/ml)

U=fuel utilization (%)

t=time (sec)

FIGURE 1. CO and CO2 concentration at the exhaust of the fuel cell and current produced at 800°C, OCV, and 0.4 V during testing in (a) coke (3g) and He (200 sccm), and (b) coke (3g) and He containing 6.97% CO.
Figure 1(b) shows testing of the fuel cell in coke and a He stream (200 sccm) containing 6.97% CO at OCV and 0.4 V produced a higher current than that observed with coke, reaching values close to 320 mA. The efficiency of the fuel cell during testing in coke and CO, determined from the data in Figure 1(b), was found to be lower than that of the fuel cell in coke despite producing a higher current. The efficiency of the fuel cell in coke and CO was calculated by relating the electric power produced by the fuel cell at the operating voltage, \( W_e \), and the enthalpy change of the carbon oxidation reaction, \( \Delta H \). The enthalpy change of reaction, \( \Delta H \), was estimated considering the amount of CO consumed during the electrochemical oxidation reaction and the low heating value of CO. The amount of CO consumed was determined by the difference in CO2 concentration in the outlet stream when switching the operation from 0.40 V to OCV.

\[
U = \frac{W_e}{\Delta H} = \frac{\text{increase in CO}_2 	ext{ concentration of (mol/ml)}}{16.5 \times 0.5 \times 18 \times 10^{-3} \times 1 \times 0.05} \times 100\%
\]

\( LHV \) = lower heating value of carbon (J/mol)

\( \text{increase in CO}_2 \text{ concentration of (mol/ml)} = [\text{CO}_2]_{OCV} - [\text{CO}_2]_{Inlet} \)

\( U \) = fuel utilization (%)

\( t \) = time (sec)

The reproducibility of these results was further investigated, quantifying the concentration of gas species at the exhaust, as summarized in Tables 1 and 2.

FIGURE 2 shows a schematic representation of the approach used for integrating two fuel cells in series and in parallel, and their corresponding fuel cell voltage and current characteristics (i.e., fuel cell voltage-current curves) during testing in H2 fuel. The experimental apparatus was intentionally constructed to allow measuring the individual performance of each cell. Inspection of Figure 2 shows integration of the fuel cell series produced a maximum current of 1.8 A, which corresponds to nearly 95% of the sum of each individual cell maximum current; the current expected from the two cells connected in a series arrangement. The maximum power output produced by the cells in series arrangement was found to be 0.35 W, as evidenced from the curves in Figure 2.

Testing of the cells in a parallel arrangement produced a fuel cell current close to that of the individual cells, with a maximum power output of...
0.495 W, 30% higher than observed for the cells in the series configuration.

The higher power outputs observed with parallel configuration was further investigated by testing a system composed of four small cells (1 cm diameter) in H2 fuel, as shown in Figure 3. Testing of the cells in the parallel configuration demonstrated the buildup of power output needed for the coal fuel cell stack. Future experiments will evaluate the performance characteristics of the fuel cell stack configuration during operation in coal and coke fuel. The efficiency of the coal fuel cell stack in the parallel configuration will be analyzed in future work.

Figure 4 shows the current density as function of time during testing of a fuel cell in coke fuel and He flow at 800°C and a load of 0.35 V. Exposure of the fuel cell to H2, CO and CO2 after 15 h of continuous operation resulted in rapid increases in the fuel cell current density. The increases of the fuel cell current density can be explained by the combined electrochemical oxidation of H2 and coke, and CO and coke. The increase in the fuel cell current density during exposure to CO2 evidenced the electrochemical oxidation of coke produced by the reaction of carbon and CO2 (C+CO2 →2CO). The effect of CO2 on the performance of the fuel cell will be further investigated in future experiments.

Conclusions and Future Directions

- Exposure of the Ni anode to CO was demonstrated to improve the fuel cell performance and decrease the fuel cell energy efficiency.
- Integration of fuel cells parallel configuration was found to produce maximum power outputs exceeding those of similar cells integrated in a series configuration by 30%.
- Long-term testing of the fuel cell in coke was demonstrated.

The proposed future research would be focused in the following directions:

- Identification of catalyst composition for long-term electrochemical oxidation of solid carbon fuels at 800°C
- Evaluation of the energy efficiency of fuel cell stacks in the series and parallel configuration.

**FIGURE 3.** (a) A digital image of 4-cell fuel cell stack, (b) voltage-current curve of the individual cells and the fuel cell stack.

**FIGURE 4.** Current density of a fuel cell during testing in coke at 800°C and a load of 0.35 V. Note: 1. Voltage changed from 0.35 to 0.5, 0.1, and 0.35 volt, respectively, the inlet gas changed from He to He/H2, He/CO2, He/CO respectively, while the voltage was kept at 0.35 volt.
• Completion of design of the fuel cell stack and testing of a small-scale (1-10 kW) coal fuel cell system.
• Fulfill reporting obligations and preparing manuscripts for publications and conference presentations.

FY 2010 Publications/Presentations

Objectives

- Molecular-morphological tailoring and evaluation of novel, low-cost hydrocarbon fuel cell membranes with high-temperature performance and long-term chemical/mechanical durability. This effort supports the Hydrogen Program stated in the Multi-Year Program Plan by developing high-temperature, low relative humidity (RH), high proton conductive membranes for use in polymer electrolyte membrane (PEM) fuel cells – focus is on alternative materials with performance up to 120°C at low RH.

- Synthesis of aromatic hydrocarbon polymers. Organic structure tailoring includes variation of linking moieties between aromatic groups, ion exchange density/distribution, molecular weight and block vs. random copolymers. Three synthetic directions by Storey, Patton, and Savin.

- Fundamental information regarding microstructure and physical properties and correlation using advanced characterization tools (Mauritz, Savin).

- Having identified superior materials and optimized membrane electrode assembly (MEA) processing, the nature/mechanisms of coupled chemical and mechanical degradation and morphological alteration investigated during accelerated ex situ degradation and PEM fuel cell testing (Mauritz).

- Mechanical/chemical/thermal stability of the membranes will be increased over a broad temperature-humidity range. MEAs fabricated from synthesized ionomers and tested for fuel cell performance and durability.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Technologies Program Multi-Year Research, Development and Demonstration Plan:

(B) Cost

(C) Performance

Technical Targets

- Synthesize bisphenolic comonomers for poly(arylene-ether-sulfone) (PAES) that contain an ion-exchange moiety on a perfluoroalkyl chain tether. Polymerize new comonomers and study membrane conductivity, accelerated degradation, and fuel cell in situ properties. Reproduce known sulfonated poly(arylene-ether-sulfone) (sPAES) benchmark polymers and subject to identical testing. Compare our materials to performance standards established by the DOE.

- Investigate influence of annealing on macromolecular structure, chain dynamics and morphology.

- Knowledge of chemical and mechanical degradation mechanisms and their inter-relationship in membranes.

Accomplishments

- Synthesized/characterized new ion-containing bisphenolic monomer, N,N-diisopropylethylammonium 2,2-bis(p-hydroxyphenyl) pentafluoropropanesulfonate (HPPS).

- Synthesized PAES copolymers with various ion contents from HPPS, bisphenol (BP), and bis(4-fluorophenyl)sulfone (FPS). Molecular weight, polydispersity index, copolymer composition characterized with nuclear magnetic resonance (NMR) and gel permeation chromatography. Thermal properties characterized with thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC).

- Developed chemistry for synthesis of triazole tethers and postmodification of PAES backbones.
Initial studies of poly(perfluoropropylene oxide)-b-poly(styrene sulfonate) (PFPO-PSS) model copolymers and extended to use novel proton conducting blocks.

- Determined equivalent weights, proton conductivities of sPAES membranes.
- Generated water vapor pressure isotherms for sPAES membranes.
- Established thermal degradative stabilities and Tgs of sPAES membranes using dynamic mechanical analysis (DMA).
- Uncovered molecular motions in, monitored kinetics of formation of sPAES membranes using broadband dielectric spectroscopy.

**Introduction**

The scope is a vertically-integrated project of synthesis-characterization-evaluation of novel hydrocarbon fuel cell membranes for high-temperature performance with excellent durability. While we continue research performed in Fiscal Year (FY) 2008 and FY 2009, the synthetic scope is broadened. The basic theme is continued which is synthesis of polymers of the PAES or poly(arylene ether ketone) type, containing ion exchange groups, e.g., sulfonic or phosphonic acid, tethered to the backbone via perfluorinated alkylene linkages. In the renewal grant, new structural variations are examined, e.g., nature of the attachment point of tether to backbone, tether length, tether branchiness, number of ion exchange sites at a comonomer. Use of N-based heterocyclics instead of acid groups for proton conduction broadens the synthetic scope. Polymer backbones will also be of the PAES and poly(arylene ether ketone) type. Use of nitrogen-based heterocyclics is proposed for high-temperature, low-RH membranes that combine high mechanical/thermal/chemical stability of aromatic hydrocarbon polymers with pendant moieties that exhibit high proton conductivities in the absence of water.

In a second new theme that broadens the synthetic scope, block copolymers will be synthesized via coupling reactions between a proton conducting block, including any of the aromatic hydrocarbon polymers discussed above and acidic polymers. Phase behavior will be mapped vs. block composition using transmission electron microscopy (TEM), atomic force microscopy (AFM), small angle X-ray scattering (SAXS). Synthesized materials will be characterized for proton conductivity and mechanical/chemical/thermal stability over broad temperature and RH ranges using a variety of spectroscopic, dielectric, microscopic and viscoelastic methods and evaluated for performance in fuel cells.

**Approach**

There are three synthetic directions in the project (Storey, Patton and Savin). Storey will synthesize bisphenolic comonomers that contain one or two ion-exchange moieties connected through perfluoroalkyl tethers and copolymerize them with biphenol and FPS to create PAES. Patton will synthesize N-heterocycle (i.e. 1H-1,2,3-triazoles) containing tethers that will be installed on PAES backbones via a post-polymerization functionalization approach. Savin will synthesize block copolymers containing proton conducting blocks (PSS) with perfluoroether blocks (PFPO) using a modular coupling approach.

Fundamental information is gathered regarding microstructure, physical properties and how they are related using advanced characterization tools by Mauritz and Savin. Having identified superior membranes and optimized MEA processing, the nature/mechanisms of coupled chemical-mechanical degradation and morphological alteration will be investigated during accelerated ex situ chemical degradation and PEM fuel cell testing by Mauritz.

**Results**

We synthesized the ion-containing bisphenolic monomer, HPPS, in three steps from hexafluoroacetone. A monomer structure was confirmed using NMR and X-ray. HPPS was copolymerized with BP and FPS to form a series of PAES with the general structure shown in Figure 1 and specific compositions as shown in Table 1.

We successfully synthesized a series of model tethers with terminal triazole moieties. Intermediate alkynyl bromides (1) were prepared by phase transfer catalyzed alkylation of propargyl alcohol with excess of appropriate dibromoalkanes (3 equivalent) to minimize bis-alkylation products. Copper-catalyzed 1,3-dipolar cycloaddition of 1 with (2-azidomethoxyethyl) trimethylsilane gave terminal N-protected triazole...
alkylbromides (2). De-protection of 2 under acidic conditions gave the terminal 1H-1,2,3-triazole alkylbromide in near-quantitative yields. These model tethers will be used for modification of PAES polymer backbones to achieve N-heterocycle containing polymers for membrane fabrication.

Optimal reaction conditions were determined for modular coupling of PFPO and polystyrene with five varying molecular weight and block ratios. Successful coupling was verified using light scattering. A sulfonation protocol was determined using acetyl sulfate under dilute conditions and successful sulfonation to afford PFPO-PSS was demonstrated using light scattering. Initial studies were performed using DSC and AFM to determine thermal transitions and thin film morphology.

EW, water vapor pressure isotherms and proton conductivities were determined for sulfonated (s) PAES and HPPS membranes and conductivities are low. Thermal degradation was studied using TGA. Glass transitions related to upper fuel cell operating temperature were identified for HPPS variants using DMA. Thermal degradation occurs immediately after the glass transition temperature (Tg). Sub-Tg relaxations can be related to physical durability in RH cycling. Evolving macromolecular motions in sPAES and HPPS were monitored in real time as kinetics of film formation was tracked using BDS. Figure 2 shows ion viscosity (IV) vs. film formation time for HPPS and sPAES samples and 2-step processes and gelation asymptotes are seen. BDS was used to study drying of these materials.

Conclusions and Future Directions

- Synthesized PAES block copolymers from HPPS, BP, and bis(4-fluorophenyl)sulfone.
- Synthesized ion containing bisphenol monomers with two tethered sulfonate moieties per bisphenol monomer unit and longer perfluorinated tethers for enhanced H⁺ conduction.
- Synthesized N-heterocycle aromatic polymer.

- Evaluated thermal properties/conductivity of 1,2,3-triazole tethered polysulfone vs. composition.
- Synthesize other compositions for model PFPO-PSS block copolymers and characterize morphology using TEM, AFM and SAXS
- Incorporate of other proton conducting blocks with PFPO using our modular approach: PBI, poly(arylene ester sulfones).
- Test membranes synthesized by Storey, Patton and Savin with BDS from -80 to 300°C; determine Tg and sub-Tg molecular motions relating to proton conductivity, high temperature stability and chemical and mechanical degradation (durability).
- Samples will be tested with 100% of either hydrophobic or hydrophilic blocks to assign broadband dielectric spectroscopy transition peaks in block copolymers.
- In situ annealing experiments will be conducted at temperatures from 80 to 140°C to obtain information on shifts in macromolecular dynamics and nature of water desorption during high temperature fuel cell operation.

Contract Number:  DE-FG36-08GO88113
Project Start Date:  August 1, 2008
Project End Date:  December 31, 2011

*Congressionally directed project

Objectives

The main goal of this project is to perform extended durability testing of the external fuel processor (EFP) for a 1-MWe solid oxide fuel cell (SOFC) power plant concept being developed by Rolls-Royce Fuel Cell Systems (US) Inc. (RRFCS). The specific objectives are to:

• Conduct long-term tests in relevant environments for the three EFP subsystems that support operation of a 1-MWe SOFC power plant. The subsystems include:
  – Synthesis-gas subsystem
  – Start-gas subsystem
  – Desulfurizer subsystem

• Determine long-term performance of key components such as catalysts, sorbents, heat exchangers, control valves, reactors, piping, and insulation.

• Evaluate the impact of ambient temperatures (hot and cold environment) on performance and component reliability.

• Determine system response for transient operation.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(C) Performance
(G) Start-up and Shut-down Time and Energy/Transient Operation

These barriers will be addressed as they relate to the three External Fuel Processor subsystems.

Technical Targets

This project addresses milestone 59 in the Fuel Cells section of the Fuel Cells Technologies Program Multi-Year Research, Development and Demonstration (RD&D) Plan. Milestone 59 is to “evaluate fuel processing subsystem performance for distributed generation against system targets for 2011.” These targets will be addressed as they relate to durability, performance (gas quality - sulphur in product stream), and transient response of the EFP subsystems.

Accomplishments

The following work has been completed since last year’s annual report (June 2009):

• Hydrogen Safety Plan was issued and approved by DOE’s Hydrogen Safety Panel.
• Completed fabrication of outdoor test facility.
• Installed desulfurizer and start-gas subsystems in outdoor test facility.
• Commissioned control software, mechanical and electrical hardware for desulfurizer subsystem.
• Commissioned control software, mechanical and electrical hardware for synthesis-gas subsystem.
• Completed 1,000-hour durability test of synthesis-gas subsystem.
Introduction

RRFCS is developing a 1-MWe SOFC power plant for stationary power application. An integral part of the SOFC power plant is the EFP. It uses pipeline natural gas and air to generate all the gas streams required by the SOFC power plant for start-up/shutdown (non-flammable reducing gas or start gas), low-load operation (synthesis gas) and normal operation (desulfurized natural gas). Thus it eliminates the need for on-site storage of high-pressure, bottled gases of nitrogen or hydrogen.

Approach

The approach for this project is to conduct durability tests in relevant environments using full-scale components for the EFP of a 1-MWe SOFC power plant. The components were designed and built as part of another project and made available for the durability testing. An outdoor test facility was constructed as part of a third project so that the EFP could be tested under hot- and cold-weather conditions that would be expected for a 1-MWe SOFC power plant operating in northeast Ohio. Figure 1 shows a photograph of the EFP in the outdoor test facility.

The durability testing includes:

- Synthesis-gas subsystem operation for multiple start-ups and 1,000 hours of operation in a heated, indoor enclosure. This subsystem is used only during low-load operation of the SOFC to balance the thermal input and is required to operate for only a few hundred hours per year. Therefore the 1,000-hour test will simulate a 5-year service life.
- Start-gas subsystem testing for multiple start-ups and 1,000 hours of steady-state operation in an outdoor (hot and cold) environment. This subsystem is used only during start-up and shutdown of the SOFC and is required to operate for only a few hundred hours per year. Therefore the 1,000-hour test will simulate a 5-year service life.
- Desulfurizer subsystem testing for 8,000 hours in an outdoor (hot and cold) environment. This subsystem operates whenever the SOFC is making power therefore it is expected to operate for much longer periods compared to the other two subsystems. The 8,000-hour test represents the time period between yearly maintenance intervals.

After completing the durability tests, post-test analyses of the hardware will be performed. Subsystem components (catalysts, sorbents, piping, reactors, insulation, valves, heaters, heat exchangers, nitrogen membrane, etc.) will be inspected for deposits, signs of wear, damage, corrosion, and erosion. Physical and chemical analyses will be performed on components as required.

The durability tests will demonstrate that the EFP subsystems are ready for a full-scale SOFC system demonstration.

Results for 2010

Synthesis-Gas Subsystem

The synthesis-gas subsystem was installed inside a room temperature test enclosure to simulate its operating environment which is inside the SOFC enclosure. The start-gas subsystem and desulfurizer subsystem were installed in the outdoor test facility since that environment would be representative of their operation outside of the SOFC enclosure in an unheated area.

The synthesis-gas subsystem was the first subsystem to be tested. It was designed to generate hydrogen from natural gas and air to support low-load operation of the SOFC. It was tested to determine its start-up characteristics and the impact of operating time on performance. The synthesis gas reactor was heated to 350°C using warm air. The heat-up required 62 minutes. Once the catalyst was at temperature the natural gas flow was initiated. Within 40 seconds the reactor began to produce hydrogen and after 120 seconds the hydrogen concentration was approaching the target level. The hydrogen production during start-up trended closely with the catalyst outlet temperature. Figure 2 shows the results from the start-up of the synthesis-gas subsystem. The total start-up time was 64 minutes. This was slightly above the 60 minute target however the start-up procedure can be modified to significantly reduce the time for heat-up and thus meet the required performance.
After start-up, the synthesis-gas subsystem was operated for 1,000 hours to characterize its durability. The reactor was cycled periodically between minimum load (15%) and maximum load (100%) conditions. The hydrogen content in the product gas slowly declined over time (see Figure 3). At the completion of the test, the hydrogen concentration had dropped to about 85% of the initial target value (15% decline per 1,000 hours). This was within the acceptable range for the synthesis-gas subsystem for the SOFC application.

The transient response for the synthesis-gas subsystem was evaluated during a load change from 17% to 50% load. The load change was performed over a 55-second period. This gave a load rate of change of about 36% per minute. This was very close to the target value of 40% per minute. A faster load rate of change is likely possible with additional tuning of the control valves. The plot in Figure 4 shows the transient response for the synthesis-gas subsystem. The hydrogen concentration in the product gas remained near the target value during the transient while the outlet temperature increased from 815 to 855°C during the same period.

The synthesis-gas subsystem was disassembled after the 1,000-hour test was completed. The reactor vessel and its internal components were found to be in good conditions with no signs of corrosion, erosion or melting. The heaters, thermocouples and control valves showed no signs of significant degradation. A light coating of carbon was observed at the outlet of the catalyst and in the outlet piping. The carbon deposition on the catalyst may have contributed to the observed reduction in hydrogen yield over time.

Samples of the catalyst were removed from the reactor and will be submitted for chemical and physical analyses. Surface area, pore volume, precious metals, carbon and sulfur contents will be determined. Small samples of the reactor components will be analyzed to quantify any metal loss due to hydrogen dusting or corrosion.
Desulfurizer Subsystem

The desulfurizer subsystem has been installed into the outdoor test facility. Natural gas and compressed air lines were connected to supply the reactant gases to the subsystem. The outlet of the subsystem was connected to a ground flare for the safe disposal of the desulfurized natural gas since a 1-MWe SOFC is not available to use the gas.

The desulfurizer subsystem’s mechanical and electrical hardware were commissioned. All hardware is operating properly. The control software also was commissioned. Its function was tested in the semi-automatic mode through all six operational states. Once the control software has been commissioned in the fully-automatic mode the desulfurizer subsystem will be ready for durability testing.

Start-Gas Subsystem

The start-gas subsystem was installed into the outdoor test facility. Natural gas and compressed air lines were connected to supply reactant gases to the subsystem. The outlet of the subsystem was connected to a ground flare for safe disposal of the start-gas since a 1-MWe SOFC was not available to use the gas. The start-gas subsystem is ready for mechanical and electrical commissioning.

Conclusions

The durability testing of the synthesis-gas subsystem was completed and test results showed that the performance was at or very near the target values. These include:

- Start-up time of 64 minutes.
- Transient response (load change rate) 36% per minute.
- Hydrogen concentration declined 15% per 1,000 hours.
- No signs of corrosion, erosion or melting of the synthesis-gas subsystem components were observed.

Future Directions

2010

- Complete post-test inspections of synthesis-gas subsystem (third quarter Fiscal Year [FY] 2010).
- Complete commissioning of start-gas and desulfurizer subsystem (third quarter FY 2010).
- Begin durability testing of start-gas and desulfurizer subsystems (fourth quarter FY 2010).

2011

- Complete durability testing of start-gas and desulfurizer subsystems (third quarter FY 2011).
- Complete inspections of start-gas and desulfurizer subsystems (fourth quarter FY 2011).
- Issue final report for project (fourth quarter FY 2011).

FY 2010 Publications/Presentations

Objectives

- Development of metal-free oxygen reduction catalysts to reduce cost, facilitate manufacturing, and enhance durability of fuel cells.
- Development of redox stable mixed ionic and electronic conductors (MIECs) for bi-electrode supported cell (BSC) symmetrical solid oxide fuel cell (SOFC) designs, to reduce cost by simplifying manufacturing, enhance durability, and greatly reduce sensitivity to thermal cycling.
- Development of durable, low-cost seals for proton exchange membrane (PEM) stacks, through the establishment of laboratory characterization methodologies that relate to cell/stack performance.
- Development of understandings and methodologies to establish hydrogen quality as it relates to PEM cell applications for transportation needs.
- Development of a first principles multiphysics durability models based on interpretations of electrochemical impedance spectroscopy (EIS) data that link the multiphysics processes, the microstructure, and the material states, with cell impedance responses and global performance, mechanistically, as a foundation for engineering durability during design and manufacture of fuel cells.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(B) Cost
(C) Performance
(E) System Thermal and Water Management
(F) Air Management
(G) Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets

Carbon-Based Catalysts: To develop non-precious-metal catalysts for PEM fuel cells with high selectivity and durability which perform as well as conventional Pt catalysts with a cost of at least 50% less than the target of 0.2 g (Pt loading)/peak kW.

SOFC Materials: Develop SOFC electrode materials that enable direct operation on hydrocarbon fuels.

Carbon-Based Catalysts: Determine PEM seals materials that have no appreciable weight loss or leachants over a 60 week test period.

Hydrogen Contamination: Establish the rate and mechanism of NH₃ transport in PEM cells over a 60-week period; identify the species of sulfur contamination on Pt catalysts in the presence of various gas species, e.g., H₂O and O₂.

Multiphysics-Based Durability Modeling: Use impedance spectroscopy to identify specific material state change driven degradation mechanisms during SOFC operation.

Accomplishments

- Metal-free oxygen reduction catalysts have been developed to reduce cost, facilitate manufacturing, and enhance durability of PEM fuel cells.
- Redox stable MIECs for BSC symmetrical (and other) SOFC designs have been developed.
- The development of durable, low-cost seals for PEM stacks, through the establishment of laboratory characterization methodologies that relate to cell/stack performance.
- Understandings and methodologies have been developed to enable the establishment of hydrogen...
quality as it relates to PEM cell applications for transportation needs
• First principles multiphysics durability models based on interpretations of EIS data have been developed that form a foundation for engineering durability during design and manufacture of BSC SOFC fuel cell designs.

Introduction

The activities of the present project are contributing to the goals and objectives of the Fuel Cell Technologies Program of the Department of Energy through five sub-projects. Three of these sub-projects focus on PEM cells, addressing the creation of carbon-based metal-free catalysts, the development of durable seals, and an effort to understand contaminant adsorption/reaction/transport/performance relationships at low contaminant levels in PEM cells. Two sub-projects address barriers in SOFCs; an effort to create a new symmetrical and direct hydrocarbon fuel SOFC designs with greatly increased durability, efficiency, and ease of manufacturing, and an effort to create a multiphysics engineering durability model based on electrochemical impedance spectroscopy interpretations that associate the micro-details of how a fuel cell is made and their history of individual use with specific prognosis for long-term performance, resulting in attendant reductions in design, manufacturing, and maintenance costs and increases in reliability and durability.

Approach

• Work on a previous DOE project, DE-FC36-05GO13108, was leveraged to create new carbon-based, metal-free catalysts for oxygen reduction.
• Develop new materials and materials designs to create a high-performance SOFC that can directly operate on hydrocarbon fuels with high power density.
• Recent advances at the University of South Carolina in controlled hydration and temperature characterization of polymer-based materials will be used to establish a methodology for characterization of materials in seals in PEM stacks, and to develop a fundamental understanding how the degradation mechanisms of polymeric materials affects the performance and life of gasket/seals in PEM fuel cells.
• On-going work with the National Renewable Energy Laboratory, Argonne National Laboratory (ANL), Savannah River National Laboratory, and Los Alamos National Laboratory forms a foundation for the work on developing an understanding of the contaminant adsorption/reaction/transport/performance relationships at low contaminant levels in PEM cells. The study will provide equilibrium and rate constants suitable for use in new and existing models, and in computer codes at ANL.
• Conceptual foundations laid by research supported by the National Science Foundation, Air Force Office of Scientific Research and several industries including United Technologies Fuel Cells are being expanded to create a multiphysics engineering durability model based on EIS interpretations that associate the micro-details of how SOFC fuel cells are made and their history of individual use with long-term performance, to achieve reductions in design, manufacturing and operating costs.

Results

Only one example of salient results is presented in the limited space available here. Other results appear in the quarterly reports.

Sr- and Mn-doped LaGaO	extsubscript{3} (La	extsubscript{0.5}Sr	extsubscript{0.5}Ga	extsubscript{0.5}Mn	extsubscript{0.5}O	extsubscript{3}−δ, LSGM) have recently been synthesized in Dr. Chen’s group and applied as sulfur tolerant anode materials for SOFCs [1]. LSGM has demonstrated very promising catalytic activity for hydrogen oxidation. In an all perovskite-type fuel cell consisting of a La	extsubscript{0.5}Sr	extsubscript{0.5}Ga	extsubscript{0.9}Mg	extsubscript{0.1}O	extsubscript{3}−δ (LSGM) pellet with a thickness of 400 μm as the electrolyte, LSGMn as the anode, and LSCF as the cathode, an impressive power density of 400 mW/cm	extsuperscript{2} has been achieved at 800°C, as shown in Figure 1, using H	extsubscript{2} as fuel and ambient air as oxidant. Furthermore, LSGMn exhibits a mixed ionic and electronic conductivity of 10 S/cm at 800°C in air and can be potentially used as an oxygen electrode. Figure 2 shows the performance of a fuel cell pellet constructed with this combination of materials subjected to a sulfur containing fuel for a period of about 100 hours. The drop in performance quickly stabilizes and when hydrogen is re-introduced as the fuel about 80% of the original performance is recovered.

Dr. Chen’s group has also recently discovered a perovskite material with a composition of Sr	extsubscript{2}Fe	extsubscript{1+y}Mo	extsubscript{6}O	extsubscript{19} (SFM) [2], showing remarkable redox stability and high conductivity (>100 S/cm at 750°C) in either a reducing or an oxidizing environment. This new perovskite material has been applied as both hydrogen and oxygen electrode materials in a symmetrical SOFC, demonstrating very promising cell performance as shown in Figure 3 [3]. In addition, such redox stable mixed ionic and electronic conducting material will potentially simplify the electrode infiltration process since both the electrodes can be infiltrated in the same step.
FIGURE 1. Measured performance of LSGM electrolyte supported (400 µm) SOFC with LSGM as an anode and lanthanum strontium cobalt iron oxide as the cathode (left) and the cell impedance (right) for materials developed under this program.

FIGURE 2. Measured performance of LSGM-electrolyte supported (400 µm) SOFC with LSGM as an anode and LSCF as the cathode when subjected to a sulfur containing fuel.

FIGURE 3. Symmetrical fuel cell SFM|LSGM|SFM performance with wet (3 vol% H₂O) H₂ or CH₄ as fuel. a) current/potential and current/power density curves; impedance spectra of single cells in b) wet H₂ and c) wet CH₄.
Conclusions and Future Directions

Future work includes the following tasks:

- **Hydrogen Quality** - Extract rate constants from experimental data for the case of a contaminant that desorbs from the catalyst surface; establish correlations between experimental data and model that will allow predictions of the effect of contaminant concentration and electrode potential.
- **Carbon Composite Catalyst** – Confirm protocol for preparation of mesoporous carbon support; improve integrity of the carbon composite catalyst layer in the membrane electrode assembly (MEA); reduce MEA resistance by decreasing the catalyst layer thickness and by increasing the specific gravity and activity of the catalyst.
- **Hydrocarbon-Fueled SOFC** - Evaluate SOFC performance using hierarchically porous electrode and LaGaO₃₋ as well as SFM-based ceramic anode.
- **Gaskets and Seals** - design new compression set tests to include various compression strains and more realistic heating/cooling cycles to fuel cell operation; develop a life prediction model.
- **Durability SOFC Modeling** - complete button cell test system and EIS test protocols; complete conductivity model of BSC electrode configuration.

Special Recognitions & Awards/Patents Issued

1. Prof. Ken Reifsnider, PI of this effort gave an invited keynote lecture at the ACS meeting in San Francisco in May, 2010.
2. The Crystal Flame Innovation Award in Research from FuelCell South was presented to Dr. Popov’s research group for research work in the field of non precious catalyst development and preparation thin film assemblies with nano-structured catalysts and the development of the pulse deposition technique for preparation of membrane electrode assemblies.

FY 2010 Publications/Presentations

Objectives

- Double the speed of the extrusion line manufacturing process without negatively affecting cell performance.
- Transfer a new membrane production process from research and development to the manufacturing floor for increased shelf life and consistent quality control parameters.
- Complete research and development on the effects of optimizing the fuel cell module electrical connections to allow enhancement of module performance.
- Design and develop industrial-grade automated Unicell production process equipment for mass production.
- Transfer the fuel cell module production from research and development to the manufacturing floor for production level assembly.

Technical Targets

- Extrusion line speed of 2 meters/minute
- Power Output: 10-12 Watts per Unicell

Approach

The objective of this project is to continue the research and development required to take a microfiber fuel cell technology to a high-volume manufacturing level while maintaining product performance and quality. This microfiber fuel cell technology has the potential to meet the need for high volume fuel cell manufacturing processes. With the sub-recipient’s patented technology all the components of a single fuel cell, i.e., the electro-catalyst of cathode and anode, the polymer electrolyte membrane, and the current collector are extruded into a single microfiber (Figure 1). As the speed of the extrusion line is increased, it is important that no bottlenecks occur in the subsequent processes.

In support of the project objectives, additional process equipment for extrusion of microfibrous fuel cells was designed and constructed based on prior designs at the research and development level. This equipment was installed at a manufacturing facility for doubling the production line speed while maintaining cell performance. In addition, a membrane preparation system was designed, installed and tested at the manufacturing facility for increased shelf life and consistent quality of production. For the next step in the process, Unicell production, research and development was conducted on the production machinery necessary for Unicell production (Figure 2). New programs and
software were developed to enhance human interface and operability for efficiency and increased productivity. For the last step in the fuel cell assembly process, module production, design enhancements for the module electrical connections were developed and tested for increased module performance. Module production was transferred from research and development to the manufacturing floor while performance targets were maintained the same as those produced at the research and development level (Figure 3).

**Accomplishments**

- Production line equipment has been procured/constructed, installed and commissioned at the manufacturing facility. High-speed production line testing continues.
- Membrane production system has been designed, constructed and installed at the manufacturing facility. Manufacturing level volumes of membrane material are now produced and successfully extruded with the requisite rheology and properties.
- A new software program was developed for single cell wrapping to enable faster wrapping speeds and increased cell throughput.
- Standard operating procedures for Module assembly and testing have been developed (Table 1). Production equipment has been purchased, installed and commissioned. Training on Module assembly has been completed and production employees have shown successful assembly at the manufacturing level.

V.O.8 Fuel Cell Balance-of-Plant Reliability Testbed*

Objectives

There are two primary objectives of this project:

- To establish a testing program resulting in a reliability database for candidate proton exchange membrane (PEM) fuel cell balance-of-plant (BOP) components; and
- To enhance the education of the technical workforce trained in PEM fuel cell system technology.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability

This project also addresses the following technical barriers from the Education section (3.9) of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

(D) Lack of Educated Trainers and Training Opportunities

Technical Targets

Reliability of the fuel cell system BOP components is a critical factor that needs to be addressed prior to fuel cells becoming fully commercialized. Failure or performance degradation of BOP components has been identified as a life-limiting factor in fuel cell systems [1]. The goal of this project will be to develop a series of test beds that will test system components such as pumps, valves, sensors, fittings, etc., under operating conditions anticipated in real PEM fuel cell systems. Results will be made generally available to begin removing reliability as a roadblock to the growth of the PEM fuel cell industry.

Stark State College students participating in the project, in conjunction with their coursework, will gain technical knowledge and training in the handling and maintenance of hydrogen, fuel cells and system components as well as component failure modes and mechanisms. This fuel cell work force development program will result in students trained in PEM fuel cell system technology.

Accomplishments

- Two testbeds have been assembled.
- The third testbed is under development.
- Students are being trained to the Hydrogen Safety Plan.
- Students are being trained on the construction, programming and operation of the testbeds.
- Several test components have been identified.

Introduction

One of the major challenges that needs to be addressed by the fuel cell industry prior to full commercialization is the reliability of the components that comprise the complete system, particularly the BOP. As a potential developer and integrator of fuel
cell systems, the Stark State College of Technology’s team member, Lockheed Martin, has identified BOP component reliability as a critical factor that needs to be addressed before fuel cell systems will be incorporated into aerospace platforms.

**Approach**

Stark State College of Technology and Lockheed Martin will develop a series of test beds that will test fuel cell system components such as pumps, valves, sensors, fittings, etc., operating under conditions anticipated in real PEM fuel cell systems. The test beds will operate continuously for months, or years, until a component fails. Parts that continue operating will have demonstrated lifetime for potential fuel cell systems. Parts that fail will be removed (the rest of the test bed restarted) and examined to learn why they failed. Feedback will be provided to manufacturers for product improvement. Results will be made generally available to begin removing reliability as a roadblock to the growth of the PEM fuel cell industry. A total of three test beds will be developed in this project – two at the Stark State College of Technology and one at Lockheed Martin. Those at the Stark State College of Technology will be built and monitored by engineering technology students as part of their education program. A database of parts, operating conditions and lifetime data will be generated and updated regularly.

**Results**

A fuel cell system consists of a fuel cell and its supporting BOP – the pumps, valves, sensors, fittings, piping, etc. needed to turn a fuel cell into a useful power plant. Components in this complex system can have long-term exposure to hydrogen, air (oxygen), high purity water, heat and other chemicals. The BOP reliability test beds will be a simplified design, simulating the conditions of an operating fuel cell. The first two test beds are designed to replicate humidified hydrogen exposure in the PEM fuel cell at ≤80°C. These test beds are a hydraulic loop simulation of the fuel cell system to test the piping, connectors, sensors, valves, pumps, etc., without the fuel cell. Testing will be done to simulate the flow rates, temperature and pressure of operation, initially under a humidified nitrogen system with eventual operation under reactant conditions. This exposure would simulate the anode flow areas just before the fuel cell entrance and conditions in the hydrogen recirculation loop. The humidified hydrogen would be circulated using a hydrogen blower such as the Parker Hannifin Model 55™ Univane rotary compressor [2].

As required by the DOE, a Hydrogen Safety Plan was prepared to address the issues of working with hydrogen. The greatest hazard is combustion from leaking hydrogen. A failure modes and effects analysis of possible hazards leading to the accumulation of hydrogen and subsequent combustion was assessed for the test bed with the associated risk mitigation to limit or eliminate the components necessary to support a fire. All participants in the Fuel Cell Balance of Plant Reliability Testbed project are required to be trained in the safe use of hydrogen and compliance with the Hydrogen Safety Plan.

Renovation of the project laboratory space at Stark State College has been completed and complies with the safety standards.

Figure 1 shows the test bed process flow diagram. The test bed design can be viewed as two “separate” pieces. The upper flow diagram designated “Life Cycle Test” is the loop that will recirculate the humidified hydrogen. This loop will be pre-tested with nitrogen for leaks before hydrogen usage. Operating conditions will be 50 psi static, 80°C, 70-95% relative humidity and 6-7 scfm flow rate in the closed-loop system. The lower loop is designated for dry nitrogen or air only. This consists of the Blower Platform and the Dynamic Response Test System. This section is for the pre- and post-test validations in our reliability testing, pump performance mapping and pressure decay (leak) testing of the components.

Test bed component selection is also critical to safe operation with hydrogen. Electronic devices required one or more of the following: Factory Mutual compliance, intrinsically safe designation, compliance with Class I, Division 1, Group B operation or designated for hydrogen use. Stark State Students have been selecting components and monitoring sensors for the operation of the test bed. All test bed equipment is commercial off-the-shelf, as components requiring non-recurring engineering costs or modification for fuel cell use were outside the scope of this project. Instruments were chosen for their compliance with materials and flow specifications. Students have been exposed to the various sensor instrumentation associated with fuel cells as well as the instrumentation and operation of fuel cells in the classroom.

Several issues with PEM fuel cell commercial off-the-shelf components have been documented as components for testing have been identified. Reliability data is incomplete for limited production components. Many components with design capabilities within the PEM fuel cell specifications have never been tested for any length of time under those conditions. Other components do not have the correct material compatibility to operate within PEM environment, especially with respect to exposure to hazardous gases and deionized water. Additionally, high development costs were necessary to modify some existing off-the-shelf components to become compatible with the PEM environment.

PFA vs. Stainless Steel

Coextrusion: Permeation-Resistant Cladding

PFA-Perfluoroalkoxy polymer

FIGURE 1. Fuel Cell BOP Reliability Test Bed Design

FIGURE 2. Pressure Decay Data for PFA Polymer Tubing
One component that has completed qualification testing is a limited run perfluoroalkoxy (PFA) polymer tubing with a permeation resistant cladding. This tubing is lighter weight than stainless steel and is resistant to deionized water, corrosion and chemicals. Initial pressure decay testing of the PFA tubing, shown in Figure 2, exhibits behavior similar in magnitude to stainless steel. The tubing must still be evaluated with respect to long-term exposure to the temperature, pressure and humidity of the PEM fuel cell environment. Other components designated for test include sensors and, potentially, valves which are known sources of reliability issues [3].

Student training has been ongoing for the operation of the test bed. The training has continued for participating students to have a greater depth of understanding in LabVIEW programming and exposure to a broader range of software programming techniques. The training has included embedded controller information for LabVIEW programming and compiling to make a stand-alone program for data acquisition, control and analysis of the data. The MET231 Fuel Cell System class visited Lockheed Martin and thoroughly reviewed the test stand setup, the hardware instrumentation devices, and software of the Lockheed Martin’s test stand. This opportunity greatly assisted the building process of the student’s first test stand.

Conclusions and Future Directions

Safety protocols are in place at both Stark State College of Technology and subcontractor, Lockheed Martin, locations to ensure the safety of individuals working with and around the reliability test beds being created through this project. The first two BOP reliability test beds are assembled and instrumented for reliability testing. Candidate components are being pre-tested in preparation for long term testing. This project continues as a cooperative program between industry and an educational institution for hands-on training of the PEM fuel cell workforce.

Future Work:

• Operation of the test beds to obtain reliability data.
• Failure analysis of failed components.
• Construction and instrumentation of the third BOP reliability testbed in the coming academic year.

V.O.9 Biomass Fuel Cell Systems*

Objectives

- Develop solid-oxide fuel cell (SOFC) materials for robust operation on renewable/biomass fuel streams.
- Identify optimal fuel-processing strategies for renewable fuels (i.e. biogas and butanol).
- Employ system modeling to optimize SOFC system configurations.
- Extend model-predictive control to integrate system hardware.

Technical Barriers

- Durability: Broaden SOFC operating window under hydrocarbon and bio-derived fuel streams.
- Performance: Increase efficiency through system optimization and balance-of-plant component integration.
- Transient operation: Develop model-predictive control algorithms for use in dynamic control.
- Balance-of-plant costs: Integrate fuel reforming and heat recuperation hardware into a single low-cost ceramic micro-channel reactive heat exchanger.

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(C) Performance
(G) Start-up and Shut-down Time and Energy/Transient Operation

Technical Targets

In this project, we conduct a range of studies to improve the durability, efficiency, and transient operation of SOFC systems. Fuel streams for these systems include anaerobic-digester derived biogas, and biomass-derived liquid fuels such as butanol. Insights gained from these studies will be applied toward the design and synthesis of SOFC materials and systems to meet the DOE 2015 Technical Target for durability (35,000 hours), start-up time (15-30 minutes), and cycle capability (250 cycles).

Accomplishments

- Established biogas fuel processing strategies and experimentation.
- Quantified performance of SOFCs under biogas reformate fuel streams, and established performance comparisons under hydrogen fuel streams.
- Demonstrated operation of low-cost ceramic micro-channel fuel reformer/heat exchanger for reformation of butanol fuel stream.
- Developed hybrid computational fluid dynamics (CFD)-chemical kinetics model to examine design tradeoffs in ceramic microchannel fuel reformer/heat exchanger.
- Utilized hybrid models to quantify effects of materials changes on ceramic heat-exchanger effectiveness.
- Developed rapid, lower-order dynamic models to map response of slower, high-order physical models for use in dynamic system control of fuel-reformer hardware.
- Demonstrated fidelity of lower-order models in mapping reformer response across numerous temperature changes.
Introduction

The objective of this project is to advance the current state of technology of SOFC systems to improve performance when operating on biomass-derived fuel streams. These fuel streams include biogas generated by the anaerobic digesters that are widely used in municipal waste-water treatment facilities, and biomass-derived butanol fuel, a gasoline-compatible liquid fuel that boasts an energy density that is 75% that of diesel fuel. In this project, we are developing new SOFC and catalyst materials to improve the robustness of systems operating under these biomass-derived fuel streams. Additionally, modeling and experimentation is being conducted to examine performance tradeoffs across numerous fuel-processing strategies for these fuels. Fuel-reforming processes are being integrated with exhaust-gas recuperation processes through development of a single low-cost ceramic micro-channel reactive heat exchanger, created in collaboration with industrial partner CoorsTek, Inc. Finally, model-predictive control strategies are being developed and applied to improve the dynamic response of the fuel-reformer hardware.

Approach

The Colorado School of Mines has assembled a strong and diverse team of scientists and researchers with broad skill sets applicable to fuel cell development. Coordinated through the Colorado Fuel Cell Center (CFCC), this team examines both the fundamental underpinnings and the key technical problems facing SOFC operation under biomass-derived fuel streams. We develop new SOFC materials for use in biomass-derived fuel streams, addressing the technical challenges and operating windows associated with fuel processing of both gaseous- and liquid-phase fuels. Through development of low-cost ceramic microchannel reactive heat exchangers with industrial partner CoorsTek, Inc., we are creating system-integration strategies to combine balance-of-plant processes into single hardware units, increasing system simplicity and decreasing cost. Model-predictive control strategies are being developed and applied to fuel-reforming hardware in an effort to improve the dynamic response of SOFC systems.

Results

Biomass-Derived Fuel Processing

In this task, we examine fuel-reforming strategies to reform two model fuels into syngas for subsequent electrochemical conversion in SOFCs. These model fuel streams include biogas generated by the anaerobic digesters and biomass-derived butanol fuel. The goal is to develop flexible, efficient fuel-processing strategies for the robust use of biomass-derived fuels in SOFCs. The effort includes computational model development on biomass-derived fuel reforming, and experimental validation and electrochemical-performance measurements of biogas-reformate-fueled SOFCs.

Ideally, the anaerobic-digester-derived biogas streams could be fed directly to the SOFC anode with no upstream reforming or fuel processing beyond trace-contaminant cleanup. Unfortunately, the composition of biogas (approximately 65% CH$_4$/35% CO$_2$) can prove problematic, leading to carbon-deposit within the stack, and rapid performance degradation. To address these concerns, we are developing upstream fuel-reforming processes to efficiently convert the biogas fuel into high-H$_2$-quality reformate to be subsequently fed into the fuel channels of a SOFC. To examine the tradeoffs in reforming approaches, a fuel-reforming facility has been constructed in the CFCC. The experiment includes extensive reactive-gas manifolding and steam addition to enable creation of a broad range of biogas-reforming streams. These mixtures are then fed to a rhodium-based catalyst coated onto high-performance strontium-hexaaluminate catalyst supports on alumina-foam monoliths. Reformate composition is measured using an Agilent micro-gas chromatograph. The experiment can be integrated with an SOFC electrochemical test stand currently on hand and operational at the CFCC.

In concert with this experiment a chemical-kinetics computational model has been developed to predict reformate composition across the range of reforming approaches. Utilizing the Sandia-developed Cantera chemically reacting flow software package, this reforming model employs porous-media transport and multi-step elementary heterogeneous chemistry for reformation of methane on a rhodium-based catalyst. The computational and experimental tools developed through this project have been used to explore three types of biogas-reforming approaches: catalytic partial oxidation (CPOX) using air as the oxidizer, CPOX using pure O$_2$ as the oxidizer, and dry (CO$_2$) reforming of biogas fuels. It is important to note that waste-water treatment facilities often include cryogenic-oxygen systems for more-efficient oxidation of water-bound wastes. This oxygen could also be directed to the fuel cell system for use in biogas fuel processing, motivating our study biogas-CPOX using pure-O$_2$ oxidizer streams.

The biogas reformate generated by these three different reforming strategies was fed to a SOFC provided to the CFCC by industrial partner CoorsTek, Inc. Performance results are shown in Figure 1 at an operating temperature of 850°C under flooded-fuel conditions. Cell performance is compared across the different biogas fuel-reforming approaches, and compared to hydrogen-fueled operation. Cell performance under CPOX reforming rivals that of pure hydrogen, while performance under dry-reforming conditions is significantly lower. As these tests were conducted under “flooded-fuel” conditions, fuel dilution and concentration polarization losses were minimized,
possibly masking the effects of the high nitrogen dilution found in CPOX-air conditions. In future studies, we will expand on this biogas fuel-processing work to include steam reforming, and more-widely explore biogas fuel-processing operating windows.

We are also examining the on-board processing of biomass-derived butanol fuel by mating efficient vaporization and mixing with high-performance ceramics-based micro-channel reactive heat-exchanger/fuel-reformer devices. This effort builds on the biogas fuel reforming experiment discussed above, adding a liquid-fuel, gas-oxidizer mixing unit and micro-channel reactive heat exchanger. We are developing the ceramic micro-channel reactive heat-exchanger technology through close collaboration with industrial partner CoorsTek, Inc, with reactor images shown in Figure 2. These micro-channel reactors offer great advantages over conventional shell-and-tube reactors through improved heat transfer and thermal regulation of reforming processes. Exothermic reforming processes can cause hot spots in conventional reactors that reduce the efficiency and effectiveness of the reforming process. Similarly, supplying heat for endothermic-reforming processes can pose significant parasitic losses in SOFC systems. In micro-channel reactors, the hot and cold streams are tightly integrated, so that thermal regulation is maximized. Additionally, this micro-channel heat exchanger is fabricated using low-cost ceramic materials ($\text{Al}_2\text{O}_3$) that are joined in a single high-temperature sintering process, greatly reducing the materials and fabrication costs of the device, which greatly decreases SOFC balance-of-plant expenses.

Ceramic heat exchangers are being fabricated at CoorsTek, and provided to the CFCC for application of a catalyst onto the reactive side of the heat exchanger. Building on the biogas-reforming work described above, a rhodium catalyst with a Sr-hexaaluminate support is utilized. The reactive heat exchanger has been used for catalytic partial oxidation of butanol to syngas; reformate compositions are shown in Figure 3 as a function of total fuel flow rate. As flow rate increases, the quality of the reformate composition is found to increase dramatically. This highlights the close coupling of heat transfer and fuel-reforming effectiveness in this type of reactor. While this demonstration is highly encouraging in validating the concept of the integrated ceramic reactive heat exchanger, further work will be conducted during the course of this program to optimize the fuel-processing conditions.

Advanced hybrid computational modeling tools are being developed that mate high-order Fluent-based computational fluid dynamics with high-fidelity Cantera-based chemically reacting flow. The tools are being applied to the integrated reactive heat exchanger discussed above, and used to examine the effects of design choices on heat-exchanger and fuel-reformer effectiveness. A result for the non-reactive case is shown in Figure 4. The flowfield appears to be well

---

**FIGURE 2.** Integrated ceramic micro-channel reactive heat exchanger: a) exploded design image; and b) photograph of heat exchanger cross section, highlight micro-channels.
balanced, with near-uniform flow conditions across the micro-channels that constitute the heat exchanger. Additionally, the gradual changes found in the temperature field create confidence that thermal stress is well balanced in the device, a significant concern when utilizing ceramic components. Further modeling work will include the chemically reacting flow simulations to provide guidance for optimizing fuel-reforming operating windows in the reactive heat exchanger.

Model-Predictive Control

Model-predictive control provides a means to incorporate fundamental physical and chemical understanding into real-time, multiple-input/multiple-output, process-control strategies. The reduced-order models are derived from large high-fidelity physical models, while system identification is accomplished by driving the physical models with actuation inputs consisting of pseudo-random binary series and observing the responses. The process depends upon having time-accurate physical models. The effort here is two-fold. First is to develop and validate the physical models for SOFC systems operating on reformed biomass-derived fuels. Unlike many fuel cell models based upon steady-state assumptions, the models here must be written to represent time-accurate transient solutions. Moreover, they must be written to accept pseudo-random binary series inputs and return high-accuracy transient response signals used for the system identification.

In this task, we are applying model-predictive control strategies to operation of fuel reformers like the micro-channel devices described previously. Initial efforts are directed toward the simpler ceramic-foam reformer utilized in the biogas experiments. We are now examining the thermal capacitance of the biogas reactor to establish dynamic response to process variations. We have successfully mapped the thermal response of the reactor under non-reactive conditions, and compared this response to dynamic-model predictions; excellent agreement was obtained. In future efforts, we will expand this work to reactive conditions; as model fidelity improves, we will expand this work to examine and control the response of the micro-channel reactive heat exchanger devices.

Future Directions

Biomass-Derived Fuel Processing

- Explore steam-reforming and anode-recycle processing of biogas fuels.
- Extend partial-oxidation experiments on butanol fuel in integrated ceramic micro-channel reactive heat exchanger.
- Develop process windows for deposit-free SOFC operation under butanol reformate.
- Extend hybrid CFD/chemical-kinetics modeling to examine effects of fuel-processing strategies on heat-exchanger effectiveness and fuel-reformate composition and quality.

System Control

- Implement explicit form for model-predictive control for use in biogas-reforming system.
- Extend model-predictive control strategy to reactive heat exchanger.
Objectives

The overall objective of this project is to optimize and scale up the process to make Dynalene FC fuel cell coolant with a great deal of reproducibility. The following are some specific objectives that would help to reach the overall goal of the project:

- Demonstrate the production of one key ingredient of the coolant (a nanoparticle) in 10 L, 20 L and 100 L batches in a pilot-scale operation and study the effect of various process parameters on the size and charge density of the particles.
- Produce the nanoparticles necessary for the fuel cell coolant, Dynalene FC, in a very consistent manner (i.e., particle size, charge density and yield).
- Optimize the filtration process for the nanoparticles to minimize the cleaning time for different scales of operation.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Durability
- Cost

Technical Targets

Dynalene FC is expected to help the fuel cell industry achieve their durability and cost targets to some degree. First of all, the coolant itself is being designed to have a life of 5,000 hrs. It is also expected to have excellent compatibility with the system materials and inhibit corrosion in the coolant loop. This will help in extending the durability of the fuel cell system components such as the pump, the radiator, valves, seals/gaskets and any other components coming in contact with the coolant. The coolant is also designed to work at -40°C, which will assist both transportation and stationary fuel cells to quickly warm up during cold starts.

The cost target for the coolant (in plant-scale production) is about $10/gallon, which is very close to the retail price of current automotive coolants. This coolant will also eliminate the deionizing filter and other hardware associated with it (i.e. fittings, valves). It is also being designed to work with cheaper, lighter and thermally efficient components such as aluminum radiators (instead of stainless steel) and brass heat exchangers.

Accomplishments

Dynalene FC has been demonstrated by field testing to maintain a very low electrical conductivity and stay stable over several years. This was possible due to the addition of a nanoparticle into the coolant. This project addresses the optimization and scale up of this nanoparticle ingredient. The main accomplishments in the first few months of the project are the design of the reactor systems, procurement of the reactors and the components and commissioning.

Introduction

This project addresses the goals of the Fuel Cell Technologies Program of the DOE to have a better thermal management system for fuel cells. Proper thermal management is crucial to the reliable and safe operation of fuel cells. A coolant with excellent thermophysical properties, non-toxicity, and low electrical conductivity is desired for this application.

Dynalene Inc. has developed and patented a fuel cell coolant with the help of DOE Small Business Innovation Research Phase I and Phase II funding (Project # DE-FG02-04ER83884). However, this coolant can only be produced in lab-scale (500 ml to
2 L) due to problems in optimization and scale up of a nanoparticle ingredient. This project will optimize the nanoparticle production process in 10 L, 20 L and 100 L reactors, optimize the filtration process, and develop a high throughput production method for the final coolant formulation.

**Approach**

Dynalene researchers have been producing the nanoparticles ingredients used in the fuel cell coolant in 100 ml, 500 ml and 2 L reactors. The main parameters that contribute to the quality of the nanoparticles are size and surface charge density. Another important factor needs to be optimized is the yield from the production as well as cleaning/filtration. At 100 ml scale, the nanoparticles were produced using magnetic stirring and the heating was provided by a constant temperature bath. At the 500 ml scale, the stirring mechanism was changed to a mechanical stirrer with impellers, while the heating mechanism was still through a constant temperature bath. At the 2 L scale, the stirring was through a mechanical stirrer whereas the heating was accomplished by pumping hot water through the jacket of the reactor. In this project (for 10 L and 100 L reactors), mechanical mixers with multiple impellers and heating systems using the jacket of the reactor will be used. Mixing/stirring mechanism as well as the heating method impacts the particle size, charge density and the yield of the reaction. Therefore, an understanding of the influence of these parameters is very essential to obtain the nanoparticles with reproducible properties. Dynalene and Lehigh University have partnered to develop the scale up criteria needed to go from a 2 L scale to a 10, 20 or 100 L scale.

**Results**

Three glass reactors (one 10 L, one 20 L, and one 100 L) were purchased by Dynalene (Figures 1 and 2). During the course of the last quarter all reactors have been received and assembled.

A great deal of time was spent modifying the 20 L reactor that was purchased in an auction and not pre-customized to the specifications necessary to complete the scope of this project. Those modifications are completed and mixing studies have begun to optimize impeller placement and mixing speed. Reactors of this size require two impellers on the stir shaft and proper placement is crucial. The mixing experiments were done using an oil containing dye along with water to simulate the monomer/water mixture that is the basis of the nanoparticle synthesis. The studies are progressing well but more thorough experiments are necessary.

The heating and cooling system for the three reactors has been completed and installed. Heating and cooling experiments on the 20 L reactor have been run with water as the medium to simulate the reaction conditions. Some minor modifications were necessary to correct some initial problems with the system.

The 10 L and 100 L reactors have been assembled and similar testing on these will be performed in the future.
Optimization experiments on the 500 ml and 2 L scale of the anionic and cationic nanoparticles have led to narrowing some of the independent and dependent variables of scale. These small-scale reactions on the cationic nanoparticles have produced two possible recipes for further scaling. Both of these recipes will be studied at the 10 L scale to determine the best candidate for further work. The variables that need to be considered for scaling are listed below and need to be monitored at each scale up step.

Independent Variables:
- Mixer type
- Angle
- Speed
- Reactor type
- Baffled/non-baffled
- Recipe
- Temperature
- Heat transfer mechanism

Dependent Variables:
- Size
- Surface charge density
- Yield
- Time of reaction

More than 20 batches of anionic nanoparticles were produced at the 2 L scale. All batches showed yield of greater than 20% solids. Purification of the nanoparticles will be carried out at this level. Purification by tangential flow filtration (TFF) requires that the solids concentration be a maximum of 8%. A large dilution was necessary to achieve the proper flow through the membrane. Purification of 500 ml scale reactions can typically take two to three days after dilution so this larger purification would definitely lead to a bottleneck in the process.

The TFF system was set up with two membranes instead of one to double the surface area for cleaning. A dilution of 2 L to approximately 16 L was necessary for purification. A system using a large reservoir and the vacuum caused by the filtering was set up to constantly replenish the water lost during the process. This allowed for continuous filtering at a constant volume and decreased the time needed for cleaning from two or three days down to one day.

Following is a list of parameters for optimization of filtration:
- Flow rate
- Pressure
- Concentration (solids percentage)
- Membrane pore size
- Membrane construction (polyether sulfone or ceramic)
- Additives
- Mixing in reservoir

Dynalene is also studying a new ceramic TFF filter system, which may speed up the filtering process. This system may also have another benefit of allowing purification of both anionic and cationic particles in the same filter. The current process requires two separate systems for filtering. An initial study showed proof of concept in a short-term test with a membrane manufacturer. A longer, more substantial trial is being scheduled at this time.

Conclusions and Future Directions
Dynalene has set up all the reactors for the nanoparticle production. After some preliminary testing, the 10 L and the 20 L reactors will be used for the synthesis of the nanoparticles. The scale up criteria developed in collaboration with Lehigh University will be verified.

The immediate tasks to be performed are as follows:
- Further testing of the heating and cooling components of the reactor system will be carried out to make sure that they are operating.
- Mixing parameters for the 10 L and 20 L reactors will be optimized.
- Scale up experiments for the anionic and cationic nanoparticles will be started.

FY 2010 Publications/Presentations
Objectives

• The overall objective of the research program is to provide new electrolyte membranes and electrode materials consisting of integrated catalysts and fluorinated electrolytes for use in PEMFC power sources.

• The research will be pursued in two thrusts, one focused on new proton-conducting fluoropolymer electrolyte membranes for use under high-temperature (95 - 120 °C) and low-humidity (25 - 50% RH) conditions, and another focused on electrolyte integration into fuel-cell electrodes by covalent attachment of electrolytes onto carbon supports.

• The objectives of work in the first thrust area are the discovery, synthesis, characterization, and evaluation of new polymeric proton-conducting electrolyte membranes.

• The objective of work in the second thrust area is to develop methods for accomplishing robust attachment of proton-conducting polymer electrolytes onto carbon supports, and to characterize the resulting materials with special attention to their mixed electronic and ionic conduction and electrochemical properties.

Technical Barriers

• This research seeks to overcome technical barriers to implementation of PEMFC technology associated with low protonic conductivity in polyelectrolyte membranes at high temperatures and low water activities.

• It seeks to develop polymer electrolyte membranes that will overcome this conductivity barrier while also retaining dimensional stability (little to no swelling on contact with liquid water) and durability (lifetimes up to 5000 hours are desired).

Abstract

Project work focusing on blended fluoropolymer ionomers, mesoporous carbon supports for PEM fuel cell electrode, and grafted electrolytes within pores of mesoporous carbon and nanocomposite mesoporous carbon / zirconis supports is reported. Blended ionomers have conductivity comparable to that of PFSA ionomers with less swelling and improved dimensional stability. Mesoporous carbon supports were prepared by a silica sol templating approach and were shown to have very high pore volume, which is posited to allow for rapid transport into and out of pores. Monomolecular (non-polymeric) electrolytes were grafted inside pores but so far improvements in fuel-cell performance have not been realized. Ongoing work will seek to graft polyelectrolytes inside support pores, which is believed to be necessary to realize improved performance.

Progress Report

1. Blended ionomers. Blends of PFSI and S-PFCB (see Figure 1 for structures) were prepared in various compositions between 70:30 and 50:50 mole ratios of PFSI to S-PFCB. The resulting blends have conductivity comparable to Nafion® 112 in the 0-70% RH range, and also lower swelling than the non-blended S-PFCB ionomer. Preliminary studies on blending heteropoly acids (HPAs) and
on electrospinning of ionomer blends were also undertaken.

2. **Mesoporous carbon supports.** Mesoporous carbon (MC) supports for Pt in PEMFC electrodes were prepared by making resorcinol-formaldehyde (RF) carbon aerogels with colloidal silica added, followed by silica removal using caustic. The resulting supports had high surface area and very high pore volume (over 4 cc/g). Platinum deposition was accomplished via formaldehyde reduction of hexachloroplatinate deposited by the incipient wetness method. In-situ CV of electrodes fabricated on glassy carbon supports (Figure 2) showed high Pt surface area and small particle sizes. Membrane-electrode assembly fabrication onto Nafion® membranes using conventional conditions (approx. 30 weight percent Nafion®) failed due to poor dimensional stability of the composite electrodes. This fact is thought to be due to Nafion® being taken up into the support pores, which left none to accomplish electrode binding. Ongoing work will focus on electrode formulations having more Nafion®, and on covalently grafted ionomers in the pores.

3. **Mesoporous carbon supports with grafted electrolytes.** Work on grafting small-molecule aryl fluorosulfonimide electrolytes onto mesoporous carbon continued and was completed this year. Grafting of monolayers of acid electrolyte onto mesoporous carbon was demonstrated using aryl diazonium salts. Ion-exchange capacities of the resulting materials were relatively low (less than 0.2 meq/g) and fuel-cell performance of MEAs fabricated using Pt/carbon having grafted aryl fluorosulfonimide electrolytes was not greatly different from that of MEAs prepared using carbon without the grafted electrolyte. We believe this reflects the relatively small amount of electrolyte that was ultimately grafted.

We desired access to a simpler chemistry for grafting larger amounts of electrolyte, possible polymeric electrolytes, inside the pores of mesoporous carbon supports. To accomplish this aim, mesoporous carbon supports were prepared using the RF method with both colloidal silica and zirconia added, followed by etching to remove silica but not zirconia. The resulting supports are nanocomposites of carbon containing nanoscale zirconia. Subsequent modification of these supports with the difunctional acid, meta-sulphophosphonic acid, was accomplished. Titration of the resulting supports confirmed incorporation of sulfonic acid groups. Ongoing work seeks to increase the amount of incorporated acid both by increasing the amount of zirconia in the carbon / zirconia composite, and also by utilizing telechelic S-PFCB polymers having phenyl-phosphonic acid end groups (see Future Directions).

**Future Directions**

Future work is planned on several fronts. Ionomer blends will continue to be studies with a focus on combinations of low-EW ionomers that can retain water and provide high conductivity, with high-EW ionomers to provide dimensional stability and limit swelling. Crosslinking strategies will be pursued that can stabilize membranes after casting. One such approach will involve new perfluorocyclopentenyl-based ionomers for which a synthesis is shown in Figure 3. The double bond in the PFCP group is a potential site for crosslinking that may be initiated thermally following membrane casting.
Work on telechelic S-PFCB polymers having terminal phenyl-phosphonic acid groups to provide anchoring sites for zirconia will be pursued to provide a route to nanocomposite carbon / zirconia catalyst supports having high ion-exchange capacities of ionomer integrated into electrolyte pores. Figure 4 presents an illustrative structure of a bound ionomer bound at a terminal phenyl-phosphonic acid group. This work will build upon our prior work demonstrating binding of meta-sulpho-phenyl-phosphonic acid onto zirconia groups in carbon / zirconia composite catalyst supports.

Publications (including patents) acknowledging the grant or contract

Objectives

We are developing first-principles based methods for predicting the solubility and diffusivity of hydrogen in amorphous metal alloys. These methods are being used to seek new alloy compositions that will allow the fabrication of dense metal membranes for hydrogen purification that will exceed the performance limitations associated with well-known crystalline metal membranes.

Technical Barriers

A number of experimental groups have demonstrated that it is possible to fabricate useful dense metal membranes from amorphous metals. Unfortunately, the large number of possible amorphous metal compositions makes experimental screening of these materials for membrane applications impractical. We are developing quantitative modeling methods that can aid in the discovery of new membrane materials by making predictions about membrane performance prior to experimental testing.

Abstract and Future Directions

Within this project, we have demonstrated the development of methods to make quantitative predictions about the performance of amorphous metal films during use as hydrogen purification membranes. The modeling framework for the analogous problem with crystalline metals is relatively well developed, but the disordered nature of the interstitial sites in amorphous metals required extensive method development. In brief, our first-principles calculations for amorphous metals proceeds by (i) using *ab initio* Molecular Dynamics methods to create representative amorphous solid structures within a periodic supercell geometry, (ii) use efficient methods based on empirical forcefields to initialize first principles calculations to find the energy of H in all interstitial sites in the material, and (iii) use efficient methods to initialize first principles calculations to locate all transition states for H hopping between adjacent interstitial sites. Once the binding sites and transition states are known, Grand Canonical Monte Carlo (GCMC) and Kinetic Monte Carlo (KMC) calculations are used to accurately describe the net solubility and diffusivity, respectively, of H in the amorphous material. These calculations include a characterization of the H-H repulsion that occurs at levels of interstitial H at which the interstitial species is not dilute. We have characterized this phenomenon via extensive first-principles calculations.

An important general property of amorphous metals is that the solubility of H in these materials is quite high due to the energetically favorable interstitial sites that are created by the amorphous material. At non-dilute concentrations, the differences that exist between various different diffusion coefficients (e.g. the self diffusion coefficient and the Fickian diffusion coefficient) become significant. Previous studies of H diffusion in crystalline metals had only examined the self diffusion coefficient. We have extended our KMC methods to allow the direct calculation of the Fickian diffusion coefficient. It is this diffusivity that is of the greatest physical interest in describing macroscopic mass transport through a membrane. In general, the Fickian diffusivity is larger than the self diffusivity at the same conditions. At high concentrations of interstitial H, the expansion of an amorphous alloy due to the interstitial H can also have a marked effect on the net solubility of H. We have developed efficient methods that allow us to quantify this effect.

We have demonstrated the validity of our modeling approach by comparing predictions from our models with experimental data that is available for permeation of hydrogen through amorphous ZrNi and ZrNiNb films. Once the effects of hydrogen-induced lattice expansion and concentration-dependent diffusion coefficients are taken into account, our model's predictions are in quantitative agreement with experimental data. Crucially, our approach does not require any experimental data, so it can be used in a truly predictive sense. We are currently using our method to screen a variety of binary and ternary alloys that are known to be good glass formers with high glass transition temperatures with the aim of identifying materials that will exhibit high permeability for hydrogen when used as membranes.

In addition to our work on amorphous metals for hydrogen purification, we have performed work on the related topic of understanding hydrogen diffusion in ionic hydrides. Specifically, we examined the diffusion mechanism of hydrogen in two prototypical ionic hydrides, MgH$_2$ and NaMgH$_3$. An interesting conclusion from this work was that the relevant species that control
the mobility of H in these materials are charged, unlike the neutral species that control interstitial diffusion in metallic systems. Understanding the characteristics of H diffusion in these two materials opened the possibility of finding dopants that would accelerate H diffusion, and we used first-principles calculations to examine a larger range of possible dopants for this purpose. We also performed similar calculations for several light metal borohydrides, including LiBH₄. A surprising outcome from these calculations is that hydrogen diffusion in these materials appears to be mediated by formation of neutral molecular H₂ within the solid.

Publications (including patents) acknowledging the grant or contract

Objectives

It is our objective to develop new theoretical and computational techniques to investigate the structure and transport properties of hydrated ionomer membranes, and thereby to enable the development of new and more useful materials for use in polymer electrolyte membrane fuel cells. Specifically, our aim is to produce a tool to predict both the nanophase structure and the proton transport properties for any given membrane material and level of hydration. In this way we hope to develop a deeper understanding of the dominant factors affecting the nature and magnitude of the proton transport.

Technical Barriers

One of the most significant technical barriers to the improvement of polymer-electrolyte fuel cells lies in our lack of understanding of the formation of the continuous hydrophilic pathways necessary for proton conduction. Another serious obstacle is the difficulty of achieving high proton conductivities in a low-humidity environment. In our research, we face the obstacle of the extremely large computer resources required for an accurate simulation of large volumes of membrane electrolyte material. This necessitates our use of a combination of theoretical analysis with united-atom simulation techniques to reach viable conclusions in reasonably short computation times.

Abstract

We have used a combination of analytical theory and molecular-dynamics simulations to investigate the effect of various material parameters on the structure and proton conductivity of Nafion-like ionomer membranes. This has included the effects of varying the length of the molecular side chains and their spacing along the polymer backbone, as well as membrane stretching, membrane poling by the application of strong electric fields, and inclusion of hydrophilic nanoparticles. Most recently we have studied the effects of confining the ionomer inside cylindrical pore channels penetrating an inert membrane.

Progress Report

During the past year we have used molecular-dynamics simulations to explore the consequences of modifying an ionomer membrane in numerous ways [1,2]. We have extended and solidified our previous preliminary results on the effects of strong electric fields on a Nafion-like ionomer, and have confirmed that an aligned structure consisting of a hexatic array of one-dimensional ion channels is thermodynamically stable. This structure has enhanced proton conductivity through the membrane, as the channels follow the direction of the applied poling field. We determined the role of some ionomer structural parameters in the formation of this ordered hexatic phase in poled membranes. We found that it is the length of the side chains that effectively controls the two-dimensional density of the cylindrical rod-like sulfonate clusters. In membranes with shorter side chains, the lattice constant of the hexatic phase is about twice the length of the sidechain. In this case the backbone matrix does not hinder the formation of rod-like clusters, and there is negligible elastic stress. However, in membranes with longer sidechains, which would give rise to larger cluster formations in an unpoled membrane, the sidechain-polymer entanglements restrict the clustering of sulfonates in the poled material. The number of cylindrical clusters in this case is thus controlled by a delicate balance between the effective sulfonate-sulfonate attraction and the elastic forces resisting backbone deformation. The latter makes the formation of larger clusters unfavorable, thereby making the two-dimensional density of induced cylindrical aggregates in poled ionomers higher than expected from theoretical predictions. We have also shown that ion diffusion in poled membranes is strongly anisotropic, and depends on the structural parameters of the hexatic phase. When the backbone segment length in homologous membranes (membranes with constant sidechain length) is decreased, thicker ionic cylinders with shorter sulfonate separations in them are formed. In this case the diffusion of protons both along the poled structures and perpendicular to them increases as an inverse function of the backbone segment length. Thick cylinders are also formed in constant equivalent-weight membranes with longer sidechains and shorter backbone segments. However, in this case the cylindrical
aggregates are highly tortuous, and this inhibits the diffusion of protons along the poled pathways.

Another area of our research concerned the effects of nanoparticle inclusions in ionomer membranes [3,4]. We first analyzed the distribution of conducting ions in these nanocomposite membranes. Our simulations showed that, in the case of neutral particles, the proton distribution is almost unperturbed. This reflects the fact that the hydrophilic channels are homogeneously distributed in the membrane. When the particle-membrane interaction is hydrophilic, however, all the conducting ions accumulate near the nanoparticle surfaces [3]. When the surface area of a single nanoparticle is insufficient to accommodate the accumulated ions, a second layer of ions is formed. We found that such ‘surface assisted’ proton clustering can drastically affect the membrane conductivity, sometimes increasing it by as much as an order of magnitude. In the case of a hydrophobic particle-membrane interaction, the diffusion pathways formed by the hydrophilic ions are repelled from the nanoparticle surface. Thus proton transport across a membrane can be optimized with the right combination of nanoparticle size and concentration.

We have also analyzed the effect of changing the length of the side chains, and the spacing between them along the polymer backbone, on the shape of the hydrophilic network of sulfonate clusters created by their partial phase separation from the hydrophobic backbone material. Various modifications of a Nafion®-like ionomer have been studied. These include ionomers having a backbone spacing up to twice that of Nafion® and those having side chains with a length up to three times that of Nafion®. We showed in detail how two membranes with the same equivalent weight but different detailed architectures can have completely different morphologies. In ionomers having longer sidechains, we find that larger sulfonate aggregates with a higher sulfonate population are formed. In ionomers with shorter side chains, the ion diffusion in small clusters is mostly based on an ion-hopping mechanism between adjacent sulfonates. Inside the larger clusters found in ionomers having longer sidechains, however, the proton transfer has additional contributions from vehicular and Grotthuss dynamics. In membranes with higher sulfonate concentration and longer sidechains, the nearest-neighbor distance between clusters becomes small enough for temporary inter-cluster bridges to be formed, and this facilitates the overall proton diffusion in the membrane.

In our most recent work we have analyzed the nano-morphology of low-water-content ionomers contained within cylindrical pores [5]. Our results reveal a strong enhancement of ion diffusion [6]. We find that when the pore diameter $D$ is larger than the length $d$ that characterizes the typical sulfonate cluster size in a bulk ionomer, the protons accumulate near the pore surface and in the central area of the pore. When $D = d$, the protons cluster mostly in the vicinity of the pore wall. For $D < d$, the continuity of the proton distribution along the pore axis is disrupted to such an extent that water-ion aggregations form a network of separate clusters aligned along the pore axis. In narrow pores the ions mostly occupy the central pore area. There is also positional correlation between the ion and sulfonate radial distributions. In smaller pores the central area is predominantly occupied by conducting ions. The calculated proton diffusion coefficients for ionomers contained in nanopores of various diameters show a nonlinear dependence on the pore diameter. We have shown that the ion diffusion at first drops and then experiences a steep increase when the pore becomes narrower. This enhancement of the diffusion is associated with the correlated movement of individual ion-water clusters: at any given time all ion clusters move in the same direction. This unexpected result
Future Directions

The goal of our work is to use simulation methods to lead us to the discovery of new morphologies of ionomer membranes that may give enhanced proton transport and robust structures in fuel-cell applications. To achieve this we will pursue several different avenues.

First, we will extend our study of the influence of nanoparticle inclusions on the structure and transport properties of ionomer membranes. We will investigate how spherical inclusions with different sulfonate and water interaction potentials change the ionomer morphology. It is expected that in the case of hydrophilic inclusions their surface can serve as a bridging pathway for facilitated proton transfer between neighboring ionomer clusters. Alternatively, hydrophobic inclusions will most probably accumulate PTFE-rich polymer backbone material on their surfaces, and could distort the shape of ionic clusters towards a more connected topology with branching channels. We intend to calculate how the proton diffusion depends on the size, hydrophilicity, and concentration of inclusions. We also plan to investigate the ionomer reaction to the charge and surface potential of nano-inclusions. It is natural to assume that inclusions with tailored surface groups capable of releasing protons into a hydrated membrane can have the potential to increase its proton conductivity.

Another area of great interest is the structure produced by taking an inert membrane that is pierced by cylindrical holes, which are then filled with ionomer. Our recent results on nanopore-constrained ionomers include the finding that ion diffusion can be strongly enhanced in narrow tubes, and so we intend to put this study on a firmer footing by extending our simulation studies to a wider variety of systems. This is important from a technical point of view, since the ionomer-filled nanopore matrix is a robust and durable platform, and has the capacity to reinforce the ionomer membrane’s mechanical stability against damage from swelling and cracking in operating fuel cells. To understand the physics behind the transition from spherical clusters of sulfonates to wire-like clusters in narrow pores is important for devising new nanocomposite materials with extremely high ion conductivities. We will also analyze how the side-chain flexibility, the length of side chains, and the nanopore-ionomer interaction parameters affect the overall ion diffusion along the nanopore axis.

Finally, we remark that all our poling and stretching molecular-dynamics simulations have so far been carried out at room temperature. We plan to extend our studies to higher temperatures and pressures to explore any possible new phases that might be formed.

Objectives

The objective of this work is to develop a model capable of describing the molecular mechanisms of proton transport in highly confined and highly acidic environments. Specifically, we seek to develop a molecular-level understanding of how confinement and acidity impact both the vehicular and structural components of proton transport. To this end, we develop a Reactive Molecular Dynamics (RMD) algorithm that is capable of describing both components of proton transport, with sensitivity for each component to the local environment. We apply this RMD algorithm to describe proton transport in four systems: (1) bulk water, (2) bulk HCl solutions, (3) carbon nanotubes, and (4) hydrated perfluorinated sulfonic acid (PFSA) proton exchange membranes (PEMs). These four systems allow us to decouple the effect of confinement and acidity on vehicular and structural components of proton transport.

Technical Barriers

This work is motivated by practical technical barriers and addresses theoretical technical barriers. On the practical side, the structure-property relationships obtained from a fundamental understanding of the molecular mechanisms of proton transport in highly confined and highly acidic environments would provide guidance for the development of next generation PEMs. On the theoretical side, the hydrated PEM in a fuel cell contains phenomena that occur over disparate time scales. At the shortest time scale, there is the description of a single proton hopping event, occurring on the order of femtoseconds (10^-15 s) and best described by quantum mechanical techniques; while at the next time scale, vehicular diffusion may take 10s or 100s of nanoseconds, which requires classical molecular dynamics simulation.

The RMD algorithm provides an efficient procedure for including both structural and vehicular diffusion in a simulation.

Abstract, Progress Report and Future Directions

Proton transport in aqueous solutions occurs through a combination of mass diffusion and structural diffusion. The structural diffusion of a proton, as a reaction, can be given as

\[ H_2O^+ + H_2O \rightleftharpoons H_3O^+ + H_2O \]

Transport of the proton by Grotthuss mechanism was implemented using a newly devised reactive molecular dynamics (RMD) algorithm. In this approach, a three step procedure was incorporated to the existing classical molecular dynamic simulation to allow the explicit proton transfer from a hydronium ion to a water molecule based on quantum mechanical transition and ground state configurations to reproduce macroscopic reaction properties. The reactive part of the RMD algorithm is composed of the following steps:

1. Satisfaction of triggers – checks whether the reactants are in a favorable configuration for the reaction to take place by satisfying a set of geometric and energetic triggers based on the transition state obtained from \textit{ab initio} calculations.
2. Instantaneous reaction – coarse grains out the reaction path and the proton gets transported instantaneously from the hydronium ion to a water molecule.
3. Local equilibration – satisfies the target heat of reaction and ensures the products are in correct ending configuration.

The algorithm was validated by modeling structural diffusion of proton in an extensively studied system for which the most reliable data are available, namely bulk water. The determination of the functional form of the triggers were based on the structure of the predominant hydrated models (Zundel and Eigen cations) necessary for the structural diffusion of protons and were parameterized to reproduce the experimental rate constant and activation energy. Using this procedure, 150 replicates of a single hydrated proton in a system of 650 water molecules were studied as a function of temperature from 280 K – 320 K. By fitting the reaction rate the model predicts the transport property of the proton. A detailed study of the two components (structural and vehicular) of the total charge diffusion was conducted. Other systems were also modeled with the new algorithm to study its sensitivity and
the adaptability to different environments. The RMD algorithm endeavors to have a valid starting and ending configuration for the structural diffusion by mapping the transition state onto a set of triggers without having to dynamically describe the transition state structure. Therefore, the algorithm is generalized by the environmentally sensitive geometric and energetic triggers.

The pH dependence of proton transport was investigated by implementing the algorithm for bulk aqueous HCl solutions with different concentrations (0.22 M – 0.83 M). The presence of the chloride ion disrupts both the structural and energetic environment for the occurrence of the reaction and was effectively captured by the triggers. Proton diffusion in water confined in carbon nanotubes of radii ranging from 5.42 Å – 10.85 Å was studied to analyze the effect of confinement on structural and transport properties of a proton. The model shows that enhanced confinement drastically reduces structural diffusion by disrupting the energetic balance around the Zundel ion.

Having independently examined the effect of acidity (HCl solution) and confinement (carbon nanotubes), we next apply the RMD algorithm to proton transport in a system that contains both confinement and acidity, namely hydrated PFSA PEMs. The structural diffusion of proton in hydrated membrane can take place via three classes of reactions.

\[
\begin{align*}
H_3O^+ + H_2O &\rightleftharpoons H_2O + H_3O^+ \\
H_2O^+ + H_2O &\rightleftharpoons nH_2O(4\alpha-n)SO_3H + nH_3O^+ \\
SO_3H + H_2O &\rightleftharpoons 2H_2O + SO_3^- + H_3O^+
\end{align*}
\]

The prevalence of each reaction is dependent on the degree of hydration of the membrane, which the first reaction being most important at high water contents and the last reaction being least important at high water contents. Equation 1 is similar to proton transport in bulk water and will take place along the center of the aqueous channels and reactions as shown in equations 2 and 3 will occur at the interface of the hydrophobic and hydrophilic regions. RMD algorithm can accommodate all the above reactions and the triggers can register the presence of the sulfonic acid groups and other environmental factors like confinement (as shown in the earlier systems). These reactions are individually implemented in three different stages to better understand the contribution of each reaction to the structural diffusion of proton in the PEM at different hydration levels. Thus the algorithm will allow us to measure the diffusivities in the hydrated membranes and provide a molecular level understanding of how the environment in the nano-aqueous regions impact proton mobility.

Objectives

Current fabrication approaches\textsuperscript{1,2} for proton exchange membrane (PEM) fuel cells rely on ill-defined, planar interfaces that reduce the performance of the system. The departure from planarity to 3-D interfaces with porosity should provide a boost in power\textsuperscript{3} due to additional surface area for catalysis to support higher mass transfer rates.\textsuperscript{4} In this project, we are investigating the integration of electrode/catalyst support, gas diffusion pathways, and ionomer into a single network based on a bottom-up, surface-directed approach. Our efforts are focusing on (1) the preparation of surface-initiated ionomer that can be grown from electrodes of essentially any geometry and is chemisorbed to the active electrode surface, and (2) the integration of this ionomer with both planar and porous electrodes that are atomically modified by Pt catalysts.

Technical Barriers

The departure from planarity to porous systems creates difficulties in integrating ionomer and catalyst uniformly throughout the porous electrode structure. We are developing an approach where the electrode surface directs the deposition of catalyst and the growth of ionomer, monomer by monomer, to achieve an exceptional level of control over the composition and structure at this vital interface. Focusing initially on the cathode, our system consists of a thin nanoporous gold support that is atomically modified by a Pt monolayer for ultra-low catalyst loadings and is integrated with ionomer through surface-initiated polymerization (SIP). The surface-directed deposition of catalyst and ionomer enables high control over the composition within nanoporous electrodes. Results under the current funding have demonstrated that proton-conducting polymers can be grown from various surfaces by surface-initiated ring-opening metathesis polymerization (SI-ROMP) of 5-(perfluoro-n-alkyl)norbornenes and subsequent rapid sulfonation of the internal olefins. These films can be integrated with Pt catalysts at interfaces for high performance in the oxygen reduction reaction.

While much of our initial work has focused on materials synthesis and integration, our most recent work is utilizing these systems to gain fundamental insight on the effects of materials composition and properties at 3-D interfaces to optimize cathode performance. Specifically, we seek to (1) establish greater versatility in the preparation of nanoporous electrodes to control pore size, porosity, and electrode thickness; (2) develop new “interfacial” ionomer systems from surface initiation, grafting, and self-assembly to fundamentally assess the effects of interfacial bonding, ionomer composition and structure, as well as free volume within the pores, on the performance of the electrode; and (3) extend these strategies to commercial carbon supports. The successful completion of these objectives will yield well-defined and molecularly integrated materials systems to achieve high utilization of catalyst/electrode surface area with ultra-low catalyst loadings. This research will improve the basic understanding of the complex reaction and transport processes that occur near the triple interface in a fuel cell environment.

Progress Report

Our initial efforts reported the surface-initiated ROMP of n-alkylnorbornenes to control film thickness and composition at electrode surfaces\textsuperscript{3} and the sulfonation of these films to facilitate proton transfer.\textsuperscript{6} More recently, we have developed an approach for the SI-ROMP of partially fluorinated films from
I. Growth of Partially Fluorinated Ionomer Films.

A major emphasis of this project has been to prepare partially fluorinated ionomer films through a surface-initiated polymerization (SIP). SIPs provide the ability to grow films of controlled thicknesses from substrates of nearly any geometry, such as 3-D, porous catalyst/diffusion layers. However, SIP of fluorinated monomers has been historically difficult due to the steric hindrance of the fluorocarbon functionality. In an important innovation, we have developed the surface-initiated ring-opening metathesis polymerization (SI-ROMP) of (perfluoro-n-alkyl)norborenes (NBFn) to form partially fluorinated polymer films (pNBFn) of tunable thicknesses ranging from tens of nanometers to microns on various substrates. The polymers are tethered to the surface on one end and upon sulfonation, have the general repeat structure as shown in Figure 1. By varying the fluorocarbon side chain of the monomer, we can tune the structure (SEM and infrared spectroscopy), transport properties (electrochemical impedance spectroscopy), and critical surface energies (contact angles) of the films. Our results indicate that the fluorocarbon side chains self-organize into fluorocarbon-rich regions. Structuring of the polymer in this manner should be highly effective for PEM fuel cell applications since O₂ would transfer through the fluorocarbon regions and protons would transfer through the sulfonated regions. We have recently published methods to sulfonate hydrocarbon and fluorocarbon films prepared by this method.

II. Extension of SI-ROMP to Carbon Paper.

To demonstrate that pNBFn films can be grown from various substrates, including those with technological relevance, we have developed an approach to grow these films from graphitic carbon paper, which has 3-D fibrous structure. Since graphitic fibers are relatively inert, we expose the carbon paper to an oxygen plasma for up to 1 min to create a few dispersed oxygen-containing surface sites across the fiber surface before attaching the polymerization initiator, which enables SI-ROMP from the fiber surface, as shown in SEM images of Figure 2. These pNBFn-modified carbon paper electrodes exhibit superhydrophobic surface properties, meaning that an impinging stream of water bounces off the surface and that a water drop on the surface will exhibit a contact angle of > 150°. Conformal, hydrophobic coatings such as these can greatly aid water management at PEM cathodes. These films can also be sulfonated to provide surface-attached ionomer to the graphitic carbon surface.

III. Integration of Ionomer Films at Pt-Modified Electrodes.

The direct wiring of ionomer films to electrode surfaces is beneficial to reduce interfacial resistances and boost electrochemical performance in many energy-related applications. However, a key issue regarding the direct chemical wiring of ionomer to electrode/catalyst interfaces is the possible deactivation of the catalyst by the chemisorption event. We have reported the surface-initiated growth and sulfonation of polynorbornene (pNB), poly(n-butylnorbornene) (pNBH₄), and poly(perfluoro-n-butyl)norborene (pNBF₄) to prepare ionomer films on gold electrodes that are pre-modified by an atomic layer of Pt. Our goal here was to demonstrate proof-of-concept systems for the integration of chemisorbed ionomer and catalyst at model electrode surfaces. In this manuscript, we have made some important conclusions. First, the ionomer films can be grown from Pt-monolayer-modified surfaces without compromising the performance or integrity of the Pt. Second, sulfonated films derived from NBF₄ and NBH₄ yield more anodic potentials for oxygen reduction than those derived from NB or unfunctionalized electrodes. These improvements are consistent with hydrophobic structuring by the fluorocarbon or hydrocarbon side groups to generate pathways for enhanced O₂ permeation near the interface. Third, we demonstrate a method to electrochemically “clean” ionomer/electrode interfaces. For example, in surface-initiated polymerizations, only a small fraction (often < 10%) of the surface sites typically yield polymer. For electrochemical applications, these inactive adsorbates can block catalyst sites on the surface and hamper the performance of the electrode. Here, we demonstrate the ability to electrochemically reduce and desorb these short, non-polymeric adsorbates from the surface without affecting the surface-attached ionomer.
We show that desorption of these short molecular components from the polymer/electrode interface reduces interfacial impedance and greatly improves the performance of the Pt/Au electrode toward oxygen reduction.

IV. Growing Ionomer Within Nanoporous Electrodes.

A key element of this project is to grow ionomer films within nanoporous electrodes to ultimately integrate ionomer, catalysts, and pores for gas diffusion into a single network. We have developed a simple fabrication scheme to prepare nanoporous electrodes\(^{12}\) with several adaptations to the technique developed by Ding et al.\(^{13}\) that makes use of a graphite roller. Successful SI-ROMP of pNBF\(_6\) throughout the nanoporous electrode has been achieved by controlling the monomer concentration in relation to the average pore size as evidenced by a combination of SEM (Figure 3), infrared spectroscopy, and electrochemical impedance spectroscopy.

**Future Directions**

For the next period, we will build on our successes with surface-initiated, partially fluorinated ionomers and nanoporous electrode films to investigate the following issues:

- Examine the effect of fluorocarbon side chain length and sulfonation levels on the transport of O\(_2\) and protons through the membranes.
- Synthesize short pNBF\(_n\) oligomers that are terminated in thiol functionality for directed self-assembly at both planar and nanoporous Pt/Au interfaces. Sulfonate these oligomers after assembly and investigate their effectiveness in promoting oxygen reduction.
- Combine the most successful approaches from the preceding two objectives with carbon paper electrodes and back-fed O\(_2\) to investigate cathode performance under realistic operating conditions.

Objectives

In this project, Shao-Horn examines whether fundamental knowledge of electrocatalytic activity established on single-crystal surfaces can be applicable to understanding of nanoparticle activity by studying the influence of surface steps and near-surface composition of Pt-based nanoparticles on electrocatalytic activity. In addition, the stability and the mechanism by which Pt alloy nanoparticles lose activity for oxygen reduction in PEMFCs are studied. Marzari at MIT investigates the effects of applied electrochemical potentials on the adsorption energies and reactions rates of fundamental electrochemical processes, respectively. The overall goal of the modeling work of Morgan at UW is to model oxidative processes on Pt in order to understand and control their influence on Pt-based-nanoparticle stability and electrocatalytic activity.

Technical Barriers

The estimated cost of PEM fuel cell systems for automotive applications is significantly higher than existing, internal combustion technologies (~$35/kW for advanced technologies). In addition, the lifetime of PEM fuel cell systems is limited to 2000 hours, significantly shorter than the required 5500 hours of operation in a vehicle. This work help identify near-surface chemical compositions of Pt-based catalysts that can provide 1) high activity to reduce catalyst and PEM fuel cell cost, and 2) stability to overcome long-term catalyst degradation problems in aggressively corrosive and oxidizing environments (e.g. PEM fuel cell cathode).

Abstract, Progress Report and Future Directions

Abstract. Our recent experimental work has shown that near-surface compositions but not surface steps, can greatly influence ORR activity. We have obtained direct evidence of near-surface compositions of Pt-Co alloy nanoparticles, which exhibit specific ORR activity 2-4 times relative to Pt. The stability of these Pt and Pt alloy nanoparticles will also be discussed. On the other hand, surface steps do not appear to influence activity for oxygen reduction unlike for methanol oxidation, from which the origin responsible for this difference will be discussed. Our recent theory work has revealed some stable hybrid Pt-O surface structures, which can play an important role in the stability and activity of Pt-based catalysts.

The influence of near-surface compositions of “Pt3Co” on oxygen reduction activity. Acid-treated “Pt3Co” supported on carbon (46 wt% Pt) with an average atomic Pt/Co ratio of 3.6 (having a number-averaged particle size of ~4 nm), was prepared from leaching of a “PtCo” sample in acid. Acid-treated nanoparticles were subsequently heat-treated at 1000 K for 3 hours in vacuum (~10^-2 Torr). Annealed “Pt3Co” was found to have a number-averaged particle size of ~5 nm. ORR activity of “Pt3Co” and Pt nanoparticles was measured by sweep voltammetry in O2 saturated HClO4 electrolyte using a rotating disk electrode at room temperature. Cyclic voltammetry of “Pt3Co” nanoparticles was performed in O2 free electrolyte, from which the electrochemical active area was obtained from integrating the charge associated with hydrogen desorption. Specific ORR activity of acid-treated (with Pt-enriched surface in Figure 1) and annealed “Pt3Co” nanoparticles normalized to the Pt surface area was compared with that of Pt nanoparticles as a function of potential in. At 0.9 V vs. RHE, the activity of acid-treated “Pt3Co” nanoparticles is ~0.74 mA/cm² ( ~2 times of Pt), which is comparable to acid-leached Pt alloy nanoparticles reported previously. On the other hand, the specific activity of annealed “Pt3Co” at 0.9 V vs. RHE (with surface-sandwich-segregation of Pt-enriched and Co-enriched, not shown here, Shuo et al., JPCC 2009) was increased to ~1.39 mA/cm² (~4 times of Pt) after annealing, which could be attributed to surface Pt sandwich-segregation structures (not shown here).
The influence of surface steps of Pt nanoparticles on oxygen reduction activity. ORR activity of Pt/MWNT samples was measured using a rotating disk electrode (RDE) and linear sweep voltammetry in O₂-saturated HClO₄ electrolyte. The electrochemical surface area (ESA) of Pt nanoparticles was obtained from integrating the charge associated with hydrogen desorption in the O₂-free electrolyte. Specific ORR activity normalized to the Pt ESA is independent of heat-treatment temperature, which indicates that surface steps on Pt nanoparticles do not greatly influence intrinsic ORR activity. Specific ORR activity of Pt nanoparticles at 0.9 V vs. RHE is ~200 mA/cm²Pt, which is in good accordance with reported specific activity.

**FIGURE 1.** Atomically resolved structures and compositions of Pt alloy nanoparticles (acid-treated), which was correlated to specific ORR activity based on electrochemically active Pt surface area. The enhanced specific ORR activity (~2 times relative to Pt) of acid-treated "Pt₃Co" nanoparticles can be related to composition variation at the atomic scale and the formation of a Pt enriched skeleton structure within individual particles (Shuo et al. JPCC 2009).
for Pt nanoparticles of comparable sizes in HClO$_4$. In addition, projecting the reported activity of stepped single-crystal surfaces onto nanoparticle surfaces of Pt/MWNT samples, no ORR activity difference was noted for Pt/MWNT samples. It is interesting to compare the role of surface steps on Pt nanoparticles on the intrinsic activity of ORR with that of MOR. Specific ORR activity at 0.85 V and specific MOR activity at 0.5 V (current density in the positive-going cyclic voltammetry) is plotted as a function of area fraction of surface steps normalized to that of 548 K (Figure 2). Specific ORR activity at 0.85 V is independent of normalized area fraction of stepped surfaces while MOR activity linearly increases with the amount of stepped surfaces on Pt nanoparticles.

Future work in Shao-Horn’s group will focus on varying near-surface chemical compositions of Pt-based alloy nanoparticles (e.g. PtAu) and studying its role in the activity and stability for oxygen reduction.

**Oxidation of Pt on Pt Nanoparticle stability.**

Pt oxidation plays an essential role in the long-term stability and catalytic properties of Pt based nanoparticle catalysis used in PEMFC cathodes. However, at present the structure, thermodynamics and kinetics of oxide phases on Pt are not known. As a first step in understanding Pt oxidation it is necessary to establish the stable Pt-O surface phases as a function of oxygen coverage. Due to the challenges of experimental determination of these complex and near monolayer surface structures we are pursuing an approach based on *ab initio* energy calculations. We have integrated previous *ab initio* studies that treat specific oxygen structures and their energetics, adjusting results to a consistent reference (see Figure 3). These results consider three major classes of oxygen surface phases, including surface, place-exchanged, and buckled oxygen structures. We have now explored a wide range of new oxygen surface structures with an intent to understand the key mechanisms (e.g., electrostatic interaction, oxygen subsurface vs. surface energetics, etc.) governing stability of oxide phases. In particular, we have developed a set of hybrid place-exchanged and buckled phases with some of the key stabilizing features of each phase. Certain hybrid structures we identified are in fact more stable than previous structures at near one monolayer composition, as can be seen by their residing on the convex hull of all the calculated energies (dark line in Figure 3). These hybrid structures are therefore likely to be the stable form of oxide on Pt near one monolayer. Our future work will further investigate additional new Pt-O structures to establish the correct stable phases that are expected during Pt oxidation.

Objectives

The objective of this work is to develop an understanding of mechanisms of the Oxygen Reduction Reaction (ORR) and to use this understanding to develop new, non-precious metal containing catalysts for this reaction. A particular focus is to mimic the active site of laccase, a protein that performs near thermodynamic four electron reduction of oxygen to water.

Technical Barriers

The slow kinetics of the ORR have long been identified as a major impediment to the development of PEM fuel cells. Consequences of these slow kinetics include a substantial reduction in the thermodynamic efficiency of fuel cells and the requirement for considerable precious metal usage in practical implementations. Our work is directed to designing new materials that will exhibit low overpotentials without the use of expensive precious metal catalyst.

Abstract, Progress Report and Future Directions

Electrocatalysis of the oxygen reduction reaction (ORR) is currently of widespread interest due to its application in fuel cell cathodes. Slow ORR reaction kinetics significantly impact the efficiency of fuel cells, resulting in cell potentials well below (ca. 0.35 V) the reversible potential for oxygen reduction of 1.229 V vs. the reversible hydrogen electrode (RHE). These lower potentials substantial degrade fuel cell thermodynamic efficiency which obviate fuel cell use. The catalyst for the ORR is usually based on Pt or another precious metal, such as Pd. The costs associated with these materials can be prohibitive. Thus, there is a search for non-precious metal ORR catalysts.

The focus of our research is to understand the mechanisms of the oxygen reduction reaction (ORR) on different electrode surfaces and then use that understanding to develop new catalysts which feature the use of materials other than Pt or other precious metals.

Substantial previous work from our group strongly suggests that the four electron reduction of oxygen in the electrochemical environment proceeds according to the so-called series mechanism in which dioxygen binds to the catalyst surface and then through a series of coupled proton electron transfers is reduced to the peroxide level. Coupling between two metal atoms then leads to spontaneous decomposition of the peroxide to form two metal hydroxides, as shown in Figure 1. These hydroxides are then reduced, forming water in acid. This understanding leads us to expect that new catalysts exhibiting four electron ORR activity will features at least two metal centers. Interestingly, the active site in the protein laccasse, which exhibits four electron reduction of water at overpotentials substantially less that found on Pt features three Cu atoms bound in close proximity to each other.

The efficacy of laccase led us to wonder if Cu coordination complexes/polymers composed of CuII coordinated with bridging azole-type ligands, such as the 3,5-diamino-1,2,4-triazole (Hdartz) ligand (Figure 2), and with other weakly coordinated ligands (such as...
water, sulphate etc.) might provide stability in addition to multi-Cu sites that could potentially bind and activate O₂. We developed a method to immobilize insoluble transition metal complexes on Vulcan and other carbons in order to evaluate their activity toward the ORR. Figure 3 shows the activity of the coordination complex formed between Cu and Hdartz in neutral solutions. The figure shows that the onset of four electron ORR activity occurs at potentials significantly more positive than that afforded by the bare carbon. We found that both the Cu metal and the Hdartz ligand were necessary for ORR activity. Figure 4 shows the variation of the onset potential for ORR activity from electrodes modified by Cu and Hdartz. The figure shows that while the onset potential of the complex is low in acid, it increases as a function of pH and is quite high (850 mV vs. RHE) in basic electrolytes.

The structure of the Cu/Hdartz complex shows that Cu forms a dimer coordinated by two of the three heterocyclic nitrogens of the triazole moiety. We thought that suitable modification of the Hdartz ligand at the 4 position might afford a more positive onset potential relative to the unmodified Hdartz ligand. The best derivative so far characterized in our group exhibits an onset potential some 150 mV more positive than that reported for the Cu/Hdartz.

The performance of the Cu/Hdartz catalyst in basic electrolyte appeared good enough that we thought to compare it with Pt. Figure 5 shows a comparison of the maximum power density achieved by four different catalysts in the alkaline (pH 14) electrochemical environment. The figure shows that while Pt particles on C are still more active than any other catalyst examined here, the Cu/Hdartz sample is second most active, and considerably better than Ag; a material previously used in alkaline fuel cell applications. The comparison with Pt is more broadly made in Figure 6, which compares the peak power generated per metal atom. The Figure shows that the Cu/Hdartz sample is considerably better than Pt on a per metal atom basis. We are presently evaluating the stability of the Cu catalyst in both the alkaline and acidic environments. A full suite of synthetic and computational approaches is coupled to this project.

Future directions involve further exploration of the Cu dimer and trimer motifs for their efficacy in the ORR. Modification of the Cu catalyst we've developed through the agency of ligand synthesis allows for modification of properties and correlation of reactivity with structure.

Objectives

- Fundamental atomic/molecular level understanding of metal-electrolyte interfaces required for efficient transformation of chemical energy of hydrogen, hydrocarbons and oxygen into electrical energy in fuel cell systems.
- Use and develop state-of-the-art ex situ and in situ surface sensitive probes and spectroscopy, in combination with density functional theory calculations to determine the most active and stable sites for adsorption of reactants, reaction intermediates and spectator species.
- From experimental and computational studies on well-characterized single crystals, form the basis for synthesis of nanoscale surfaces to have optimal catalytic properties for the O-O, H-H, O-H, and C-H bond making and bond breaking events in environments of interest for fuel cell technologies.

Technical Barriers

- Fundamental understanding of metal-electrolyte interfaces will transform electrocatalysis from a largely phenomenological subject into a discipline that will be able to address many challenges, opportunities and research needs in the areas of basic science of materials for clean and efficient energy conversion.
- The novel concept of tailored nanoscale oxygen reduction catalysts will significantly reduce noble-metal loading necessary to make the fuel cell technology economically competitive and sustainable.
- New materials will revolutionize catalyst performance in fuel cell systems, not only for the oxygen reduction reaction, but also for a wide range of reactions that are required for the implementation of a hydrogen-based economy, thereby leading the nation to more secure energy independence and a cleaner environment for future generations.

Abstract

The low rate of the oxygen reduction reaction in low/moderate temperature fuel cell systems is the main limitation for a wide application of this technology. We present here a science-based approach that will allow obtaining predictive understanding of the factors that determine the reactivity and stability of the ORR at electrified metal-solution interfaces at nanoscale dimensions. This approach is based on (i) fine tuning of the electronic properties of metal surface atoms; (ii) systematic alternation of the interfacial properties that constitute the entire electrochemical double layer structure; and (iii) molecular patterning of metal surfaces, aimed at the design of surfaces where the sites of poisonous spectator species are blocked, while providing the sufficient number of free metal sites needed to chemisorb the reactant and reaction intermediates. We demonstrate that depending on the geometric/electronic properties of the catalyst as well as supporting electrolytes (including the nature of anions and cations, temperature and pH) the activities of the ORR and oxidation of small organic molecules can range from 50 fold increase to 50 fold decrease. This behavior is discussed in the light of the role of covalent and non-covalent interactions in controlling spectators’ coverage which determine the number of free active sites for high turnover rates of the electrochemical reactions.

Progress Report

(i) Fine tuning of the electronic properties of metal surface atoms; importance of covalent bonds.

(a) Catalytic activity.

Much of the art and science of catalyst development has been based on understanding chemisorption trends of oxygenated species, considering that the kinetics of both the oxygen reduction reaction and of the oxidation of small organic molecules is governed by the nature of metal-oxygen covalent bonds. This approach we used in the development of PtNi and PtCo catalysts for the ORR. The rate of the ORR, expressed in terms of turnover frequency (TOF, defined as the number of electrons produced per active-site per second), on various of cathode materials (Figure 2) demonstrate that if grown
into “gigantic” 30 nm octahedra our Pt$_3$Ni nanoparticles with TOF=2800 s$^{-1}$ would be expected to yield 10-fold higher Pt mass activities than current Pt/C. The mechanism of improvement/deactivation occurs through the change of electronic properties ($d$-band center and work function) of the nanosegregated Pt-Ni surface alloys. By studying the ORR on Pt$_3$Ni(1099)=20(111) x(100) and Pt$_3$Ni(1077)=8(111)x(100) stepped surfaces (Figure 2) we find that to preserve the TOF of Pt$_3$Ni(111) minimum width of (111) facets should be 20 Pt atoms.

(b) Stability.

The design of cathode catalysts must be guided by two equally important fundamental principles: optimization of their catalytic properties as well as the ability of their surfaces to preserve nobility in hostile electrochemical environments. In our experiments, stability of bimetallic surfaces is monitored as the potential-induced relaxation and disordering of the surface structure, which is examined by utilizing a combination of surface x-ray scattering, scanning tunneling microscopy and electrochemical methods. Figure 2 summarizes electrochemical measurements, which show that Pt$_3$Ni(111) and stepped surfaces are stable up to 1.05 V.

(ii) Fine tuning of the electrochemical double layer structure: importance of non-covalent bonds.

Classical models of metal electrode-electrolyte interfaces have generally focused on covalent interactions between adsorbates and the corresponding solid surfaces (see previous section). Recently, we have demonstrated that these traditional models for describing the catalytic activity of the electrochemical interfaces is not sufficient[3], and to understand electrocatalytic trends in the oxygen reduction reaction (ORR), the hydrogen oxidation reaction (HOR), and the oxidation of methanol on Pt surfaces in alkaline electrolytes, noncovalent interactions, such as hydrogen bonding, cation-water, and cation–OH$_{ads}$ bonding, must also be taken into consideration. All these systems are generally applicable in alkaline fuel cells.

We used a combination of experimental and theoretical techniques to find that cation-specific noncovalent interactions between hydrated alkali-metal cations $M^+$($H_2O)_x$ and adsorbed OH species increase in the same order as the hydration energies of the corresponding cations and likely result in an increase in the concentration of OH$_{ads}$–$M^+$(H$_2$O)$_x$ or (H$_2$O)$_{x+1}$–$M^+$–H$_2$O–OH$_{ads}$ clusters relative to the bulk (Figure 2). These trends are inversely proportional to the activities of the ORR, the HOR and the oxidation of methanol on Pt: Cs$^+ > K^+ > Na^+ >> Li^+$.

(iii) Molecular patterning of metal surfaces.

We developed a new approach that can be used for the rational design of cathode catalysts for phosphoric

**FIGURE 2.** The rate of the ORR on Pt$_3$Ni(111), Pt$_3$Ni(1099) and Pt$_3$Ni(1077) and factor of improvement vs. Pt(111). Potential window of stability is around 1.05 V, exemplified as the “grey zone.”

![FIGURE 3](image)

**FIGURE 3.** Left: Models for noncovalent interactions between hydrated alkali-metal cations and adsorbed OH and the formation of OH$_{ads}$–$M^+$(H$_2$O)$_x$ or (H$_2$O)$_{x+1}$–$M^+$–H$_2$O–OH$_{ads}$ clusters. Right: DFT activity mapping. Nature Chemistry 1 (2009) 466-472[3]
acid fuel cells. This approach is based on molecular patterning of metal surfaces with inert CN adsorbates\cite{4}. We find that on Pt(111) modified by irreversibly adsorbed CN activities of the ORR can go from 25-fold increase in the presence of sulfuric acid anions and 10-fold increase in the presence of phosphoric acid anions (Figure 4 left), to no effect in the presence of weakly adsorbing perchloric acid anions. Interestingly 50-fold decrease is observed in alkaline solutions (Figure 4 right). This enormous increase in activity suggests that the CN$_{ad}$ molecules can block the sites for adsorption of spectator phosphoric acid anions but still provide sufficient number of free Pt sites needed first to chemisorb the O$_2$ molecule and then to break the O-O bond (Figure 5b). Equally dramatic deactivation in alkaline solution is rationalized based on anticipated blocking effect of CN$_{ad}$-M$^+$($\text{H}_2\text{O}$)$_x$ clusters for adsorption of O$_2$ molecule and reaction intermediates\cite{4} (Figure 5c).

**Future Directions**

We will continue to (i) create novel states of catalytic materials by manipulating both covalent and non-covalent interactions at electrochemical interfaces; (ii) characterize, electronic properties of nanostructured interfaces by developing and using ex-situ and in-situ surface characterization techniques and theoretical...
methods; (iii) understand fundamental principles that
govern efficient bond making and bond breaking events
at electrochemical interfaces; and (iv) optimize the active
sites by an iterative process, guided by the fundamental
understanding of electrochemical interfaces.

Objectives
The goals of this program include (a) fabrication of new nanoporous electrocatalytic metals by electrochemical dealloying, (b) development of methods to tailor the surface chemistry and composition of nanoporous metals, (c) tailoring the activity of nanoporous to optimize hydrogen oxidation and oxygen reduction, (d) integration of nanoporous metals into fuel cells as low precious metal loading catalysts.

Technical Barriers
Implementation of low precious metal fuel cells in the commercial sector will require new approaches to the materials design of catalytic materials, particularly toward the inefficient oxygen reduction reaction at the cathode. Dealloying as a chemical route to the production of ultra-high surface area conductive metals allows facile synthesis of highly active nanostructured core-shell and composite catalysts with a wide variety of compositions that may lead to large decreases in loading at fuel cell cathodes.

Abstract
The development of new catalysts for hydrogen fuel cell reactions is a critical step in the development of this technology. Factors for which there is room for improvement include improving the catalyst activity, particularly toward oxygen reduction, and the development of carbon-free catalyst layers in the membrane electrode assembly that are not prone to corrosion. A materials system that may be a potential solution for both of these problems simultaneously are nanoporous metals made by selective electrochemical dissolution of one component of a multi-component alloy (dealloying). More specifically, alloys are chosen such that as the majority alloy component is dissolved, the secondary component diffuses along the alloy/electrolyte interface, reconstructing the material into a high surface area crystal with open porosity, high surface area/volume (ligament and pore sizes 5-10 nm), and intrinsic electrical contact to all surface area. In the last year, we have focused on the formation of core/shell nanoporous NiPt (np-NiPt) and related alloys. By impregnating the matrix np-NiPt of with a protic, hydrophobic ionic liquid that absorbs oxygen from the external environment, we have created a composite catalyst that geometrically confines oxygen in the catalytic region and leads to orders-of-magnitude increases in that mass activity of the composite over nanoparticle-based catalysts.

Progress Report

Formation of nanoporous metals by dealloying that are suitable for electrocatalysis. Nanoporous metals made by dealloying require the fabrication of single-phase multi-component alloys from which the majority component is electrochemically dissolved. During dissolution, the remaining alloy components diffuse along the metal/electrolyte interface and re-form as a porous metal. The porous metal, notably, occupies the same lattice as the parent material, so porosity exists on a scale much smaller than the grain size, and grain boundaries do not play a role in its properties. The lack of grain boundaries also adds to morphological stability because sintering (for instance, of nanoparticles) is usually driven by grain boundary energy reduction. This year we have been closely studying dealloying of Ni(Pt)x (x > 0.75) alloys (Figure 1), for which we find a the average pore and ligament size to be nearly 2 nm. This yields specific surface areas of 44 m2/g, essentially equal to that of nanoparticles, and a baseline requirement for fuel cell catalysis.

One important reason we have focused on the NiPt system is that we have found that the remaining porous metal composition usually sits near the NiPt3 composition. This suggests that during dissolution there is accumulation of a passivating Pt layer over a porous NiPt ligament core, i.e., it is a core/shell nanoporous metal with a composition close to that of the most active catalyst for oxygen reduction known. This was a prediction based on earlier work (DOE7,8) in this program, and electrochemical assays back up this hypothesis.
Assessment of nanoporous NiPt toward oxygen reduction. The assessment of np-NiPt in half-cell reactions toward oxygen reduction are consistent with the core/shell hypothesis. By extrapolating the surface kinetic current of np-NiPt to a roughness factor of 1 (by examining oxygen reduction on samples with different depth of porosity), we find the kinetic current to sit in-between the values associated with single crystal low-index surfaces (Figure 2A), again, consistent with the geometric picture of the (functionally single crystal) porous metal having multiple facet orientations within the porous matrix.

Highly enhanced oxygen reduction activity in composite nanoporous NiPt/Ionic Liquid composite catalysts. Although np-NiPt is highly active toward oxygen reduction, obviously its mass activity drops off as the pore depth becomes deeper (Figure 2B). Part of this is due to the extra mass, and some of this is due to the reactants not effectively penetrating deeply into the pores. That is, the active area for oxygen reduction is actually smaller than the geometric surface area measured by hydrogen underpotential deposition; in fact, we've shown that there is a dependence of the active surface area with the overpotential (DOE1). On one hand, this is a challenge for all nanoporous metal electrodes unless they can be fabricated as
ultra-thin membranes (such as we did with Pt-plated nanoporous gold leaf, DOE4), but it has also turned into an opportunity to make a brand new kind of oxygen reduction catalyst.

The presence of nanoporosity allows a secondary phase to be impregnated into the porous matrix. We hypothesized that if this second phase were an ionic liquid (IL) that is protic (proton conducting), hydrophobic, and contained a high oxygen solubility (higher than aqueous solution), then the composite np-NiPt/IL catalyst would have higher mass activity to oxygen reduction than np-NiPt alone because oxygen that approached the composite would be chemically biased to remain near the catalytic surface until it was reduced. Two ionic liquids (MTBD-beti, MTBD-Tf2N) were found to have these characteristics, and composite catalysts could be made simply by dripping the IL onto the porous metal. Figure 3 shows representative oxygen reduction curves in O₂-saturated 0.1 M HClO₄, and shows that the composite catalyst shifts the oxygen reduction curve nearly 50 mV to lower overpotentials. This is a huge shift, and the mass activity of the composite catalyst (Figure 2B), while still dependent on pore depth, at 2.3 mA/microgram at 0.9 V vs. RHE, is still over 20 times more mass active than Pt nanoparticles (0.1 mA/microgram at 0.9 V). At these low overpotentials, the np-NiPt/IL composite catalyst may be the most mass active catalyst toward oxygen reduction yet discovered.

**Future Directions**

**Integration of nanoporous metal/ionic liquid composite catalysts into fuel cells.** The promising results of oxygen reduction on the np-NiPt/IL composite catalysts were found in idealized half-cell electrochemical studies. The obvious next step is to integrate such catalysts into fuel cells. We have already integrated unsupported np-NiPt ground-up powders into PEM MEAs, and shown good results (namely, identical performance to supported Pt/C down to 0.7 V). To date, to make more efficient composite catalysts, we have synthesized particles of Ni₈₀Pt₂₀ that are ~20 nm in diameter and tested these for oxygen reduction. We see a large increase in activity when the particles are dealloyed, and are working toward impregnation of the particles with IL.

**Electrochemical and surface science investigations of the oxygen reduction reaction in nanoporous metal catalysts.** So far, it is just a hypothesis that the mechanism of enhanced oxygen reduction in the composite catalyst is due to higher oxygen solubility (and the ensuing retention of oxygen near a catalytic surface). The detailed reaction kinetics of oxygen reduction in this material as a function of oxygen and proton concentration and temperature, as well as the physical characteristics of the IL (viscosity, oxygen solubility) must be examined.

**Publications (including patents) acknowledging the grant or contract**

Objectives

The goals of this work are to: 1) determine the controlling elementary reaction pathways and intrinsic kinetics involved in the oxygen reduction reaction over Pt and Pt based alloys and their potential dependent behavior, 2) establish the influence of the extrinsic reaction environment including the surface coverage, alloy composition, solution phase and electrochemical potential and 3) understand the mechanisms that control metal dissolution.

Technical Barriers

Electrocatalysis is controlled by the complex interplay between the active catalytic sites and the influence of their complex environment at the electrified aqueous/metal interface.[1-3] The most active electrocatalytic materials exquisitely integrate the atomic assembly of the active metal sites responsible for the elementary bond making and breaking steps, together with the carbon support to carry out efficient electron transfer, and polymer electrolyte and water to facilitate proton transfer, thus establishing an optimal three-phase interface. Understanding the elementary catalytic processes along with the atomic scale features that control them, however, is obscured by the complexity of this three phase interface and the dynamic changes that occur to it under operating conditions. We are developing a first-principles framework and simulations tools that can be used to elucidate the elementary molecular catalytic transformations that occur in the oxygen reduction reaction (ORR) and the distinct role of the surface structure, alloying surface coverage, solution phase and applied potential on ORR and dissolution.

Abstract and Recent Progress

The ability to follow the molecular level transformations that control electrocatalysis and the mechanisms responsible for metal dissolution are obscured by the complex nature of the water/solution interface.[1-3] In addition to the complexity of the interface, there are a number of challenges in appropriately simulating electrochemical systems which require calculations carried out at constant potentials as they involve grand-canonical ensembles. Current ab initio methods, however, are based on a canonical formalism whereby the number of electrons is held constant. We have recently developed an ab initio approach based upon density functional theory that can be used to simulate different electrochemical and electrocatalytic systems that we describe as the double reference method.[3-6]

The DFT double-reference method is used in this work to simulate the electrochemical double-layer and calculate the elementary reaction energies and activation barriers over a range of potentials applicable to a working PEM cathode. In the first phase of this work, we have focused examined the oxygen reduction reaction (ORR) over different single surfaces Pt and Pt-based alloys and are beginning to transition to Pt nanoparticles in order to explore structure sensitivity.

The initial reduction of molecular oxygen (O\textsubscript{2,ads} + H\textsuperscript{+}_\text{aq} + e\textsuperscript{-} → OOH\textsubscript{ads}) was found to proceed through a proton-coupled electron transfer step followed by the addition of hydrogen to the bound O\textsubscript{2}* to form the surface OOH* intermediate. The transition state for this step is shown below in Fig. 1A. The calculated activation barrier was found to be strongly dependent on potential as is shown in Fig. 1B. The resulting barriers were found to be in good agreement with measured activation barriers over a range of potentials reported in the literature.[7-9]

Over the potentials of interest, the barrier was found to be nearly equal to the overall reaction free energy for this step. At a potential of 1.2 V-NHE, the first reduction barrier (0.7 eV) is close to that calculated for O\textsubscript{2} dissociation (0.77 eV). However, the reaction energy, and likely the activation barrier, for O\textsubscript{2} dissociation is not a strong function of electrode potential. At 0.8 V-NHE, the barrier to the first reduction step (0.3 eV) was calculated to be substantially
lower than that for $O_2$ dissociation. Therefore, at operating potentials, the dominate reduction pathway is expected to proceed through the initial reduction, in agreement with previous experimental and theoretical suggestions. [10-11] The subsequent dissociation of the $OOH^*$ intermediate that forms to $O^*$ + $OH^*$ occurs with an activation barrier of less than 0.1 eV. A detailed reaction path analysis indicates that the ability of the catalyst to break the O-O bond should not directly relate to the ORR performance.

At potentials above 0.8 V, the reaction is limited by reduction of the $OH^*$ intermediates that form on the surface. Below 0.8 V, the reaction was calculated to be limited by the initial reduction of $O_2$ to form the peroxo intermediate. Through a series of calculations carried out over different pseudomorphic Pt overlayers, we defined the optimal oxygen binding energies to carry out both the initial $O_2^*$ and subsequent $OH^*$ and $O^*$ reductions. This defined a series of different Pt-alloys which can meet the optimal binding energies. The results are consistent with previous reported work for $O_2$ reduction.[12-13]

Our more recent efforts have focused on the effects of $OH^*$ coverage on each of the elementary steps in the ORR mechanism and analyzing Pt dissolution for different Pt and Pt alloy surface structures.

Coverage Effects

The presence of surface hydroxyl intermediates were found to significantly alter the adsorption energies for all intermediates and their reaction energies and activation barriers. We examined the influence of coverage on: $O_2^*$ dissociation and $O_2^*$, $O^*$, $OH^*$ and $OOH^*$ reduction. The results for all of these reactions clearly show a linear relationship between the changes in the strength the initial adsorbed intermediate and the changes in their barriers for reaction. The adsorption energies for these intermediates are guided by the complex interplay between both attractive and repulsive interactions with $OH^*$ surface intermediates which result from hydrogen bonding and lateral repulsive interactions. These interactions are functions not only of their relative distances to one another but also in their specific orientation with respect to one another as hydrogen-bonding is directional. While the activation barrier for the reduction of $O^*$ is found to have the highest activation barrier especially at higher potentials, the coverage of $OH^*$ can considerably reduced the barrier as a result of stabilizing the calculated transition states.

Activation of Water and Dissolution of Pt

We have used the double reference approach to map out the surface phase diagrams for water, hydride, hydroxide, oxygen-covered surfaces, as well as solvated Pt ions and their corresponding passivated oxide over Pt(111), Pt(100), and Pt(110) and PtCo alloy surfaces in order to establish the lowest energy surface structures and the energies required to transition between one another phase to another over a range of potentials. The results have been used to show that the more coordinatively unsaturated surfaces more favorably activate water and subsequently undergo dissolution than surfaces comprised of more coordinatively saturated metal atoms. The introduction of Co appears to enhance the reactivity of Pt when Co is in the surface layer but decreases its activity when it's located below the surface.

Simulating Electro catalytic Kinetics

We have constructed a 3D kinetic Monte Carlo simulation algorithm that can begin to simulate the kinetics of the oxygen reduction over different sized cuboctahedral Pt particles as function of potential, temperature and reaction conditions. The simulations track the elementary molecular transformation that occur and as such can follow the changes surface coverages, the rate of water and hydrogen peroxide...
production as well as the potentials at which reactions proceed. The initial simulations reveal that at potentials about 0.8 V the surface is predominantly covered with surface hydroxyl intermediates. We are beginning to extend these initial efforts to provide relevant information on particle size effects on the kinetics for ORR.

Future Work

We are currently extending the work to other Pt-based alloys (Pt-Ni, Pt-Fe), and Pt nanoparticles. More specifically we have focused on the activation of water and its dissolution over large 201 atom Pt nanoparticles in a box of over 450 water molecules. These have been very difficult calculations as there are tremendous challenges in converging the lowest energy water structure at a given potential at the surface of the nanoparticle. An appropriate water surface structure is critical in establishing the appropriate electrochemical and electrocatalytic behavior. We will complete these studies and examine the O2 reduction mechanism as a function of potential.

Objectives

The long-term objectives of our research effort are two folds: 1. Advance significantly our fundamental understanding of sulfur poisoning of Pt-based mono- and bi-metallic nanoscale electrocatalysts through careful interrogation of long and short range electronic effects caused by the poisonous sulfur-metal bonding. 2. Investigate and establish correlations among the surface d band center, the frontier orbitals of the metal surface as represented by the surface local density of states at the Fermi level (E_f-LDOS), and the associated electrochemical reactivity.

Technical Barriers

Lack of detailed molecular level information on how sulfur-metal interaction poisons heterogeneous catalysts in general and electrocatalysts in particular impedes significantly the pace of developing practically viable sulfur-tolerant catalysts. Achieving the aforementioned objectives should help in a significant way the development of sulfur-tolerant catalysts by providing much needed molecular level electronic/geometric structure – functionalities relationships.

Progress Report

**In situ Spectroscopic Development.** Over the last year, we have developed capability of electrochemical (EC) in situ surface-enhanced IR adsorption spectroscopy (SEIRAS) and surface-enhanced Raman spectroscopy (SERS), as shown respectively in Figure 1 and 2. These spectroscopic developments have broadened significantly our molecular level investigative power in achieving a deeper mechanistic understanding of sulfur poisoning of Pt based electrocatalysts.

**Adsorption and Oxidation of Sulfur on Pt Nanoparticles.** We have carried out a detailed EC investigation of the adsorption and oxidation of S on commercial Johnson-Matthey (J-M) Pt black (Pt-B) and carbon-supported Pt (Pt/C). These two samples have different size (7 nm vs 4 nm), different boundary condition (inter-grain boundaries due to NP segregation in Pt-B vs NP isolation in Pt/C), and different surface roughness. By carefully analyzing the EC data obtained on 10 consecutive S-electro-oxidation (S-EO) strippings of 7 samples prepared with different S adsorption times, we were able to identify a Pt-S₂ to Pt-S absorption structural transformation.

**In situ EC ¹⁹⁵Pt NMR Investigation of Ru@Pt and Au@Pt/C NPs.** The first step to delineate how S adsorption alters the structural and electronic properties of bimetallic NPs is to establish what are the starting structural and electronic properties of these NPs. To this end, we have carried out the first in situ EC ¹⁹⁵Pt NMR investigation of Ru@Pt and Au@Pt/C NPs that will enable us to move in this direction. The former sample was prepared by scaling up the EG based wet chemistry synthesis we had developed[1] from 5 mg to ~ 100 mg. The starting Ru black had an average particle size of 3 nm. The targeted Pt packing density (PD) was...
0.4. TEM, XRD, CO stripping and MOR measurements showed results that were in good agreement with the results of the 5mg synthesis[1], demonstrating the feasibility of the scaling-up synthesis. The latter Au@Pt sample was prepared by first synthesizing carbon-supported 30% mass Au NPs. The Au NPs had an average size of 3.5 nm. The Pt was then added in the second step in which the starting Pt ions were reduced by ascorbic acid[2]. The sample studied here had a Pt PD of 3.8. About 80 mg of the NPs were used for NMR measurements.

Figure 3 shows the area-normalized $^{195}$Pt NMR spectra of as-prepared and EC-cleaned samples for Au@Pt (a) and Ru@Pt (b) respectively. The spectrum of a 2.5 nm commercial Pt/C is also shown for comparison. The as-received Au@Pt sample had been on shelf for very long time (>12 months) so the spectrum shows clearly a Pt oxide peak at 1.089 G/kHz. After EC-cleaning (by the setup shown in Fig.1), the Pt oxide peak disappeared and the whole spectrum moved up field as happened to pure Pt/C sample[3]. Although still lacking direct spectral evidence, we think that the peak appeared at the low-field side at 1.0975 G/kHz after EC-cleaning is from the surface Pt atoms. The fraction of the area under this peak can be estimated by a Gaussian deconvolution as indicated by the dashed blue line, which gives a value of 0.53, a value of fraction for Pt surface atoms in Au@Pt NPs that is in good agreement with that estimated electrochemically. However, the peak position is low-field shifted from 1.1000 G/kHz, the peak position for the surface Pt atoms in Pt/C NPs. The up-field part of spectrum is compressed towards low field as many alloyed systems do and also is more structured that that of Pt/C.

On the other hand, the as-prepared Ru@Pt sample was very fresh (only had a shelf life of a couple days) so no clear Pt oxide peak appeared. After the EC-cleaning, the spectrum also did not show spectral change as dramatic as that of the Au@Pt NPs. However, as that of the Au@Pt sample, it is very different from that of the pure Pt/C, with a broad dominant peak centered at 1.1053 G/kHz. Assuming that this is the surface peak, the ratio of the area under this peak can again be obtained by Gaussian deconvolution that gives a value of
The peak is high-field shifted from 1.1000 G/kHz, in the opposite direction from that of the Au@Pt. The origin of the remaining 26% signals is still unclear but clear difference in spectrum between Ru@Pt and Au@Pt highlights different electronic effect caused by the underlying Ru and Au cores.

If the deposited Pt atoms form mono-atomic islands on the surface of the core NPs, then they should have very similar electronic properties and coordination numbers. This is indeed the case for the Ru@Pt NPs as demonstrated by the spin-lattice and spin-spin relaxation times $T_1$ and $T_2$ measurements taken at four different spectral position of the dominant peak centered at 1.1053 G/kHz (Figure 4). As can be seen, the four $T_1$ and $T_2$ data sets are statistically the same with each other. The solid curves are the fits of all four data sets to an exponential saturation-recovery function $A_\infty - (A_\infty - A_0)\exp(-\tau/T_1)$ for $T_1$ and to a J-coupling modulated exponential decay function $[4] S(\tau)/S_0 = \exp(-2\tau/T_2)\left[P_0 + \exp(-\tau/T_{2J})\left[P_0 \cos(\tau/T_2) + P_2 \cos^2(\tau/T_2)\right]\right]$ with $P_0 + P_1 + P_2 = 1$ for $T_2$ respectively. In the former equation, $A_\infty$ is the fully relaxed NMR amplitude, $A_0$ is the residual amplitude after the saturation pulses, and $\tau$ is the time interval between the saturation pulses and the signal reading pulses. In the latter equation, $J$ is the nuclear-nuclear spin J coupling constant, $P_0$, $P_1$, and $P_2$ are the probability for a $^{195}$Pt nuclear spin having zero, one, and two neighboring $^{195}$Pt nuclear spins respectively, $T_{2J}$ is the time constant accounting for the spread in J values due to environmental heterogeneity, $S_0$ is the equilibrium NMR amplitude (the same as $A_0$), and $\tau$ is the time interval between two Hahn echo pulses. The fits give $T_1 = 1.05\pm 0.05$ ms, $T_2 = 348\pm 22$ $\mu$s, $T_{2J} = 209\pm 79$ $\mu$s, $J = 5.9\pm 0.3$ kHz, $P_0 = 0.69\pm 0.04$, and $P_1 = 0.19\pm 0.03$. Using a local Knight shift gradient parameter $[4] \delta = 0.15$, the local Pt atomic fraction estimated from the $P_1$ value is about 0.37 $[5]$. Since for a pseudo-morphic Pt monolayer on a Ru(0001) surface, the Pt fraction among all the next-nearest neighbors is 6/9, a local Pt atomic fraction of 0.37 is thus consistent with a Pt PD of 0.4 of mono-atomic Pt islands.

On the other hand, it is a quite different story for the Au@Pt sample whose results of $T_1$ and $T_2$ measurements are shown in Figure 5. They are qualitatively different from those of Ru@Pt and varied substantially from a spectral position to the other. Table 1 lists the fitted parameters that give the solid curves in Figure 5. The local Pt atomic fractions estimated from the $P_1$ values at 1.0975 G/kHz, 1.1001 G/kHz, and 1.1105 G/kHz are 0.14, 0.53, and 0.59 respectively. The $T_1$ and $T_2$ were also shorted as the spectral positions moved up-field, indicating that a substantial part of the Pt atoms went inside the Au NPs through exchange with the underlying Au atoms.

Using the two-band model $[6]$, we calculated the s-like and d-like $E_F$-LDOS for surface Pt atoms in Ru@Pt and Au@Pt. They are $D_{s,EF} = 3.7$ Ry$^{-1}$-atom$^{-1}$, $D_{d,EF} = 13.3$ Ry$^{-1}$-atom$^{-1}$ for the former and $D_{s,EF} = 4.3$ Ry$^{-1}$-atom$^{-1}$ and $D_{d,EF} = 10.1$ Ry$^{-1}$-atom$^{-1}$ for the latter respectively. Namely, Pt on Au has higher s-like but lower d-like $E_F$-LDOS. How these differences in the $E_F$-LDOS are related to the observed electrocatalytic activity is still unclear at this moment and the Pt PD dependence study should be revealing. Nonetheless, the above EC-NMR investigations demonstrate again the unique investigative power of the technique.

**FIGURE 4.** The spin-lattice relaxation $T_1$ (a) and spin-spin relaxation $T_2$ (b) data of the EC-cleaned Ru@Pt sample measured at different spectral position. The solid curves are the fits to the exponential recovery (a) and J-coupling modulated slow-beat (b) equations.
Future Directions

The immediate future directions of research include, but are not limited to, detailed in situ spectroscopic (NMR/SEIRAS/SERS) investigations of Pt/C, Ru@Pt, and Au@Pt NPs as functions of Pt PD and sulfur coverage.

Objectives
The main goal of the proposed work is to undertake a fundamental investigation of the ways of modifying the nanostructure of precious metal-free carbon catalysts and their functional groups to enable their use as oxygen reduction reaction (ORR) catalysts in proton exchange membrane (PEM) fuel cells and direct methanol fuel cells (DMFC). The project targets investigation of the nature of active sites and the ways to create these active sites for oxygen reduction reaction by molecular tailoring of the carbon nanostructures and surface moieties.

Technical Barriers
Platinum supported on carbon is the current catalyst used for ORR at the cathode in PEM and direct methanol fuel cells. The cost and availability of platinum is a barrier in wide-spread applications of PEMFC and DMFCs. Carbon-based ORR catalysts offer an alternative. The role of heteroatoms and the nature of the active site in these catalysts are heavily debated and need to be better understood before increased activity, current density and stability of these catalysts can be achieved. The work we are doing aims to develop a better understanding of the role that heteroatoms play in these catalysts, especially in terms of the active site.

Abstract
Heteroatom-containing carbon nanostructures are being investigated as catalysts in the oxygen reduction reaction (ORR) for PEM and direct methanol fuel cells. Heteroatoms including nitrogen, phosphorus and sulfur are being incorporated into various carbon nanostructures to study the role that heteroatoms and nanostructure play in ORR activity and selectivity. It has been found that sulfur can be used as a growth promoter in nitrogen-containing carbon nanostructures (CN_{x}), but does not participate in ORR and introduction of phosphorus can increase ORR activity in CN_{x}. Oxygen surface groups can increase the selectivity of CN_{x} catalysts. Additionally, nanostructure control is being developed to study the role of graphitic edge planes plays in ORR. Work is also ongoing in examining the corrosion characteristics of the catalysts developed. Full fuel cell tests with the most active catalysts are also in progress.

Progress Report

Investigation of the role of sulfur in CN_{x} catalysts.
Commercially, carbon nanofibers are produced using a sulfur growth promoter to increase yield. The impact of sulfur use on the end-use of nanofibers is not commonly discussed or understood. When we introduced sulfur, in the form of thiophene, into the acetonitrile pyrolysis feed used to produce nitrogen containing carbon nanostructure (CN_{x}) catalysts, the CN_{x} yield increased. Through X-Ray Photoelectron Spectroscopy (XPS), temperature programmed desorption (TPD) and temperature programmed oxidation (TPO) experiments, it was found that sulfur was both adsorbed to the CN_{x} surface and incorporated into the graphitic matrix. As long as acetonitrile was still in the fiber growth feed, ORR activity was unaffected by the growth promoter concentration or the amount of sulfur incorporated into the CN_{x}. These results also indicate that sulfur, as incorporated in this study, does not play a role in ORR activity. This work is in press with Applied Catalysis B.

Incorporation of phosphorus heteroatoms into CN_{x}. Phosphorus, when incorporated into CN_{x} has the potential to impact the electrocatalytic ORR activity. Heteroatom incorporation may also affect physical and chemical characteristics, ORR activity and selectivity, as well as, stability. Phosphorus added to the growth media of nitrogen-containing carbon nanostructures was found to dramatically improve the electrocatalytic activity for oxygen reduction. Phosphorus doping was achieved by growing carbon-nitrogen-phosphorus catalyst (CN_{x}P_{y}) over triphenylphosphine- and iron acetate-impregnated magnesia support in N_{2} saturated with CH_{3}CN at 900°C. Catalysts grown in phosphorus-containing media showed improved onset of activity, increased current density and higher selectivity for water formation. The incorporation of both phosphorus and nitrogen into graphite materials allows for the tailoring of the physical and electrochemical properties. Initial results from this study have been submitted to Carbon.
**Oxygen functionalities.** Oxygen functional groups are commonly found on carbons when exposed to an oxidizing environment such as air. Oxygen functional groups affect properties critical for fuel cell catalysts, including hydrophilicity, elicit an activity increase and create anchoring sites for other functional groups or metals. CN_x was subjected to a nitric acid treatment in order to enhance the surface oxygen content and explore the role that oxygen functional groups have on ORR for CN_x catalysts. Nitrogen-containing carbon nanofibers were treated in HNO_3 to impart them with oxygen functional groups. With this treatment, ORR activity was found to increase slightly while selectivity to water formation markedly increased. Work continues with oxygen functional groups to identify the oxygen species that contribute to activity. *Preliminary results from this sub-area are published in Topics in Catalysis.*

**Tailoring the catalyst nanostructure.** The tailoring of nanostructure has been studied using different methods. The most active CN_x catalysts previously made by our research group had a mixture of nanostructures, but contained 60-70% stacked cup nanofibers. Studies were performed to increase the stacked cup nanofiber content. A solvothermal decomposition technique was used for preparing uniform 6nm iron oxide nanocrystals that were deposited on silicon wafers. CH_3CN pyrolysis was performed on the Fe nanoparticles. Unlike carbon nanofibers grown on Fe- or Co-impregnated VC, Al_2O_3, SiO_2, and MgO supports, which led to a mixture of carbon structures ranging from multi-walled nanotubes to nano-onions, this preparation gave exclusively “stacked-cup” structures. Since these stacked cup CN_x catalysts had very low yields because of the low surface area of the polished silicon wafer support, efforts are underway to prepare iron oxide nanoparticles on a silica support, by controlling the size and nanogeometry of the particles through organometallic synthesis techniques. Acetonitrile pyrolysis will, then, be performed, followed by washing, leaving behind the nitrogen containing carbon nanostructures.

Another avenue we followed was the synthesis of stacked platelets. This nanostructure was studied because of its increased edge plane exposure, hypothesized to be the location of the ORR active sites. Stacked platelets were made by passing a stream of CO:H_2 over an Fe:Cu unsupported catalyst. These stacked platelets were post-treated to incorporate oxygen and nitrogen functional groups into the nanostructure. They were oxidized in concentrated HNO_3:H_2SO_4 to add oxygen functional groups to the more active edge planes. The oxidized platelets were treated at two different temperature levels with ammonia to incorporate nitrogen into the nanostructure. It was found that oxidation of the platelets increased activity, but not as significantly as treatments in ammonia did.

**Electrochemically accelerated carbon corrosion.** Accelerated electrochemical corrosion of CN_x catalysts was performed through a chronoamperometric hold of 1.2V vs. NHE in 0.5M H_2SO_4 electrolyte utilizing a rotating disk electrode system. The progression of carbon corrosion was monitored by measuring the intensity of an oxidation intermediate, the hydroquinone/quinone electrochemically active redox couple. Half-cell testing of CN_x oxygen reduction catalyst materials showed superior carbon corrosion resistance compared to Vulcan carbon, the most commonly used material as cathode catalyst support. CN_x materials grown over an iron-impregnated support at 900°C in an acetonitrile atmosphere had a higher oxygen reduction activity than materials without an iron growth catalyst. When oxygen reduction activity was monitored before and after carbon corrosion testing, carbon corrosion resilience trended with oxygen reduction activity. Electrochemical ORR testing was observed to promote the corrosion resistance of highly active CN_x catalysts, but have no impact for materials that have low ORR activity. *This work has been submitted to Electrochimica Acta.*

**Examination of the parameters that impact RRDE measurements.** The parameters that impact the measurement of activity and selectivity through voltammetry techniques, such as rotating ring disk electrode (RRDE), were examined. The selectivity values measured using the RRDE technique for different catalyst loading levels on the disk were compared. A positive correlation between the selectivity and catalyst loading was observed for both CN_x catalysts and commercial Pt/VC.

Another parameter which affects the RRDE measurements is the aging of the catalyst ink before being applied to the electrode. A dramatic decrease in the ring current with aging coupled by a more modest increase in the disk current was observed with RRDE ink aging. The onset of activity does not appear to change with ink aging. When experiments were repeated with Pt/VC catalysts, similar changes in selectivity were observed, indicating that this was not a phenomenon specific to CNx catalysts. *This work is in review with Electrochemical and Solid-State Letters.*

**Full PEM fuel cell testing of heteroatom-doped carbon materials.** Procedures for fabricating membrane electrode assemblies (MEAs) have been modified from those used for Pt-based catalysts reported by Los Alamos National Laboratories for our CN_x catalysts. Method optimization for enhanced performance for non-noble metal catalysts is ongoing. With the addition of an Arbin 50W hydrogen/direct methanol fuel cell test stand, CN_x catalyst MEA performance and stability are being explored.
Initial computational chemistry studies: Computer exploration of heteroatoms in graphite materials. As a collaborative effort with Professor Christopher Hadad, density functional theory (DFT) calculations have been initiated for nitrogen 1s orbital energies in polycyclic aromatic hydrocarbons (PAHs), which have a similar electronic structure to carbon-nitride catalyst materials. A strong correlation between DFT B3LYP method N 1s energies and experimental XPS N 1s energies was established for the PAHs studied. Additionally, experimental ionization potentials trended strongly with the DFT adiabatic ionization potentials. This calibration will be extended to larger and more complex molecules that are more like CN\textsubscript{x} catalysts.

Correlation between activities of CN\textsubscript{x} catalysts in ORR and ODH reactions. There have been reports in the literature citing the activity of carbon-based materials in oxidative dehydrogenation (ODH) reactions. Although the source of activity in these materials was not clear, the pre-treatments that involved O\textsubscript{2}, N\textsubscript{2}O and HNO\textsubscript{3} suggested possible oxygen and nitrogen functional groups playing a role in catalyzing the reaction. While some research has been conducted connecting carbon nanostructure to ORR activity, there is far less literature connecting carbon nanostructure to ODH activity. We initiated a study to examine the activity nitrogen-containing carbon nano-structures in oxidative dehydrogenation of lower alkanes and explore if any correlations existed between the ODH and ORR activities over this group of catalysts. There was a strong correlation between ODH and ORR activities observed. XPS analysis demonstrated that ORR and ODH activity trends between catalysts followed the percentage of oxygen present as quinone groups as well as the pyridinic nitrogen groups. The correlation may suggest a shared active site between the ORR and ODH reactions although alternative explanations cannot be ruled out. This work is in press with Catalysis Letters.

Future Plans

Work on all sub-areas mentioned in the above progress report will continue. Some specific areas of particular interest are listed here:

- Determination of the role of phosphorus carbon-nitrogen nanostructures: Phosphorus was shown to impact the electrocatalytic ORR activity when incorporated into CN\textsubscript{x}. The phosphorus content and local bonding environment will be probed to ascertain what the role of phosphorus is.

- Poisoning CN\textsubscript{x} catalysts: The nature of activity in non-noble metal CN\textsubscript{x} materials is still debated in the literature. To determine if the activity is imparted by a Fe-N\textsubscript{x} type active site, activity testing will be performed on the CN\textsubscript{x} material before and after exposure to several common catalyst poisons that bond strongly to iron.

- X-ray Absorption Spectroscopy (XAS) characterization. The XAS techniques are powerful tools to provide information about the coordination chemistry, formal oxidation state of a selected element being studied as well as the species, distances and coordination number of the atoms surrounding it. These techniques can be very useful in elucidating the molecular structure of the CN\textsubscript{x} catalysts. Heteroatom-containing carbon nanostructures grown on different transition metals will be characterized using XAS techniques. Our recent proposal to Advance Photon Source (APS) of Argonne National Laboratory was accepted and we are given beam time at Sector 10.

- Computational chemistry studies to complement the experimental work. A collaborative effort is in progress to gain insight into the oxygen reduction reaction over the nitrogen-doped carbon catalysts using computational chemistry. It is planned to use both cluster models and periodic boundary models to explore the possible ORR mechanism over the nitrogen-doped carbon catalysts in acidic solution. Experimental techniques will be used in tandem to refine the ORR mechanistic pathway.

**Objectives**

The design and optimization of novel water-gas shift catalysts for the production of pure hydrogen depends on a better understanding of catalyst structure and function. We are carrying out a coordinated research program to understand the active sites and reaction mechanism for the water-gas shift on promising metal-oxide catalysts for industrial applications.

**Technical Barriers**

Our goal is to develop the ability to predict, and ultimately design, improved cost-effective water-gas shift low temperature catalysts. These catalysts and the knowledge gained about their behavior will improve the performance and operation of industrial processes used for the production of pure hydrogen.

**Abstract**

The water-gas shift reaction (WGS: CO + H₂O → H₂ + CO₂) is a critical process in providing pure hydrogen for catalytic processes in the chemical industry and fuel cells. High purity hydrogen is needed in massive quantities for the synthesis of ammonia and nitrogen-based fertilizers and for essential hydrogenation processes within the food industry. Furthermore, improved air-tolerant, cost-effective WGS catalysts for lower temperature processing are needed to enable mobile fuel cell applications in a hydrogen fuel economy. The design and optimization of WGS catalysts depends on a better understanding of catalyst structure and function. We are carrying out a coordinated research program to understand the active sites and reaction mechanism for the WGS on promising metal-oxide catalysts. In the initial funding period, our studies with inverse oxide/metal catalysts have shown the crucial role that an oxide can play in the WGS process. By combining nanoparticles of noble metals (Cu, Au and Pt) and ceria over a titania support, we have obtained extremely active WGS catalysts. Our work indicates that highly active WGS catalysts are bifunctional with the metal and oxide catalyzing different parts of the reaction. In the future, we will be working with three different types of catalyst configurations: metal/oxide, oxide/metal and mixed-metal oxide, with the aim of optimizing the performance of the metal and oxide phases. Our goal is to develop the ability to predict, and ultimately design, improved cost-effective WGS low temperature catalysts. Our approach exploits unique capabilities available for *in-situ* studies in the BNL catalysis programs, and at BNL facilities such as the National Synchrotron Light Source (NSLS) and the Center for Functional Nanomaterials (CFN).

**Progress Report**

Since the start of this project 2.5 years ago, seventeen articles have been published by members of the research team examining different aspects of the WGS on metal/oxide catalysts (see separate list of publications). Work was done with high-surface area powders and model catalysts, combining sophisticated techniques for bulk and surface characterization with state-of-the-art theoretical calculations. We have strategically directed part of our efforts to develop synchrotron-based techniques useful for *in-situ* characterization of catalysts and mechanism studies: Quick XAFS, combined XRD/XAFS and combined XAFS/IR.

A. *In-situ* XRD and XAFS studies of the WGS reaction on CuFe₂O₄, CuMoO₄ and Ce₁₋ₓCuₓO₂.

Cu-Fe oxides are used as WGS catalysts in several industrial processes. The structure of CuFe₂O₄ is known as an “inverse spinel” (Figure 1). Copper ions sit predominantly on octahedral sites and iron atoms alternate between octahedral and tetrahedral sites. XRD data collected while performing the WGS on CuFe₂O₄ showed that up to ~ 200 °C, there were no changes in the tetragonal structure of CuFe₂O₄ and no WGS activity was detected. From 200 to 300 °C, CO attacks the oxide and partial reduction leads to the segregation of metallic Cu with the onset of WGS activity. At 350 °C, one has an active WGS catalyst which contains a mixture of Cu, CuFe₂O₄ and/or Fe₂O₃. A Rietveld refinement gave a mole ratio of ~ 1 for the diffraction lines of copper and the CuFe₂O₄/Fe₂O₃ spinel. *In-situ* experiments of x-ray absorption spectroscopy at the Cu...
K-edge indicated that essentially all the Cu\(^{2+}\) initially present in CuFe\(_2\)O\(_4\) was reduced to metallic Cu\(^0\).\(^2\) Our XRD and XAFS results point to metallic copper as an active species for the WGS.\(^2\) This is consistent with studies performed in our group for the water-gas shift on CuMoO\(_4\), Ce\(_{1-x}\)Cu\(_x\)O\(_{2}\), and CuO-ZnO powder catalysts.\(^1,3\) In all of these systems, catalytic activity was seen only after a Cu\(^{2+}\) → Cu\(^0\) transformation. A highly active phase consists of metallic Cu dispersed on a partially reduced oxide support (MoO\(_3\), Ce\(_{2-x}\)O\(_x\), Fe\(_3\)O\(_4\)).\(^1,3\) These studies help to solve a long debate about the oxidation state of Cu in oxide-based WGS catalysts.\(^3,15\)

B. WGS activity of Cu nanoparticles supported on well-defined oxide surfaces. Since CuFe\(_2\)O\(_4\), Ce\(_{1-x}\)Cu\(_x\)O\(_2\), CuO-ZnO, or CuMoO\(_4\) show significant water-gas shift activity only when the Cu cations in the mixed-metal oxide are reduced to metallic copper, Cu nanoparticles were deposited on a series of well-defined oxide surfaces and their WGS activity was measured in a batch reactor.\(^4,10\) The WGS activity of the Cu nanoparticles supported on MgO(100) was 2-3 times larger than that of Cu(100).\(^5\) Even better WGS catalysts were obtained when Cu was deposited on CeO\(_2\)(111) or TiO\(_2\)(110).\(^6,9\) An apparent activation energy of 13.8 kcal/mol was found for the WGS on Cu/MgO(100).\(^6\) This is smaller than the value of 15.2 kcal/mol observed on Cu(100), and substantially larger than the values of 7-9 kcal/mol seen for the apparent activation energies of the Cu/ CeO\(_x\)/Cu(111) and Cu/TiO\(_2\)(110) catalysts.\(^6,9\) Post-reaction surface characterization pointed to the lack of O vacancies in the Cu/MgO(100) catalysts.\(^6\) This is in contrast to results found for Cu/ CeO\(_x\)(111) and Cu/TiO\(_2\)(110), where the oxide support exhibits a significant concentration of O vacancies as a consequence of the WGS reaction.\(^6,9\) The oxygen vacancies present in Cu/ CeO\(_x\)(111) and Cu/TiO\(_2\)(110) could help in the dissociation of the water molecule and reduce the apparent activation energy for the WGS process.\(^9\)

C. WGS reaction on inverse CeO\(_x\)/Cu(111) and CeO\(_x\)/Au(111) catalysts: Active role of the oxide. Several studies dealing with metal/oxide powder catalysts and the WGS indicate that the oxide plays a direct role in the reaction,\(^15,16\) but due to the complex nature of these systems there is no agreement on what exactly this role is. To address this issue, we performed experiments on inverse CeO\(_x\)/Au(111) and CeO\(_x\)/Cu(111) catalysts.\(^7\) After depositing Ce atoms on Cu(111) under an atmosphere of O\(_2\), one obtains CeO\(_x\)/CuO/ Cu(111) systems.\(^5\) Upon reaction with CO, the CuO is easily reduced and one obtains CeO\(_x\)/Cu(111) inverse catalysts.\(^5\) The oxidation state of Ce in these systems is a mixture of Ce\(^{3+}/Ce^{4+}\). The deposition of ceria nanoparticles on top of Cu(111) produces a phenomenal increase in the WGS activity.\(^5\) A comparison of the WGS activities of CeO\(_x\)/Cu(111) and Cu/CeO\(_x\)(111) shows that an optimization of the physical and chemical properties of the oxide component is as important as the optimization of the properties of the metal component.\(^5\)

D. Controlling the nature of mixed-metal oxide catalysts at the nanometer level: High WGS activity of M/CeO\(_x\)/TiO\(_2\)(110) surfaces (M= Au, Cu, Pd). Recently, there has been a strong interest in understanding phenomena associated with the deposition of oxide nanoparticles on the surface of a second (host) oxide.\(^7\) At BNL, STM, photoemission, and density-functional calculations were used to study the behavior of ceria nanoparticles deposited on a TiO\(_2\)(110) surface.\(^4\) The titania substrate imposed non-typical coordination modes on the ceria nanoparticles. In the CeO\(_x\)/ TiO\(_2\)(110) system, the Ce cations adopt a geometry and an oxidation state (+3) which are quite different from those seen in bulk ceria or for ceria nanoparticles on metal substrates.\(^4,10\) The results of STM show the formation of CeO\(_x\) dimers which form small linear arrays on top of the TiO\(_2\)(110) substrate (see Figure 2). An increase in the stability of the Ce\(^{3+}\) oxidation state leads to an enhancement in the chemical and catalytic activity of the ceria nanoparticles.\(^4,10\) The co-deposition of ceria and gold nanoparticles on a TiO\(_2\)(110) substrate generates catalysts with an extremely high activity for the production of hydrogen through the water-gas shift reaction (see Figure 3). Au/ CeO\(_x\)/TiO\(_2\)(110) was found to be much more active than Au/TiO\(_2\)(110) or even Au/CeO\(_x\)(111).\(^4\) On the TiO\(_2\)(110) surface, the ceria nanoparticles help to disperse the Au atoms and to dissociate the water molecule.\(^4,10\) While Au surfaces and nanoparticles interact poorly with water,\(^4\) density-functional calculations predict an exothermic process for the dissociation of water on CeO\(_x\)/TiO\(_2\)(110) with almost no activation barrier.\(^8,11\) The enhanced stability of the Ce\(^{3+}\) state in CeO\(_x\)/TiO\(_2\)(110) is an example of structural
promotion in catalysis documented for the first time on the atomic level.4 Thus, the exploration of mixed-metal oxides at the nanometer level may open new avenues for optimizing catalysts through stabilization of non-conventional surface structures with special chemical activity.4,10,18 The Cu/CoOx/TiO2(110) and Pt/CoOx/TiO2(110) systems are also excellent WGS catalysts.10 In the future, we plan to extend this type of studies to high-surface area powders. A first set of studies for a Pt/CoOx/TiO2 powder shows a very good WGS catalyst.18

Future Directions

The studies described above indicate that highly active water-gas shift catalysts are bifunctional with the metal and oxide catalyzing different parts of the reaction. To optimize these complex systems one must understand the nature of the active sites in each component of the catalyst and determine how they interact with the reactants (CO, H2O) and possible intermediates (OH, HOCO, HCOO, CO3, and HCO3) of the WGS.19 In the future, we plan to work with catalysts in which the oxide phase contains or combines ceria, titania and molybdena. Cu, Au, Pd or Pt will constitute the metal phase. This selection of oxides and metals is based in our previous studies. The high WGS activity of ceria- and titania-based catalysts is well documented in the literature.13,16,20 They are expected to be the next generation of WGS catalysts for industrial applications. We will identify methodologies for developing highly efficient WGS catalysts optimizing the performance of the metal and oxide phases. The scheme at the left shows the three different configurations in which a metal and an oxide will be combined in our catalysts. The most complex and promising is the mixed-metal oxide configuration in which nanoparticles of a metal and an oxide can interact with the reactants.4,10,18 Our experience indicates that a coordinated approach is necessary to address fundamental issues for the WGS on metal/oxide catalysts. Thus, we propose three research thrusts: (i) in-situ studies; (ii) model system studies; and (iii) theoretical calculations. The overarching questions of catalyst state, reaction mechanism, and nanoparticle size and morphology interconnect these thrusts. As in the past, we will be taking advantage of a unique set of techniques available at BNL for in-situ studies (XRD, XAFS, TEM, IR, XPS). The experiments will closely coupled to theoretical studies on the chemisorption of the reactants, the stability of possible intermediates, and activation barriers for elementary reaction steps, providing critical guidance in developing a complete picture of structure and mechanism in this important process.

Objectives

Electrocatalysts based on inexpensive, earth-abundant metals are needed since most fuel cells are based on platinum, an expensive, precious metal. Our objective is to design and synthesize biologically inspired functional model complexes that catalyze the oxidation of hydrogen and the production of hydrogen. Our research focuses on molecular complexes containing ligands bearing pendant amines that function as proton relays.

Technical Barriers

The Basic Energy Sciences workshop report, Basic Research Needs for the Hydrogen Economy, emphasized the need for “developing catalysts that rely less on noble metals, which will become a limiting resource in large-scale hydrogen energy systems.” Because of limited supplies and the high cost of platinum, alternatives that use abundant, inexpensive metals are being studied in our research. We seek an understanding of how molecular complexes of nickel, cobalt and manganese can function as catalysts for oxidation of H₂ and for production of H₂ by reduction of protons. The challenges involve synthesis and design of ligands and metal complexes, obtaining an understanding of mechanistic details of the reactions, and development of highly active electrocatalysts with low overpotentials.

Abstract, Progress Report and Future Directions

Renewable energy sources such as solar, wind, or geothermal provide the possibility of large amounts of carbon-free energy, but the temporal variation in electricity output from these sources will require energy storage. Studies of H₂ are a critical part of efforts to rationally design electrocatalysts for energy storage as fuels. Low-temperature proton exchange membrane (PEM) fuel cells require platinum, an expensive noble metal of low abundance. Lower costs for fuel cells are expected to lead to broader and more diverse applications of fuel cells for conversion of H₂ to electricity. The cost of Ni, Co, or Mn is typically about three or four orders of magnitude less than the cost of Pt, so dramatic cost savings may be obtained by development of catalysts using these inexpensive, earth-abundant metals. This goal has already been achieved by biological systems that oxidize and produce H₂ using iron and nickel under exceedingly mild conditions.

Our objective is to synthesize biologically inspired functional models that provide high catalytic activity with low overpotentials, by recognizing that some of the most salient features enabling the remarkable capabilities of Nature’s catalysts can be replicated synthetically. In the [FeFe] enzyme, it is thought that an N atom near the iron assists in the heterolytic cleavage of H₂, and that this pendant amine shuttles protons from the catalytically active metal site to the proton conduction channel. Our efforts focus on the design of biologically inspired complexes that use abundant metals and have a pendant amine; we seek functional rather than structural models of the [FeFe] or [FeNi] hydrogenases.

Our work has demonstrated that complexes based on nickel, an inexpensive, abundant metal, can be used as electrocatalysts for H₂ production with rates (up to about 800 s⁻¹ at 22 °C) comparable to those of [NiFe] hydrogenase enzymes, and with overpotentials of 100-300 mV. Another important need is for catalysts with improved tolerance to CO, since the Pt catalyst in fuel cells is sensitive to CO impurities at the ppm level. The nickel-based hydrogen oxidation catalysts developed by our group have been demonstrated to have remarkable tolerance to CO; they function under 5% CO, with no detectable loss of activity.

Pendant amines in the diphosphine ligand can lead to a profound acceleration of the catalytic rates in nickel electrocatalysts for oxidation of H₂. In our series of electrocatalysts for oxidation of H₂, the thermodynamic driving force for the addition of H₂ increases in the order [Ni(dp^3)₄N₂]⁺⁺ < [Ni(dp^3)₂(dp)₂]⁺⁺ < [Ni(dp^3)₂(dp)₂N₂]⁺⁺ < [Ni(dp^3)(PNP)₂]⁺⁺ (PNP = Et₂PCH₂N(Me)CH₂PEt₂). The turnover frequencies, which correspond to the rates of H₂ addition, show the reverse order. These rates correlate with the number of amines positioned near the metal ion in the second coordination sphere of each complex (not the total number of
pendant amines). These comparisons indicate that two positioned pendant bases are important for achieving the fast catalytic rates observed for \([\text{Ni}(\text{PCy}_2\text{NBz}_2)_2]^{2+}\) in the oxidation of \(\text{H}_2\), and for \([\text{Ni}(\text{PPh}_2\text{NPh}_2)_2]^{2+}\) in the production of \(\text{H}_2\). The role of the two amines positioned in close proximity to the metal serves to stabilize, through hydrogen bonding interactions, both the binding of the dihydrogen ligand on nickel and the heterolytic cleavage of \(\text{H}_2\).

Nickel catalysts for reduction of oxygen to water were also discovered, again with pendant amines on the ligands facilitating these reactions involving transfers of multiple protons and electrons. No activity for catalytic reduction of oxygen was found for related complexes lacking the proton relay in the ligand.

Our progress on cobalt complexes shows that our approach of using pendant amines in the second coordination sphere of nickel complexes can lead to the development of new classes of catalysts based on other earth-abundant, inexpensive first row metals. Catalytic reduction of protons by \([\text{Co}(\text{PPh}_2\text{NPh}_2)(\text{CH}_3\text{CN})]^{2+}\) occurs with a turnover frequency of 90 s\(^{-1}\) for production of \(\text{H}_2\) and essentially 100\% current efficiency. This reaction occurs at the half-wave potential of the \(\text{Co(II/III)}\) couple (-1.00 V vs. \(\text{Cp}_2\text{Fe}^+/\text{Cp}_2\text{Fe}\)). The overpotential of this reaction was calculated to be 285 mV, so this cobalt catalyst operates at a fast rate and with a relatively low overpotential. In contrast to the nickel complexes, where two relays were found to be optimal, the cobalt catalysts need only one ligand containing a positioned pendant amine. Much remains to be done in terms of future catalyst development. These discoveries point to new directions that we propose to study in detail, since our knowledge of the mechanistic details of these cobalt complexes is scant compared to the understanding we now have for the nickel complexes.

We recently began a new study of manganese complexes. Manganese is not normally even considered in studies of catalytic oxidation of \(\text{H}_2\) or for production of \(\text{H}_2\), but we believe that with appropriate ligands, a new class of catalysts could result. We have synthesized a series of Mn complexes of general formula \([\text{(P-P)}(\text{P’-P’})(\text{CO})\text{Mn}]^{n+}\) and have studied their binding of \(\text{H}_2\). The reaction of \(\text{H}_2\) with \([\text{PPh}_2\text{NPh}_2]^{n+}(\text{dppm})(\text{CO})\text{Mn}]^{n+}\) produces an \(\eta^2\)-\(\text{H}_2\) complex. A related complex with electron-withdrawing aromatic groups on the second
diphosphine reacts with $\text{H}_2$ (1 atm) to give *heterolytic cleavage of H}_2 at room temperature*, with the H$^-$ being located on the Mn and the H$^+$ being transferred to the N.

In proposed future work, we will focus on the design and development of Co, Mn, and Fe complexes; we seek to obtain an understanding of the molecular reactivity that will allow us to design and discover new, robust, highly active catalysts for oxidation and production of $\text{H}_2$. We propose new studies of how changes in the first and second coordination spheres will alter catalytic activity and the mechanism. New studies on iron complexes are being initiated; iron is a very attractive metal since it is cheap, non-toxic, and the metal used by the biological catalysts that have the highest rates for $\text{H}_2$ production/oxidation. We propose the synthesis of a new series of ligands with enhanced hydrogen bonding capabilities.

**Publications acknowledging DOE Hydrogen Fuel Initiative Funding**

Objectives

The research is geared toward fundamental understanding of composition/structure/function relationships in supported, heterogeneous catalysts for reactions that produce hydrogen from hydrogen-rich molecules. The role of particle composition, size, and structure and the effect of supports and promoters on adsorptive and catalytic properties are investigated. A particular goal is to determine if the catalytic activity for hydrogen production from methanol can be significantly improved by preparing catalysts which only partially adsorb CO under reaction conditions. The catalysts are supported metal, alloy, carbide, and nitride nanoparticles and clusters with an emphasis on clusters in the size range <1 nm, i.e., ~2-50 atoms.

Technical Barriers

Catalysts for the reforming of hydrogen rich organic molecules, such as methanol, to produce molecular hydrogen exhibit poor activity at low temperature due in large part to poisoning by CO, an inevitable byproduct of the chemistry. We hypothesize that catalyst performance can be improved greatly by using subnanometer size metal and alloy clusters on suitable supports. Advanced techniques for synthesis, stabilization, characterization, theory and testing are employed to investigate and understand the chemical and catalytic properties of these materials.

Abstract

The objective of the research is a fundamental understanding of composition/structure/function relationships in supported, heterogeneous catalysts for reactions that produce hydrogen from hydrogen-rich molecules. The focus of the work over the last two years has been the synthesis, stabilization, characterization, catalytic evaluation and computation of supported metal cluster catalysts in the size range <1 nm, i.e., ~2-50 atoms. New synthetic and stabilization strategies and computational understanding have been achieved for ultra-small, supported metal particles. The research integrates efforts in: 1) synthesis and stabilization of uniform, supported clusters and oxide promoters; 2) characterization of cluster size, atomic structure, stability, and electronic structure during synthesis, pretreatment, and catalytic reaction; 3) investigation of catalytic and chemical events on the clusters that are relevant to hydrogen production; 4) computational quantum chemical modeling to understand and predict experimental results. Future work will emphasize experiments and computations of alloy, carbide, and nitride nanoparticles and clusters.

Progress Report and Future Plans

Experimental Catalyst Synthesis, Characterization and Reaction Studies

Pd nanoparticle catalysts were synthesized and stabilized by atomic layer deposition (ALD). [1] Alternating exposures of palladium (II) hexafluoracetacetonate (Pd(hfac)_2) and formaldehyde (HCOH) produce well dispersed, discrete Pd nanoparticles on high surface area mesoporous silica gel supports. The average Pd particle size by TEM and EXAFS is ~2 nm. Smaller particle sizes have been achieved using lower reaction temperatures and by depositing support layers prior to metal particle reduction with HCOH. Additional layers of support serve to stabilize the particles against sintering and deactivation. Other ALD noble metal systems, including Pt, Ru, and Ir, were targeted for achieving sub-nanometer particles for hydrogen production. In-situ EXAFS revealed details of the Pt nanoparticle formation. [2] Supported sub-nm Ir nanoparticles (<0.5 nm, Fig. 1a) were prepared, the smallest reported to date. A detailed study of ALD Pt-Ir alloys has also been performed, representing the first study of ALD metal mixtures. [3] Finally, a variety of ALD noble metal alloy nanoparticles including Pt-Ir, Pt-Ru, Ir-Ru, and Pt-Pd (Fig. 1b) were prepared.
Size-selected cluster synthesis of various sized cluster catalysts using a mass-selected ion beam has been combined with the development of an in-situ reaction cell and surface-sensitive tools at 12-ID of the Advanced Light Source. Catalysts can be characterized by synchrotron-based X-ray absorption and scattering and simultaneously monitored for catalytic activity. [4,5]

The performance for methanol decomposition by the ALD catalysts is shown in Fig. 2. The methanol conversion increases monotonically with increasing temperature reaching ~100% at 280°C. At all temperatures the selectivity was nearly 100% to CO and H₂. Catalysts prepared using ALD ZnO as the underlying support showed much lower conversion and rapid deactivation at the higher temperatures due to Pd “dissolving” into the ZnO substrate. By applying one cycle of ALD Al₂O₃ on top of the Pd/ZnO catalyst, the activity was enhanced, and the catalyst deactivation was mitigated. This Al₂O₃ over-coating method stabilizes the Pd/ZnO and effectively prevents the dissolution of Pd into the ZnO substrate. [1]

Smaller Pd₈₋₁₂ clusters formed by ion beam deposition were found to promote decomposition to CO and hydrogen but suffered from poisoning. Larger Pd₁₅₋₁₈ clusters preferentially produce dimethyl ether and formaldehyde, without signs of poisoning. A thin ALD titania overcoat applied on Pd₁₅₋₁₈ improves the sintering-resistance via a mechanism involving partial encapsulation of the Pd. [6] It also changes the selectivity so that CH₂O prevails.

Future synthesis and catalytic experimentation efforts will target subnanometer alloy and nitride particles with weaker bonds to CO. Guidance in the selection of particle size and composition will be provided by computations as described below.

**Computational Catalysis Studies**

Periodic plane wave calculations were employed to determine the activity and reaction pathways of supported and unsupported M₄ and M₈ (M=Pd, Cu, and Co) clusters for methanol decomposition. [7,8] The structures of oxidized Cu clusters have also been studied. [9] For Pd (primarily Pd₄) clusters, the decomposition of methanol begins with C-H bond breaking to form hydroxymethyl (CH₂OH), followed by steps involving formation of hydroxymethylene (CHOH), formyl (CHO), and carbon monoxide (CO). This pathway is shown in Fig. 3. O-H bond breaking as the first step, followed by formation of methoxy (CH₃O) and formaldehyde (CH₂O), was slightly less favorable. C-O bond cleavage is much less energetically favorable, and
no feasible pathways involving C-O bond formation to yield dimethyl ether (CH₃OCH₃) were found. All reaction intermediates bind slightly more strongly to clusters than to extended surfaces. The effects of an alumina support were also calculated. [7] Overall, the results indicate that larger Pd clusters and inclusion of the alumina support did not significantly affect the reaction pathways. The combination of bare and supported cluster results clearly shows that CO adsorbs in a deep well (Fig. 3) that can poison the methanol decomposition reaction, supporting the proposal in the experimental studies of Vajda et al [6] where little product is observed until the temperature is high enough for CO desorption. The reaction pathways on Cu₄ and Co₄ clusters are distinctly different from the Pd₄ clusters. [8] Methanol decomposition to form CO and H₂ is shown in Fig. 3 for Cu₄ and Co₄ along with that of Pd₄. The overall trends are not affected by adding the support. The Co₄ cluster pathway is very favorable both thermodynamically and kinetically for dehydrogenation, but since CO adsorption is also very favorable, it is likely to poison methanol decomposition at low temperatures, similar to the result for Pd clusters. In contrast, CO poisoning of the Cu₄ cluster is less of a problem, but the dehydrogenation steps are not favorable. This strongly indicates a need to find other clusters that combine the favorable aspects of the Co and Cu clusters for methanol decomposition while, at the same time, not suffering from the deficiencies of these elements. Pathways involving C-O bond cleavage are less energetically favorable for the Cu₄ and Co₄ clusters.

The data on adsorption energies and activation barriers can be analyzed in terms of Brønsted-Evans-Polanyi (BEP)-type curves. BEP relations are often implicitly assumed to hold for surface reactions, but to the best of our knowledge, this kind of relationship has not been considered for subnanometer clusters. Fig. 4 shows a BEP plot for all elementary reactions studied for Pd₄ and Pd₈ clusters. According to this BEP relationship, the thermodynamically most endothermic step should have the highest activation barrier and vice versa. C≡O dissociation is the most endothermic step in Fig. 4, C–O, O–H and C–H scission have intermediate energetics, and C–H dissociation is the most exothermic. The equation relating transition and final state energies is provided in Fig. 4 and has a slope of 0.85; this value, close to unity, suggests that the transition states in the reaction networks are final state-like in character, where the final state is defined in the exothermic direction for each elementary step. This type of analysis has also been carried out for the reactions on Cu₄ and Co₄ clusters. The relationships derived will be utilized in screening studies in our future plans to identify promising systems.

**Publications**

Objectives

- Provide fundamental understanding of hydroxide conducting systems.
- Explore stability and basicity of cations.
- Relate cation chemistry and structure to stability and conductivity.
- Elucidate importance of carbonate in hydroxide conducting systems.

Technical Barriers

Alkaline membrane-based electrochemical systems have been limited by: 1) the poor stability of tetraalkyl ammonium ions employed as covalently tethered cations in current anion exchange membranes; 2) the decreased conductivity of hydroxide compared to protons; and 3) the role of carbonate/hydroxide equilibrium in these systems. Alkaline systems have shown improved electrocatalysis and the ability to operate without precious metal catalysts (like platinum). If systems based on alkaline membranes could achieve good stability and conductivity, they would play a major role in enabling commercial competitiveness of fuel cell systems.

Abstract

The advantages of an alkaline system for fuel cells are improved efficiency, and the enablement of non-precious metal catalysis, a critical showstopper to widespread implementation of traditional (acidic) fuel cells. Alkaline systems have seen much less research interest by the fuel cell community compared to competing technologies due to concerns with carbonate formation and the inability to produce membranes of acceptable stability. Still, no fundamental investigations quantifying the role of carbonate formation have been made and investigation of cations other than those based on quaternary ammonium has been very limited. This project addresses both of these points, and probes fundamental aspects of hydroxide conductors for conductivity and stability. We will emphasize the investigation of families of cations that show promise, but have been largely overlooked by the ion exchange community. The project includes quantum mechanics (QM) and molecular dynamics (MD) modeling which allow us to probe the chemical stability and conductivity of target cations, the functional component of anion exchange materials. This modeling work will be closely tied to the characterization of traditional cations and the synthesis and characterization of non-traditional cations potentially suitable for incorporation into anion exchange membranes. Finally, the role of carbonate (or bicarbonate) versus hydroxide anion in these systems will be elucidated. The team we have assembled is eminently and uniquely qualified to successfully achieve these goals. The results of the work proposed here will provide a greater understanding of the fundamental aspects of hydroxide conductors for fuel cells and electrolysis applications, and the development of hydroxide-stable cations may lead the way for the next generation of fuel cells and electrolyzers.
trimethylammonium (BMTA) cation. The best of these, an ether-linked ammonium showed more than a 3x improvement in stability, a meaningful increase when considering applications.

Significant advances in this project have come from studies of cation stability and center on the role of water and solvation in cation stability. In hindsight, the fact that water availability (eg., # of waters per hydroxide) would play a role in cation stability seems fairly obvious, yet this phenomenon had been only minimally reported in the literature and not in the context of membranes (although many vendors of these materials ship them hydrated with instructions to keep wet). Our results demonstrate that the impact of solvation is greater than what many would have expected, and show that under many conditions hydration is far more important than temperature for degradation. The importance of ylide formation (which may also be related to water content and solvation) as a degradation pathway has been highlighted by our chemical and computational studies.

Our studies have involved both experimental and computational studies of cation degradation. In our computational work, all reaction energies and free energies of energy barriers for transition states were estimated by Gaussian 03 software, with B3LYP/6-311++G(2d,p) level of theory and the polarizable continuum model (PCM) to account for the solvent. We have also made qualitative and quantitative findings from ab-initio MD simulations performed with VASP software and the rPBE functional. These studies have shown that by treating the water molecules in the hydroxide solvation shell explicitly and the bulk water molecules implicitly, the calculated reaction barrier free energies are in much better agreement with experimental values. We have recently demonstrated the utility of a QM-molecular mechanics (MM) hybrid algorithm and umbrella sampling technique for faster calculation of reaction energy barriers, and shown that in carbonate or bicarbonate form, reaction barriers for decomposition are significantly (>10kcal/mol) higher than in hydroxide form.

Our thermal analyses of crystalline TMAOH pentahydrate used EGA (evolved gas analysis) to probe degradation chemistry. The results from these studies have allowed us to benchmark mechanistic details and correlate the results with our computational studies. The identity and quantities of the gases that were evolved upon decomposition of TMAOH pentahydrate were analyzed by a combination of thermogravimetry (TG), FT-IR spectroscopy and mass spectrometry (TG-FTIR and/or TG-MS). We have focused primarily on ammonium based cations: BMTA, tetramethyl ammonium, ethyltrimethyl ammonium and phenyltrimethyl ammonium have received the most attention. Mechanistic studies using partially deuterated or judiciously substituted alkyl ammonium cations has allowed us to study the interplay of the various decomposition mechanisms; Hoffman degradation, nucleophilic attack and ylide formation. Furthermore, an ether linked ammonium, and two other literature referenced nitrogen-centered cations have shown increased stability compared to BMTA.

**Future Directions**

Our primary focus remains on fundamental investigations into the mechanisms and reaction barriers associated with cation degradation. This involves both quantifying and understanding the rates of current materials, and the pursuit of advanced cations with improved durability. Additional studies will include investigation into conductivity (basicity) and the role of carbonate. We have already begun modeling studies of carbonate and bicarbonate solutions of the cations under investigation and will use these alternate salt-forms to better probe stability and durability experimentally. Now that we have verified our ability to quantitatively assess cation stability under well hydrated conditions, we can and will include many other cations, including phosphonium, and expand our studies of phosphazenum and sulfonium which had been limited due to the surprisingly high stability we had observed with ammonium based cations. The calculations on reaction energies and free energies of reaction barriers for these cations are already under the way based on our established computational models. Preliminary result shows that the degradation of trimethyl amino sulfonium by hydroxide has a more negative reaction energy than ammonium cations such as TMA or BMTA (-48 kcal/mol vs. -25~29 kcal/mol). We have already received other advanced cations that have been shown to have good performance and durability in fuel cell applications in a collaborative agreement from Yushan Yan’s group.

Our experimental studies will incorporate fixed humidity into our thermal gravimetric analysis (TGA) studies. To date we have focused either on liquid based cation degradation (primarily in NMR tubes at elevated temperatures) or decomposition under drying conditions where degradation of cations is greatly impacted by the loss of water (typical TGA). As water content is critical in the degradation of cations, by including controlled humidity in our studies we will be more able to probe the sensitivity of durability on water content and better isolate degradation products.

Our synthesis of novel cations will focus on triaminosulfonium, triaminosulfoxonium and phosphazenum derivatives because these materials have demonstrated the potential to be much more stable to attack by hydroxide ion than the more conventional trialkyl ammonium ions. We will also expect to expand our studies to include oligomers and polymers such that we can study the stability of the cation tether, the role of polymer architecture on properties and durability.
and the role of carbonate/bicarbonate on the stability and conductivity of these systems. Advanced NMR techniques, including magic-angle spinning (MAS), $^1$H-$^{13}$C cross polarization, nuclear spin-relaxation time, and two-dimensional NMR techniques will be utilized to obtain information about the ionic structure, mobility of the charge carriers (conductivity), and polymer – cation interactions.

Objectives

Our research aims to achieve a fundamental understanding of the transport behavior in planar microfluidic membraneless fuel cells and to take advantage of their unique properties, including the lack of a physical membrane and the ability to utilize different pH solutions in fuel and oxidant streams to optimize power output and efficiency. We have identified the borohydride/cerium ammonium nitrate fuel/oxidant combination as one capable of delivering over 0.25W/cm². This was only enabled by detailed fundamental studies of the redox reactions of sodium borohydride as fuel and numerous potential oxidants.

Technical Barriers

While membraneless fuel cells have numerous attractive features, their performance has been limited by a low utilization efficiency of fuel and oxidant as well as relatively low energy density. In our investigations we have been able overcome these limitations through the use of “structured” electrodes (herringbone micromixers) and the identification of high-energy (and high solubility) fuel and oxidant couples. While the scale-up of these devices to deliver 2-10 watts remains a challenge, we have begun studies that we feel will overcome this limitation.

Abstract

Unconventional fuel cell technologies are combined to create a system that not only avoids most typical fuel cell drawbacks, but also achieves the highest power density yet recorded for a non-H₂ fuel cell. Rigorous electrochemistry is used to characterize the high-energy-density fuel BH₄⁻, providing important mechanistic insight for anode catalyst choice and avoiding deleterious side reactions. All major fuel cell oxidants used in place of O₂ are compared in a detailed, uniform manner, and a powerful new oxidant, cerium ammonium nitrate (CAN), is described. The high-voltage BH₄⁻/CAN fuel/oxidant combination is employed in a membraneless, room temperature, laminar-flow fuel cell, with herringbone micromixers which provide chaotic-convective flow which, in turn, enhances both the power output and efficiency of the device.

Progress Report

Previous research centered around a membraneless, laminar-flow fuel cell described earlier, with the goal of creating a high power density device for portable power applications. A transport-enhancing, chaotic-convective flow design was employed to boost power and efficiency. The fuel cell system was studied from both analytical and practical standpoints, with electroanalytical studies of fuel and oxidant accompanying performance testing in this microfluidic fuel cell device.

As a potential fuel, BH₄⁻ has been the subject of intense investigation, as its energy density is superior to that of MeOH, yet its kinetics are much faster, its onset potential is much lower, and it does not poison the anode or any known cathode material. However, BH₄⁻ does suffer from a deleterious, acid-catalyzed conversion to H₂ in aqueous media. This decreases its effective concentration in solution, in turn decreasing its power output.

Our rigorous study of BH₄⁻ oxidation at Pt and Au revealed a number of misconceptions in the literature about BH₄⁻’s reaction mechanism. We found that, unexpectedly and most surprisingly, BH₄⁻ has more problems with hydrolysis to H₂ at Au than at Pt surfaces, and that low-potential current at Pt stems from direct BH₄⁻ oxidation, rather than H₂ produced via BH₄⁻ hydrolysis (Figure 1). Though Au is the literature preferred BH₄⁻ anode, we found that Pt is the superior catalyst, capable of delivering just as much current as Au, but at potentials nearly 0.5V lower. This difference translates to a 0.5V gain in operating voltage for direct BH₄⁻ fuel cells that use Pt rather than Au anodes.
Our fuel cell studies with our new oxidant cerium ammonium nitrate (CAN), showed that BH$_4^-$ was actually the limiting reagent, largely due to its limited stable solubility. BH$_4^-$’s hydrolysis to H$_2$ is first order with respect to BH$_4^-$ and must be stabilized with highly concentrated base, and above 3M NaOH, various fuel cell components were degraded. Since 3M NaOH can hold only 0.15M BH$_4^-$, we studied BH$_4^-$ oxidation in nonaqueous solvents to improve its maximum stable solubility and, therefore, its maximum current/power.

We found that BH$_4^-$ had a solubility higher than 0.4M in DMSO, DMF, diglyme, and EtOH, and higher than 0.3M in MeOH. As literature suggested, BH$_4^-$ will undergo a conversion to H$_2$ in MeOH and, to a lesser extent, in EtOH, similar to its hydrolysis to H$_2$ in water, and it did not appear to be stable in diglyme, either. Thus, DMSO, DMF, and EtOH appeared to be the most promising solvents, but BH$_4^-$ was found to have a disappointing onset potential of around -0.1V vs. NHE in these solvents, which is 0.7V more positive than its onset in alkaline solution. We continue studying these solvent systems to determine if 0.4M BH$_4^-$ in organic solvents has superior performance as compared to 0.15M BH$_4^-$ in 3M NaOH, and whether specific additives can enhance BH$_4^-$ oxidation.

Laminar-flow fuel cells provide the tremendous advantage of fuel cell operation without a membrane, but usually require that the oxidant be dissolved in solution, so as to have fluid fuel and oxidant streams with which to establish laminar flow. Since O$_2$’s solubility in water and other solvents is minimal, highly soluble oxidants with high onset potential and fast kinetics are needed to generate high power density. All fuel cell oxidants with literature precedent were characterized in detail, in a uniform manner, at the common catalysts Pt, Au, and GC, and all oxidants were compared using their best respective catalysts (Tables 1 and 2).

Almost every oxidant was found to have a critical weakness. H$_2$O$_2$ established high current density but catalytically decomposed to form laminae-disrupting O$_2$ bubbles. MnO$_4^-$ produced tremendous voltage and current, but quickly precipitated at its electrodes. VO$_2^+$, used in “vanadium redox battery” fuel cells, has fundamentally low current. ClO$^-$ poisons Pt, Au, and even GC. Only our new oxidant, CAN, performed in a trouble-free manner, exhibiting the highest onset potential of +1.6V vs. NHE, with reasonable current. It was the only practical alternative oxidant found, although its low solubility limits its max current, and higher-power fuel cells will need a better oxidant.

$^*$Determined from RDE of VO$_2^+$ at Pt and Au assuming n = 1. See Results and Discussion for details. $^*$Calculated from the density of pure H$_2$O$_2$ liquid. (O$_2$) was studied at its maximum aqueous solubility of ~1.27 mM rather than 5M.
Both BH$_4^-$ and CAN were employed in a membraneless, room-temperature, laminar-flow fuel cell. Electrodes with microfabricated, staggered-herringbone micromixers were employed to separately convect the fuel and oxidant streams, disrupting laminae enough to bring unreacted fuel and oxidant to the anode and cathode, respectively, without allowing the fuel and oxidant streams to mix. We were able to achieve current densities of 0.4 A/cm$^2$ (Figure 2) and power densities of 0.27 W/cm$^2$ (Figure 3).

Comparison with literature values are difficult, as other groups use high-surface area electrodes but normalize to geometric area. By normalizing outputs to catalyst loading, our system achieved the highest power density yet recorded for a non-H$_2$ fuel cell. Whereas MeOH and BH$_4^-$ fuel cells use 1.5-3M fuel at 60°C and provide up to 30 and 220 mW/mg catalyst, our system used 0.15M fuel at room temperature and produced 1,230 mW/mg Pt.

Future Directions

We are continuing to use innovative experimentation to develop fundamentally new fuel cell chemistries and transport. New oxidants are being analyzed to find a replacement for CAN with higher maximum current density. We are testing BH$_4^-$ at less expensive catalysts and in new solvent systems to improve its current output as well. A fuel cell 60 times larger than described above has been built and is undergoing testing to demonstrate that laminar flow fuel cells are scalable. New fuel cell fluid flows and geometries are being investigated to improve the overall device efficiency.

Publications (including patents) acknowledging the grant or contract

Objectives

The proposed project aims to explore enhancements in the electronic and ionic transport properties of nano-scale oxides and surfaces, and to utilize these materials to enhance the performance of reduced-temperature solid oxide electrochemical cells (i.e., fuel cells and electrolyzers). The project is focuses on electrode materials, and the use of nano-scale materials to enhance properties and surface areas to increase electrochemical reaction rates. Also, we are exploring the enhancement of electronic and oxide-ion transport properties, which help limit the reduced-temperature performance. Stability of nano-scale materials is also being explored.

Technical Barriers

Decreasing the operating temperature of solid oxide electrochemical cells is desirable from a number of perspectives including easing seals/interconnect materials issues, reducing balance of plant costs, and enabling applications in portable devices and transportation. However, reduced temperature significantly degrades performance, due to increased electrode polarization resistance and reduced electronic and ionic conductivities. The long-term stability of nano-scale materials needs to be investigated.

Abstract, Progress Report and Future Directions

The goal of this project is to utilize nano-structures, and any enhancements in electronic and ionic transport properties resulting from the nano-scale features sizes and/or high surface density, to address the electrode polarization and conductivity issues currently limiting low-temperature solid oxide fuel cell (SOFC) performance. In this update we highlight recent research results including nano-scale catalysts and effect of grain size on ionic conductivity.

Infiltrated Cathode Materials

On the cathode side, we have studied the effect of solution additives and processing techniques on the phase purity and performance of nano-composite cathodes produced via infiltration. In addition to achieving record low cathode performance from a single infiltration, simple models have been developed to predict the electrode polarization resistance.

Sm_{0.5}Sr_{0.5}CoO_{3-δ} (SSC) nano-particles with hemispherical radii of ~ 20 nm have been produced by nitrate infiltration Ce_{0.9}Gd_{0.1}O_{1.95} (GDC) scaffolds. Polarization resistance, \( R_p \), predictions were made using the modified Tanner, Fung, Virkar model. The measured polarization resistances for SSC-GDC agreed well with the modified form of Tanner, Fung, Virkar model, as did those of La_{0.6}Sr_{0.4}Co_{0.2}Fe_{0.8}O_{3-δ} (LSCF)-infiltrated GDC cathodes. An exceedingly low polarization resistance of 0.1 \( \Omega \) cm\(^2\) at 600°C was achieved with a single infiltration. We expect that with multiple infiltrations, polarization resistances of this magnitude will be achievable at 500°C.

The coarsening behavior of infiltrated LSCF electrodes, and the associated changes in polarization resistance, have been studied. In order to accelerate changes to manageable time frames (normal cell life times are expected to be > 40,000 h), cathodes were maintained at temperatures higher than expected for operation (700-850°C). Field-emission scanning electron microscope (SEM) and polarization resistance measurements were used to detect changes. With time, LSCF nano-particles were observed to agglomerate together, coating less of the CGO scaffold and growing larger in size. Correspondingly, the polarization resistance increased substantially. The results are being fit to both standard coarsening power-law models and being used to constrain/validate phase-field modeling. The aim is to develop sufficiently detailed mechanistic models to allow accurate prediction of lifetimes at normal operating temperatures (500-700°C) for extended times.

Novel Anode Materials

The mixed conducting oxide, LaSr_{2}Fe_{2}CrO_{9-δ} (LSFCr) is a promising new anode. Ni cermets are the most commonly used SOFC anodes because of their excellent electrochemical performance in hydrogen fuel, but Ni is susceptible to sulfur poisoning and carbon
coking, which are detrimental to anode performance. Oxide anodes have potential for lower operating temperatures, while also being stable to higher impurity concentrations and active to different fuel compositions.

LSGM electrolyte supported fuel cells with LaSr$_2$Fe$_2$CrO$_9$ and LaSr$_2$Fe$_2$CrO$_9$/GDC composite anodes have been fabricated and tested. The LaSr$_2$Fe$_2$CrO$_9$ anode cells typically yielded peak power densities of 400-455 mW/cm$^2$ at 800°C with corresponding electrode polarization resistances of 0.27-0.40 Wcm$^{-2}$. The LaSr$_2$Fe$_2$CrO$_9$/GDC (50:50 wt%) anode cells yielded similar performance as the pure LaSr$_2$Fe$_2$CrO$_9$ compounds with peak power densities 400-480 mW/cm$^2$ and polarization resistances of 0.25 - 0.40 Ωcm$^{-2}$. The similar performance of the anodes with and without GDC suggests that the LaSr$_2$Fe$_2$CrO$_9$ anodes are not limited by their oxygen ion conductivity. Currently, oxygen relaxation experiments are underway to determine the surface exchange rate and oxygen diffusivity of LaSr$_2$Fe$_2$CrO$_9$ under anodic conditions.

This group has also developed a novel class of anodes where nano-scale metal catalyst particles nucleate during cell operation. To investigate the precipitation of Ru nano-particles from (La,Sr)(Cr,Ru) O$_3$ (LSCRu), fuel cells with LSCRu/GDC anodes were operated in an environment of humidified H$_2$ condition at 800°C for 120 hr. Focused ion beam (FIB) cross-sectional TEM revealed that the density of the Ru particles was non-uniform across the thickness of the anode and the particles were only found at the LSCRu surface facing the electrolyte. It was observed that the average size and the area density of the formed Ru nano-particles was 2.9 nm and 5.1 x 10$^4$ particles/μm$^2$, respectively. It was also confirmed that the Ru nano-particles are crystalline, which is in good agreement with the results obtained from reduced LSCRu powders. These results confirm that the performance increases seen in LSCRu/GDC anodes are, in fact, due to Ru nano-particle exsolution.

We have developed models to describe Ru exsolution from LSCRu using phase field methods. The model indicates that as time evolves, the concentration of the Ru atoms in the LSCRu decreases and the Ru nano-particles increase in size and form hemispherical shapes on the LSCRu surface. While most of the growth is taking place through the bulk, the majority of the coarsening takes place via surface diffusion.

Transport In Nano-Scale Materials

Work in the Mason group has focused on continued application of the novel “nano-Grain Composite Model” (n-GCM) to characterize the local properties of fuel cell electrolytes as a function of grain size. As the n-GCM requires independently measured grain core dielectric constants as an input parameter, one side project in the Mason group has been to characterize grain core (or single crystal dielectric constant) behavior over the temperature range of interest.

Using these grain core dielectric constant data, the n-GCM model was then applied to determine local properties of the four electrolyte systems: yttria stabilized zirconia (YSZ), tetragonal zirconia polycrystal (TZP), strontium- and magnesium-doped lanthanum gallate (LSGM), and gadolinia doped ceria (GDC). It was found that in each case, whereas grain core conductivities are not significantly different from that of the microcrystalline counterpart, the local grain boundary conductivities are significantly enhanced at the nano-scale, compared to conventional microcrystalline electrolytes. Despite the consistent increase in local grain boundary conductivity in the nano-grained samples, the total conductivity was seen to decrease monotonically with decreasing grain size in all four systems. This effect is due to the fact that grain boundaries remain barriers to transport (compared to grain cores) at the nano-scale, and there are many more grain boundaries in nano-crystalline samples.

The n-GCM also allows determination of electrical grain boundary widths, calculated from the volume fraction of grain cores. These values have been in excellent agreement with reported acceptor dopant segregation widths at grain boundaries. Furthermore, in collaboration with the Marks group we have shown that electrical grain boundary widths in our nano-YSZ samples agree with yttrium segregation widths measured on those same samples.

The Lattice Monte Carlo methodology has been used to study microstructure and thermodynamic properties of yttria stabilized zirconia, YSZ. Here a topological lattice representing the underlying crystal structure was described by a set of occupation numbers on two distinct sets of sites, defining (Y, Zr) and (O, vacancy) populations which were randomly sampled. A Cluster Expansion (CE) of energy at T=0 was developed as a polynomial in the occupation numbers, with coefficients determined variationally by fitting to a set of ‘training configurations’ whose energy was determined from fully self-consistent geometrically relaxed Density Functional (DF) calculations on supercells. Finite temperature free energy was developed by inclusion of vibrational entropy, in the harmonic approximation, using ensemble averages based upon the cluster expansions. The constant volume specific heat was developed directly as variation of internal energy with T, yielding results in good agreement with experiment. Two-body radial distribution functions were developed, again as ensemble averages at specified T, to display and help understand correlations between Zr-vacancy, vacancy-vacancy, Y-Y, etc site occupancy. The principal observations were that: (1) the oxygen coordination sphere around Zr is less populated than...
that of Y, (2) vacancies tend to associate as 2nd neighbors with Y dopants, just as observed previously for vacancy-Zr association, (3) Y atoms tend to cluster together, and (4) vacancies repulse each other, as expected in terms of Coulomb interactions; however, a noticeable tendency toward vacancy ordering on the 3rd neighbor shells is predicted. Similar analyses for LSM, LSCrRu and LSCF are ongoing.

Objectives

The overall goal of this project is to elucidate the role of metal ions anchored on oxide supports, and the role of oxide structures in stabilizing the metal ions in their active state for catalyzing reactions of interest to fuel reforming for hydrogen generation. The concentration and types of oxygen defects are strong functions of the size, shape, and composition of the oxide nanoparticles. Novel chemical synthesis techniques are employed to control the size and shape of oxide nanoparticles used to evaluate the structure sensitivity of the reactions of interest; and to design catalysts with optimal metal distribution on the oxide supports.

Technical Barriers

Novel catalysts for the efficient conversion of fuels to hydrogen that possess the required high stability for practical fuel cell application are needed. These catalysts should also be highly active and contain minimum amounts of costly platinum metals to allow rapid development of hydrogen generation and purification schemes for use with low-temperature fuel cells. The current DOE project investigates trace amounts of sub-nm clusters and ions of gold or platinum in nanostructured oxides (ceria, iron oxide, zinc oxide) as potential new catalysts meeting these requirements. Our findings to date point to the importance of the particle size, shape, and oxygen defect density of the host oxide for proper distribution of the active metal sites to effectively catalyze the low-temperature water-gas shift and methanol steam reforming reactions. Abstract

The project follows a comprehensive and complementary approach to elucidate the metal-oxide interaction at the atomic scale for the reactions of interest to fuel processing for hydrogen generation. Accordingly, different activities in the synthesis, characterization, and testing of the catalysts are underway at Tufts and at Columbia. Various oxides, namely; ceria, iron oxide, zirconia, and zinc oxide, are prepared, typically by hydrothermal techniques, as single crystals with nm-dimensions which have moderately-high surface areas and can thus be used as practical metal supports. Such nanocrystals serve as platforms to study how different surfaces can disperse the deposited metals, e.g. Au or Pt, and to identify potential shape effects for the reactions under investigation. The results can be compared to extended single crystal surfaces investigated under vacuum in a systematic way, bridging the pressure and materials gap between surface science and catalysis.

During the past year, several parallel efforts have continued at both schools, and these will be detailed in the annual report. Briefly, we have completed a detailed structural study of Cu-doped ceria for the WGS reaction. We have also completed a comparative study of Pt-metals and Au in ceria nanoshapes for the methanol decomposition reaction, and found that Au on ceria follows the methylformate pathway without any CO production up to 250 °C, while the Pt metals on ceria easily decompose methoxy to CO and H₂. The latter are thus not suitable candidates for methanol steam reforming because their selectivity to H₂ would be limited by the WGS reaction equilibrium. The Flynn group at Columbia has continued the STM/STS study of the structural effects of Au adatoms on Fe₂O₃(111) surfaces and the adsorption of CO and H₂O. As already reported, the CO adsorbs linearly atop the Au adatoms, the latter bound tightly over the uncapped surface oxygens of the Fe-terminated surface. Present data from the H₂O adsorption at 260K indicate that water molecules preferentially adsorb on the Fe atoms neighboring the Au adatoms. To complement this study, nanoshapes of Fe₂O₃ were made and Au was deposited on them by various techniques to examine the Au/Fe₂O₃ interaction and reactivity as a function of the magnetite shape. This work is in progress.

We have also conducted an extensive study of Au on CeO₂ nanoshapes as catalysts for the SRM reaction, and more recently prepared Au/ZnO nanoshapes, and compared this catalyst to Au/ceria. On both oxides, sub-nm gold clusters and atoms are present
on the active catalyst, while gold nanoparticles are inactive. An important mechanistic finding is that the SRM reaction proceeds through the methyl formate route on fully dispersed gold on ceria or zinc oxide. Interestingly, the WGS pathway is not involved in the SRM reaction on Au/CeO$_2$ or Au/ZnO. Methanol dehydrogenation, methyl formate hydrolysis and formic acid decomposition are the steps producing CO$_2$ and H$_2$. While both reactions are catalyzed by Au/ceria at the same low temperatures, we have found that methanol is the preferred adsorbate on gold. Since the water-gas shift reaction is not part of the SRM pathway below 250°C, the selectivity to H$_2$ exceeds the equilibrium value based on the former reaction. The practical implications of these findings are obvious.

Report Highlights

During the past year we have focused on the investigation of potential shape effects of ceria and zinc oxide on the water-gas shift (WGS) and steam reforming of methanol (SRM) at low temperatures. We have found that a small amount (<1wt.%) of gold fully dispersed on ceria single crystals prepared as nanorods (10±2.8 by 50-200 nm) of (110) and (100) crystal surfaces) shows excellent catalytic activity in both the SRM and the WGS reactions at temperatures < 250°C. The ceria nanorods bind and stabilize gold as atoms and clusters (< 1nm, TEM invisible). On the other hand, gold nanoparticles (~ 3nm) deposited on the (100) surfaces of ceria nanocubes (30±11 nm) are inactive for either reaction up to 250°C. On ZnO nanoshapes, we find that gold can be dispersed fully on short nanorods and nanopolyhedra comprised of the polar (0001) surfaces. These are highly SRM- active and selective to H$_2$. Figure 1 compares CH$_3$OH-TPSR results over these two types of catalysts, and a commercial Cu-ZnO catalyst, UCI (G-66B). The maximum hydrogen yield was obtained on the Au-CeO$_2$ nanorods.

Methylformate (not shown) is produced from the coupling of methanol on the gold catalysts. With surface water, this is hydrolyzed to formic acid, which decomposes to produce CO$_2$ and H$_2$. Fig.2 shows SRM-TPSR on the Au/CeO$_2$ nanorods. There is a wide temperature window over which only these two products are measured by mass spectrometry. The production of CO begins above 250 °C. Thus, Au/CeO$_2$ is an excellent prospect for the low-temperature SRM reaction, coupled with PEM fuel cell operation. The water-gas shift reaction is not part of the pathway.$^{2,3}$ This is interesting because this same catalyst is very active for WGS even at 150 °C.$^5$ We have further investigated the catalyst selectivity in steady-state isothermal tests and found that the WGS reaction is suppressed by methanol; i.e. methanol, not CO, is the preferred adsorbate on gold. The results from 1% Au/ZnO nanopolyhedra were similar. Since the water-gas shift reaction is not part of the SRM pathway below 250 °C, the selectivity to H$_2$ exceeds the equilibrium value based on the former reaction. The practical implications of these findings are obvious.

Overall, we have found that the shape effect of the oxide nanocrystals is indirect, i.e. the catalytic activity depends on the number of fully dispersed gold species on ceria or zinc oxide. The shape effect simply means that the (110) surfaces of ceria and the (0001)surfaces of zinc oxide achieve better dispersion of gold than other surfaces. Indeed, in kinetic measurements, we found the same activation energy for Au on any ceria shape. The rates, properly scaled with the amount of dispersed gold are the same, i.e. the TOFs are the same. In conclusion, the Au/Ceria catalyst shows good activity and stability for both the WGS and SRM reactions. Because of its

![FIGURE 1. Methanol-TPSR](image1)

![FIGURE 2. (CH3OH + H2O)--TPSR](image2)
high CO₂ selectivity in SRM below 250°C, this catalyst merits further evaluation for practical applications to future fuel processing and fuel cell systems.

**Future Directions**

All the activities highlighted above are continuing in the near future. A new task in the project, already underway, is the synthesis, characterization and evaluation of surface alloys on nanoscale oxides for the reactions of methanol under study. Of particular interest is the PdAu system, which is being evaluated on ZnO. We will continue to focus a major part of our effort on detailed examinations of the shape effect of the oxide host and propose general catalyst design guidelines as appropriate. The desired outcome is a good mechanistic understanding of the chemistries under investigation, and the evolution of the key catalyst structures.

Objectives

Primary objectives are to prepare and elucidate the promoting properties of materials that possess high activity for the conversion of H₂ and related small molecules (H₂O, O₂, CO and CH₃OH) in polymer electrolyte fuel cells. One area of research focuses on the study of catalyst materials. Protocols are being developed for probing the structure and benchmarking the activity of Pt and Pt bimetallic nanometer-scale catalyst against Pt single crystal electrode standards. A second area targets fuel cell membrane and the advancement of simple methods based on infrared spectroscopy that can be applied broadly in the study of membrane structure and transport properties.

Technical Barriers

Research aims to identify and overcome factors that limit the stability and performance of polymer electrolyte fuel cell catalyst and membrane materials. Methods are being developed to assess effects of catalyst composition and structure on the rate of electrocatalytic reactions. Techniques are under investigation to assist the design of robust, proton conductive membranes, which resist reactant crossover.

Abstract, Progress Report and Future Directions

A. Fuel Cell Membrane and Catalyst-Membrane Architectures Probed by Vibrational Spectroscopy:

Infrared and Raman spectroscopy were investigated as probes of structures within proton conductive materials that limit or enhance performance in polymer electrolyte fuel cells. The following were primary accomplishments: (a) least squares modeling in conjunction with infrared spectroscopy was demonstrated as a useful approach to detect differences in the response of hydrophilic and more hydrophobic functional groups in ionomer materials undergoing changes in hydration state [1]; (b) strategies developed during the project through studies of model Nafion membranes [2,4] were adapted to investigate new bis(perfluoroalkylsulfonyl) imide [5] and fluoroalkyl phosphonate [6] ionomer materials; (c) the capabilities of Raman spectroscopy were explored for its potential to enable depth profiling of practical fuel cell membrane and in situ studies of fuel cell catalyst-membrane architectures.

In initial work, transmission infrared measurements were performed on thin (~1 µm) Nafion® films [1,3] and freestanding (~50 µm) Nafion® 112 fuel cell membrane [2,4]. Effects of hydration on polymer functional groups [1] and water molecules inside membrane pores and channels [2] were examined. Figure 1 shows a series of infrared spectra recorded during the hydration of a thin Nafion® membrane. The region that encompasses the fundamental ionomer vibrations is displayed. The arrows indicate the shifts in band position and intensity that accompany water uptake. The spectra were examined by applying a least squares approach [7,8]. A diffusion equation that describes molecular transport within a cylindrical pore [9-11] was used to predict the time dependent uptake of water into the membrane [1,3]. The analysis revealed bands for vibrational modes for the more hydrophobic polymer functional

![Figure 1: Infrared spectra of a Nafion® film cast onto a ZnSe optical window recorded during hydration in 100% relative humidity air starting from a dry state. Spectra were recorded at times of 0 min, 0.75 min, 1.5 min, 2.25 min, 6.75 min and 28 min after exposure to humid air. The arrows indicate the direction of band intensity change with increasing hydration time. The inset shows the Nafion® polymer structure. See Ref. 1 for details.](image-url)
groups (-CF₂ and -C-O-C-) changed as predicted by the diffusion equation, whereas the response of the prominent band for the asymmetric S-O stretching mode of the hydrophilic -SO₃⁻ group (near 1064 cm⁻¹ (Fig. 1)) was more complicated. The deviations exhibited by the -SO₃⁻ group vibrations were similar to those that we found for the O-H stretching modes of water inside membrane pores and channels [3]. The different responses observed for the hydrophilic and more hydrophobic ionomer functional groups were ascribed to the more complicated water structures that form in the vicinity of -SO₃⁻ groups, due to neighboring solvated cations. Full details of the study are presented in Ref 1.

Subsequent efforts focused on extending strategies developed for the study of Nafion® membrane to new bis(perfluoroalkylsulfonyl) imide [5] and perfluoroalkyl phosphate [6] ionomer materials. Studies showed the vibrations of the side chain ether groups are sensitive to the nature of the charged end group. In hydrated Nafion®, the symmetric -C-O-C- stretching mode of the ether closest to the -SO₃⁻ group appears as a low energy shoulder on the band for the ether closest to the ionomer backbone at 983 cm⁻¹ (Fig. 1) [12]. The splitting of -C-O-C- modes has been attributed to the different environments experienced by the two side chain groups in hydrated Nafion® [12]. We observed that substitution of the -SO₃⁻ group by a bis(sulfonyl) imide (-SO₂NSO₂CF₃) moiety lifts the apparent splitting of ether group modes leaving only the 983 cm⁻¹ band [5]. Similar effects are being detected with different types of phosphonate end group substitutions [6]. In accord with earlier studies [12], the spectral perturbations are being examined with consideration of the possible differences in the solvent environment in the vicinity of the charged end group.

The project also investigated Raman spectroscopy for applications in the study of ionomer materials. Raman spectra that were recorded from Nafion® materials are displayed in Fig. 2. Ongoing experiments are exploring effects of the Raman excitation wavelength on the spectral signals. The long-term benefits of Raman spectroscopy are its potential to enable depth profiling within fuel cell membrane via confocal measurements and in situ studies of fuel cell membrane-electrode assemblies.

B. Catalyst particle properties and electrochemical activity: A second effort investigated Pt and Pt bimetallic fuel cell catalyst [13-15]. Emphasis was on the use of Pt single crystal electrodes as standards to benchmark catalyst activity [14, 15]. Pt single crystal electrodes were grown in the PI’s laboratory, and building on the group’s earlier investigations of vibrational coupling in CO adlayers on Pt(s)-[4(111) x (100)] and related surfaces [16-18], initial experiments focused on kinetic measurements of CO oxidation. Quantitative electrochemical techniques for determining CO coverage on Pt were applied. Following studies that employed low index Pt surface planes [14], techniques were extended to the stepped Pt(s)-[4(111) x (100)] surface [15]. The saturation coverage for CO on a Pt(s)-[4(111) x (100)] electrode was determined for the first time and found to be consistent with expectations based on ultra high vacuum surface science experiments on the system [19-21]. Our study also included the first kinetic measurements of sub-saturation coverage CO monolayer oxidation. Current-time transients recorded in potential step experiments could be fit by numerically solving the rate equations [22] to the Langmuir-Hinshelwood model of adsorbed CO electrochemical oxidation. Fig. 3 shows the changes that occur in experimental current-time transients as initial CO monolayer coverage is lowered. The comparison to the current-time transients determined by solving the reaction rate equations for CO monolayer electrochemical oxidation is detailed in Ref 15. The experiments laid groundwork for our subsequent benchmarking in kinetic studies of electrochemical reactions for small molecules (O₂, CO, CH₃OH) over practical catalyst materials.

Objectives

Through a combination of theoretical and experimental methods, we want to identify, synthesize, and test surface-modified materials having desirable properties for hydrogen catalysis and storage. In particular, we are designing and studying new materials with: (i) high catalytic activity and CO resistance for hydrogen fuel-cell anode reactions, (ii) resistance to carbon poisoning for CH₄ reforming, (iii) the ability to catalyze the dissociation and diffusion of hydrogen into the bulk for hydrogen purification and light metal-hydride storage, and (iv) high catalytic activity for hydrogenation/dehydrogenation of unsaturated/saturated hydrocarbons for chemical storage of hydrogen.

Technical Barriers

Succeeding in our scientific objectives should help overcome the following “H₂ economy”-related technical barriers: (i) developing cheaper and more poison-resistant anode catalysts for low temperature fuel cells, (ii) improved efficiency of H₂ production from natural gas, (iii) improved hydrogen purification and storage materials, and (iv) efficient chemical storage of H₂ on chemical bonds found within appropriate “H₂-carrier” molecules.

Abstract

The development of more efficient chemical processes through improved catalyst design has been an important goal for well over a century. Recent developments of new tools in surface science and theory can aid in achieving this goal. One such tool, Density Functional Theory (DFT), can both elucidate reaction mechanisms as well as test novel catalyst architectures for specific reactions. Using these methods, we recently identified a new class of bimetallic alloys that exhibit superior catalytic activity for hydrogen-related reactions [J. Greeley and M. Mavrikakis, Nature Materials 3, (2004) 810]. This class of alloys, namely Near-Surface Alloys (NSAs), is comprised of alloys wherein a solute metal is present near the surface of a host metal in concentrations differing from the bulk. The architecture of these alloys gives them remarkable properties, different from the properties of their constituent metals as well as bulk alloys of the same components. As the catalytic properties of NSAs are directly connected to the precise atomic layer-by-layer structure of their near surface region, we have also needed to develop and implement accurate nanosynthesis techniques for the preparation of the theoretically predicted optimal nanostructures. Our work has been focused in three main areas: (i) the elucidation of fundamental principles of industrially relevant reactions using state-of-the-art DFT, (ii) the application of these principles to discovering novel alloys (specifically, NSAs) with superior catalytic properties and (iii) the synthesis and characterization of these alloys for H-related reactions using innovative chemical and electrochemical techniques.

Over the last few years, we have made progress on these three fronts for a variety of important reactions, as follows:

A. We have theoretically identified and experimentally synthesized and tested for their reactivity Ru-core/Pt-shell (Ru@Pt) nanoparticles that are highly active for the preferential oxidation (PROX) of CO in the presence of H₂ at room temperature. Using DFT, we elucidated the fundamental principles behind this high activity, invoking a novel H-assisted O₂ dissociation mechanism to explain this unusually high reactivity at low temperatures. Other core-shell nanoparticles are currently in the synthetic-protocol design and characterization phase.

B. Using a combination of DFT, microkinetic modeling, and reactivity experiments, we have investigated the kinetics of the water-gas-shift (WGS) reaction on Cu and Pt catalysts; we
proposed a novel mechanism including the formation of a carboxyl (COOH*) intermediate. Additionally, we have begun investigating the promotional effect of iron oxide (FeO) for the Pt-group catalyzed WGS reaction. We also investigated CO₂ chemistry for Cu-Pt NSA systems, relevant for the WGS and methanol synthesis reactions.

C. We predicted the presence of subsurface H in an Au-Ir NSA system. Using electrochemical methods, we have synthesized Au*/Ir (Au overlaid on Ir) NSA catalysts and tested their adsorption of hydrogen, validating such predictions and opening the door to new catalysts with stable subsurface hydrogen.

D. We have begun to extend DFT calculations to electrochemical reactions and study core-shell based catalysts for these important reactions. We have focused on several reactions relevant to fuel cells, including: oxygen reduction (ORR) for fuel cell cathodes; methanol electroxidation for direct methanol fuel cell anodes; and hydrogen electroxidation for H₂-PEM fuel cell anodes. In ORR, we use a new electrochemical model to understand the high activity of Pt overlayers over Pd and other surfaces for this reaction. We also use this model in methanol electroxidation to parameterize the onset potential, allowing us to screen for better electrocatalysts.

Progress Report and Future Directions

Space limitations won’t allow us to expand on any of the topics outlined in the abstract, but (A) and (C):

(A) Core-Shell Nanoparticles for preferential oxidation reactions

Our DFT work identified Ru-core/Pt-shell nanoparticles (Ru@Pt—see Figure 1, left panel) as a promising PROX catalyst. Our experiments showed that these catalysts indeed possess a much lower onset temperature for CO and H₂ oxidation than the constituent metals, physical mixtures or bulk alloys of Pt and Ru. Additionally, the selectivity to CO oxidation on these catalysts at low temperatures is excellent.

One thrust of our work over has been to explain this increased activity using first-principles methods. We find that a Pt skin pseudomorphically deposited on a Ru host provides a different pathway for O₂ dissociation in the presence of hydrogen (H). This novel result highlights the ability of hydrogen to assist in O₂ dissociation on Pt-Ru surface alloys (see Figure 2), thereby lowering the activation energy barrier to oxidation, thereby increasing the activity of the core-shell nanoparticles considerably.

The discovery of this H-assisted path is of interest for several reasons. First, using this new mechanism, we can identify catalysts that may show similar or even better characteristics for PROX by adding a third metal to the alloy. Second, the existence of such H-assisted dissociation may not be limited to O₂ dissociation. We have begun a study of similar dissociation pathways for other relevant intermediates, such as CO₂ which would allow us to better understand the surface chemistry of multiple reactions important to H₂ production and purification, but also for alkane fuels production (e.g.: Fischer-Tropsch synthesis).

(C) NSAs for Hydrogen-related reactions

Another focus of our research has been in synthesizing and characterizing submonolayer alloys for hydrogen-related reactions. Recently, we have deposited submonolayer amounts of Au on an Ir(111) surface and compared the uptake of hydrogen to that of a pure Ir(111) surface using electrochemical techniques. While STM demonstrates that Au is clearly deposited on the surface as a thin film, counter-intuitively, it does not block hydrogen adsorption. Using DFT, we analyzed the interaction of H with this NSA and showed possible reasons for this anomalous behavior. We found that hydrogen at the Au-Ir interface is stabilized as compared with hydrogen on the Au surface (see Figure 3). Such subsurface H has been implicated as

![FIGURE 1. Schematic of core-shell particles, alloy particles and physical mixtures.](image1)

![FIGURE 2. Direct and H-assisted preferential oxidation mechanisms.](image2)
a reaction intermediate in hydrogenation reactions in other systems. Additionally, the subsurface hydrogen may have a promoting effect on further reaction; the presence of subsurface H in the Au-Ir system upshifts the d-band center from -4.10 to -3.02 eV, leading to a significant increase in the reactivity of the pure Au-Ir surface. We plan on continuing this analysis by looking at submonolayer Au alloys on other transition metals to see if this reactivity change is unique to Au-Ir or can be found in other NSA systems. Additionally, we have begun looking at alloy stability and formation on other than close-packed surfaces of transition metals.

Abstract

By utilizing a range of different synthesis methods, we were able to demonstrate that through careful tailoring of composition and structure of both the active metal component and the oxide support matrix in nanocomposite catalysts, it is possible to design catalysts that combine exceptional high-temperature stability with high catalytic activity. Activity and stability of these materials was demonstrated through application in catalytic hydrogen production via catalytic partial oxidation of methane and water-gas-shift. Finally, implementation of these nanocomposites into a “macroscopic” support structure was demonstrated.

Progress Report

Below, we will use select examples from the project results to highlight and illustrate major findings from the investigations based on systematic tailoring of composition and structure of the support and the active (metal) component in order to reconcile high thermal stability with high activity in nanocatalysts.

Tailoring for Stability via Embedding: Metal-BHA Nanocomposites

Based on a rather straightforward, single-pot synthesis, a wide range of high surface area metal/oxide nanocomposite materials was successfully synthesized (including Pt, Rh, Pd, Au, Ni, Cu, Fe, Co, and Zn as (active) metal components, and BHA (barium-hexaaluminate), silica, magnesia, ceria, and La2O3 as oxide matrices) and the thermal stability of these materials was demonstrated. In particular BHA-based materials showed excellent high-temperature stability, which could be traced back to a simple “caging” of metal nanoparticles in the highly interconnected pore network of the BHA matrix. This is illustrated in figure 1 (bottom) shows the close agreement between Pt particle size (bars) and BHA pore neck size (blue line) for a Pt-BHA catalyst after calcinations at 600°C. Through a simple dip-coating procedure, it was furthermore possible to anchor this nanocomposite material onto different support structures, resulting in a robust, easy-to-handle catalyst formulation without compromising the carefully controlled nanostructure of the catalyst (see figure 1, top). The resulting catalysts showed excellent activity in partial oxidation of methane (Pt-BHA) as well as in chemical looping combustion (Ni-BHA & Cu-BHA) and chemical looping steam reforming (Fe-BHA). Overall, these results indicate
that it is possible to reconcile activity and stability of nanomaterials via simple nanostructuring.

Tailoring for Stability via Encapsulation: Metal@Silica Core-Shell Materials

As alternate approach for the stabilization of metal nanoparticles, direct encapsulation with porous oxide shells was pursued. This was motivated by the fact that the above described approach is limited with regard to the minimum metal nanoparticle size which can be stabilized: Since the particles are stabilized via a simple mechanical ‘caging’, smaller stable particle diameters require increasingly smaller pores and hence ultimately result in mass transfer limitations. In contrast to that, direct coatings of nanoparticles can be kept sufficiently thin that mass transfer limitations (MTL) should be avoidable.

We were able to demonstrate fine control over key dimensions of silica-encapsulated metal nanoparticles (M= Ni, Cu, Co, Fe, Pd), including size of the metal nanoparticles (from sub-nm clusters up to ~20nm), size of the M@SiO₂ particle, thickness of the silica shell (see fig. 2, top), and presence or absence of a cavity inside the silica shell (see insets in fig. 2). Again, excellent high-temperature stability was demonstrated along with high activity & selectivity in catalytic methane partial oxidation (CPOM, see fig. 2, bottom), and a critical shell thickness for avoidance of MTL was demonstrated.

Tailoring for Stability via Alloying: Bimetallic Nanocomposites

As third alternative for achieving high-temperature stable metal nanoparticles, the alloying of the metal nanoparticles with a second metal was investigated. This was motivated by the aim to increase the stability limits of metal NPs without the use of a stabilizing matrix (as in the two approaches above), i.e. by transitioning from stabilization via structural tailoring to stabilization via compositional tailoring.

One can expect that the addition of a second, higher-melting point metal will result in increased thermal stability, since sintering is known to be strongly correlated with the melting point of a metal. Using Pt-BHA as starting material and carefully adjusting the composition of the metal nanoparticle via step-wise increase in the second metal (for PtRh, PtSn, and PtPd), we found that such stabilization is indeed possible. Unexpectedly, however, it was observed that this stabilization extends to much higher temperatures than predicted by the (initial) composition of the alloy. This was traced back to a sacrificial self-stabilization of the nanoparticles, which bleed out the lower melting point component (M₁) in a continuous, distillation-like process. This results in the formation of larger nanoparticles which are composed of pure M₁, while retaining the entire original population of small metal nanoparticles, which get increasingly enriched in M₂. Overall, this brings about a remarkable self-stabilization of the catalyst, as demonstrated using methane combustion as test reaction. While this stabilization mechanism has limitations due to the fact that the alloying with the second metal must not negatively affect the reactivity of the catalyst, it is remarkable in its simplicity and the fact that it is not dependent on a specific support.

Tailoring for Activity via Composition & Structure: Metal/Mixed-Oxide Catalysts

Finally, the concept of tailoring via composition and structure was applied to a more complex case in which the support takes on a key reactive role (beyond acting as a stabilizing matrix). Water-gas-shift (WGS) over
Au/ceria catalysts was chosen as test system. Based on a similar microemulsion-templated sol-gel synthesis as of the BHA-based materials above, high surface area ceria and ceria/lanthana mixed oxides were synthesized, characterized, and, after Au deposition, utilized in WGS. A strong correlation between composition, reducibility, and activity of the catalysts was observed, were addition of moderate amounts of La (up to ~25%) resulted in significant improvements in WGS activity (see fig. 4).

Utilizing an alternate (hydrothermal) synthesis, ceria and mixed oxide nanorods were also synthesized and compared to the nanoparticulate catalysts. Structuring the catalyst into nanorods results in a strong increase in WGS activity which again can be traced back to the increased reducibility of the oxides (due to predominant exposure of low-stability surface orientations).
Future Directions

The project ended in August 2009, and no extension was applied for. However, the results demonstrate the potential of tailoring catalyst activity and stability via careful compositional and structural control at the “nano-level”, and we are currently extending this concept onto related catalytic reactions.

### Objectives

This program involves studies of platinum monolayer electrocatalysts for the $O_2$ reduction reaction (ORR) aiming at producing ultimately low Pt content electrocatalysts with high activity and high stability, supported by metal-, alloy-nanoparticles, nanorods, nanowires, as well as oxide-, carbide-, nitride- and hollow metal-nanoparticles, and carbon nanotubes. Theoretical calculations are carried out for a deeper insight into the kinetics of the ORR. Studies using well-defined surfaces are carried out to gain understanding of the atomic-scale phenomena involved in the interactions of Pt monolayers with supporting surfaces, as well as developing new efficient catalysts for ethanol oxidation.

### Technical Barriers

The project is focused at developing several Pt monolayer catalysts that are likely to have the highest Pt mass activity, and excellent potential to overcome the obstacles hindering the broad application of fuel cells. The results will enhance our understanding of the metal monolayer-support interactions for a viable approach for controlling chemical reactivity in the top atomic layer. In addition, we explore the catalyst capable of C – C bond splitting at low overpotentials in the oxidation of small organic molecules.

### Progress Report

**Improved understanding of factors affecting the ORR activity of Pt monolayer**

We examined the effects the thickness of the Pt shell, lattice mismatch, and particle size on specific and mass activities from the changes in effective surface area and activity for oxygen reduction induced by stepwise Pt monolayer (Pt ML) depositions on Pd and Pd$_x$Co nanoparticles. The core-shell structure was characterized at the atomic level using Z-contrast scanning transmission electron microscopy coupled with elementsensitive electron energy loss spectroscopy.

The enhancements in specific activity are largely attributed to the compressive strain effect based on the density functional theory calculations using a nanoparticle model, revealing the effect of nanosize-induced surface contraction on facet-dependent oxygen binding energy. The results suggest that moderately compressed (111) facets are most conducive to the ORR on small nanoparticles and indicate the importance of concerted structure and component optimization for enhancing core-shell nanocatalysts' activity and durability.

In the nanometer range, a particle’s size and shape profoundly affect the ORR specific activity because both the surface fraction of active facets and the facet-dependent binding energy for oxygen vary with size. These results point the way to tailoring a Pt shell’s structure and properties by controlling core particle’s components, size, and shape, for high activity and durability of the ORR electrocatalysts.$^{1,2}$

![FIGURE 1. ORR specific activities at 0.9 V measured at 10 mV s$^{-1}$ (symbols, left axis) and surface fraction of atoms on the (111) facets (solid and dashed lines, right axis) as a function of particle size. Improving activity and stability of Pt monolayer electrocatalysts for the ORR

Several methods for improving Pt ML catalysts have been developed based on understanding of the factors affecting the ORR. The new strategies include:
1. Surface and sub-surface modification of cores to tune the interaction with a Pt ML.
2. Reducing number of low-coordination surface atoms by Br- adsorption/desorption.
3. Using smooth surfaces of Pd nanorods and nanowires to support a Pt ML.
4. Contracting Pt-Pt separation with hollow particles
5. Using intermetallic compounds as supports

Sub-surface modification of cores to tune the interaction with a Pt ML

This strategy is based on the expectation that a monolayer of a metal can be driven in sub-surface of support. The subsurface layer of Ir in Pd support, obtained by galvanic displacement of a Cu monolayer by Ir and annealing at 350°C to induce segregation of Pd to the surface and Ir into the particle, enhances the ORR kinetics at Pt monolayer on PdIr nanoparticles (Fig. 2). The subsurface Ir causes a Pd skin to contract, so Pt monolayer on PdIr/C is compressed more than on Pd/C. The Pt-O bond will weaken and ORR activity increased. This was verified by the data in Fig.2.

Modifying surface properties by alloying the core.

Au submonolayer, deposited on a Pd3Co surface by displacing Co atoms in the surface, or AuPd alloy, as a support for Pt monolayer cause a significant increase in the activity of and stability of such catalysts compared with original PtML/Pd3Co/C catalyst. The Pt/Au3Pd/C catalyst has a high activity and durability, i.e., E1/2 =0.901V before and 0.895V after 30,000 potential cycles from 0.75-0.95V, dwell time 30 sec, of an accelerated stability test. The increased catalytic activity and durability originate from the reduced Pt oxidation (PtOH formation), which inhibits the ORR and is a precursor of Pt dissolution, as inferred from in situ XANES spectra of Pt L3 edge.

Ordered intermetallic compound cores

A new class of core-shell electrocatalysts for the ORR consists of a Pt monolayer shell and ordered intermetallic compound cores. We coupled highly stable, inexpensive intermetallics with a Pt monolayer producing electrocatalysts with high activity, low metal content, and very high stability. Our data indicate strategies suitable for selecting the types of intermetallic compounds as the support for a Pt monolayer.

Smooth support surfaces

Smooth surfaces, having a small number of low-coordination atoms, are suitable support for a Pt monolayer for the ORR due to a reduced Pt oxidation that takes place on such surfaces. This assertion has been verified with the Pd surfaces, obtained by removing low-coordination atoms using Br- adsorption/desorption, Pd nanowires (Fig. 3a) and Pd nanorods used as a support for a Pt monolayer. Unprecedentedly high Pt mass activity of 3.4 A/mg has been obtained (Fig. 3b).

Electrocatalysts for ethanol oxidation

Further studies of the ternary Pt-Rh-SnO2/C electrocatalysts capable of splitting the C-C bonds at room temperature involved varying the atomic ratio Pt:Rh:Sn = 3:1:x, where x varies from 2 to 6. The catalysts composed of homogeneous PtRh alloy and SnO2, having all three constituents coexisting in single nanoparticles with the average particle size around 1.4nm and a narrow size distribution. While all the electrocatalysts investigated exhibited high catalytic activity for ethanol oxidation, the most active one had the composition with the Pt:Rh:Sn = 3:1:4 atomic ratio.

Future Directions

We plan to continue with exploring the interaction of Pt monolayers with smooth surfaces of Pd nanorods, nanowires, and nanotubes. This will help in developing of Pt ML catalysts with predominantly high-
coordination atoms deposited on smooth cores of: i) Pd or its alloy nanorods, nanowires or nanotubes cores; ii) Pd or Ir alloy nanoparticles with refractory metals that preclude core dissolution in acid environment. We will study the ternary catalysts for ethanol oxidation using CeO$_2$ instead SnO$_2$. Magnelli phases will be selected as support because they are conductive and stable in acids. Our new method of depositing metal on oxide surfaces will be employed for designing active catalysts.

Patents

1. Two patents issued; three patent applications submitted in 2009.
Objectives

- Develop new synchrotron radiation based x-ray diffraction and spectroscopy methods that allow in-situ probing of the intermediates in the oxygen reduction reaction (ORR) on the cathode in fuel cells where both species identification, geometric and electronic structure properties can be fully characterized.
- Gain insight into how various catalytic properties on Pt surfaces can be modified due to alloying.
- Perform combinatorial synthesis and high throughput electrochemical screening methodologies of alloy catalyst with different chemical compositions and structures to obtain optimum performance.

Technical Barriers

This project addresses the following technical barriers by understanding the mechanistic pathway of the ORR reaction and by establishing fundamental guidelines to design new low Pt containing catalyst by optimizing the geometric and electronic structure of catalyst along the mechanistic pathway.

- Electrode performance
- Low cost
- Durability

Abstract

We have discovered a new family of Pt-Cu nanoparticle/nanopore catalyst that exhibits the highest ever reported ORR activities of up to 5-6x compared to pure Pt electrocatalysts. The composition of the surface, lattice arrangement and electronic structure of these catalysts have been characterized by synchrotron based x-ray diffraction and photoelectron spectroscopy methods. We discovered an order of magnitude reduction of Cu in near surface region of these catalysts, due to electrochemical leaching and a lattice contraction in the nanoparticle/nanopore structures. This affects the overall reactivity by weakening the bonding of intermediate oxygenated species.

We have undertaken a major effort to obtain in-situ information during electrochemical conditions of the nature of intermediate oxygenated species that controls the rate of the ORR. With high resolution Pt L edge spectroscopy of a single Pt monolayer we have observe the evolution of a surface Pt oxide layer.

Progress Report

While the oxidation of pure hydrogen is not considered a technical hurdle in fuel cells, the power loss at the cathode during the electroreduction of oxygen is found to be significant. Therefore the identification of a catalyst for the electroreduction of oxygen with improved performance is a major scientific priority. Pt has been the only metal which offers a good compromise in terms of performance and durability, and catalyst costs dominate at high Pt loading. Our goal is to understand the mechanistic pathway of the ORR reaction and to design new low Pt containing catalyst by optimizing the geometric and electronic structure of catalyst along the mechanistic pathway.
Dealloying is the preferential dissolution of the electrochemical more reactive component from a bimetallic alloy (precursor) consisting of a less reactive (here Pt) and more reactive metal (here Cu). We have shown that dealloyed Pt-Cu nanoparticles show uniquely high catalytic reactivity for the oxygen reduction reaction (ORR) in fuel cell electrodes (1-4). Dealloyed Pt catalysts, however, meet and exceed the technological activity targets in realistic fuel. Owing to their reactivity, dealloyed Pt catalysts can reduce the required amount of Pt by more than 80%. Despite this importance, the mechanistic origin of their enhanced reactivity remains poorly understood.

We have shown based on a combination of electron microscopy, x-ray photoelectron spectroscopy and anomalous x-ray diffraction studies of dealloyed Pt-Cu catalysts (6) that a core-shell structure is formed during dealloying, which involves removal of Cu from the surface and subsurface of the precursor nanoparticles. X-ray diffraction shows that the resulting Pt-rich surface shell exhibits compressive strain that depends on the composition of the precursor alloy. Based on model electron and x-ray spectroscopy experiments of strained Pt films on Cu(111) the existence of a downward shift of Pt d-band resulting in a weakening of the bond strength of intermediate oxygenated species due to strain (see fig.1). Theoretical simulations of the fuel cell catalytic process also shows that strain enhance the overall reactivity via a weakening of the oxygen adsorption bond strength. The stoichiometry of the precursor, together with the dealloying conditions, provides experimental control over the resulting surface strain and thereby allows continuous tuning of the surface electrocatalytic reactivity – a concept that can be generalized to other catalytic reactions.

To build on the above results and to better understand the structure-activity relationships in dealloyed Pt-alloy electrocatalysts, we have used uniform, single phase, polycrystalline Cu,Pt thin films and single crystal Cu,Pt(111) as model catalysts for accurate characterization of structure and the resulting ORR activity enhancement. Anomalous x-ray diffraction (AXRD) is used to study the structure of the dealloyed Pt-Cu thin film (lattice constant and composition) (7). We have obtained a detailed understanding of the structure and composition relationships in these Pt-skeleton structures prepared by dealloying base metal rich alloy. Compositional inhomogeneity of the dealloyed films is observed with a Pt enriched surface region and Cu depleted interior. The composition of Cu depleted interior is different from that of as-deposited Cu,Pt showing that dealloying of Cu occurs at the surface and proceeds into the interior, leaving a compressively strained Pt-enriched surface region as shown in Fig. 2. Work on single crystal Cu,Pt(111) is ongoing, but qualitatively consistent with the film studies.

Mechanistic understanding of fuel cell cathode reaction

In order to develop more efficient fuel cell catalysts it is essential that we can gain information regarding the nature of intermediate species during oxygen reduction reaction (ORR) that contribute to the sluggish kinetics. Hard x-rays penetrate several millimeters
through electrolyte solutions, thus providing a unique capability for in situ x-ray absorption spectroscopy (XAS) studies of active fuel cell catalysts under electrocatalytic conditions. Of particular interest is determining the nature of Pt–O interactions at high potentials since this is essential for understanding the origin of the overpotential of the electrochemical oxygen reduction reaction (ORR). We have chosen to study a well-defined, simple model system, consisting of one monolayer Pt on a Rh(111) single-crystal surface. By tuning the energy to the Pt L₃ absorption edge this allows for the – intrinsically bulk sensitive – hard x-ray spectroscopy to probe only surface Pt atoms and their interaction with oxygen. Fig. 3 shows the L-edge x-ray absorption spectra (XAS) of a Pt monolayer on Rh(111) detected using High Energy Resolution Fluorescence Detection (HERFD), where the life time broadening of the Pt L-edge has been experimentally removed, resulting in much higher resolved spectral features (8). By using the L₂-edge, the unoccupied Pt 5d-states are probed. The intensity increase, broadening, and shift of the spectra with increasing potential have been identified, through theoretical spectral simulations, to result from the development of a Pt surface oxide. Complementary extended x-ray absorption fine structure (EXAFS) measurements have been carried out under identical conditions. Pt-Pt and Pt-O bond lengths and coordination numbers have been derived, confirming the interpretation of the growth of a surface Pt oxide (8). Weaker changes in the spectral features at lower potentials can be related to adsorbed hydrogen and to the presence of other oxygenated species.

Future Directions

We will continue the in-situ spectroscopy studies of the ORR of a single Pt monolayer to other substrates which are expected to bind oxygen stronger where we expect that the onset of Pt surface oxide formation will occur at lower potentials. We will also extend these studies to nanoparticles of Pt with different sizes since there is a hypothesis that small nanoparticles could induce oxide formation at lower potentials. We will also continue our effort to develop in-situ spectroscopic techniques to the soft x-ray regime. We will extend the studies of the dealloying process to Pt-Cu single crystals. We are currently exploring dealloyed bimetallic Pt systems other than Pt-Cu. Current studies focus on dealloyed PtCo3 and PtNi5. Dealloying behavior of these bimetallic compounds is unknown to date. Preliminary results suggest a similar core shell behavior for PtCo3 as found in PtCu3. PtNi5 showed less susceptibility to leaching. Future experiments will include morphological studies of dealloyed PtCo3 and PtNi5, monitoring of the compositional changes upon extended cycling protocols.

Objectives

We aim to develop new understanding that can foster the development of better catalyst materials for proton-exchange membrane cathodes. To achieve this goal, we focus on answering these questions: 1) How the catalytic surface and its environment change as the reaction takes place; 2) What are the effects of the dynamics of the catalyst and that of the surrounding medium on the catalytic activity and stability; 3) What is the effect of important side reactions on the catalytic process.

Technical Barriers

One of the main problems of current alloy cathode electrocatalysts is their strong dissolution trend especially when platinum is combined with less “noble” transition metals. Upon dissolution, metal ions cause other problems such as membrane degradation, or upon ion reduction, particle agglomeration. In this study, we determine the mechanisms that trigger metal dissolution and analyze possible alternative materials that may help mitigate the problem.

Abstract

We present results from a systematic density functional theory study of core-shell alloy surfaces, with monometallic cores of the 3d, 4d, and 5d groups. The analysis reveals that all the 4d and 5d pure cores may serve as relatively stable cores, and their beneficial effect on the Pt monolayer may be further tuned by alloying them to another element, here chosen from 3d or 5d groups. The Pd,X cores enhance the stability of the surface Pt atoms both in vacuum and under adsorbed oxygen; however, the high oxygen-philicity of some of the X elements induces their surface segregation that may cause surface poisoning with oxygenated species and metal dissolution in acid medium.

Based on the above DFT studies, we introduce a new class of catalytic materials with enhanced activity and high stability of the surface and core atoms against dissolution in acid medium. The significant stability improvement found in the new material is due to the addition of a small-radius species that locates in the interstitial sites of the top subsurface layers locking the core transition metal atoms in their positions, thus avoiding their segregation to the surface and posterior dissolution, which is driven by the oxidative acid environment. We illustrate our findings by a detailed analysis of the durability and activity enhancement for the platinum/iron-carbon/iridium system.

Progress Report and Future Directions

1. Surface stability of Pt-monolayers on pure cores. Calculated electrochemical potential shifts (DU) for surface Pt atoms on top of pure 4d and 5d transition metal cores show that the core elements have little tendency to segregate to the surface, and in some cases (Ir and Rh) they have large antisegregation energies. It is interesting that DU decreases as the difference of charges between the surface and the subsurface becomes smaller, indicating that a large charge transfer between the top surface and the subsurface has a stabilizing effect on the surface Pt atoms. We concluded that in principle, these systems could be stable core candidates. Our calculations indicate that the difference in binding energies $B_{O_H} - B_{O}$ that correlates with previous reports on activation energy for OH formation, follows the order Ag > Au > Pd > Pt > Rh > Ir. On the other hand, the O binding energies follow the core order Rh < Ir < Au < Pd < Pt < Ag; this order is the opposite to that of the reported ORR currents: Pd > Au > Rh > Ir; thus, Pt/Pd having an intermediate strength for O adsorption and for OH formation yields the highest ORR activity. It is interesting that the OH adsorption energies (that we shown to be driven by both electronic and geometric effects) follow the core order Ag < Au < Rh < Ir < Pd, and all of the Pt-skin surfaces yield OH adsorption energies weaker than those on Pt(111). In summary, the analysis of stability and activity of the pure cores suggests that combining 4d or 5d elements with 3d elements would provide alternative formulations for core-shell alloys. According to our results, the group of 4d and 5d metals yield weaker O and OH energies, indicating good ORR activities, and their positive DU suggests that if these cores are alloyed with 3d elements
having a large negative d-band center value (such as Co, Ni, Cu), beneficial activity effects may be enhanced.

2. Surface stability of Pt-monolayers on alloy cores. Analysis of segregation trends of Pd and X from the core to the surface as functions of the electronic charge of the atom X in the subsurface for Pt/Pd₃X alloys indicates that the strength of antisegregation of X towards the surface increases with the degree of oxidation of the atom X in the subsurface. On the other hand, Pd has a slight tendency to segregate to the surface that increases with increasing oxidation degree of X in the subsurface. The Pd-segregation data shows two groups: one including elements of the period 6 (Ir and Re), and the other with elements of period 4 of the periodic table. In both cases the less positively charged Pd atoms tend to migrate to the surface, whereas X atoms tend to remain in the core, thus establishing an attractive electronic interaction with the Pt surface atoms bearing slightly negative charges. This polarization of the metal overlayer/transition-metal substrate has been discussed by other researchers based on experimental and theoretical evidence.² ³ Under 0.25 ML of O, the Pd segregation trend is not very different from that found on the clean surface, but a strong segregation pattern is found for Ir, Cr, V, Ti, and Re, and weaker for Co and Fe. We found that the Ir segregation trend changes drastically from that found in the pure Ir core, since the cohesive properties of the pure Ir system are lost in the alloy. Given our findings respect to segregation trends, it is of interest to analyze the stability of Pt atoms against dissolution when Pt is on the surface of these alloys. These trends reveal a clear correlation of the stability of the Pt atoms on the surface and the degree of oxidation of the atom X in the subsurface, reinforcing our earlier conclusion that a strong attractive electronic interaction may be established between the Pt monolayer and the subsurface alloy layer. The calculated binding energies per Pt atom of the monolayer to the core increase in the order Ir < Co < Fe < Re < V < Ti < Cr, that follows (except for Cr) the order shown by the stability of Pt atoms, both for a clean surface and under adsorbed O. Thus the presence of a relatively small concentration of the X elements in the PdₓX core enhances the stability of Pt atoms on the surface of the core-shell alloys. This result is in agreement with previous XPS binding energy shifts and DFT analysis of a metal adlayer on a transition metal substrate revealing heterometallic bond formation attributed to orbital rehybridization effects. With respect to reactivity, although the O binding energies on the Pt-skin surfaces are relatively weak compared to that on Pt(111), these energies increase under segregation of Pd and in some of the surfaces there is a strong increase under segregation of X, especially for Ti, V, Cr, and Re that are known to have strong affinity for oxygen.

Although we have shown that these cores impart high stability to the surface Pt atoms, another factor to evaluate is the trend of the X core elements to dissolve in acid medium inferred from their experimental redox potentials. It is clear that all the elements would dissolve at more negative potentials than pure Pt (1.18 V). In addition, as remarked by Greeley and Nørskov dissolution tendencies follow trends in segregation energies. Based on this, we remark that our calculated segregation trends add significant information regarding dissolution of core elements under oxidation conditions. With respect to the ORR activity of the group of Pt/PdₓX alloys, all the O binding energies are much lower than those on Pt/Pd, following the order Re < V < Ti < Co < Fe < Ir = Cr, the same order is approximately followed by the strength of O adsorbed when Pd segregates. However, on surfaces where the X element has segregated, the binding energies of O to these elements is significantly higher, with the order being changed to Co < Fe < Ir < Cr < Ti < V < Re, that except for small differences is the same order that is followed by the OH binding energies. Thus, within this formulation, Pt/PdₓCo and Pt/PdₓFe stand out as promising alloys in both activity and stability aspects. However, the present analysis also suggests that Pt/Pdₓ,ₓ₅ alloys with 0<y<1 are excellent candidates for ORR catalysis.

3. Design of a core/shell material with an active and durable Pt surface. Based on the above analysis, we inferred that an active surface that is also resistant to dissolution in acid medium requires a stable core that in addition is able to alter the Pt electronic structure increasing its ORR activity. Thus, we investigated a new class of core-shell materials composed by a platinum monolayer over a composite core where an extra element has been added to the transition metals in order to anchor them to the core, thereby retaining their beneficial properties towards the surface atoms and enhancing the stability of the catalyst against dissolution.⁵ We demonstrated the properties for the composite system Pt/Fe-C/Ir depicted in Figure 1.

We first evaluated the effect of the presence of subsurface interstitial carbon on the surface electronic
and geometric properties of the Pt monolayer. We determined oxygen adsorption energy strength (signaling catalytic activity),\(^4\) segregation energy of the subsurface metal atoms on the clean surface and under 0.25 ML of adsorbed oxygen (related to surface stability and activity),\(^4\) electrochemical potential shift on clean surface and under 0.25 ML of adsorbed oxygen (onset of Pt dissolution),\(^5\) and binding strength (per Pt atom) of the top surface to the core (a measure of surface stability). We noted that the largest electrochemical potential shift corresponds to the alloy core in absence of carbon; however this structure has a significant iron surface segregation trend which affects the catalyst durability.\(^6\) Instead the structure where carbon fills the subsurface shows an optimal combination of activity and stability properties.

One of the best characteristics of the proposed composite core-shell material is the antisegregation of transition metal atoms toward the surface even in presence of adsorbed oxygen; this feature is explained from the analysis of the electronic structure as given by the Bader electronic charges.\(^7\) Without carbon, the geometric stress introduced by the Pt overlayer on the core generates a charge transfer that results in an excess of electrons in the surface and a deficit in the first subsurface layer, as found in previous experimental\(^8\) and theoretical studies.\(^3\) A similar charge transfer effect occurs between the Ir and Fe atoms of the 4th and 5th layers. In presence of carbon, the iron atoms transfer charge not only to Pt and Ir but also to carbon, as revealed by the increase of the positive charges on Fe as the C concentration increases. The charge transfer Fe-C denotes their strong affinity and bonding resulting from orbital hybridization, which prevents iron segregation towards the surface, even under adsorbed oxygen. The increased stability is also associated with the polarization of the first two layers, which determines the high binding of the overlayer to the core.

In summary, we have demonstrated the potential durability and activity properties of a new class of core-shell composite materials. The enhanced durability arises from the use of carbon in the interstitial sites of the subsurface that anchors the transition metals in their positions impeding their segregation to the surface while keeping their beneficial properties that favor ORR activity on the top platinum monolayer. We are currently exploring other core-shell designs that may offer similar catalytic and extended durability properties and we expect to address other challenges such as the presence of surface defects on the performance of the new material. Interesting systems include the use of a Pd monolayer (instead of Pt), although Pd dissolution may happen at lower potentials than those of the Pt monolayer, according to the trend of their redox potentials.

Future Directions

We are extending our design of dissolution-resistant catalysts to other core combinations. This extended study will allow us to optimize the cost and feasibility of fabrication. We have been discussing possible fabrication of our proposed new catalytic design with experimental groups and we have some ideas for making the systems more realistic keeping the same basic beneficial features. In addition, we are developing and implementing a kinetic Monte Carlo (KMC) technique to evaluate the evolution of the surface as a function of time, under reaction, and under applied potential. The KMC program requires as input the rates of the diffusion and migration processes from the subsurface and on the surface that we have already obtained in our previous and current DFT analysis.

Objectives

This project involves the development and application of a unique multiscale computer simulation methodology for studying proton solvation and transport in proton exchange membranes (PEMs) for fuel cell applications. A key component of the project is an atomistic reactive molecular dynamics MD simulation approach that allows for the explicit and accurate treatment of proton shuttling in the MD simulation of complex systems having large system sizes and long MD simulation times. Another key objective is the bridging of the molecular scale proton transport information to mesoscopic models of PEMs that connect the proton transport with the features of the polymer morphology.

Technical Barriers

The computer simulation of the proton conductance behavior of proton exchange membranes must involve a description of the relevant physics over a wide range of length and time scales. These scales range from those involving the breaking and making of chemical bonds at the Angstrom and picosecond scales during the proton shuttling process through mediating water molecules, to the mesoscopic collective proton transport behavior of the polymer membrane behavior at the micrometer and microsecond scales. A systematic multiscale computational approach must therefore be developed and implemented, often within a high performance computing environment, to correctly describe proton exchange membranes.

Abstract

The solvation and transport of hydrated protons in proton exchange membranes (PEMs) such as Nafion® will be described using a novel multi-state reactive molecular dynamics (MD) approach, combined with large scale MD simulation to help probe various PEM morphological models. The multi-state MD methodology allows for the treatment of explicit (Grotthuss) proton shuttling and charge defect delocalization which, in turn, can strongly influence the properties of the hydrated protons in various aqueous and complex environments. A significant extension of the methodology to treat highly acidic (low pH) environments such as the hydrophilic domains of a PEM will be presented. Recent results for proton solvation and transport in Nafion® will be described which reveal the significant role of Grotthuss shuttling and charge defect delocalization on the excess proton solvation structures and transport properties. The role of PEM hydration level and morphology on these properties will also be described.

Progress Report

A. Simulations of Explicit Proton Transport in Nafion® as a Function of Water Loading (Hydration). Novel atomistic reactive molecular dynamics(MD) simulations of 1100EW Nafion® were performed for water loading of 15H2O/SO3- 10H2O/SO3-, 7H2O/SO3- and 6H2O/SO3-. This work has extensively utilized the self-consistent iterative multi-state empirical valence bond (SCI-MS-EVB) method,1 a generalization of the MS-EVB approach which allows for the treatment of solvation and the transport of multiple excess protons under intermediate to high acid concentrations at an affordable computational cost. In addition to its exceptional computational efficiency relative to ab initio molecular dynamics, the SCI–MS-EVB method also scales linearly with the number of protons in the simulation box. The recently developed MS-EVB3 parameterization, which is also based on a more accurate un derlying water model,3 was also employed. These simulations have provided a better understanding of the physics of proton solvation and transport in the Nafion® membrane as a function of water loading. The dynamical evolution of the excess protons, water distributions (cf. Fig. 1), and the cooperative motion of the sulfonate/hydronium ion pairs, as well as their associated solvation structures at different water loading levels, were the focus of this study.

The center of excess charge (CEC)4 of the net positively charged hydrated proton electronic charge defect, which best characterizes the instantaneous location of the excess proton charge and most physically accurately describes the effects of Grotthuss proton
shuttling, was used to characterize the structure and
dynamics of the highly acidic Nafion® environment.
The water distributions were also characterized by
radial distribution functions of the water molecules.
As depicted in Figure 1, water clusters of water loading
level $6H_2O/\text{SO}_3^-$ are characterized by the high peak at
$\sim 0.26\text{nm}$, while the relatively lower peak at the same
position and the slightly larger amplitude at longer
distance for water loading level $15H_2O/\text{SO}_3^-$ indicate
the existence of a water network that can facilitate the
observed higher proton conductance.

The unusual proton transport behavior discovered
previously in this project was further studied at
different water loading levels. The excess proton
CEC displacement vectors were decomposed into a
continuous displacement component due to "vehicular"
(classical Einstein) diffusive motion and a component
due to the discrete "hopping" displacement due to
the identity change of the protonated water molecule
via Grotthuss shuttling. The overall mean squared
displacement (MSD) could then be written as the sum
of the MSD of each component and an overlap term
which describes the correlation of the two displacement
vectors. Figure 2 displays the different components of
the MSD for the two water loading levels, $10H_2O/\text{SO}_3^-$
and $6H_2O/\text{SO}_3^-$. (The diffusion constant is proportional
to the slope of the MSD at long times.) At all water
loading levels studied, hopping (discrete) diffusion
is somewhat faster than the vehicular motion. More
interestingly, as the water loading level increases, the
diffusion constant of discrete motion increases faster
than that for the continuous motion (e.g., at $10H_2O/\text{SO}_3^-$
), indicating the onset of water network formation which facilitates the Grotthuss hopping more than vehicular
diffusion.

B. Large Scale Molecular Dynamics of Nafion®
Morphological Models. Atomistic molecular dynamics
simulations of a very large scale were performed to
study hydrated Nafion® systems. The simulations were
large enough (~ 2 million atoms, ~50 nm box length)
to directly observe several hydrophilic domains at the
molecular level. These systems consisted of six of the
most significant and relevant morphological models of
Nafion® to-date: (1) the cluster-channel model, (2) the
parallel cylinder model, (3) the local-order model,
(4) the lamellar model, (5) the rod network model, and
(6) a ‘random’ model that does not directly assume
any particular geometry, distribution, or morphology.
Each system was initially built to closely approximate
the proposed hydrophilic cluster structure in a given
model. Molecular dynamics simulations were then
used to observe resulting changes from and behavior of
the assumed initial configurations. These simulations
revealed fast intercluster ‘bridge’ formation and network
percolation in all models. Sulfonate groups were found
inside these bridges and played a significant role in
percolation. Sulfonates also strongly aggregated around
and inside clusters. Cluster surfaces were analyzed to
study the hydrophilic-hydrophobic interface. Interfacial
area and cluster volume significantly increased during
the simulations, and radial distribution functions and
structure factors were also calculated. All nonrandom
models clearly exhibited the characteristic experimental
scattering peak, underscoring the insensitivity of
this measurement to hydrophilic domain structure
and highlighting the need for future work to clearly
distinguish morphological models of Nafion®.

C. Proton Transport in Non-Aqueous Electrolytes.
Anhydrous proton conduction media are important
targets for applications in high temperature fuel cells
given the difficulties with water as an electrolyte
under such conditions. The MS-EVB methodology
was therefore successfully extended to simulate excess
proton transport in liquid imidazole, which is a target

---

**FIGURE 1.** Radial distribution function of water molecules of water loading level $6H_2O/\text{SO}_3^-$ (black line) and $15H_2O/\text{SO}_3^-$ (red line).

**FIGURE 2.** Mean-squared displacement (MSD) versus time of excess protons in Nafion. Dashed lines are water loadings of $6H_2O/\text{SO}_3^-$ and solid lines are $10H_2O/\text{SO}_3^-$. Black denotes total diffusion, red is the continuous "vehicular" diffusion component, and blue is the discrete (Grotthuss hopping).
non-aqueous electrolyte (or chemical derivatives of imidazole). As in aqueous systems, this approach allows proton transfer to simultaneously occur on both reaction sites (donor and acceptor) of the imidazole molecule. The underlying imidazole and imidazolium models were described by the generalized Amber force field (GAFF), while the imidazole MS-EVB model was parameterized to reproduce the \textit{ab initio} proton shuttling potential energy surface (PES) of a protonated imidazole dimer in the gas phase. In bulk phase at 393K, the MS-EVB simulation yielded a proton diffusion coefficient of 0.20 Å$^2$/ps and a Grotthuss hopping rate of 1/36 ps$^{-1}$, and both results are in good agreement with experiment. Despite the prevalence of a classical-like imidazolium structure with highly localized protonic charge defect, the charge delocalization was found to not be negligible process in the simulations. Rather, it was shown to enhance the rate of proton diffusion by approximately 40\% through Grotthuss shuttling. Analysis of the MS-EVB states revealed that the imidazolium ion’s first solvation shell by imidazole molecules is highly ordered, through the formation of hydrogen bonds, while the second solvation shell is highly disordered. Together with the importance of charge delocalization, this result demonstrated that reorientation of imidazole rings in the second solvation shell is the rate-limiting step for proton transfer.

**Future Directions**

Now that the atomistic-scale reactive MD (SCI-MS-EVB) simulations of proton transport in PEMs are well in hand, the role of polymer morphology in defining the mesoscopic proton conductance behavior can begin to be explored. This effort will involve increasingly larger SCI-MS-EVB simulations for select PEM morphological models, coupled to new mesoscopic simulation methods to describe both the polymer morphology and the proton transport on a unified, larger length and time scale, footing.

Objectives:

The long-term goal of this program is to create materials and methods that can be used to fabricate ultrathin (< 10 nm) membranes for the separation of H₂ from CO₂. The immediate objectives of this research are to examine the feasibility of (i) creating thin films via the layer-by-layer (LbL) deposition method, which exhibit reverse size-selectivity, and (ii) introducing a molecular sieving mechanism into ionically cross-linked (i.e., “glued) Langmuir-Blodgett (LB) bilayers.

Technical Barriers:

Of the three main methods that are currently available for separating gases (i.e., adsorption, cryogenic and membrane methods), it is membrane technology that holds the greatest opportunity for improvement. Based on current technologies, it has proven difficult to prepare membranes that are thinner than ca. 100 nm without introducing major defects and losing selectivity. Thus, the creation of defect-free membranes that are less than 10 nm in thickness, which afford high flux rates and permeation-selectivities that exceed the “upper-bound”, would significantly increase the competitiveness of membrane technology for gas separations. This program seeks to create such membranes for the separation of H₂ from of CO₂.

Abstract.

An ionic linker strategy has been developed for converting poly(ethylene oxide) into a polyanion that can form polyelectrolyte multilayers (PEMs) via the layer-by-layer deposition method. These polyanions have been combined with poly(allylamine hydrochloride) (PAH) to produce 7 nm-thick membranes having modest reverse He/CO₂ permeation selectivity favoring CO₂ by a factor of 1.3, and exceptional CO₂/N₂ size-selectivity, favoring CO₂ by a factor of >200. For these measurements, He has been used as a surrogate for hydrogen for safety reasons. In addition, a calix[5] arene-based surfactant has been synthesized that will be used to test the feasibility of introducing a molecular sieving mechanism into ionically cross-linked (i.e., ‘glued) Langmuir-Blodgett (LB) bilayers.

Progress Report

A. Reverse Selectivity of Layer-by-Layer Thin Films Derived From a Poly(ethylene oxide)-Based Polyelectrolyte. Polymers that contain poly(ethylene oxide) (PEO) are of considerable current interest as membrane materials for the separation of acid gases from light gases and hydrocarbons; e.g., the removal CO₂ from H₂/CO₂ and CO₂/N₂. The main virtue of PEO for such separations is its affinity towards CO₂, which results in relatively high solubility and permeability. In principle, the creation of ultrathin PEO-based films that combine high flux rates with such selectivity properties could lead the way to advanced materials and processes for the purification of hydrogen, as well as the removal of CO₂ from flue gases. While there have been several reports in the literature of gas permeation across polyelectrolyte multilayers (i.e., PEMs), to our knowledge, none have exhibited preferential CO₂ permeation over H₂ with film thicknesses below 10 nm.

We have now shown how poly(ethylene oxide) (PEO) can be converted into a polyelectrolyte using an ionic linker strategy, and that this polymer is suitable for forming polyelectrolyte multilayers (PEMs) (Scheme 1). Specifically, we showed that I can combine with poly(allylamine hydrochloride) (PAH) to form (PEMs) via the layer-by-layer (LbL) deposition method (Scheme 2). We have also shown that such materials, in the form of 7 nm thin films, exhibit reverse size-selectivity favoring the permeation of CO₂ over He by a factor of 1.3. In the course of these studies, we also discovered that the permeation selectivity with respect to CO₂/N₂ (flue gas) has been found to be exceptional, favoring CO₂ over N₂ by a factor >200.
Significance. This work has led to the introduction of a fundamentally new structural motif of polyelectrolytes that can be used for the construction of PEMs based on an ionic linker strategy. It has also demonstrated the feasibility of creating films that are 7 nm in thickness, which exhibit reverse size-selectivity, when poly(ethylene oxide) is converted into a polyanion. While the reverse He/CO₂ selectivity is only modest for such membranes (i.e., ca. 0.8), its size-selectivity for CO₂/N₂ (>200) is exceptional; the latter could be practical interest for membrane-based separations of flue gas.

B. A Calix[5]arene for Glued Langmuir-Blodgett Membranes. During the course of the current grant period, a calix[5]arene-based surfactant, 3, has been successfully synthesized and characterized using the sequence of reactions that are shown in Scheme 3.

Significance. The successful synthesis of 3 now provides us with an opportunity to determine whether a molecular sieving mechanism can be introduced into ionically cross-linked (i.e., “glued”) Langmuir-Blodgett (LB) bilayers. Specifically, since the maximum internal pore diameter of the calix[5]arene framework (0.36 nm) is closer to the kinetic diameter of CO₂ (0.33 nm), as compared to the calix[6]arene framework (0.48 nm), and since H₂ (0.28 nm) has a smaller kinetic diameter, one would expect that molecular sieving could make a significant contribution to the permeation selectivity of calix[5]arene-based, glued bilayers.

Future Directions:

1. Poly(ethylene oxide)-containing Polyelectrolyte Multilayers. Our preliminary results with layer-by-layer thin films made from 1/PAH are sufficiently encouraging that they warrant a detailed examination. Obvious extensions of this work, which will be explored, include a systematic study of the influence of (i) polyelectrolyte concentration, (ii) the size the poly(ethylene oxide) used to form the polyanion, (iii) the molecular weight of the polyanion that is used (iv) the formation of PEMs from polyanions and polycations that both contain poly(ethylene oxide).

2. Introducing a molecular sieving mechanism into ionically cross-linked Langmuir-Blodgett (LB) bilayers. Our expectation is that by decreasing the pore diameter of the calix[n]arene framework from n=6 to n=5, we will observe an intrinsic permeation behavior of this film that crosses the upper bound. Such behavior would lend strong support for a molecular sieving mechanism. To test this hypothesis, we will examine the barrier properties of two types of membranes: LB bilayers that have been glued together with (i) PSS, and (ii) poly(acrylic acid). It should be noted that in
a previous study, we have shown that a calix[6]arene analog of 3, formed glued LB bilayers with poly(acrylic acid) at pH 3.5 having exceptional He/CO₂ permeation selectivity; that is a selectivity of ca. 150, which lies close to the upper bound.¹¹ We think it’s likely that the calix[5]arene analog (3) can “push” the barrier properties of such membranes across the upper bound, but this needs to be confirmed by experiment.

3. A Change from He to H₂. Until now, we have used He, extensively, as a surrogate for H₂ because it has a similar size, similar permeation behavior, and because it is non-combustible. However, we now intend to measure the permeation of H₂, directly, in a fume hood for laboratory safety.

Objectives

Electrodes in solid-oxide fuel cells (SOFC) and electrolyzers (SOE) are typically composites of an electronic conductor and the electrolyte material. The objective of this work is to develop a fundamental understanding of how interactions between the various components of the composite affect catalytic and electrochemical performance. Another objective is to use these insights to design nanocomposites that provide stable, high performance for these applications.

Technical Barriers

A major barrier in the development of SOFC and SOE electrodes is the difficulty in preparing composites that are stable to the conditions under which they will be exposed. Under working conditions, the electrode composites are exposed to high temperatures, low P(O2), and potentially high electric fields at three-phase boundary sites. At the fuel-side electrode, they can be poisoned by sulfur or carbon formation and damaged by redox cycling. Sintering and solid-state reactions between the components are major problems.

Abstract

Oxide-oxide interfaces for fuel and air electrodes in solid-oxide fuel cells and electrolyzers have been studied using cells in which the ceramic-based electrodes were formed by infiltration of porous YSZ with conductive and catalytic components. For the fuel electrodes, it is shown that both a microstructure with porous features and the presence of a catalyst are crucial for good performance. For the air electrode, surface area seems to be the primary factor in determining performance, since cathodes formed from different perovskites, all based on the LaFeO3 but having widely different ionic conductivities, exhibited similar performance. Finally, model studies of perovskite-YSZ interfaces, involving nanoparticles deposited onto a YSZ(100) crystal, show that interactions between the perovskite and the YSZ surface can cause the perovskite to spread over the YSZ surface following high-temperature calcinations.

Progress Report

Work on SOFC and SOE is being carried out in three general areas: 1) Infiltrated SOFC anodes (the cathode for an SOE); 2) infiltrated SOFC cathodes (SOE anodes); and 3) studies of model systems for understanding perovskite-YSZ interfaces.

SOFC Anodes/SOE Cathodes

Most of our recent work in this area has focused on developing ceramic-based anodes because of their stability towards sintering and their tolerance towards carbon and sulfur, relative to the Cu-based anodes that we started with.

A particularly interesting material, developed by a collaborator, Prof John Irvine (St. Andrews University), is La0.8Sr0.2Cr0.5Mn0.5O3 (LSCM), a perovskite that is stable and conductive under reducing conditions. Ceramic anodes were prepared by infiltration with the nitrate salts to produce composites with 45-wt% LSCM in a 65% porous yttria-stabilized zirconia (YSZ) scaffold. SEM micrographs indicate that the LSCM coats the YSZ pores following calcination at 1473 K. Composites produced in this manner exhibited conductivities at 1073 K of approximately 1 S/cm in air and 0.1 S/cm in humidified H2. Although SOFC with LSCM-YSZ anodes exhibited very poor performance at all temperatures, the addition of 0.5-wt% Pd and 5-wt% ceria exhibited maximum power densities at 1073 K of 1.1 W/cm2 and 0.71 W/cm2 in humidified (3 % H2O) H2 and methane, respectively.

To better understand the catalytic requirements of LSCM-YSZ electrodes, fuel-cell performance was measured after the addition of various catalysts to the LSCM-YSZ composite electrodes. The addition of 0.5 to 1-wt% Pd, Rh, or Ni was sufficient to increase the maximum power density of SOFC in humidified H2 at 973 K from less than 100 mW/cm2 in the absence of a
catalyst to above 500 mW/cm². The addition of either 1-wt% Fe or 5-wt% ceria also improved power densities but to a lesser extent. Finally, the use of Pt paste as the current collector increased performance to a similar extent as intentionally adding a catalyst, showing the importance of using inert materials in electrode testing.

Because LSCM has a low ionic conductivity and appears to form a coating over the YSZ, the high electrode performance that we achieved was very surprising; therefore, we made various measurements to understand why this was the case. Scanning electron microscopy (SEM) showed that the LSCM underwent microstructural evolution upon heating and redox cycling. Although the LSCM formed a film on the YSZ scaffold after heating to 1473 K, treating this microstructure at 1073 K in H₂ caused the formation of an interconnected array of ~10nm scale particles, offering an attractive structure with extensive triple phase boundary regions where electrochemical reactions can occur. Thermodynamic measurements (coulometric titration) demonstrated that the reduction of LSCM and La₀.₉Sr₀.₁MnO₃ (LSM) occur over a similar range of P(O₂) and that reduction is the likely cause for formation of the microscale array.

**SOFC Cathodes/SOE Anodes**

Based on the hypothesis that the ionic conductivity of the perovskite is critical in determining the performance of perovskite-YSZ composites when used as the air electrode, we measured the ionic conductivity of La₉Ni₀.₆Fe₀.₄O₃ (LNF) and La₀.₉Sr₀.₁Ni₀.₆Fe₀.₄O₃ (LSNF), as well as LaFeO₃ with Ba, Sr, and Ca dopants. All of these materials are good electronic conductors and but their ionic conductivity differed by more than 10². We then tested fuel cells with cathodes made by infiltration of each of these perovskites, followed by calcinations to either 1123 K (at which temperature each of the perovskites formed small particles on the YSZ scaffold) or 1373 K (at which temperature each formed a film). None of the perovskites underwent solid-state reactions with the YSZ at 1373 K. The performance of the fuel-cell electrodes was found to be indistinguishable for each of the perovskites, raising the question concerning whether ionic conductivity really is a limiting factor in cathode performance.

To determine whether the addition of infiltrated catalysts could influence the performance of cathodes, we examined the effect of adding various dopants to composite cathodes prepared by infiltration of either LSF or La₀.₉Sr₀.₁MnO₃ (LSM) and calcined to either 1123 or 1373 K. The addition of dopants had little influence on the 1123-K composite electrodes but all dopants tested improved the performance of the 1373-K composites. With 1373-K, LSF-YSZ electrodes, the open-circuit impedances decreased dramatically following the addition of 10-wt% YSZ, 0.5-wt% Pd, 10-wt% Ce₀.₈Sm₀.₂O₁.₉ (SDC), 10-wt% CaO, and 10-wt% K₂O. Similarly, the 1373-K, LSM-YSZ electrodes were enhanced by the addition of 10-wt% CeO₂, 1-wt% Pd, and 10-wt% YSZ. Since the improved performance was close to that of the corresponding LSF-YSZ and LSM-YSZ electrodes that had been calcined to only 1123 K, we concluded that the improvement was related to structural changes in the electrode, rather than improved catalytic properties or ionic conductivity.

**Model Perovskite-YSZ Interfaces**

The interaction between LSM nanoparticles and a YSZ(100) crystal was investigated in order to understand the structural changes that occur with increasing annealing temperature. Measurements were performed using AFM, XPS, and SEM/EDX. After depositing nanoparticles of LSM directly onto YSZ(100), samples were annealed from 1123 to 1523 K. The particles gradually decreased in height and eventually disappeared completely. Subsequent reduction in H₂/H₂O at 973 K resulted in the reappearance of nanoparticles. Studies were carried out on identical regions of the sample allowing the same nanoparticles to be characterized at different temperatures. Morphological changes indicate the formation of a thin layer of LSM, and XPS results support that observation by indicating an increase in signal from the La and Sr and a decrease in signal from the Y and Zr with increasing temperature. SEM/EDX was used to verify that the nanoparticles in the reduced sample contained La. The changes in the LSM/YSZ morphology may be important in explaining the non-stationary behavior observed in operating fuel cells.

Abstract, Progress Report and Future Directions

We have performed multi-scale simulations of proton transport, water percolation and membrane dynamics in a number of promising fuel cell membranes. Our work takes into account the membrane morphological changes with hydration level, but is also informed by detailed *ab initio* quantum chemical calculations. At the most fundamental scale, our simulations capture the quantum mechanical characteristics of proton transfer as a function of hydration level for models of existing and proposed membranes. This provides us with fundamental understanding of the role of acidic pendants in proton dissociation. At the next higher level, our simulations determine the changes in proton hopping as a function of hydration level using quantum hopping molecular dynamics (Q-HOP MD) that is parameterized based on quantum chemical calculations. We are also using quantum mechanics/molecular mechanics (QM/MM) simulations starting from equilibrated configurations generated by classical MD to examine combined proton and water molecule transport. At higher scales, we use classical MD with reactive and conventional force fields to compare changes in membrane morphology and water network percolation in hydrated Nafion®, Dow, Hyflon, SPEEK and Sulfonyl-Imide-based novel membranes. We are also exploring structure and dynamics in ionic liquids, such as triflic acid and diethylmethyl amine to understand anhydrous membranes. These simulations provided an integrated understanding of the influence of acidity and water network percolation on conductivity of PEMs.

*Ab initio* electronic structure and dynamics of acidic pendants in PEMs: We have examined proton dissociation in acidic units that are the building blocks for several promising polymeric electrolyte fuel cell membranes. Minimum energy structures for four acidic moieties with clusters of up to 6 water molecules were determined using density functional theory at the B3LYP/6-311G** level starting from chemically rational initial configurations. The perfluorosulfonylimide acid group (CF$_2$CF$_2$SO$_2$NHSO$_2$CF$_3$) was observed to be the strongest acid, due to the substantial electron withdrawing effect of both fluorocarbon groups. The hydrophilic functional group (CH$_3$OC$_6$H$_4$OCH$_2$C$_6$H$_4$SO$_3$H) of sulfonated polyetherether ketone (SPEEEK) membrane was found to be the strongest base with the acidic proton dissociation requiring the addition of six water molecules and the hydrated proton being more tightly bound to the conjugate base. Even though both perfluoro sulfonyl
imides and sulfonyl acids (hydrophilic functional groups for sulfonyl imide and Nafion® ionomers respectively) required only three water molecules to exhibit spontaneous proton dissociation, the largest possible solvent-separated hydronium ion was attained only for the sulfonyl imide moiety. These results provide a scientific basis for understanding the improved conductivity of perfluorinated sulfonyl imide-based membranes relative to that of the widely-used Nafion® membrane.

**Water network percolation and proton hopping in Nafion membrane:** We have used percolation analysis following classical MD simulations of Nafion® for a large number of hydration levels \( \lambda = 1, 3, 5, 7, 9, 11, 13.5 \) and 20 water molecules per sulfonate groups) to examine water clustering, connectivity of clusters and persistence of spanning clusters as a function of hydration level in Nafion® membrane. We have also used quantum hopping (Q-HOP) molecular dynamics method to compute the mean residence times (MRTs), rate constants and activation energies for proton transfer. At low hydration levels \( \lambda \leq 5 \), clusters of water molecules and hydronium ions are isolated from each other and proton residence time on a water molecule is about 220 ps at 300 K. The average number of clusters decreases from more than 25 for \( \lambda = 5 \) to fewer than 4 for \( \lambda = 7 \). Multiple SO\(_3^–\) groups confine the H\(_3\)O\(^+\) ion. Vehicular proton transport is hindered by steric hindrance and long-range structural transport is not possible due to the lack of connectivity of H\(_2\)O molecules.

Water network percolation occurs between \( \lambda = 5 \) and \( \lambda = 6 \) in agreement with estimates based on infrared spectroscopy experiments. This threshold was determined based on multiple criteria. In fact, we have proposed a new criterion for detecting percolation based on the relative probabilities of finding water molecules in the smallest and largest clusters. Near the percolation threshold, clusters are linked from time to time by mobile H\(_2\)O molecules, so that transient spanning clusters form and disappear. At high hydration levels \( \lambda \geq 9 \), a persistent spanning cluster permeates the membrane and creates water channels along which the proton can hop. At high \( \lambda \), the proton residence time on a H\(_2\)O molecule drops by two orders of magnitude from the value at low \( \lambda \). At higher hydration, proton transfer is faster due to ease of solvation of the proton, whereas at higher temperatures, protons are more mobile because thermal effects generate a larger number of favorable proton transfer geometries. At high \( \lambda \), the rate constants approach that of proton transfer in bulk water. The proton diffusion coefficient for \( \lambda = 15 \) at 300 K is about 1.1x10\(^{-5}\) cm\(^2\)/s in good agreement with experiment. The understanding of water percolation and dynamics of proton transfer generated by this work could help in the design of future polymer membrane materials that have lower uptake of water and yet offer faster proton transfer and transport.

**Nanophase structural dynamics of phenylated sulfonated poly ether ether ketone (Ph-SPEEK membrane):** We used classical MD to model solvated Ph-SPEEK membranes in the presence of hydronium ions. We characterized the nanophase structure and dynamics as a function of hydration level for \( \lambda = 3.5, 6, 11, 25, \) and 40; where \( \lambda \) is the number of water molecules per sulfonyl group. Pair correlation function analyses reveal that the nanophase segregation increases with salvation. The water and hydronium ion diffusion coefficients also increase with \( \lambda \). While the average number of hydrogen bonds between hydronium ions and sulfonyl groups are dramatically affected by the hydration level, their average lifetime remains constant. The membrane is found to be relatively rigid and its overall flexibility shows little dependency as a function of water content. Compared to Nafion®, water and ion diffusions are considerably smaller at lower hydration levels at room temperature. However, at \( \lambda = 25 \) and 40 these coefficients are comparable to that of Nafion® at

**FIGURE 1.** Perspective projection of H\(_2\)O molecules and H\(_3\)O\(^+\) ions in Nafion for hydration levels of \( \lambda = 3 \) and 13.5. SO\(_3^–\) is shown as a large (yellow) bead. The backbone and pendant are shown as a transparent surface. Both percolation probability and spanning cluster formation probability reach almost 1.0 for \( \lambda \geq 7 \).
the same solvation levels. This study also indicates that solvent diffusion for Ph-SPEEEKK membranes at low hydration levels can be significantly improved at high temperatures.

Future directions include ab initio molecular dynamics of proton transport in model hydrated pendants and ionic liquid systems; extension of QM/MM simulations to novel membranes; and large scale massively parallel reactive force simulations of the anode/electrolyte interface. The proposed work addresses several different length scales and represents the logical progression of effort from the work accomplished to date under this project.

This work is supported by the Division of Chemical Sciences, Office of Basic Energy Sciences, U.S. Department of Energy (DOE). The computations were performed using the Molecular Sciences Computing Facility (MSCF) in the Environmental Molecular Sciences Laboratory (EMSL), a national scientific user facility sponsored by the DOE’s Office of Biological and Environmental Research (OBER) and located at PNNL. This work benefited also from resources of the National Energy Research Scientific Computing Center (NERSC), which is supported by the Office of Science of the U.S. DOE.

Objectives

The program aims to design, synthesize and test rare earth phosphate materials for proton conducting applications in the temperature region of 300-550 degrees Celsius. The program relies on three major approaches: a theoretical understanding of proton conduction in rare earth phosphates employing quantum chemical computation and molecular simulation; the chemical design, synthesis, and proton conductivity measurement of nano-composite materials expected to exhibit facile proton conduction; and the structural and dynamical characterization of the nano-composite materials using a range of advanced characterization methods including nanoscale structural and chemical electron microscopy, vibrational and x-ray spectroscopy, and nuclear magnetic resonance (NMR).

Technical Barriers

Hydrogen, as well some biofuels, can be advantageously used for electric power generation in fuel cells that can operate between 350-550°C, significantly lowering materials cost, simplifying catalysis, and extending fuel cell lifetimes. An essential component to enable this technology is the development of appropriate proton conducting membranes. However, these membranes are not presently available. This program examines the fundamental aspects of proton conduction in doped rare earth phosphates to provide such membranes.

Abstract

Lanthanum and Cerium phosphates with modified grain boundaries were synthesized and characterized, showing proton conductivity in amorphous, nanometer grain boundary layers as high as 10⁻³ S/cm at 500°C. First principles computation revealed that proton conduction in rare earth phosphates, such as LaPO₄, proceeds by intertetrahedral hopping. Temperature-dependent °H MAS-NMR results below 150°C confirmed computed proton activation energies for local motion. It was shown that dramatic increases in proton conductivity in La-phosphates resulted from the introduction of Al, Sr, and Ca leading to glasses and glass-ceramics conductors with a conductivity of ~10⁻⁴ S/cm at 440°C in dry argon, a record to date. The (LaSrAl)PO₄ glasses have a melting point of about 800°C, and can allow for easy membrane production by common glass processing methods, and may be thermally manipulated further to yield nanocomposite glass-ceramics with even higher expected conductivities. This finding points to way to easily-fabricated thin proton conducting membranes for hydrogen/air fuel cells operating in the technologically advantageous range of 300-500°C.

Progress Report

The electrical properties of [La(1-x)Mₓ]P₃O₉ metaphosphate glasses, where M is Ba, Sr, Ca, and 0≤x≤0.8 were investigated in the 300 – 500°C range. The protonic conductivity increases two orders of magnitude from the unsubstituted to the 60% substituted glass reaching a maximum conductivity of about 10⁻⁵ S/cm at 450°C. The activation energy is found to be approximately independent of concentration though dependent on the type of modifying substitutional cation, and decreases from about 1.04 eV for Ca and Sr to ~ 0.96 eV for Ba. AC impedance measurements were used to find the DC ionic conductivities. Mean ion travel distances at the frequencies, νZ* or νΜ*, associated with the maximum in Z” or M” were found to be up to 30 times larger than the average oxygen spacing in the glasses. While diffusion coefficients derived from conductivities, Dσ, were vastly lower than an uncorrelated diffusion coefficient computed from first principles, the travel distance at νZ* or νM* derived from a simple random walk expression using DΓ were surprisingly close to those derived from the more rigorous statistical treatments. The ratio ξ=Dσ/DΓ<<1 may be interpreted as indicative of highly correlated ion motion and strongly reduced mean attempt frequencies, together with a mean activation energy for motion increased by ΔE=Eσ-EΓ over that of the uncorrelated intertetrahedral motion of an ideal crystal characterized by DΓ.
Al$_2$O$_3$ was added to a 2CaO-La$_2$O$_3$-5P$_2$O$_5$ metaphosphate, to replace 10% of the Ca$^{2+}$ ions by Al$^{3+}$, forming a phosphate with the nominal composition 1.8CaO-0.1Al$_2$O$_3$-La$_2$O$_3$-5P$_2$O$_5$. The effect of Al$_2$O$_3$ addition and heat treatment on the microstructure and conductivity of the resulting glass-ceramics was investigated by XRD, SEM, TEM, and AC impedance spectroscopy. Upon transformation from glass to glass-ceramic, conductivities increased significantly. The glasses were isochronally transformed at 700°C and at 800°C for 1 hr or 5 hrs, in air, following heating at 3 or 10°C/min. With Al$_2$O$_3$ addition, after a heat treatment at 700°C, 100–300 nm nano-domains of LaP$_3$O$_9$ crystallized from the glass matrix. Annealing at 800°C produced a further order of magnitude conductivity increase for the Al-free glass, but less so for the Al-containing glass.

Structural and electronic properties of cerium orthophosphate (CePO$_4$), a mixed electronic and protonic conducting electrolyte, are calculated using density functional theory (DFT) and beyond, and compared with experiments. A Hubbard-like parameter U is employed to reduce the self-interaction for localized Ce 4f states. As U is varied from 1-5 eV, the band structure is found to undergo significant changes, with the Kohn-Sham gap varying between 0.8 and 4.3 eV. Interestingly, the lattice parameters are unchanged, indicating structural properties are far less sensitive to U. The valence band energies and the optical band gap of CePO$_4$ are measured using photoemission and optical reflectance spectroscopy. The structure was determined using XRD. The choice of U = 3 eV provides the best match between the calculated density of states and the experimental photoemission and optical reflectance spectra. The activation energy of the minimum energy path for proton transfer will be calculated and compared to that of LaPO$_4$, another proton conducting electrolyte.

Rare earth phosphate ceramics have been investigated as proton conductors for applications in fuel cells, hydrogen sensors, and hydrogen separation membranes. Protons are incorporated into the materials as charge-compensating defects when the phosphates are doped with aliovalent cations. Protons bond to oxygen atoms on the phosphate tetrahedra and are thought to move through the material via intertetrahedral transfer. Lanthanum orthophosphate (LaPO$_4$), a monoclinic material with space group P21/n, is an established proton conductor. This behavior is thought to be due to mixed proton and hole conductivity. Under reducing conditions, proton conductivity is thought to dominate, whereas under oxidizing conditions, the carrier is thought to be electron holes.

**Future Directions**

- Doped nanocomposite RE-phosphates are synthesized from quenched glass melts, by controlled thermal annealing to manipulate the glass-ceramic nucleation and growth, to exploit conductivity enhancement that can result from such architectures.
- First-principle calculations at NERSC in conjunction with conductivity measurements and heteronuclear correlation and pulsed gradient NMR are used to elucidate the proton conduction mechanisms.
- Advanced high resolution chemical and structural characterization carried out in the facilities at the National Center for Electron Microscopy and the Molecular foundry to support NMR and vibrational spectroscopy studies.
- AC and DC conductivities are measured on the REP glasses and glass ceramics as a function of composition and water vapor exposure, to determine the proton transference numbers.
- Detailed structural elucidation of the nanocomposite materials is done using several multidimensional and multi-quantum NMR techniques, with an emphasis on understanding the impact of aliovalent substitution on proton dissolution in rare earth phosphates.

Objectives

We are seeking to understand the connections between the hydrated morphology and the local dynamics of water in polymer electrolyte membranes (PEMs) of different equivalent weights (EWs) at various hydration levels through the measurement of their dielectric response. Dielectric relaxation behavior provides correlations between the polymer environment and the cooperative solvent dynamics, which can unveil important insights into water and proton transport in these membranes.1,2 It is widely accepted that water confined in systems such as reverse micelles possesses different dynamics as compared to bulk/free water.3,4

The choice to conduct measurements at microwave frequencies (1 to 20 GHz) is due to the observation that the principal absorption band, attributed to a Debye type relaxation of molecular origin, in pure bulk water occurs at about 18 GHz.3-5

Technical Barriers

All hydrated PEMs were removed from their equilibration chamber just prior to the dielectric measurement at room temperature in open atmosphere using single post dielectric resonators (SPDR). However, we observed that there is a rapid loss of water in them. As the dielectric properties are strongly dependent on the water content, it is critical to precisely control the RH of the test environment. Also, the SPDRs were unable to yield the dielectric constants for hydrated Nafion® 117 (thickness 185 microns) because the Q factor of the resonator with this sample under test is smaller than 100.

Abstract

EW is an important factor in determining the structure of the membrane and the dynamics of protons and water molecules within the membrane. The behavior of the acid form of the polymer is dramatically affected by the presence of water. The dielectric properties of PEM are dictated by the molecular structure of the system and the physical state of water in these materials. The dielectric spectra can provide insights into both the state of water and indirectly, the hydrated structure of polymer. Thus, knowledge of the state or nature of the water in the membrane is critical to understanding the mechanisms of proton transfer and transport in PEMs.

When hydrated, these membranes exhibit a nanophase-separated morphology with the hydrophobic backbone of the polymer separated from a network of water and ions (both fixed SO3⁻ groups and hydrated protons).6 The rigidity of the backbone and the crystallinity of the polymer confine the water; and with the significant density and distribution of the pendant anionic groups give structural ordering to the water in the membrane.7,8

Project Report and Future Directions

The split-post dielectric resonator (SPDR) technique is a well established and accurate method for characterization of the dielectrics in the laminar forms up to 20 GHz.9,10 Since no electrodes are involved this method, measurements are not affected by electrode/ferroelectric interfacial effects (i.e. dead layer). The split-post resonator consists of two low loss dielectric packs in a metal enclosure. The resonator uses TE01δ mode of the electromagnetic field, which is insensitive to the presence of air gaps between the tested sample and the dielectric resonator. Our SPDRs were custom built to measure the dielectric response frequencies of: 1.9, 5, 10, 15, 18 and 20 GHz. The characterization of a PEM sample consists of two steps through measurement of the resonant frequency and quality factor of the (i) empty resonator, and (ii) resonator with the membrane. The first measurement provides the input for calculation of the dielectric permittivity. The real part of the complex permittivity is computed from the measured resonant frequencies with a SPDR both with and without the membrane sample from the following equation:

$$\varepsilon' = 1 + \frac{f_0 - f_s}{hf_0K_\varepsilon (\varepsilon', h)}$$
where \( h \) is the thickness of the measured substrate, \( f_0 \) is the resonant frequency of the empty SPDR, \( f_s \) is the resonant frequency of the SPDR with the dielectric sample, and \( K_\varepsilon \) is a function of \( \varepsilon_r \) and \( h \). The latter is calculated for a number of \( \varepsilon_r \) and \( h \) using the Rayleigh-Ritz technique. An iterative procedure is used to evaluate the values of \( K_\varepsilon \) and \( \varepsilon_r \) from the above equation.

All the PFSA membranes (including Nafion\textsuperscript{®} 117, Solvay E8705S, etc) were pretreated by cleaning in 1M HNO\textsubscript{3} at 80\(^\circ\)C for 1 hr and in DI water at 80\(^\circ\)C for 1 hour. They were then washed in DI water and stored in deionized water prior to placement in the SPDR for measurement under fully hydrated conditions. The films were weighed after removing any surface water to obtain the wet weight. They were then dried over P\textsubscript{2}O\textsubscript{5} for determination of the dry weight.

The isopiestic equilibration scheme of Pushpa et al\textsuperscript{11} was employed to control the membrane water content, enabling the study of the relative permittivity of the membranes over a range of water contents. Equilibration of the samples over the aqueous LiCl is critical in establishment of reliable and reproducible water contents in the membrane. The dried membranes were then equilibrated over aqueous LiCl solutions for at least 1 week. The concentrations of the LiCl solutions were selected to encompass the different regions' observed on the water adsorption isotherms for Nafion\textsuperscript{®} 117 as shown in Table 1.

**TABLE 1. Water adsorption isotherm data for Solvay films (EW 790 and 870)**

</table>

The water adsorption isotherm data for the Solvay films (Table 1) was obtained by measuring the weight of the films under fully hydrated conditions (100% RH), and following 1 week of equilibration in chambers at 96.4% RH and 75% RH. The dry weight of each of the films was also obtained by drying them over P\textsubscript{2}O\textsubscript{5} for a week. The water uptake was calculated from the following:

\[
\lambda = \left( \frac{W_{\text{wet}} - W_{\text{dry}}}{18.015} \right) \left( \frac{\text{EW}}{W_{\text{dry}}} \right)
\]

Hence, it is critical that the RH of the samples be controlled precisely during the actual measurements. We have designed a relative humidity controlled glove box for future experiments that will enable us to perform all our measurements under precisely controlled conditions of humidity and temperature. The equilibrated films, SPDRs, and weighing balance will all be placed in the glove box at a previously set RH to coincide with the activity of the LiCl solution and then equilibrated prior to making the dielectric measurements in-situ. The loss from these membranes in air. As the dielectric properties are strongly dependent on the water content, the dielectric constant depends on how long the sample has been out of the chamber as shown in Figure 2.
dielectric response of completely dry samples of Solvay PEM (EW870) was measured at 1.9 GHz, 5.2 GHz and 10 GHz as shown in Figure 3. The values varied from 3.8 to 3 as frequency changed from 1.9 GHz to 10 GHz.

Our SPDRs were unable to measure the dielectric constants for fully hydrated Nafion® 117 with a thickness of 185 µm. From the graph in Figure 4, it is clear that the resonant frequency shifts can be substantial in thick high permittivity samples. The SPDR cannot measure the permittivity of the sample if the Q factor of the resonator with sample under test is smaller than 100. It is recommended to keep resonant frequency with sample within 10% of the resonant frequency of the resonator. If the Q factor < 100 or the resonant frequency shift > 10%, spurious modes, whose frequencies are changing faster with permittivity than for the TE mode, may overlap with the proper mode disturbing measurements. For all our future measurements we will use Nafion® 112 as our standard material. It has the same EW as Nafion® 117 but with a thickness of 51 microns.

We also plan to cast our own films on glass substrates using ionomer solutions of different EWs to achieve the desired thickness.

VI. MANUFACTURING R&D
INTRODUCTION

The Manufacturing R&D (research and development) sub-program supports research and development needed to reduce the cost of manufacturing hydrogen and fuel cell (FC) systems and components. The manufacturing R&D effort will enable the mass production of components (in parallel with technology development) and will foster a strong domestic supplier base. Activities will address the challenges of moving today's laboratory-produced technologies to high-volume, pre-commercial manufacturing to drive down the cost of hydrogen and FC systems.

In Fiscal Year (FY) 2010, manufacturing projects continued in the following areas: novel electrode deposition processes for membrane electrode assembly (MEA) fabrication, high-volume FC leak-test processes, novel assembly processes for low-cost MEAs, gas diffusion layer cost reductions, and fabrication technologies for high-pressure composite storage tanks.

GOAL

Research and develop technologies and processes that reduce the cost of manufacturing FCs and related systems.

OBJECTIVES

- **Fuel Cells** — Presently, FC stacks are fabricated in very small quantities, and the cost of these stacks for non-automotive applications is approximately $5,000/kW (at volumes of tens of units), which is more than 20 times the projected cost of about $140/kW for stacks in 2010 at low volume (1,000 stacks/year) and over 60 times the cost of $25/kW at high volume (500,000 stacks/year) for automotive applications. The projected high-volume cost includes labor, materials, and related expenditures, but does not account for manufacturing R&D investment. The objective of manufacturing R&D is to enable cost reduction in fuel cell stacks for stationary and transportation power systems.

- **Hydrogen Storage** — The objective of hydrogen storage manufacturing R&D is to reduce the cost of making high-pressure carbon composite hydrogen storage tanks by a factor of 10 from 2010 costs, to be in line with the Hydrogen Storage sub-program’s cost targets.

FY 2010 TECHNOLOGY STATUS

This sub-program focuses on the manufacture of component and FC technologies that will be needed in the early stages of commercialization. Research investments are focused on reducing the cost of components currently used (or planned for use) in existing technologies, as well as reducing the cycle times of the processes being developed. Progress toward attaining the manufacturing R&D goals is measured in terms of the ability of funded research to reduce the cost of producing FCs, and to increase manufacturing processing rates and annual manufacturing capacity.

3 Ibid.

The current costs for hydrogen and FC technologies are about $20/kWh for a 700-bar gas-phase hydrogen storage system (projected to high volume) and about $3,000/kW for polymer electrolyte membrane FC stacks fabricated at very low volume.

**FY 2010 Accomplishments**

FY 2010 saw a number of advancements in manufacturing of FCs and storage systems:

- **Gas Diffusion Layer (GDL) Fabrication:** Ballard developed a process model for controlling GDL coating conditions, resulting in significant improvement in quality yields and GDL cost reduction of 53%.
- **Electrode Deposition:** W.L. Gore demonstrated—using their cost model—that a new three-layer MEA process has the potential to reduce MEA cost by 25%.
- **High Pressure Storage:** Quantum and Boeing demonstrated advanced filament winding and fiber placement processes that reduce storage system costs by 10%.
- **MEA Manufacturing:** BASF developed a predictive model and evaluated electrode variation and defect impacts on MEA performance using their new on-line X-ray fluorescence (XRF) technique.
- **Stack Testing:** UltraCell constructed and tested their leak-test and conditioning stand.
- **Component and Stack Measurement:** The National Renewable Energy Laboratory developed and tested an internal resistance-based test stand for detection of multiple defects such as pinholes, electrical shorts, and electrode thickness variations.
- **Sensors:** The National Institute for Science and Technology developed and tested non-contact sensors for bipolar plate process control.

**Budget**

The President’s FY 2011 budget request for the Fuel Cell Technologies Program includes $5 million for Manufacturing R&D.

---

FY 2011 Plans

In FY 2011, activities in the Manufacturing R&D sub-program will reduce MEA cost by 25%, reduce storage system costs by 10%, demonstrate impact on MEA performance through use of on-line XRF techniques, further reduce GDL costs beyond the 53% reduction already achieved, further develop stack leak testing, and further develop NREL’s component and stack measurement capabilities. The Program plans to initiate a solicitation for manufacturing process improvement for high-temperature stationary-power FC systems and will complete a process model for high-temperature stationary FC manufacturing.

VI.1 Fuel Cell Membrane Electrode Assembly Manufacturing R&D

Objectives

NREL and its collaborators are developing capabilities and knowledge related to in-line quality control that will assist manufacturers of polymer electrolyte membrane (PEM) fuel cell membrane electrode assembly (MEA) components (membranes, coated electrodes, and gas diffusion media) in transitioning to high-volume manufacturing methods. Our main tasks are to:

- Evaluate and develop in-line diagnostics for MEA component quality control and validate diagnostics in-line.
- Investigate the effects of MEA component manufacturing defects on MEA performance and durability.
- Further refine and validate models to predict the effects of local variations in MEA component properties.

These objectives have strong support from our industry partners. Our specific development activities have been and will continue to be fully informed by direct input from industry. As new technologies emerge and as the needs of the industry change, the directions of this project will be adjusted.

Technical Barriers

This project addresses the following technical barriers, from the Manufacturing R&D section (3.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of High-Volume Membrane Electrode Assembly (MEA) Processes
(F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing Milestones

This project is contributing to achievement of the following DOE milestones, from the Manufacturing section (3.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 1: Develop prototype sensors for quality control of MEA manufacturing. (4Q, 2011)
- Milestone 2: Develop continuous in-line measurement for MEA fabrication. (4Q, 2012)
- Milestone 3: Demonstrate sensors in pilot-scale applications for manufacturing MEAs. (4Q, 2013)
- Milestone 4: Establish models to predict the effect of manufacturing variations on MEA performance. (4Q, 2013)

Accomplishments

NREL has accomplished the following:

- Developed a system and techniques to identify by areal infrared thermography various MEA and MEA component defects, such as membrane pinholes, electrode catalyst non-uniformity, micro-cracks in gas diffusion media, and MEA shorting.
- Extended our membrane thickness imaging technique to non-polyfluorosulfonic acid (PFSA) membranes and PEM electrolysis membranes.
- Installed and commissioned a research web-line to simulate continuous roll-to-roll processing of MEA component materials for evaluation of diagnostics under process-like conditions.
• Demonstrated fabrication methods to repeatedly create membrane and electrode defects that simulate real as-manufactured defects to study the effects of defects on MEA performance.
• Used LBNL models to qualitatively explain key behaviors of MEAs with defects and to understand the behavior of MEAs under the different excitation diagnostic techniques.
• Continued collaboration with three of DOE’s competitively awarded manufacturing research and development (R&D) projects, in accordance with our project charter.
• Completed work on a Phase I Small Business Innovation Research project with partner Proton Energy Systems related to quality control measurements on PEM electrolyzer MEAs.

Introduction

In Fiscal Years (FYs) 2005-2007, NREL provided technical support to DOE in developing a new key program activity: Manufacturing R&D for hydrogen and fuel cell technologies. This work included a workshop on manufacturing R&D, which gathered inputs on technical challenges and barriers from the fuel cell industry, and subsequent development of a roadmap for manufacturing R&D. In late FY 2007, NREL initiated a project to assist the fuel cell industry in addressing these barriers, initially focusing on in-line quality control of MEA components. The project is relying on and utilizing the unique and well-established capabilities of NREL’s National Center for Photovoltaics for developing and transferring diagnostic and process technology to the manufacturing industry.

Defects in MEA components differ in type and extent depending on the fabrication process used. The effects of these defects also differ, depending on their size, location in the cell relative to the reactant flow-field, cell operating conditions, and which component contains the defect. Understanding the effects of these different kinds of defects is necessary to be able to specify and/or develop diagnostic systems with the accuracy and data acquisition/processing rates required for the speed and size scales of high-volume continuous manufacturing methods. Furthermore, predictive capabilities for manufacturers are critical to assist in the development of transfer functions and to enable assessment of the effects of material and process changes.

Approach

NREL and its partners are addressing the DOE Manufacturing milestones listed previously by evaluating, developing, and validating (in-line) diagnostics that will support the use of high-volume manufacturing processes for the production of MEA component materials. Prioritization of this work is based on inputs from our industry partners on critical manufacturing quality control needs. We are focusing on diagnostic capabilities not addressed by commercially-available in-line systems. Understanding that specification of the required accuracy and precision of a diagnostic device to measure or identify material property variability or defects requires information about how this variability affects the functionality of the MEA, we are developing test methodologies to identify threshold values of size and/or extent of each important type of variability or defect. Threshold values are being elucidated by statistically designed experiments using MEA components with created defects of defined size or extent. These results will be validated by MEAs with components having actual as-manufactured defects of similar scale. Key behaviors identified by these tests are being modeled to provide additional understanding and, where modeling capabilities are lacking, additional refinement will be made so that predictive capabilities for the identified effects of defects are developed.

Results

Work continued on the NREL-developed optical instrument. We extended the demonstrated capability to image thickness and identify defects of PFSA-based membranes, non-PFSA membranes, and thicker membranes for applications such as direct methanol fuel cells and PEM electrolyzers, an example of which is given in Figure 1. We also progressed in our assessment of using this same general technique to measure catalyst uniformity in an areal fashion. In addition to this optical platform, we evaluated the feasibility of using infrared thermography as a rapid method to check for MEA and MEA component defects. Using work done by several of our industry partners as a basis, we further developed and refined the excitation methods for a variety of target MEA defects. We also assessed the response time of the technique to better understand how it might be applied to in-line process measurements. As examples of the potential of this technique, Figure 2 shows the identification of a void in an electrode coating, and Figure 3 shows the identification of a micro-crack in the microporous layer of gas diffusion media. The inset in Figure 3 shows an LBNL simulation of this defect modeled as a series of discontinuities of thermal and electrical conductivity. With this modeling, we can better understand how to optimize the measurement technique for in-line use. The electrode sample depicted in Figure 2 also is an example of our work to develop fabrication methods for MEA component defects. In this case, we used ultrasonic spraying as a highly repeatable process with excellent control of spray pattern and catalyst loading. The inset graphic

is a validation of the intended loading using X-ray fluorescence. To provide a platform upon which to evaluate these and other diagnostics, we installed and commissioned a research web-line, shown in Figure 4. With this unique capability, and using MEA component roll goods from our industry partners, we will assess the accuracy, repeatability, and resolution of different diagnostic techniques under conditions simulating manufacturing process lines.

**Future Direction**

- Design a prototype in-line configuration for the membrane thickness imaging technique and implement this system on our research web-line.
- Evaluate the feasibility of using infrared thermography as an in-line imaging diagnostic and develop a prototype system to install on the research web-line.
- Complete our evaluation of the NREL-developed optical instrument to measure platinum uniformity of electrodes.

**FIGURE 1.** Two-dimensional image of an alternate membrane material measured with the NREL optical instrument. The image shows bubble and pinhole defects as well as thickness variations (color contrast). An area approximately 3" by 2" is shown.

**FIGURE 2.** Two-dimensional infrared thermography of a 25 cm² electrode fabricated with a 1 cm² void in the center. White indicates higher loading, dark indicates lower loading, with black signifying the absence of platinum. The inset shows a validation of this measurement using an X-ray fluorescence scan from one edge of the sample to the other, through the void.

**FIGURE 3.** Two-dimensional infrared thermography of a commercially-available gas-diffusion layer with a series of micro-cracks in the microporous layer. The inset shows modeling from LBNL simulating this defect as a discontinuity in thermal and electrical conductivity.

**FIGURE 4.** The Research Web-Line
VI. Manufacturing

- Use single and segmented cell test methods to understand threshold sizes for critical MEA component defects like membrane pinholes and electrode voids.
- Study the growth rates of as-manufactured defects in cells.
- Continue to gain critical insights on the electrochemical and thermal behavior of MEAs with defects from the LBNL MEA models.
- Continue to work with our industry partners to ensure the relevance of our studies to their evolving needs and directions.

**FY 2010 Publications/Presentations**

VI.2 Reduction in Fabrication Costs of Gas Diffusion Layers

Objectives

- Reduce the fabrication costs of gas diffusion layer (GDL) products by:
  - Reducing the number of process steps.
  - Replacing batch processes with continuous processes.
  - Utilizing in-line measurement tools to reduce costly ex situ testing.
- Develop and implement new, high volume GDL process technologies.
- Produce high-performance, low-cost GDLs at sufficient volumes for near-term fuel cell markets.
- Research, develop, and implement new in-line process control and measurement tools consistent with high volume manufacturing.
- Advance the understanding of the relationship between process parameters, ex situ GDL properties and fuel cell performance to maximize production of high performance, low-cost GDLs for near-term markets.

Technical Barriers

This project addresses the following technical barriers from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Lack of High-Volume Membrane Electrode Assembly Processes
- Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing Milestones

This project will contribute to the achievement of the following DOE milestones from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 1: Develop prototype sensors for quality control of MEA manufacturing. (4Q, 2011)
- Milestone 2: Develop continuous in-line measurement for MEA fabrication. (4Q, 2012)
- Milestone 3: Demonstrate sensors in pilot scale applications for manufacturing MEAs. (4Q, 2013)

Accomplishments

- Reduced GDL costs by 40% from $36/kW to $21/kW from Fiscal Year (FY) 2008 to FY 2009 by:
  - Increasing the manufactured width from 40 cm to 80 cm wide.
  - Implementing process control tools to improve product uniformity, reduce the amount of ex situ testing and improve yield and scrap rates.
  - Installing new equipment allowing us to process rolls over 800 m long.
- Demonstrated multilayer coating capability on our production line:
  - Produced short rolls of both anode and cathode material.
  - Verified performance of both in a 50 cm² test stand against a commercial baseline material.
  - Addressed issues relating to micro-cracking in the microporous layers (MPLs) by modifying MPL ink properties and modifying process drying conditions.
- Demonstrated the ability to manufacture MPL inks using a dynamic mixer:
  - Produced three separate commercial inks on a 2-inch continuous extruder designed for our process.
  - Produced a short roll of anode material.
Verified performance of this anode GDL in a 50 cm² test stand against a commercial baseline material.

- Identified, purchased and installed new process control tools for multilayer coating, in-line mixing and heat treatment processes.
- Used Raman and Fourier transform infrared (FTIR) spectroscopy to determine the impact of sintering on Teflon® - poly-tetrafluoroethylene (PTFE) distribution in the GDL and are currently developing a link between the size and frequency of PTFE agglomerates and PTFE distribution in the GDL.
- Examined the size and shape of pores in the GDL using high-resolution X-Ray tomography (HRXRT) in an effort to find a link to performance.
- Examined each step of the manufacturing process and found relationships between specific process parameters and critical GDL properties. This will help make a more stable, consistent product and allows for the development of enhanced designs to improve performance in specific applications.

**Introduction**

This project addresses the Manufacturing R&D sub-program’s goal of research, development and demonstration of technologies and processes that reduce the manufacturing cost of proton exchange membrane (PEM) fuel cell systems. Specifically, this project reduces the fabrication costs of high-performance GDL products, while increasing manufacturing capacity and improving product uniformity. The end result of this program will be low-cost, high-performance GDLs for near-term fuel cell markets, such as back-up power or materials handling. A conceptual design of a Greenfield manufacturing plant that is capable of meeting the 2015 GDL target price of $4/kW at specified volumes will also be developed.

**Approach**

The largest barrier to the implementation of fuel cell products is cost. The cost of the GDL was evaluated in 2008 and was determined to be around $36/kW, almost 10 times the DOE cost target for 2015. A breakdown of the cost of the GDL revealed that the majority of BMP’s GDL cost was due to manufacturing labor, specifically for ink mixing, coating and quality control, as shown in Figure 1.

It was determined that much of that cost could be removed by reducing the number of process steps, replacing slow batch processes with faster continuous processes, and utilizing modern on-line tools to improve product quality and reduce the amount of ex situ testing.

**Results**

Throughout the first two years of this project, BMP has been able to reduce the fabrication costs of GDLs by 40% from $36/kW to $21/kW, as shown in Figure 2. This has been accomplished by increasing the manufactured width of the GDL from 40 cm to 80 cm, installing new web-handling equipment to allow for processing of rolls in excess of 800 m long, and implementing better process controls to improve yield and scrap rates. As a result of these efforts, the plant capacity has more than doubled, which allows for production of low-cost, high-performance GDLs at volumes suitable for near term markets.

Ballard has also identified further cost reductions for 2010 and 2011 based on the implementation of multilayer coating and in-line mixing. Initial single cell validation work, shown in Figure 3, has been done to demonstrate that GDLs manufactured with this new technology perform as well as standard baseline materials. For this validation work multilayer coating was performed with standard inks and the in-line ink was applied with standard single layer coating processes, so that each process could be evaluated independently.

In addition to the cost reduction work, Ballard has examined every step in their manufacturing process to find relationships between process variables and critical GDL properties. These relationships have allowed Ballard to make adjustments during processing to meet specific customer targets, allowing for more stable, consistent product leading to improved yield.
VI. Manufacturing

Morgan – Ballard Material Products

rates and cell performance. This work should allow for the development of enhanced GDL designs that are tailored for a specific application and should help in manufacturing parts with tight tolerances.

The Pennsylvania State University, under the direction of Dr. Michael Hickner, is working with BMP to develop an in-line method for measuring the chemical homogeneity of the GDL. Specifically, Penn State is looking at using Raman spectroscopy to determine the PTFE agglomerate size and frequency prior to sintering utilizing one-dimensional scanning, as shown in Figure 4. It is believed that this work will be useful in more accurately controlling the PTFE distribution in the GDL and allow for real-time adjustments of processing parameters to reduce variability both down-web and cross-web. HRXRT is also being used by Penn State to evaluate the effects of pore size and shape on GDL performance. They are also working on actively doping the powders used in the MPL inks, to allow us to determine the amount of penetration or MPL intermixing associated with both of our standard and multilayer coating processes.

Conclusions and Future Directions

BMP was able to significantly reduce the fabrication costs of GDLs, while more than doubling manufacturing capacity and improving product quality throughout Phase 1 of this project. Multilayer coating and in-line mixing technologies have been demonstrated and single-cell validation testing showed no significant performance difference when compared to baseline material. In addition, Ballard has been able to relate critical process parameters to key GDL properties and performance, which will allow for more stable, consistent GDL product, improved GDL design and increased production yields. This work will be beneficial for production of high-performance, low-cost GDLs for near-term fuel cell markets.

The Pennsylvania State University, under the direction of Dr. Michael Hickner, has developed a method for characterizing PTFE distribution in the GDL using Raman scanning. They have also used HRXRT to examine the size and shape of pores in the GDL. This work is important in understanding how variations in the PTFE distribution or pore structure may influence GDL performance.

In the next year, the future activities of this project include:

- Conduct short roll uniformity studies to establish product uniformity with new process technologies.
- Generate a production length roll to demonstrate capability.
- Validate performance of new low-cost GDLs utilizing all new process technologies with both single cell and stack testing.
VI. Manufacturing

• Complete installation of all on-line process control tools including vision system for the coating line.
• Determine manufacturing capability with all new process technologies with a goal of achieving six sigma standards.
• Continue development of process variable, product property, and fuel cell performance relationships to direct new process specifications.
• Continue investigation of Raman scanning and HRXRT work as a method of characterizing GDL properties.

VI.3 Modular, High-Volume Fuel Cell Leak-Test Suite and Process

Objectives

- Design a modular, high-volume fuel cell leak-test suite capable of testing in excess of 100,000 fuel cell stacks per year (i.e., 50 fuel cell stacks per hour).
- Performance leak tests in-line during assembly and break-in steps.
- Demonstrate fuel cell stack yield rate to 95%.
- Reduce labor content to 6 minutes.
- Reduce fuel cell stack manufacturing cost by 80%.

Technical Barriers

This project addresses the following technical barriers from the Manufacturing R&D section (3.5.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing Milestones

This project will contribute to achievement of the following DOE milestones from the Fuel Cells sub-section of the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 9:** Select stack assembly processes to be developed. (4Q, 2010)
- **Milestone 10:** Develop automated pilot scale stack assembly processes. (4Q, 2012)
- **Milestone 12:** Demonstrate pilot scale processed for assembling stacks. (4Q, 2013)

Accomplishments

- Developed a specification for the leak-test suite laboratory prototype.
- Designed leak-test suite prototype.
- Fabricated leak-test suite prototype.
- Installed leak-test suite prototype at UltraCell facility at Vandalia, OH.
- Tested and evaluated leak-test suite prototype.
- Created fuel cell stack quality metrics.
- Developed techniques for analysis of dynamic mechanic analysis data from the leak-test suite prototype.
- Characterized individual fuel cell stack components using leak-test suite prototype.
- Developed a finite element model capable of modeling the dynamic mechanical properties of fuel cell stacks.

Introduction

There are three fluid circuits in a fuel cell stack. Any fluid leakage between these circuits or to the external atmosphere leads to reduced individual cell or stack performance and results in a failure during stack testing. Fuel cell stacks are typically hand assembled and tested, and it is very time-consuming. Furthermore, the leak-test equipment is often composed of expensive analytical devices, with extensive and excessive capabilities, that are not well suited to rapid testing of stack assemblies in medium- or high-volume manufacturing environments. High labor content and expensive test equipment limit the amount of online leak checks during the assembly process, leading to high scrap rates and low yields.

The development of a Modular, High-Volume Fuel Cell Leak-Test Suite and Process is proposed to address these challenges by reducing labor content; providing more robust, high confidence automated testing; and increasing the speed and throughput at
which manufacturing is performed. Each leak-test component will be highly specialized to its specific task and optimized for high throughput, thereby allowing for dramatic cost savings. A variety of methods will be employed to test for leaks between the fuel cell fluidic paths and the environment during the entire process from build to break-in to final test. The test suite will enable manufacturers to select modular test components as needed.

Approach

Six leak-test methods were proposed in the project. These tests include crossover current, current interrupt, voltage decay, pressure decay, flexo-tiltometer test, and fuel cell sensor for coolant leak. These methods will be investigated, and some will be selected to implement in the leak-test suite. These tests will automatically perform in-line during fuel cell stack manufacturing. The leak-test methods not only check the overall leakage, but also identify the location of leak and accelerate the diagnostics and remediation of fuel cell stacks.

Phase I of the project focuses on the analysis of current manufacturing processes, stack failure modes, and leak-test processes. A variety of leak-test methods will be surveyed, and recommendations for the leak-test suite will be made. A leak-test suite prototype will be designed, fabricated, and evaluated. A leak-test suite with 50 stacks per hour capability will be designed. Phase II will focus on pilot production line modification, leak-test suite fabrication, integration, and verification. A limited production test run will be carried out to validate the 50 stacks per hour operation.

Results

A specification for the leak-test suite laboratory prototype was developed. The specification includes required functions, detail procedures to perform these functions, hardware, software, graphical user interface, gas interface, electrical interface, heating system, and compression stand. The design of a leak-test suite lab prototype was completed. A programmable automation controller, CompactRIO, was chosen to control and acquire data for the leak-test suite and prototype. A personal computer LabVIEW application is used for data display, storage, and analysis. CompactRIO is a low-cost reconfigurable control and acquisition system designed for applications that require high performance and reliability. The human machine interface of the leak-test suite prototype includes nine major screens. The main screen will be displayed when the application is started. From this screen the operator can log in, monitor the status of the peripheral devices and change the operating mode. The setup screen is used to enter the parameter files for the tests. The files are entered in Excel spreadsheets. The parameters are divided into eight groups: general parameters, break-in parameters, performance parameters, alarms, temperature controller, report, summary, and notes. When the screen is first accessed, the operator can select and load the desired parameter file. When changes are made to any parameter, the operator can save the file for future use. The prototype can be operated manually and automatically. When in manual mode, the operator can manually control hydraulic press, gas, pneumatic, temperature, crossover current, and stack height. Diagnostic screen displays inputs and outputs. The test screen displays test results. Notes screen is provided to allow the operator to enter notes that can be referred to in the future. The faults screen displays a list of faults as they occur. The calibration screen is used to scale the various input and output functions. The system screen displays human machine interface operation and real-time error, which is used for debug during installation. The user control section is used to perform maintenance on the user database and the user access levels.

The fabrication of the prototype was completed. The leak-test suite lab prototype was installed at the UltraCell manufacturing facility in Vandalia, OH. The whole leak-test suite is shown in Figure 1, and the detail of the fixture is shown in Figure 2. All the functions of the prototype were tested individually. The sequences of multiple functions were then tested to ensure the logic is correct.

The prototype can perform all manufacturing processes which include inline leak-test, compression, bolting, break-in, and performance test (Figure 3). All these processes except bolting are carried out automatically. The prototype monitors all processes, quickly identifies failures, and provides diagnostic information. Safety features were implemented in the

FIGURE 1. Leak-Test Suite Prototype
prototype to protect the operator. The prototype can be used for both research and manufacturing with a simple change in the test protocol. A leak-test was repeated five times during the fuel cell stack manufacturing process (Figure 3). The leak-test can be added or removed easily. The average time for each leak-test is 9.3 min. This demonstrated that the leak-test can be performed at a rate greater than 5 stacks/hour. The results obtained from the prototype were compared with existing manual test protocols. It was demonstrated that the new instrument can reliably detect individual cell failures.

Techniques for analysis of dynamic mechanical analysis data from the prototype was developed and used in the leak-test suite prototype to characterize individual components in a fuel cell stack. This provides a necessary database for both the modeling effort and in validation of the new instrument capability. The application of a dynamic force to the fuel cell stack during assembly is expected to reveal how the various components press against each other. However, interpretation of the data requires a theoretical framework that can be used to quantitatively interpret the results. To this goal a finite element model has been developed to explore how the assembled materials respond.

Conclusions and Future Directions

The conclusions include the following:

- Developed a specification for the leak-test suite laboratory prototype. The specification includes required functions, detail procedures to perform these functions, hardware, software, graphical user interface, gas interface, electrical interface, heating system, and compression stand.
- Designed leak-test suite prototype. The prototype was designed with functions and features for research and development as well as manufacturing uses.
- Fabricated leak-test suite prototype.
• Installed leak-test suite prototype at the UltraCell facility at Vandalia, OH.
• Tested and evaluated leak-test suite prototype. The prototype can perform all manufacturing processes which include inline leak-test, compression, bolting, break-in, and performance test. All these processes except bolting are carried out automatically. The prototype monitors all processes, quickly identifies failures, and provides diagnostic information. Safety features were implemented in the prototype to protect operator.
• Created fuel cell stack quality metrics.
• Developed techniques for analysis of dynamic mechanical analysis data from the prototype.
• Characterized individual fuel cell stack components using the new leak-test suite prototype. This provides a necessary database for both the modeling effort and in validation of the new instrument capability.
• Developed a finite element model capable of modeling the dynamic mechanical properties of fuel cell stacks. This effort is critical in understanding how complex assemblies such as fuel cells actually respond to the applied dynamic forces.

Future directions include the following:
• Fabricate, integrate, test, and evaluate the leak-test suite.
• Modify pilot production line to accommodate the leak-test suite.
• Test run pilot production line with the leak-test suite.
• Validate the leak-test suite.

**FY 2010 Publications/Presentations**

VI.4 Manufacturing of Low-Cost, Durable Membrane Electrode Assemblies Engineered for Rapid Conditioning

Phase 2 Objectives

- New Process Exploration:
  - Investigate equipment configuration for low-cost MEA production.
  - Investigate raw material formulations.
  - Map out process windows for each layer of the MEA.
- Fuel Cell Heat and Water Management Modeling and Validation:
  - Efficiently optimize electrode and gas diffusion media (GDM) thermal, geometric, and transport properties and interactions.
- Multi-Layer Mechanical Modeling:
  - Develop a deeper understanding of MEA failure mechanisms.
  - Use model to optimize mechanical durability of the MEA structure targeted by the new low-cost process.
- MEA Optimization:
  - Utilize modeling results and designed experiments.
- Low-Cost MEA Conditioning Research
- Scale-Up and Process Qualification
- Stack Validation

Technical Barriers

This project addresses the following technical barriers from the Manufacturing section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of High-Volume Membrane Electrode Assembly (MEA) Processes
(D) Manual Stack Assembly

Contribution to Achievement of DOE Manufacturing Milestones

This project will contribute to achievement of the following DOE milestones from the Manufacturing and Fuel Cells sections of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

3.5 Manufacturing R&D

4. Establish models to predict the effect of manufacturing variations on MEA performance. (4Q, 2013)
VI. Manufacturing

3.4 Fuel Cells: Membrane Electrode Assemblies
Meeting All Targets

38. Evaluate progress toward 2015 targets. (4Q, 2012)

Accomplishments

- Direct Coating Process Development:
  - Primary and alternative paths for direct-coated 3-layer MEA process development have been determined.
  - Direct coated anodes and cathodes have demonstrated performance which is equivalent to Gore’s current commercial MEAs in ‘current automotive’ operating conditions when paired with control electrodes.

- Gore has demonstrated mechanical durability of a 12 micron expanded polytetrafluoroethylene (ePTFE) reinforced membrane. In previous testing, GORE™ MEAs exceeded 2,000 hours of accelerated mechanical durability testing, which has been equated to achieving 9,000 hours of membrane durability in an 80°C automotive duty cycle. This exceeds the DOE 2015 membrane durability target of 5,000 hours.

- A quasi-static elastic/plastic layered structure MEA mechanical model has been modified to include visco-elastic/plastic behavior. Mechanical property experiments which are required to calculate model input parameters are 35% complete. The final model will be used to predict reinforced MEA lifetime for a variety of temperature and relative humidity (RH) cycling scenarios. The model will also be used to explore different reinforcement strategies and optimize mechanical durability of the MEA structure targeted by the new low-cost process.

Introduction

Over the past 20 years, great technical progress has been made in the area of improving power density and durability of fuel cell stacks, so much so that most of the requisite technical targets are now within reach. Yet, three major technical challenges remain. First and foremost is meeting the cost targets. The second challenge is producing components that are amenable for use in a high-speed, automotive assembly line. One impediment to this latter goal is that stack components must currently go through a long and tedious conditioning procedure before they produce optimal power. This so-called “break-in” can take many hours, and can involve quite complex voltage, temperature and/or pressure steps. These break-in procedures must be simplified and the time required reduced, if fuel cells are to become a viable power source. The third challenge is to achieve the durability targets in real-world operation. This project addresses all three challenges: cost, break-in time, and durability for the key component of fuel cell stacks – MEAs.

Approach

The overall objective of this project is to develop unique, high-volume manufacturing processes for low-cost, durable, high-power density 3-Layer MEAs that require little or no stack conditioning. In order to reduce MEA and stack costs, a new process will be engineered to reduce the cost of intermediate backer materials, reduce the number and cost of coating passes, improve safety and reduce process cost by minimizing solvent use, and reduce required conditioning time and costs. MEA mechanical durability will be studied and optimized using a combination of ex situ mechanical property testing, non-linear mechanical model optimization, and in situ accelerated mechanical durability testing. Fuel cell heat and water management will be modeled to optimize electrode and GDM thermal, geometric, and transport properties and interactions. Unique enabling technologies that will be employed in new process development include:

- Direct coating which will be used to form at least one membrane-electrode interface.
- Gore’s advanced ePTFE membrane reinforcement and advanced perfluorosulfonic acid ionomers which enable durable high-performance MEAs.
- Advanced fuel cell testing and diagnostics.

Results

Low-Cost MEA Process Development

Primary and alternative paths for direct-coated 3-layer process development have been determined. Experiments targeted at both paths have made substantial progress, and direct-coated electrodes have demonstrated performance equivalent with the current commercial electrodes in specific operating conditions (Table 1). Figures 1 and 2 show performance of direct-coated electrodes paired with opposing control electrodes in a range of operating conditions which can be used to assess the viability of an MEA for different applications (automotive, stationary, portable, etc.), or for dynamic operation within a single application.

Future experiments will combine direct-coated anodes and direct-coated cathodes. These direct-coated MEAs will be produced according to the primary and/or alternative paths for process development.

The primary path is to directly coat the cathode electrode on a backer-supported reinforced membrane to form a 2-layer intermediate rolled-good. The next
The alternate path is to directly coat the anode electrode onto a backer-supported reinforced half-membrane to make an anode-side 1.5-layer intermediate rolled-good. The cathode electrode is then directly coated onto a backer-supported reinforced half-membrane in a similar process. In the final step, the backers are removed from the anode-side and cathode-side 1.5-layers intermediates and the webs are laminated together to form the 3-layer product.

Mechanically Durable 12 μm Reinforced Membrane

Gore has demonstrated mechanical durability of a 12 μm reinforced membrane (see Figure 3). The 12 μm membrane construction has also demonstrated high performance due to reduced resistance and increased water back-diffusion (see Figure 3). In previous testing, GORE™ MEAs exceeded 2,000 hours of accelerated mechanical durability testing, which has been equated to achieving 9,000 hours of membrane durability in an 80°C automotive duty cycle. This exceeds the DOE 2015 membrane durability target of 5,000 hours. The

Multi-Layer Mechanical Modeling

A quasi-static elastic/plastic layered structure MEA mechanical model has been modified to include visco-elastic/plastic behavior. Mechanical property experiments which are required to calculate model input parameters are 35% complete.

Nafion® PFSA NR-211 membrane is used for the model membrane and the temperature, RH, and time dependant properties are calculated from the ongoing experimental results. The viscous properties are modeled using a 2-layer viscoelastic constitutive model. This material model consists of an elastoplastic “arm” that is in parallel with an elastoviscous “arm.” The elastoplastic arm consists of an elastic spring (stiffness $K_p$) and a plastic component (yield stress $\sigma_y$ and hardening $H'$). Yielding according to the Mises criterion is used here. The elastoviscous arm has two elements, one spring (stiffness $K_v$) and one dashpot (using a time hardening law $\epsilon_v = A \sigma_v^n$). Thus, the instantaneous elastic stiffness of the material the sum of the elastic elements, $K_p + K_v$. In summary, the parameters that are required for this model are $K_p$, $\sigma_y$, $H'$, $K_v$, $A$ and $n$. These properties are determined from the experimental results.

FIGURE 2. Direct-Coated Cathode Performance (PL = platinum loading in mg/cm²)
Tensile testing was conducted for a range of displacement rates to investigate the influence of this parameter on the mechanical response. The rates (0.01 mm/min to 250 mm/min) are selected so that the full visco-elastic-plastic constitutive equations can be determined. The relationships obtained from the MEA testing are “composite properties,” combining the properties of the membrane with the electrodes. The constitutive equations for the electrodes will be obtained via reverse analysis. Figure 4 shows the comparison between the MEA and previously conducted experiments on Nafion® 211 membrane at T=45°C and RH=50%. The mechanical response of the MEA and Nafion® 211 membrane is different at medium or high displacement rates. However, at low displacement rates the mechanical response of the MEA and Nafion® 211 membrane is very similar.

Conclusions and Future Directions

The combination of Gore’s advanced materials, expertise in MEA manufacturing, and fuel cell testing with the mechanical modeling experience of the University of Delaware and the heat and water management experience of the University of Tennessee enables a robust approach to development of a new low-cost MEA manufacturing process.

- Low-cost direct-coated electrodes have demonstrated performance equivalent with the current commercial electrodes in specific operating conditions. Future low-cost MEA process development experiments will be focused on improving direct-coated cathode performance in very wet and very dry conditions. Gore will also combine direct-coated anodes with direct-coated cathodes on a durable 12 µm reinforced membrane. This construction will be produced according to the primary and/or alternative paths for direct coating process development.

- Fuel cell heat and water management modeling will be used to efficiently optimize electrode and GDM thermal, geometric, and transport properties and interactions. Direct-coated electrodes will be paired with the most appropriate GDM materials identified in this study. In this way, GDM will enable maximum performance and durability of the low-cost 3-layer MEA.

- A quasi-static elastic/plastic layered structure MEA mechanical model has been modified to include visco-elastic/plastic behavior. Mechanical property experiments which are required to calculate model input parameters are 35% complete. When data collection is complete, the model will be validated with MEA accelerated durability testing. The final model will then be used to predict reinforced MEA lifetime for a variety of temperature and RH cycling scenarios. The model will also be used to explore different reinforcement strategies and optimize mechanical durability of the MEA structure targeted by the new low-cost process.

Project Start Date: September 1, 2008
Project End Date: June 30, 2012

Objectives

The high level objective of the proposed work is to enable cost-effective, high-volume manufacture of high-temperature proton exchange membrane (PEM) membrane electrode assemblies (MEAs) by:

- achieving greater uniformity and performance of high-temperature MEAs by the application of adaptive process controls (APC) combined with effective in situ property sensing to the MEA pressing process; and
- greatly reducing MEA pressing cycle time through the development of novel, robust ultrasonic bonding processes for high-temperature (160-180°C) PEM MEAs.

Technical Barriers

This project addresses the following Manufacturing R&D technical barriers of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of High-Volume Membrane Electrode Assembly (MEA) Processes

(F) Low Levels of Quality Control and Inflexible Processes.

Contribution to Achievement of DOE Manufacturing Milestones

This project will contribute to achievement of the following DOE milestones from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 2**: Develop continuous in-line measurement for MEA fabrication. (4Q, 2012)
- **Milestone 3**: Demonstrate sensors in pilot scale applications for manufacturing MEAs. (4Q, 2013)
- **Milestone 4**: Establish models to predict the effect of manufacturing variations on MEA performance. (4Q, 2013)

Accomplishments

- Validated COMSOL\(^1\) models of both thermal and ultrasonic pressing thermal processes.
- Completed promising initial experiments on the use of alternating current (AC) impedance measurement for adaptive process control of the thermal sealing process, resulting in MEA performance that exceeds specifications.
- Demonstrated major reductions in sealing process cycle time (~90%) and energy consumption (~95%) with the use of ultrasonics.
- MEAs sealed ultrasonically demonstrate a significant (~30 mv) improvement in activation losses when compared to thermally sealed MEAs.
- Initial durability tests of ultrasonically sealed MEAs show no measurable degradation after a 190-hour standard test protocol with 25 start-stop cycles.
- Manufacturing cost models show the potential for significant cost reductions by the use of both ultrasonics (84%) and adaptive process controls (38%) for MEA sealing.
- Submitted 10 publications and conference presentations.

\(^1\) Multiphysics modeling and engineering simulation software
**Introduction**

To realize the tremendous potential that fuel cell technology has to improve the world’s environment and reduce our dependence on fossil fuels, it is essential that high-volume, high-quality manufacturing technologies are developed in parallel with the materials and designs for MEAs, stacks, and the other stack components, which is currently not the case. There are currently three main barriers to the development of high-volume fuel cell manufacturing. First, the current practice involving extensive testing and burn-in of components and stacks will not allow the industry to achieve the necessary cost targets and throughput for stacks, components, and systems. Second, for the current process used to press low-temperature (e.g. Nafion®) MEAs used in both PEM fuel cell and direct methanol fuel cell it is common to thermally press for as long as 1½ - 5 minutes. Even the pressing process for high-temperature (polybenzimidizole, or PBI) MEAs, while much shorter than for Nafion®-based MEAs of about one minute, is still too long for high-volume manufacture. Third is the variability of MEA performance. The component materials, including gas diffusion layers or gas diffusion electrodes, membranes or catalyst-coated membranes, and gasketing materials all exhibit variations in key properties such as thickness, porosity, catalyst loading, and water or acid content and concentration. Yet, it is common practice to employ a fixed combination of pressing process parameter values (time, temperature and pressure), regardless of these variations. As a result, MEAs exhibit variations in physical and performance related properties.

The research being conducted in this project will help reduce all three of these barriers by reducing the unit process cycle time for MEA pressing by the use of ultrasonic sealing, and by minimizing the variability in performance of MEAs produced using adaptive process control. This will in turn help lead to the reduction or elimination of the practice of burn-in testing of fuel cell stacks. All of these benefits will contribute to a reduction in manufacturing costs for MEAs.

**Approach**

The current state of practice in MEA manufacturing calls for the application of fixed pressing process parameters (time, temperature, and pressure), even though there are significant variations in incoming material properties of the membrane and electrodes including thickness, mechanical properties, and acid/water content. MEA manufacturers need to better understand the relationships among those incoming material properties, the manufacturing process parameters, the resulting MEA physical and electrochemical properties, and the eventual electrical performance of the MEA in a stack.

We plan to address the problems associated with different methods of pressing high-temperature MEAs, particularly PBI with phosphoric acid as the electrolyte, by applying APC techniques and ultrasonics. Through extensive experimentation and testing, we will develop analytical and empirical models of the relationships among incoming component material properties, the manufacturing process parameters, the resulting MEA properties, and the performance of the MEA in a stack. With the knowledge gained and new hardware designs, we will then attempt to identify one or more key properties (such as electrochemical impedance spectroscopy response, porosity, spring constant, or AC impedance) of the MEA that can be measured in situ during the thermal or ultrasonic pressing process, and then correlate these properties to the eventual physical and electrochemical performance of the MEA in a stack. If we are successful in identifying such an in situ measurement(s), adaptive control algorithms along with integrated process parameter and MEA performance sensing capabilities will be developed to allow us to vary the thermal and ultrasonic pressing process parameters in real time in order to achieve optimal uniformity of MEA performance.

We anticipate that the APC and processing techniques being investigated can be applied equally well, with certain modifications, to the pressing of both high-temperature and low-temperature MEAs, although the focus of this work will be on the former because of our extensive experience with these materials and the enhanced performance they offer (e.g., high operating temperature, no water management issues, high CO and H₂S tolerance). Our research is not application specific as the results may be applied to a broad range of fuel cell applications.

**Results**

We are now in the second year of our research project, and have achieved significant results in all areas of investigation.

We have completed our initial designed experiments of ultrasonic sealing of high-temperature MEAs, and with the use of analysis of variance we have identified the main affects of process parameters on MEA performance. The most dominate process parameter has been identified as the post sealing heat treatment of MEAs in order to eliminate excess water and to achieve a stable acid content and thickness of the MEAs. Using a 95% confidence level criterion we have also identified the anvil backer stiffness, booster amplitude, and applied pressure as having a significant affect on MEA performance. Figure 1 shows representative polarization curves for ultrasonically sealed MEAs, compared to the specification polarization curve provided by BASF Fuel Cell. Initially we were concerned by the steeper slope of the curves in the ohmic loss region. However,
by working with BASF scientists we have confirmed that this is, in fact, the result of the higher contact resistance of the current collectors in our test cells, and the resistance of the flow field plates made of a different graphite material. Of more importance, however, is the fact that all MEAs produced using ultrasonic sealing demonstrates a significant improvement in the activation region of the curve, with a 30 mv improvement being typical. We believe that this is the result of the ultrasonic process resulting in a higher acid content and retention of the acid in the membrane and at the reaction sites in the catalyst layer rather than in the gas diffusion layer. Titration tests have confirmed the higher acid content of ultrasonically sealed MEAs compared to thermally sealed MEAs.

In order to assess whether or not ultrasonic sealing of MEAs may have an adverse affect on MEA durability we have conducted accelerated durability tests on three ultrasonically sealed MEAs. The test protocol used was the standard durability test protocol used by BASF Fuel Cell, consisting of 190 hours of testing during which 25 start-stop cycles were performed, including thermal cycling, load cycling, and reactant shut-off. Figure 2 shows the plot of cell voltage and current density for one such test. In all cases there was no measurable degradation in performance over the test duration. Typically, if there would be a durability problem with an MEA it would be manifested within the first 100 hours of an accelerated durability test.

We have been investigating the potential of applying adaptive process control techniques to the thermal sealing process, coupled with in situ sensing of properties of the MEA during the sealing process that can be correlated to MEA performance. One sensing technique being investigated involves sensing the AC impedance of the MEA during sealing. Figure 3 shows plots of the real value of complex impedance, and also the corresponding phase angle. While we have been unable to correlate the impedance value with MEA performance we have been successful in correlating the...
phase angle of the AC impedance to MEA performance. Using a “man-in-the-loop” technique we were able to use the phase angle measurement to control the sealing process duration based on the time to achieve a target phase angle value, with the objective of achieving more uniform MEA performance. With this technique we were able to produce MEAs that all met or exceeded the BASF performance specification, with an average 60% reduction in cycle time. Next we will implement an automated control scheme on the precision press and then evaluate uniformity of MEA performance.

Our efforts at modeling of the relationships among MEA component materials, manufacturing process parameters, and performance of the resulting MEAs are showing good preliminary results. We have developed thermal models of both the ultrasonic sealing process and the conventional thermal sealing process using COMSOL. Figure 4 shows plots of the temperature distribution within MEAs during ultrasonic sealing, on the top, and thermal sealing, on the bottom. These models have been experimentally verified using miniature thermocouples embedded between each layer of the MEAs during pressing. It is important to note that the two processes are significantly different in that thermal sealing adds heat from the outside in, while ultrasonic sealing generates heat from within the MEA at the interfaces between material layers. This explains why ultrasonic sealing is a much more efficient and effective process at raising the materials to the required critical process temperature. We have also completed preliminary compression models of both thermal and ultrasonic pressing. These models help us to understand exactly what happens to the acid and water during the pressing process. In the future the thermal and compression models will be coupled to better describe the pressing process and how it affects MEA performance.

During Phase I we completed a detailed manufacturing cost analysis that included the following cost factors: capital depreciation, tooling, space, labor, chilled water, heating, ventilation and cooling, maintenance, electricity, and waste disposal. We did not include MEA materials costs in the analysis, nor did we consider any secondary cost savings that might result, such as reduced costs of stack rework due to greater uniformity of MEA performance. The results of our analysis indicate that the use of adaptive process controls for thermal sealing may result in a 38% process cost savings, and the use of ultrasonic sealing may result in an 84% process cost saving. During Phase II we will update this cost analysis prior to our Phase II milestone review.

During the past year we have successfully passed our Phase I milestone review and have been approved to continue into our Phase II research project.

Conclusions and Future Directions

We are very encouraged by the results we have achieved during the past year. We have found the use of ultrasonic sealing to be a very robust process with the potential to significantly reduce unit process cycle time, improve MEA performance, reduce MEA failure rates, and achieve substantial manufacturing cost reductions. Our investigations into the use of adaptive process control to achieve more uniform MEA performance and shorter pressing times is likewise very encouraging. The Phase I manufacturing cost analysis has shown the potential to significantly reduce manufacturing costs for high-temperature PEM MEAs.

Major activities planned for the remainder of Phase II include:

- Completion of our post sealing heat treatment process optimization design of experiments for both thermal and ultrasonic sealed MEAs.
- Continue modeling of the relationships among incoming MEA properties, manufacturing process parameters, and MEA performance.
- Full factorial process optimization designed experiments for ultrasonic sealing.
• Designed experiment for ultrasonic sealing of low-temperature PEM MEAs.
• Cell level testing of MEAs produced using optimized process parameters.
• Continue durability testing of ultrasonically sealed MEAs.
• Implementation of automated adaptive process control on a commercial precision thermal seal press.
• Continue to seek additional properties that can be measured in situ and that correlate to MEA performance.
• Initiation of stack level testing of MEAs.
• Coordinate low-temperature MEA testing support by National Renewable Energy Laboratory personnel.
• Update of manufacturing cost analysis and comparison with our Phase II cost targets.

Contract Number: DE-EE0001047

Subcontractor: Los Alamos National Laboratory (LANL), Los Alamos, NM

Project Start Date: October 1, 2007 Revised Interagency Agreement (October 1, 2009)  
Project End Date: October 1, 2009 Revised Interagency Agreement (October 1, 2011)

Objectives

Develop a pre-competitive knowledge base of engineering data relating fuel cell performance variation to bipolar plate manufacturing process parameters and dimensional variability.

Technical Barriers

This project addresses the following technical barriers from the Manufacturing R&D – Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(B) Lack of High-Speed Bipolar Plate Manufacturing Processes  
(F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing Milestones

This project will contribute to achievement of the following DOE milestone from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 13 Complete development of standards for metrology of proton exchange membrane fuel cells. (4Q, 2010)

Accomplishments

- Co-developed LANL/NIST statement of work (SOW) including an initial testing protocol to facilitate an official collaborative agreement for LANL through DOE to conduct fuel cell performance testing using NIST fabricated and verified experimental plates (10/2009).
- Initiated experimental plate testing at LANL and completed preliminary testing report with protocol recommendations (4/2010).

Introduction

Based on a workshop organized by the Center of Automobile Research and NIST in December 2004; industry bipolar plate manufacturers identified a need for engineering data that relates geometric bipolar plate tolerances to fuel cell performance. This need is in response to pressure from fuel cell designers to produce lower cost plates, as such, plate manufacturers are being forced to consider potential quality related trade-offs to achieve desired cost targets. To justify these trade-offs, manufacturers are questioning the relevance of stated tolerances on dimensional features of bipolar plates; thus expressed a desire for published engineering data relating performance and dimensional quality of the plates that can be used as a reference when making these decisions. In response to the identified need, this project was conceived in 2004 and partially funded through the NIST Advanced Technology Program Intramural Competition for a period of three years (Fiscal Year [FY] 2005-FY 2007). In 2008, funding was provided through DOE in an attempt to bring this project to a successful completion by the end of FY 2008.

To date, the reference single-cell design has been selected, the fabrication and dimensional verification of all experimental plates has been completed according to a statistically based design-of-experiments, and the NIST single cell performance capability has established and verified. All that remains is the performance testing of the experimental plates. Unfortunately, progress has been delayed due to membrane degradation issues.
followed by difficulties associated with obtaining the required on-site facility safety upgrades needed to permit continuous and sometimes unattended multi-day fuel cell performance operation required to reduce performance variability associated with start-up and shut-down. Due to the potential importance of the outcome of this project the deadline for completion was extended through FY 2010. The facility upgrade difficulties forced us to adopt an alternative and hopefully more efficient plan where LANL will conduct the performance testing. This activity is currently underway.

**Approach**

Using a statistically-based design-of-experiments (Table 1), fabricate experimental “cathode” side flow field plates (Figure 1) with various well defined combinations of flow field channel dimensional variations; then through single-cell fuel cell performance testing using a well defined protocol, quantify the performance affects, if any, and correlate these results into required dimensional fabrication tolerance levels.

**Results**

In the absence of a DOE Annual Merit Review Progress Presentation and Annual Progress Report submission during 2009, the following details results from October 2008 to the present.

- Validated NIST’s single-cell testing performance proficiency to a higher level through successful participation in second single-cell performance intercomparison organized by the US Fuel Cell Council Joint Hydrogen Quality Task Force/DOE North American Hydrogen Quality (Participants included: LANL (Reference Lab), Hawaii Natural Energy Institute, University of Connecticut, University of South Carolina, Clemson/Savannah River).

**FIGURE 1.** Concept - Reference Single Cell and NIST Fabricated Cathode Flow-Field Plates
• Performed long-term stability testing of the reference single-cell with chosen components and NIST fabricated anode and cathode flow-field plates. For this testing, the fabricated plates for both sides are the reference “optimal geometry” plates having dimensional variations less than 5 um.

• From this testing we concluded:
  – Performance stability can only be achieved through continuous operation during the entire testing process for each assembly of the cell with substitute experimental cathode plates. More specifically, this means that start-up and shut-down introduced variability and a typical testing cycle including a stabilization period takes approximately 2 to 3 days.
  – Although the membrane was chosen based on what were considered sound recommendations, the membrane exhibited substantial and not always predictable degradation. This was independently verified by LANL through testing we requested of the same membrane supplier.

• Facility safety upgrades needed to support unattended continuous operation encountered significant difficulties and delays therefore a SOW was developed in cooperation with LANL where the testing would be conducted by LANL to hopefully ensure a timely completion of this project.

• LANL performed initial testing of the NIST single-cell using their membrane of choice and reached the following conclusions (Figures 2 and 3):
  – Reuse of the same membrane from one single-cell configuration to the next where experimental cathode plates are swapped out between each configuration is not possible, as the disassembly and reassembly process results in significant degradation and sometimes operational failure.
  – The initial range and testing points selected in the testing procedure co-developed by NIST and LANL in the SOW did not extend far enough to show the mass-transport region and subsequently the target point for alternating current impedance investigation did not fall within this region as needed to elucidate plate-to-plate differences.

**Conclusions**

• Progress significantly delayed due to issues involving facility safety upgrades of the NIST Fuel Cell Testing Laboratory needed to support unattended and continuous fuel cell operation.

• Alternative plan formulated with the oversight and assistance of DOE program management where LANL was subcontracted to conduct performance testing thus enabling the quickest possible completion.

• Membrane and protocol weaknesses/limitations, as well as, proposed solutions were identified through NIST and LANL preliminary performance testing.
Future Directions

- Proposed protocol and membrane solutions will be tested by LANL.
- Assuming the solutions prove adequate, LANL will perform and complete performance testing of experimental plates.
- NIST and LANL expect to complete analysis of results and publication of the conclusions by January 31, 2011.

Disclaimer

Certain commercial equipment, instruments, or materials are identified in this paper in order to specify the experimental procedure adequately. Such identification is not intended to imply recommendation or endorsement by NIST, nor is it intended to imply that the materials or equipment identified are necessarily the best available for the purpose.

Contract Number: DE-EE0001047  
Project Start Date: October 1, 2007 Revised Interagency Agreement (October 1, 2009)  
Project End Date: October 1, 2009 Revised Interagency Agreement (October 1, 2011)

Objectives

- Identify and evaluate the capability and uncertainty of commercially available non-contact, high-speed scanning technologies for applicability to bi-polar plate manufacturing process control.
- Using capabilities identified in the first objective, demonstrate smart assembly concept (new under revised interagency agreement).

Technical Barriers

This project will address the following technical barriers from the Manufacturing R&D – Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(B) Lack of High-Speed Bipolar Plate Manufacturing Processes  
(F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing Milestones

This project will contribute to achievement of the following DOE milestones from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 7.** Develop manufacturing [quality control measurement] processes for graphite resin, natural flake graphite, and metal plates. (4Q, 2010)
- **Milestone 12.** Demonstrate pilot scale processes for assembling stacks. (4Q, 2013)
- **Milestone 13.** Complete development of standards for metrology of PEM fuel cells. (4Q, 2010)

Accomplishments

- Evaluated and concluded that photogrammetry is not a potential measurement solution for this application (9/2009).
- Assessed the capabilities and performance of several in-house instruments for use as a test bed for Phase II Sensor Testing (Accuracy as a Function of Scan Rate) and found only one that was marginally acceptable and most likely not the ultimate setup (12/2009).
- Discovered through initial Phase II testing, using our intermediate test bed with the laser spot triangulation probe, promising performance for some parameters but approach/sensor combined performance limitations for others (1/2010).
- Designed and procured (awaiting delivery) the necessary components to facilitate the fabrication/assembly of a dedicated sensor evaluation platform meeting all desired performance specifications. This dedicated platform is necessary to overcome the limitations identified in the previous two bullets and it will ultimately provide us the translation mechanism to evaluate these sensors over the desired range of scan rates (5/2010).

Introduction

Based on input from numerous bipolar plate manufacturers, we initiated an internally funded project in the summer of 2007 to develop, integrate, and evaluate non-contact, high-speed sensors or system of sensors for application in the dimensional process control of bipolar plates. This effort initially focused on determining the measurement needs of plate manufactures; this included learning what the common plate materials were and the current methods of fabrication and inspection. Using this information,
we attempted to identify what, if any, alternative commercially available measurement technologies existed that would be suitable for in-line high-speed inspection or if a solution needed to be developed. Since 2008, DOE has provided funding support for this project and in 2009 the project scope was modified to include demonstrating the concept of “Smart Assembly.” This additional objective, the concept of “Smart Assembly” is that if plate parallelism is measured and tagged to each plate, then assembly can be done in an automated fashion where plates are configured ideally to minimize the overall stack parallelism. This will allow lower tolerances on individual plate parallelism.

To date, an informal survey of plate manufacturers indicates that they are using vision-based ex situ systems for inspection of plate dimension. With the nature of the plate materials used and features of interest this approach is subjective, potentially not fully automatable, and does not have the accuracy required for evaluating the tighter tolerance demands. Furthermore, plate manufacturers have not yet looked for potential high-speed in-line solutions as high production volumes have not yet been demanded. In regards to measurement technology, numerous well qualified solutions for topography characterization exist but accuracy of lateral dimensions seem questionable for this application as these systems were not originally intended for those types of measurements.

Ultimately this project aims to enable cost reduction and rapid commercialization by providing plate manufacturers with a traceable, high-speed, fully automated solution for process control and intelligent stack assembly along with the information needed to optimize inspection scan rates as a function of the accuracy requirements.

**Approach**

Our approach includes the identification and/or development, integration, and evaluation of high-speed non-contact sensors or system of sensors for application in process control of bipolar plates. The evaluation will include: suitability based on typical plate materials and methods of fabrication, ability to quantify the dimensional parameters of interest to the accuracy required to evaluate those parameters against the tightest tolerance demands, and the flexibility to vary the scan rate (velocity). This variability in scan rate will enable fabrication rate flexibility that can be selected in relation to accuracy required. During this process we intend to develop measurement evaluation protocols for both sensors and plates to support and substantiate our efforts and to support future evaluation efforts as new sensors become available. Inclusive in these measurement protocols will be approaches for achieving contractual traceability requirements to support international product acceptance. Lastly, assuming a suitable measurement solution is obtained; demonstrate the concept of “Smart Assembly.”

**Results**

Although an ongoing effort, we have conducted research to determine the scope of potential measurement solutions, common plate materials, typical high-speed plate fabrication methods, and the plate dimensional parameters of interest along with the associated range of tolerances encountered. In general, the measurement solution must be able to perform lateral and topographical (vertical) measurements on both graphite (diffuse) and metallic (shiny) plates, at high incident angles commonly encounter due to tapered sidewalls (a product of many high-speed fabrication techniques or by design), capable of scan rates of up to minimally 100 linear mm/s (300 mm/s desired), and to an accuracy suitable for evaluating these parameters against tolerances ranging from 0.05 mm down to 0.012 mm.

Our initial efforts resulted in the procurement of two potentially promising structured-light non-contact sensors, both of which were evaluated based on ability to measure both graphite and metallic plates, as well as, their sensitivity or lack of as a function of incident angle (Phase 1). From this testing, one of the sensors, a 30 um diameter laser spot triangulation probe showing the best promise from the initial testing was mounted to the spindle of a 3-axis machine tool where it was tested in a scanning configuration to evaluate its sensitivity to measurements of feature height and to demonstrate the feasibility of lateral measurement by tying profile data to velocity of the translation mechanism.

Over the past year, the testing of this sensor moved to another test bed that provided us with a platform for evaluating the sensor accuracy as a function of scan speed (Phase 2). As part of this process numerous in-house measurement instruments were evaluated for velocity stability and velocity range capability. Unfortunately, none of these instruments satisfied the needed stability of 0.01 mm/s and minimum selectable and stable velocity of 100 mm/s. The coordinate measuring machine (CMM) chosen as an intermediate test bed has a maximum velocity of 70 mm/s and stability of 0.03 mm/s at 30 mm/s as measured using a the velocity output of a laser interferometer. Although this test bed did not meet the desired requirements it did allow us to discover numerous performance limitations and determine their cause based on the sensor and/or the approach used to quantify lateral dimensions.

Using this intermediate test bed for the laser spot triangulation probe we assessed the performance using “gage blocks” for absolute testing and sample fuel cell plates characterized using a more accurate reference
system for repeatability and correlation testing at 30 mm/s (Figure 1).

The laser spot triangulation probe demonstrated a repeatability of 1.5 um and errors on the order of 2 um or less on the width of flow field channels with “sharp” edges such as those produced by machining. Figure 2 shows flow field channel width comparison data between the non-contact laser triangulation spot probe and reference measurements performed on our dual-probe micro-feature CMM. The plate used is a carbon composite plate with machined flow field channels. The flow field consists of three individual channels in a serpentine configuration. This particular plate was a reject from an initial machining process employed to make experimental plates for our other plate manufacturing project. In this instance, as you scan across the plate with the channels oriented perpendicular, each individual channel is measured several times and the data shows each channel has a different average width. For this project this is the perfect plate in that the data shows excellent agreement between the non-contact probe and the reference data and it shows the non-contact probe has the sensitivity to see these subtle differences (approximately 10 to 20 μm) between the channels.

Unfortunately, the reality is that bipolar plates manufactured by typical high-speed fabrication techniques, such as, injection molding compression molding, and stamping have chamfered edges and tapered sidewalls (Figure 3). The effect of this was apparent for the gage block and injection molded bipolar plate measurements where width errors of 10 um or more were common.

Using the machined plates in Figure 1 and the injection molded plates shown in Figure 3 along with reference values obtained using a more accurate dual-probe micro-feature CMM, height errors where found to be within the range of 1 to 7 um.

In addition, we demonstrated feasibility for plate parallelism measurement by conducting a simple test using the machined graphite plates where data was collected as the laser spot triangulation probe was translated across the plate overlapping the edges of the plate to collect data from the reference surface upon which the plate was fixtured. The reference plate for

FIGURE 1. Laser Spot Triangulation Probe Mounted to Z-Axis of CMM. Setup Shows Reference Gage Block, Machined Flow Field Plates from NIST Project 1, and Scanning Pictorial.

FIGURE 2. Laser Spot Triangulation Probe Comparison Data Using a Machined Flow Field Plate with Real Channel-to-Channel Differences in Width

FIGURE 3. Example Output from Laser Spot Triangulation Probe of a Injection Molded Plate
our test was a porous ceramic square vacuum chuck encased in a granite frame. The flatness of the entire surface, ceramic area and frame is less than 2 um. By applying a least-squares linear fit to the profile data that corresponds to the reference surface then removing the slope of the best-fit line from both the reference plane data and the plate surface data, the variation in parallelism between the bottom plane and plate, top plane, can be quantified. This was simplified in that we scanned only one profile line rather than numerous lines across the surface and that we used one probe and a reference plane. Application on a real production line would utilize two or more opposing probes where the differences would be analyzed.

Concurrent to this effort, we also explored photogrammetry as a potential measurement solution and we procured a “laser line” triangulation based probe similar to the individual “laser spot” probe that has thus far shown promising results. Photogrammetry was conceived as a possible solution shortly after the 2008 DOE Annual Merit Review Meeting; however our research shows that this is a “no-go” even with the enormous advancements in the resolution of digital single lens reflex cameras due to the aspect ratio between the channel depth and width.

Conclusions

• Photogrammetry is not a potential measurement solution for this application due to aspect ratio between channel depth and height.
• Phase 2 Preliminary Testing Conclusions:
  – On our intermediate probe testing platform, at a translation speed of 30 mm/s, the laser spot triangulation probe has the potential to meet the needs for this high-speed non-contact application, if limitations due to the interaction of the probe with chamfered edges and tapered sidewalls can be overcome.
  – Height errors are acceptable and for the most part sensor based only, but lateral errors are a function of the sensor and our approach that obtains position using the sampling rate of the probe in conjunction with the known velocity of the probe translation mechanism.
• Devised a new approach that synchronizes the probe data collection with the position of a precision stage with an adjustable translation velocity. This approach eliminates the need for a calibrated (known) and stable translation velocity.
• Designed, procured (awaiting delivery), and fabricated all necessary ancillary equipment (two stages and associated controllers, framing, and fixturing mechanisms) to assemble a dedicated sensor test bed to implement our revised approach (Figure 4).

Future Directions

• Assemble and test new non-contact sensor test bed.
• Test new approach for measurement of lateral dimensions.
• Investigate edge-effect.
• Using the variable translation speed of the new test bed, perform rigorous characterization of the laser spot triangulation probe accuracy as a function of scan speed up to 300 mm/s.
• Test line-based triangulation probe.
• Extend testing to other probing technologies as appropriate.

Disclaimer

Certain commercial equipment, instruments, or materials are identified in this paper in order to specify the experimental procedure adequately. Such identification is not intended to imply recommendation or endorsement by the National Institute of Standards and Technology, nor is it intended to imply that the materials or equipment identified are necessarily the best available for the purpose.

Acknowledgements

The work detailed in this report would not have been possible without the contributions of the following, all are NIST personnel and guest researchers unless otherwise noted: Dennis Everett, Bala Muralikrishnan, Wei Ren, and Ted Doiron.

FY 2010 Publications/Presentations

Objective

Evaluate the suitability of optical scatterfield metrology (OSM) as a viable measurement tool for in situ process control of catalyst coatings.

Technical Barriers

This project will address the following technical barrier from the Manufacturing R&D Fuel Cells section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(F) Low Levels of Quality Control and Inflexible Processes

Contribution to Achievement of DOE Manufacturing Milestones

This project will contribute to achievement of the following DOE milestones from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

• **Milestone 1.** Develop prototype sensors for quality control of membrane electrode assembly (MEA) manufacturing. (4Q, 2011)

• **Milestone 2.** Develop continuous in-line measurement for MEA fabrication. (4Q, 2012)

• **Milestone 13.** Complete development of standards for metrology of proton exchange membrane (PEM) fuel cells. (4Q, 2010)

Accomplishments

• Secured 3M as a provider of catalyst-coated membrane (CCM) samples necessary to evaluate the potential sensitivity of the OSM technique to the measurement of catalyst loading. (07/2008).

• Developed an initial 12-layer three-dimensional optical model of the 3M nano-structured thin-film (NSTF) CCM in an attempt to predict the optimal configuration of the OSM instrument parameters (i.e., wavelength of the light source, illumination angle, polarization) to guide the experimental investigation efficiently.

• Demonstrated sensitivity of the OSM technique to Pt loading to a level of 0.01 mg/cm² using 3M PtMnCo NSTF (01/2010) and 3M pure Pt NSTF CCMs (06/2010).

• Secured another major manufacturer as a supplier of conventional Pt on C CCM samples for our next round of testing to further define the range of applicability of the OSM technique.

• Developed a formal collaboration plan with the National Renewable Energy Laboratory (NREL) that provides both organizations the ability to leverage each others’ capabilities in support of their own individual projects, share proprietary samples and information from industry partners using a special three-way non-disclosure agreement (NDA) executed with each interested industry partner (ongoing).

• Demonstrated our support of the NIST/NREL collaboration by providing NREL with defects fabricated using our dual beam gallium focused ion beam (FIB)/scanning electron microscope (SEM) in order to extend NREL’s membrane hole defect performance study to hole diameter sizes smaller than 150 um (3/2010).

Introduction

The need for high-speed, in situ process control measurement techniques for controlling the quality of the platinum-based catalyst layer has been identified during numerous DOE sponsored and non-DOE sponsored workshops. Current techniques for the various parameters of interest (e.g., SEM
and X-ray fluorescence [XRF] to name a few) are extremely expensive and not easily amendable to in situ application in a manufacturing production line. The Precision Engineering Division within the Manufacturing Engineering Laboratory has years of expertise with a technology identified as OSM [1], specifically its development as a process control tool for the semiconductor industry. This technique is a combination of the best attributes of traditional bright-field optical microscopy and scatterometry. More precisely, this technique takes traditional optical metrology beyond the Rayleigh criteria and focuses on the complex optical signatures of subwavelength size features, where the response can be optimized by varying the illumination angle, varying the illumination source wavelength, and application of various image analysis algorithms. Although quantitative in other applications, this technique is being used in a comparative form thus far in this application and must be correlated to measurements of the parameter of interest using the appropriate reference metrology. As such, the development for new applications requires research to optimize the OSM tool and establishing the appropriate reference metrology tool, along with the development of the appropriate analysis algorithms for both. Please refer to the stated reference for more technical details on the technique.

Prior to this project, this technique has only been applied to very discrete uniform structures, such as those typically encountered in the semiconductor industry. Because of this, the application of the OSM technique to random subwavelength structures has long been a goal but does present significant challenges. The underlying principle is that even random subwavelength structures exhibit some type of repeatable optical signature and that changes in these signatures can be correlated with the various manufacturing parameters of interest to control the quality of the product.

The overall objective of this project is to provide PEM, CCM and gas diffusion electrode manufacturers with an automated high-throughput approach for performing process control inspection of Pt loading with sensitivity equal to or better than that currently provided with XRF and other parameters of interest simultaneously. Simulations will give insight and enable manufacturers to tune their measurement equipment to the parameters of interest. For dual-side simultaneous catalyst-coating operations, this method will provide the ability to concurrently perform Pt loading measurements on both sides of a CCM independently versus XRF which is a “total” sample loading measurement.

**Approach**

To ensure accuracy of the technical details related to the fabrication and performance of catalyst layers, this project depends heavily on support from MEA manufacturers, as well as, other experts in the field. From the beginning, we have actively engaged MEA manufacturers and industry experts in an effort to identify the critical parameters of the catalyst layer and to solicit from them sample packages that vary these parameters to enable us to conduct a sensitivity study of the proposed technique.

Our initial focus over the last year or two, driven by industry input, has been to demonstrate the technique's sensitivity to catalyst loading. Then if the technique is sensitive to catalyst loading, determine how broadly applicable it is. To satisfy the second task, sensitivity studies must be conducted over the entire range of catalyst types (Pt and Pt alloys), support structures (conventional carbon-based and novel non-carbon-based supports), and substrates (membrane and both paper and woven cloth gas diffusion layers [GDL]).

The development and implementation of this technique integrates experimental work with simulation driven predictions to maximize efficiency.

**Results**

During the last year our efforts have been focused on simulation model development and experimental data collection based on 3M’s NSTF CCM, which was the first sample set we received from a major supplier. This first sample set included three NSTF CCMs with PtMnCo catalyst loadings of 0.10, 0.15, and 0.20 mg/cm². Experimentally we collected data which successfully demonstrated that the OSM technique is sensitive to catalyst loading and that the sensitivity of the technique for this specific CCM is on the order of 0.01 mg/cm². This is very comparable to the inline XRF systems available. Figure 1 shows the final reflectivity data for two different runs. The first run involves three repetitive measurements at the same location on each sample thus representing what we refer to as base repeatability. The second run involves three repetitive measurements on each sample but each measurement is at a different location. Figure 2 is additional data supporting sensitivity of the tool to catalyst loading; however in these measurements we are varying the wavelength of the illumination source. This data was collected varying different instrument parameters, illumination angle and wavelength, not only to show sensitivity to the parameter of interest but also in an attempt to determine the settings that optimize this sensitivity. These two instrument parameters are only a sampling of the variables that have been tested and that can be optimized based on the application.

To understand further the applicability of the technique we then acquired another sample set that included four 3M NSTF CCMs with pure Pt catalyst loadings of (0.05, 0.10, 0.15, and 0.20) mg/cm². Again the experimental results obtained in late May of 2010 showed sensitivity to the loading differences but more
carefully collected data sets are needed to verify the exact level of this sensitivity. Concurrent with the experimental evaluation we have worked on simulation model development which supports the experimental data in that it predicts trends, but the accuracy of the models need improvement as we are lacking the true optical properties for the materials involved. Figure 3 shows our preliminary modeling efforts.

Over the last year we have also undertaken a parallel effort where we worked with NREL to develop a collaborative agreement between the two organizations.

This agreement was described in a one-page summary that we sent to all of our industry partners in the fall of 2009. This summary explained a coordinated effort for achieving each of our project’s goals and that this is justified by the fact that the individual projects of both organizations were related but complimentary,
and such a relationship would enable us to leverage our relationship with our industry partners together to maximize efficiency through the sharing of samples and information. Finally, the summary recommended that this agreement would be facilitated by three-way NDAs among NREL, NIST, and each industry partner. Without this, both organizations would negotiate individual NDAs with each industry partner and in some instances for the same sample and information requests, in essence doubling the number to NDAs needed. Furthermore, this agreement formalizes the commitment of both organizations in leveraging each other’s capabilities in support of each organization’s individual projects without the need for funding transfers.

Because of the relationship between the NIST/NREL Collaborative Agreement, NIST reference metrology, and the OSM project we have combined this arrangement with the OSM project. To date all our industry technical partners have concurred with the proposed benefits. Several NDAs have been completed but others still remain outstanding. The following figures represent our recent efforts to demonstrate our commitment to the collaboration, in that, we provided defects fabricated using dual-beam SEM/gallium FIB in support of NREL’s desire to expand their membrane defect study to sub 150 um features (Figure 4) [2].

**Conclusions**

- Demonstrated OSM technique sensitivity to catalyst loading using two 3M NSTF CCM sample packages, one with pure Pt and the other with a PtMnCo alloy catalysts.
- Developed preliminary simulation model of 3M NSTF CCM to ultimately guide efficient experimental measurement efforts and manufacturer tool customization.
- Procured (awaiting delivery) an ellipsometer with a integrated variable environmental chamber for experimental determination of optical properties “n” and “k” for materials comprising each CCM design used for OSM sensitivity testing to support a more accurate simulation model.
- Secured a manufacturer/supplier of conventional Pt on C CCMs and a sample package for further OSM catalyst loading sensitivity testing, in an effort to more precisely define the range of applicability.
- Developed a collaborative agreement with NREL to leverage resources between organizations and industry partnerships.
- Demonstrated support of this collaborative effort by fabricating membrane defects in support of NREL defect studies.

**Future Directions**

- Use ellipsometer and additional special material sample packages to determine optical properties for 3M’s NSTF CCM.
- Refine simulation model using these optical properties and demonstrate correlation between the model and experimental results.
- Determine the level of sensitivity of the OSM technique to catalyst loading using pure Pt NSTF CCM.
- Continue experimental catalyst loading sensitivity testing using conventional Pt CCMs.
- Secure supplier(s) of catalyst-coated, paper and cloth, GDL samples.
- Develop a conceptual compact tool design suitable for manufacturing lines.
- Work with NREL and industry partners to determine the next most sensible catalyst loading parameter to study with the OSM technique.

**Disclaimer**

Certain commercial equipment, instruments, or materials are identified in this paper in order to specify the experimental procedure adequately. Such identification is not intended to imply recommendation or endorsement by NIST, nor is it intended to imply that the materials or equipment identified are necessarily the best available for the purpose.

VI.9 High-Speed, Low-Cost Fabrication of Gas Diffusion Electrodes for Membrane Electrode Assemblies

**Objectives**
- Reduce cost in fabricating gas diffusion electrodes through the introduction of high-speed coating technology, with a focus on materials used for combined heat and power generation (CHP).
- Relate manufacturing variations to actual fuel cell performance in order to establish a cost-effective product specification.
- Develop advanced quality control methods to guide realization of these two objectives.

**Technical Barriers**
This project addresses the following technical barriers from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan (Section 3.5):
- Lack of High Volume Membrane Electrode Assembly (MEA) Processes
- Low Levels of Quality Control and Inflexible Processes

**Contribution to Achievement of DOE Manufacturing R&D Milestones**
This project will contribute to achievement of the following DOE milestones from the Manufacturing R&D section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan (Section 3.5.7):
- Develop continuous in-line measurement for MEA fabrication. (4Q, 2012)
- Establish models to predict the effect of manufacturing variations on MEA performance. (4Q, 2013)

This project addresses coating speed and uniformity of gas diffusion electrodes (GDE), a critical component for MEA fabrication. One sub-task is to develop a continuous X-ray fluorescence (XRF) analyzer that directly measures catalyst deposition level and distribution on rolled goods, ultimately guiding improvements in through-put and uniformity. This sub-task directly contributes to the forth quarter 2012 goal for in-line measurement. Another sub-task is to develop models that predict the effect of manufacturing variations in catalyst distribution and porosity in GDEs, and relate these variations as six-sigma limits for a component specification. The establishment of a model that predicts MEA performance based on manufacturing variations in GDEs contributes to improving the quality of the component as well as achieving the forth quarter 2013 DOE milestone above.

**Accomplishments**
- Developed an innovative on-line analyzer ahead of plan. For the first time have a complete “map” of precious metal catalyst level and distribution throughout the roll during coating.
- Team has established a framework for understanding ink stability issues:
  - For cathode, identified an additive that significantly improved key quality indicator by reducing the incidence of surface agglomerates on the GDE by ~80%.
- Established first critical task milestone: full length coating on carbon cloth whereby coating length increased by double.
- Identified a path to higher speed coating through reduction of coating steps by ~30%.
Introduction

The basis of this project is to create GDEs at a far lower cost than those currently available. GDEs are critical components of MEAs and represent the highest cost subcomponent of the MEA. Cost reduction will be accomplished through development of a higher throughput coating process, modeling the impact of defects due to the higher speed process, and overcoming these limitations and providing a six-sigma manufacturing specification that relates performance to defects. The main focus of the effort is creating next-generation inks through advanced additives and processing methodologies. As part of our approach, we will also develop on-line quality control methods such as determination of platinum concentration and distribution during the coating process. We will also develop correlations between manufacturing parameters and performance as well as establish models to predict the effect of manufacturing variations in MEA performance.

For this reporting period we designed, built, and validated an on-line analyzer for determination of loading and distribution of precious metal catalyst during coating. This accomplishment directly contributes to DOE’s goal of improving quality control instrumentation throughout the manufacturing process. We also developed improved ink formulations that led to lower defects during longer coating runs – a first step towards reduction in cost.

Approach

GDEs are comprised of a gas diffusion layer coated with catalyst. The gas diffusion layer is simply carbon cloth or a non-woven carbon paper that has been coated with carbon black and serves as a current collector for the catalyst. For both the carbon black and catalyst, a hydrophobic binder is added to achieve critical porosity and hydrophobicity in the final structure. Of the carbon black, catalyst, or hydrophobic binder none are highly soluble in aqueous solutions. Aqueous solutions must be used as solvents since the use of organic solvents with a highly active catalyst is too dangerous in a production environment. Also, the hydrophobic binder is shear-sensitive, meaning it becomes less stable when pumped or subjected to shear forces in the coating applicator. Thus, the challenge in this project is overcoming the inherent physical limitations in these materials through advanced formulations and processing.

Our approach to solving this challenge begins with identifying key quality GDE metrics that relate directly to ink performance, develop an understanding of the forces behind ink stability, and introduce solution measurement methods that relate ink performance to the quality metrics. With more stable ink formulations, we anticipate being able to coat longer and wider webs at higher speeds or lower numbers of application passes. This process is supplemented by two other activities that ultimately lead to lower cost GDEs. We will develop a model that will predict the impact of manufacturing variations on MEA performance, and use this model to determine the level of coating quality needed to maintain consistent current and voltage. Also, we will create on-line instruments to lead more precise coating processes.

Results

Our first objective was to develop the in-line analytical method to follow improvements in coating. For developing continuous in-line analysis of catalyst deposition, we selected a custom XRF engine designed by X-Ray Optical Systems in New York. The key to their technology is the use of micro-capillary tube optics that amplifies the fluorescence signal and thus allows a greater signal with low powered X-ray tubes. Traditional commercial XRF units need a long time to obtain a signal – roughly 60-90 seconds and would not be able to provide an accurate measurement on webs moving 8-10 cm/s. We exploited the high signal gain of the micro-capillary tube in order to facilitate very short acquisition times and thus obtain detailed distribution maps of catalyst being coated on rolls of gas diffusion layers. The following are design targets and achievements to date, and a photo of the device is shown in Figure 1.

- Safely used by production staff. Employed extensive guards and auto-shut-off switches.
- Date acquisition rate 25 ms: 10 ms achieved.
- Rail scan 10 m/s: 20 m/s achieved.
- Instrument variation +/-2.5%: <+/1% preliminary achieved.

FIGURE 1. Picture of Custom-Designed In-Line Analyzer for Precious Metal on Gas Diffusion Electrodes
• Minimum level <1 g/m² Pt: initially achieved 1.7 g/m² but believe can exceed minimum with parameter optimization.

We identified a key quality parameter for coating that relates directly to ink performance – agglomerates. Agglomerates are precipitations of catalyst, binder, or catalyst and binder that form protrusions on the gas diffusion electrode surface, interrupting the smooth coating. In the extreme case, these protrusions can pierce the membrane in the MEA. See Figure 2 for examples. As part of investigating the forces that destabilize our ink formulations, we found that the measurement of the zeta-potential of our solutions provided a measurable characteristic that is related to ink stability. For aqueous formulations, one typically needs charge to stabilize the particles and zeta-potential values between 15 and 25 mV are typically desired. For our base formulations, we obtained zeta potentials between 5 and 10 mV and when attempting to apply this ink to longer rolls of GDL developed significant agglomerations.

Using a combination of the zeta potential and developmental scale coating runs, we identified an additive that stabilized the cathode catalyst. A key to selection of this additive was to find a material that met the following selection rules: 1. stabilize ink components, 2. can be removed through higher processing temperature so no residuals remain that could interfere with catalyst performance, and 3. no significant change in porosity or hydrophobicity introduced through the use of the additive. Through this process we identified an additive that reduced cathode agglomerates by 77% over baseline formulations when scaled to the full production coating machine.

Lastly, we identified a new high energy process that facilitates creating more concentrated inks. By increasing the concentration of the catalyst and binder in the ink, we can reduce the number of application passes needed to achieve a final catalyst loading, and thus effectively “increasing speed” by actually reducing the number of coats. Although preliminary as of this writing, by using this new formulation we have reduced the number of application coats by 30% when using developmental scale coating machines.

Conclusions and Future Directions

We have developed a methodology to create more stable ink formulations, and have applied this to reduce a key quality feature – agglomerates on the electrode surface while increasing the length of GDL coated. A new instrument has been introduced for following our catalyst coating distribution and uniformity, and providing critical feedback on improvements in formulation and ink processing. A new high energy process for ink making has been identified with encouraging preliminary results. Thus, by being able to produce greater amounts of GDEs over shorter times, we can create a path to the higher volumes of MEAs targeted by the Department of Energy objectives.

Upcoming Focus:

1. Further improve additives combined with the high energy process.
2. Leverage these improvements towards either higher speed coating and/or reduction in number of passes as well as full-width coating.
3. Continue modeling and validation of the impact of manufacturing defects on performance.
4. Using the approach developed for carbon cloth gas diffusion electrodes, develop ink formulations appropriate for non-woven carbon paper gas diffusion electrodes.
VI.10 Development of Advanced Manufacturing Technologies for Low Cost Hydrogen Storage Vessels

• Pacific Northwest National Laboratory (PNNL), Richland, WA

Cost-Sharing Partner:
Boeing Research and Technology, Seattle, WA

Project Start Date: September 26, 2008
Project End Date: March 31, 2012

Project Objective

Develop new methods for manufacturing Type IV pressure vessels for hydrogen storage with the objective of lowering the overall product cost by:

- Optimizing composite usage through combining traditional filament winding (FW) and automated fiber placement (AFP) techniques,
- Exploring the usage of alternative fibers on the outer layers of the FW process,
- Investigating dry-tape technology which could drastically shorten the manufacturing time,
- Building economic and analytical models capable of evaluating FW, AFP, and tape fabrication processes including manufacturing process variables and their impact on tank mass savings, material cost savings, processing time, manufacturing energy consumption, labor and structural benefits, and
- Studying polymer material degradation under hydrogen environment.

Technical Barriers

The project addresses the following technical barriers from the Hydrogen Storage section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) System Weight and Volume
(B) System Cost

This study will contribute to achieving milestone 24 of the Manufacturing R&D section of Multi-Year Research, Development and Demonstration Plan:

Develop fabrication and assembly processes for high-pressure hydrogen storage technologies that can achieve a cost of $2/kWh.

Accomplishments

- Refined the stress analysis approach to predict stresses in the transition areas between the domes and the cylinder section.
- Designed new AFP and FW patterns to create better transition between the two fibers, thus further reducing stresses.
- Improved programming of the tow-placed system to reduce the cycle time for off-part motion by about 50%.
- Designed the geometry of the liner and boss at each end of the layup mandrels as the surfaces for fiber placement, forming the tow-placed end-caps in a stand-alone operation.
- Fitted end-caps onto liner well using a heat gun and a filament-wind helical.
- Identified that there are no cost-competitive alternative fibers other than carbon fibers at this time.
- Tape fabrication processes, mechanisms, equipment schematics, and micrographs were documented for presentation to team members and DOE reviewers. Tape development was advanced by new diagnostic capabilities applied to the first generation of prototype tapes. Remedies for bubble defects found in first generation tapes were developed.

Introduction

The goal of this project is to develop an innovative manufacturing process for Type IV high-pressure hydrogen storage vessels, with the intent to significantly
lower the costs. Part of the development is to integrate
the features of high precision AFP and commercial
FW with the potential of using alternative fibers on the
outer layers of FW. As a potential, dry-tape technology
is being investigated by LLNL, which could shorten
production cycle time.

In this project period, stress analysis approach has
been refined after the second vessel failed burst test
unexpectedly. Boeing has improved programming of
the tow-placed system to reduce the cycle time for off
part motion. The first set of AFP is no longer directly
placed onto the liner, instead the end-caps are formed
on the layup mandrels that have the geometry of the
liner and boss at each end. These end-caps fitted well
on the liner with the aid of a heat gun and a FW helical.
Alternative fibers are being investigated for outer layers
of FW. Quantum and Boeing supplied manufacturing
cost information to PNNL to refine the cost model,
which has been used to assess the cost sensitivities of
this manufacturing technique compared to the baseline
FW process. LLNL continues to develop an advanced
composites manufacturing process that should be
particular well suited to the production of pressure
vessels. PNNL and LLNL will expand on their activities
in separate reports.

Approach

The approach on stress analyses has been improved
by taking the transition areas between the domes and
the cylinder section into account. The original method
analyzed the domes and the cylinder section separately,
which contributed to not realizing the failure mode of
the second vessel in the model.

Since manufacturing tow placed end-caps became
a stand-alone process, different winding sequences have
been investigated to prevent the end-caps from wrinkling
upon laying down the first FW helical.

Results

Stress Analyses

The first vessel tested in October of 2009 passed
the burst test at 23,771 psi, exceeding the requirement
of European Commission (EC) 79-2009 standard of
22,804 psi. After passing the burst test, the composite
design was refined to further reduce fiber usage on the
next vessel. The overall design of second vessel required
two layups of AFP. Instead of having fiber directly
placed onto the liner for the first AFP layup, end-caps
formed on foam tools were delivered to Quantum for
installation. The completed vessel was burst-tested in
December of 2009, but it failed at 18,666 psi, which
is below the EC 79 standard. Since the second vessel
failed unexpectedly, the approach on stress analyses was
revisited to understand why the failure was not realized
in the model.

Stress analyses on each of the first and second
vessels were based on three individual analyses on
forward dome, aft dome, and cylinder section. However,
this analysis method failed to evaluate the stresses in
the transition areas between the domes and the cylinder
section. Instead, two integrated analyses are necessary.
One is for the forward dome and the cylinder section,
and the other is for the aft dome and the cylinder
section. On the forward dome, the patterns from AFP
and FW are fed into the stress analysis model, but
the material placed in the cylinder section by AFP is
manually replaced with material of the hoops. This
simulates the real-world situation, where hoops make up
for the fiber that is missing between the domes wrapped
by AFP. The same methodology also applies for the aft
dome.

With this improved approach, stress analyses were
performed on the AFP and FW patterns from the second
vessel. The results confirmed that maximum stress was
observed at the transition areas between the domes and
the cylinder section. It is consistent with the actual burst
location, which is between the aft dome and the cylinder
section. As a result, the AFP and FW patterns have been
modified to reduce stresses at the transitions to levels
below those seen in the cylinder section of the vessel.

Third Vessel Development

The Boeing team continues to build tow-placed
layups for the latest iteration of storage vessel design.
Boeing uses the current delivery head design with
improved heating capabilities. In these recent efforts,
improvements to the programming of the system allow
for the acceleration of the off-part motion between the
end of one course and the start of another course. This
improvement reduces the cycle time for off-part motion
by about 50%.

In the build process for the current, third vessel,
layup mandrels having the geometry of the liner and
boss at each end are used as surfaces for fiber placement.
This forms the tow-placed end-caps in a stand-alone
operation. A picture of the end-caps for the most recent
vessel-design iteration is shown in Figure 1.

The first set of AFP end-caps made by Boeing
according to the modified patterns from stress analyses
was received in May for developing the third vessel.
The liner with end-caps was installed onto a winding
machine. FW patterns were laid down according to the
design. All hoop layers went onto the liner smoothly.
As soon as the first helical layer was laid down, the
end-caps wrinkled. The wrinkles were caused by air gaps
between the AFP end-caps and the liner. The tension
from the FW carbon fiber compressed the AFP end-
caps toward the cylinder section, but the end-caps were
constrained from movement in the axial direction due to FW hoop layers already placed over the edge of the AFP end-caps. This resulted in the wrinkles in the AFP end-caps. The wrinkles made these end-caps no longer useful.

On the second set of end-caps received from Boeing, it was decided to use a FW low-angle helical to capture the end-caps. The liner with end-caps was placed on a winding machine. Heat was applied to the end-caps using a heat gun. Once both end-caps started to soften and become pliable, a low-angle helical that closed around both forward and aft bosses was applied to hold the end-caps tight. Then the helical was cut off before laying down the first set of FW pattern. Once FW was finished, the vessel was put on B-stage until the surface became tack free. The vessel was then shipped back to Boeing in late June. Boeing now has the task of laying-up the next sequence of tows in this hybrid design. Once this is done, Quantum will finish the vessel with the final courses of filament wound material.

Alternative Fibers

Various alternative fibers are being investigated to further lower the cost of manufacturing fuel storage vessels by utilizing lower tensile strength fibers on the outer layers of FW due to lower stresses in comparison to the inner layers. Possible alternative fibers could include glass, basalt, Saffil, alumina, boron, and silicon carbide.

Glass and basalt fibers were investigated initially, but they have been eliminated at this stage of the research because the tensile moduli are significantly lower than the carbon fiber, which is 33.4 Msi. Quantum expects that unless the tensile modulus of the fibers on the outer layers is equal or higher than those of the inner carbon layers, the outer layers will not carry significant percentage of the pressure load. As a result, Saffil, alumina, boron, and silicon carbide fibers were further investigated. However, all these fibers have been disqualified for consideration because the fibers either do not have the required tensile modulus, are not available in continuous form, or too expensive.

Without finding an alternative fiber that is cost-effective for the application, the focus shifts back to searching for an alternative carbon fiber. The alternatives include Toray T300, Zoltek Panex35, Toho Tenax HTR40, and Cytec T-500C. After initial review, the most promising candidates are Zoltek and Toho because of their material properties and pricing.

Cost Model

PNNL developed cost models using Quantum and Boeing’s manufacturing data to compare the costs of traditional filament wound tanks with the hybrid FW+AFP tanks. Two bounding manufacturing scenarios were considered, one that optimized the composite layup without concern for machine usage and one that considered 100% machine usage. The first hybrid tank produced by Quantum and Boeing exceeded the required burst pressure and saved 11.1 kg of the 76 kg baseline (14.6%). Eliminating 11.1 kg of carbon fiber composite significantly outweighed the added manufacturing cost (for machinery and factory space) of the hybrid process. The cost model estimates that the tank cost is reduced from $23.45 to $21.75 per kWh of hydrogen based on $11/lb of carbon fiber. The gravimetric efficiency is also increased from 1.5 to 1.67 kWh/kg. Further details are provided in PNNL’s annual report.

Dry-Tape Development

Although many details of the best dry-tape processes remain proprietary, a broad spectrum of coarse economic analyses quantifies their cost advantages. Among the alternative tape fabrication processes, LLNL has been reducing two to practice. These two have been chosen, not because they will perform best (either structurally or economically), but because their development might be affordable given the limited funding available. Both alternatives LLNL is developing are capable of the speed that underlies tape fabrication economic advantages. However, those advantages degrade rapidly if any structural performance is sacrificed by the microstructure built up by fabrication. This subproject’s Phase 2 milestone will achieve full technical proof of concept by demonstrating that at least 90% of the tensile strength and 50% of the shear strength of conventional epoxy matrix composites is preserved in tape fabrication.

The first generation of tape specimens was built by pultrusion in the autumn of 2009. However, the tape specimens possessed a shortage of infused matrix in their acute-angled corners, and have occasional thin bubbles.
along the fiber axis. These microscopic defects would make that generation vulnerable to significantly reduced strength in shear. Therefore, second generation tape prototyping is underway, with new materials processing due to begin in July.

Conclusions and Future Direction

- AFP end-caps can be manufactured as a stand-alone process.
- Lower cost carbon fibers with equal tensile modulus to inner fiber and low tensile strength are still the most cost-effective alternative fibers. Down-selection will be based on price and performance.
- The third vessel has gone through the first set of AFP and FW. Boeing will be laying up the next sequence of tows. Quantum will apply the final courses of FW and perform a burst test.
- If the burst test goes well, the next composite design iteration will incorporate an alternative fiber on the outer layers of FW. Two vessels will be built for burst test and ambient cycle test.
- Boeing has started the process for the design and build of an improved head design. The new head will include features that allow fiber placement into tighter locations, such as in the polar radius. Other features will include advanced heating, cutting, and teardown capabilities.
- The cost model will be updated to reflect the improvements in tank manufacturing methods.
- PNNL will continue hydrogen degradation testing of polymer liner materials.
- Continue dry-tape development.

FY 2010 Publications/Presentations

VII. SYSTEMS ANALYSIS

VII.0 Systems Analysis Sub-Program Overview

Introduction

Systems Analysis supports decision-making by providing a greater understanding of technology gaps, options, and risks; the contribution of individual technology components to the overall system (i.e., from fuel production to utilization); and the interaction of the components and their effects on the system. Analysis is also conducted to assess cross-cutting issues, such as integration with the electrical sector and the use of renewable fuels. Particular emphasis is given to assessing stationary fuel cell applications, fuel quality impacts on fuel cell performance, resource needs, and potential infrastructure options.

The Systems Analysis activity made several significant contributions to the Program during Fiscal Year (FY) 2010. Several analytical tools, including the Stationary Fuel Cell Power Model, the Hydrogen Demand and Resource Analysis (HyDRA) tool, and the Macro-System Model (MSM) were updated and peer reviewed to support the analytical process. Resource, infrastructure, and early market analyses were conducted to better understand supply and demand issues. In particular, biogas from waste treatment facilities and landfill systems was identified as a large resource with the HyDRA model and was determined to be predominately located near urban centers that can provide feedstock for fuel to be used in stationary fuel cells for power generation. A cost model was developed to evaluate the cost of removing impurities from these resource streams. In addition, a study was initiated to evaluate the impact of the biogas impurities on fuel cell performance and durability. The Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model was modified to enable criteria pollutants to be evaluated on a life-cycle basis for stationary fuel cells for combined heat and power production in comparison with other competing technologies such as natural gas microturbines, internal combustion engines, and electrical generation from natural gas and coal fired systems. Risk analyses were also conducted to help identify key research and development (R&D) gaps for fuel cell systems and areas of high risk in terms of meeting targets and timelines.

Goals

Provide system-level analysis products to support the overall Program by evaluating technologies and pathways, guiding the selection of research, development, and deployment projects, and determining technology gaps, risks, and benefits.

Objectives

• By 2011, enhance the MSM to include the stationary electrical generation and infrastructure.
• By 2014, complete environmental studies that are necessary for technology readiness goals.
• By 2015, analyze the potential benefits of fuel cells for multiple applications such as portable, stationary, and backup power; and assess resource needs, infrastructure requirements, and potential interactions with the electric power sector.
• Provide analysis of Program milestones, including risk analysis, independent reviews, financial evaluations, and environmental analysis, to support the Program’s needs prior to the technology readiness milestone.
• On an annual basis, update the well-to-wheels and life-cycle analyses for technologies and pathways for the overall Program by incorporating technological advances and changes.

FY 2010 Status

Systems Analysis focuses on examining the economics, benefits, risks, opportunities, and impacts of fuel cells and renewable fuels within a consistent, comprehensive analytical framework. Analysis conducted in FY 2010 included identifying early markets for fuel cells and opportunities to reduce cost through various mechanisms, such as tax credits and other legislation. The Systems Analysis sub-
program has transitioned from activities focused on key model development to the application of the models for completing critical program analyses. As evidenced by the completed and ongoing analysis activities shown in the “Accomplishments” section, the initial strategy of the Systems Analysis sub-program has been effective in providing critical analysis results that help guide the Program’s overall hydrogen and fuel cell activities.

**FY 2010 Accomplishments**

**Models**

- The MSM, a dynamic engineering transition model, was updated to include infrastructure and resource analysis for diverse resources, various regions, and a variety of hydrogen production pathways. The model is used for the simulation of the performance and evolution of hydrogen infrastructure, using a distributed architecture to link existing and emerging models for system components. Infrastructure and resource analysis capabilities were made feasible by the addition of the resources model, HyDRA, and the infrastructure model, HyPRO, to the MSM.

- The Fuel Cell Power Model, developed by National Renewable Energy Laboratory (NREL) to evaluate costs from combined heat and power generation for polymer electrolyte membrane fuel cells, phosphoric acid fuel cells (PAFCs), and molten carbonate fuel cells (MCFCs), was upgraded to include business and financial analysis useful to multiple entities such as building owners, fuel cell vendors, station owners, utilities, and fleet operators. The model features analysis of power, heat, and hydrogen fuel costs based on capital equipment costs, feedstock prices, operating climate conditions, and the heat and power loads for the system.

**Infrastructure Analysis**

- Infrastructure analysis conducted by Oak Ridge National Laboratory with the HyTrans model, NREL with the Scenario Evaluation and Regionalization Analysis model, and Sandia National Laboratories revealed that synergies between fuel cells for stationary power generation and transportation could be realized in the early phases of market adoption of hydrogen for light-duty fuel cell vehicles. Widespread deployment of combined heat, hydrogen, and power (CHHP) could reduce the problem of hydrogen availability in the early stages of transition to fuel cell vehicles. Results of this analysis indicate that hydrogen produced from CHHP could result in smaller stations with higher capital utilization and lower hydrogen cost, supplementing hydrogen supplied from distributed natural gas–based steam methane reforming (SMR).

- Analysis conducted by NREL with the Fuel Cell Power Model indicates that hydrogen produced from a stationary fuel cell would have a lower cost than hydrogen produced from an SMR system at low volumes, as exhibited in Figure 1 (stationary fuel cells have the unique ability to produce hydrogen in addition to heat and power and to use diverse renewable fuels such as waste gas or biogas). This factor will be important during the early stages of transportation fuel cell adoption because hydrogen demand and resultant hydrogen production will be at low volumes.

- DOE participated in an infrastructure workshop sponsored by the International Partnership for Hydrogen and Fuel Cells in the Economy to examine the key drivers and gaps to early market infrastructure development for light-duty vehicles. Providing adequate fueling infrastructure for consumers is one of the key barriers to hydrogen fuel cell vehicle commercialization. The outcomes of the workshop included the following ideas:
  - Develop low-cost 100 kg/day starter stations
  - Define a “line of sight” path to business profitability
  - Create co-ops or public-private partnerships
  - Enact policies and incentives to make hydrogen more attractive to investors
  - Explore innovative ways to boost hydrogen demand by serving multiple applications
  - Promote novel business models that utilize new methods of financing
  - Leverage existing natural gas and hydrogen infrastructure to reduce costs
Environmental Analysis

- Argonne National Laboratory (ANL) enhanced the well-to-wheels analysis capabilities of the GREET model by including analysis of criteria pollutant emissions from stationary fuel cells for combined-heat-and-power (CHP) generation and CHHP generation. The analysis shows that fuel cell systems for CHP and CHHP produce significantly less carbon monoxide, particulate matter and oxides of nitrogen (NOx) emissions than conventional generation technologies. For example, Figure 2 shows that PAFCs and MCFCs emit at least 80% less NOx than other conventional generation technologies without after treatment.
• ANL has started the impact analysis of feedstock quality on stationary fuel cell performance and the costs associated with meeting the required feedstock quality specifications. The feedstocks being assessed include natural gas, landfill and anaerobic digestion biogases, and syngas from coal and biomass gasification. The key impurity analysis shows sulfur, siloxanes, heavy metals, and halides are detrimental to the fuel cell anode. Ammonia, carbon monoxide, and hydrocarbons are less damaging for higher-temperature fuel cells such as solid oxide fuel cells (SOFCs) and MCFCs. Further R&D will be needed to determine separation technologies and costs to remove these contaminants from the feedstock streams.

Resource Analysis

• Analysis by Lawrence Livermore National Laboratory of the impact of water on hydrogen production has found that it will have a minor effect—of less than $0.10/gasoline gallon equivalent. The assessment included an examination of water permitting and allocation on water cost, and found that these effects varied from region to region. Water was found to be abundant at a national level, but permitting and allocation at a regional level could be problematic in regions with high water stress such as California, Arizona, and Colorado. Expansion of industrial water demand for applications such as hydrogen production in these regions may encounter water availability limits before reaching a cost constraint.

• NREL developed a model to examine the cost of purifying biogas streams to enable them to be used in a fuel cell or in hydrogen production from steam methane reforming. Biogas—which can come from landfills, wastewater treatment plants, and farms—is an abundant energy source that is often strategically located near major urban centers; however, it contains contaminants such as ammonia, sulfur, hydrocarbons, siloxanes, and heavy metals. This model will supplement other models in the DOE portfolio for hydrogen production cost analysis, fuel cell electrical cost analysis, and greenhouse gas emission evaluation.

Programmatic Analysis

• Pacific Northwest National Laboratory analyzed the commercial benefits of the Fuel Cell Technologies (FCT) Program by tracking the commercial products and technologies developed with the support of the Program (Figure 3). The results show 198 patents were issued and 28 products were commercialized by 2010 as a result of research funded by FCT in the areas of storage, production, delivery, and fuel cells, which will be highlighted in the FY 2010 Pathways to Commercial Success Report.

• A workshop was held in FY 2010 to identify gaps to reduce costs for fuel cells for distributed CHP generation in the 200-kW to megawatt range. The gaps identified included:
  – High cost of feedstock contaminant removal
  – Need for higher power density
  – High cost of balance-of-plant components

![FIGURE 3. Cumulative Number of Commercial Technologies as a result of Energy Efficiency and Renewable Energy Funding for Hydrogen and Fuel Cells](image-url)
- Need for increased stack and cell durability
- Need to reduce platinum content of phosphoric acid fuel cells

**Budget**

The budget for the Systems Analysis activity is consistent with the goals and objectives of the sub-program and enables assessment of fuel cell applications for energy storage, stationary power generation, specialty applications, and light duty transportation. The FY 2011 budget request includes funding for resource and infrastructure analysis, as well as fuel quality evaluation, environmental analysis, overall program analysis, modeling, and systems integration. New fuel cell opportunities for energy storage and transmission will also be explored.

**FY 2011 Plans**

In FY 2011, the Systems Analysis sub-program will focus on conducting analyses to determine technology gaps for fuel cell systems and infrastructure for different applications, and utilizing fuel cells and hydrogen for energy storage and transmission. Analyses will be focused on understanding the tradeoffs and regional impacts of fuel cells with other alternative fuels and the electrical sector on a well-to-wheels basis, and the synergies of linking stationary fuel cell power generation with the electrical sector. The FY 2010 appropriation included $5.5 million for Systems Analysis; the FY 2011 request is $5 million. The budget request for FY 2011 reflects the focus on early market analysis, fuel cell technology evaluations, renewable fuel benefits, as well as resource and infrastructure analysis.

VII.1 Scenario Evaluation, Regionalization and Analysis (SERA) Model

Objectives

The Scenario Evaluation, Regionalization and Analysis (SERA) model\(^1\) is a geospatially and temporally oriented analysis model that determines the optimal production and delivery scenarios for hydrogen, given resource availability and technology cost. The objectives of the most recent phase of the project are:

- Expanding the interoperability of SERA with the Hydrogen Demand and Resource Analysis (HyDRA) model [1]. The interoperability with HyDRA generally involves providing compatible data formats and conforming to HyDRA's data schemas.
- Developing sub-models within SERA to represent a variety of alternative infrastructure development pathways, including the utilization of stationary power combined heat and power (CHP) or combined heat, hydrogen, and power (CHHP) applications, and hydrogen production from biogas resources. These pathways are sensitive to various time metrics associated with infrastructure dynamics.
- Continuing and expanding the work on case studies using the SERA model, focusing on early markets in California and also extending the analysis to national scenarios.

---

\(^1\) SERA was formerly known as the Hydrogen Deployment System Modeling Environment (HyDS-ME).

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section (4.5) of the Fuel Cell Technologies Program’s Multi-Year Research, Development and Demonstration Plan:

- (B) Stove-piped/Siloed Analytical Capability
- (D) Suite of Models and Tools
- (E) Unplanned Studies and Analysis

Contribution to Achievement of DOE Systems Analysis Milestones

This project is contributing to achievement of the following DOE milestones from the Systems Analysis section of the Fuel Cell Technologies Program’s Multi-Year Research, Development and Demonstration Plan:

- Milestone 5. Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for various hydrogen scenarios.
- Milestone 24. Complete the linear optimization model (HyDS) to analyze the optimum production facilities and infrastructure for hydrogen demand scenarios.

Accomplishments

Completed first-of-kind preview studies:

- Wind-hydrogen infrastructure study.
- Spatiotemporal refueling modeling analysis.
- Analysis of CHHP competition with on-site steam methane reforming (SMR).
- Constructed new spatially and temporally detailed baseline scenarios:
  - Staged rollout of fuel cell electric vehicles (FCEVs) by urban area in a manner fully consistent with published National Academy of Sciences (NAS) scenarios.
  - Analysis of FCEV rollout on national scale.

Achieved significant enhancements in SERA usability:

- Two-way interoperability with HyDRA.
- More detailed and adaptable cost models.
- Revisions to user interface.
- Improvement of database schema.
Introduction

The SERA model fills a unique and important niche in the temporal and geospatial analysis of hydrogen infrastructure build-out for production and delivery. It nicely complements other hydrogen analysis tools and is well suited to contribute to scenario analysis involving the temporally specific geospatial deployment of hydrogen production and transmission infrastructure. Its key capabilities are (i) an optimization of the physical build-out of hydrogen infrastructure, (ii) the unified treatment of production, transmission, and distribution, (iii) the ease with which new technologies can be added to an analysis, (iv) the consistent physical and economic computations, (v) the ability to estimate costs and cash flows, (vi) the spatial and temporal resolution of hydrogen infrastructure networks, (vii) regional specificity, and (viii) the allowance for exogenously specified urban hydrogen demands. Its internal architecture is flexible, and it is compatible with geographic information systems and the H2A models [2,3]. SERA is designed to answer questions such as: Which pathways will provide least-cost hydrogen for a specified demand? What network economies can be achieved by linking production facilities to multiple demand centers? How will particular technologies compete with one another?

Approach

In order to answer such questions, SERA supports analyses aimed at identifying optimal infrastructure to meet specified annual urban hydrogen demands, perhaps coupled to other multiple objectives and constraints. Cash flows are computed, detailed by infrastructure component, city, and region, and these provide insights into components of hydrogen costs, which are determined by year, volume, and locality.

Four methods of long-distance hydrogen transport are considered: pipeline, gaseous truck, liquid truck, and railroad. The major use of SERA is for studying potential turning points in infrastructure choice via sensitivity analysis on infrastructure, feedstock, and fuel cost inputs in the context of the complex transient and transitional interactions between increasing hydrogen demand and hydrogen infrastructure construction. With carefully constructed input data sets, SERA can also weigh tradeoffs between investments in various infrastructure types, given policy constraints (greenhouse gases, etc.). Figure 1 shows the interrelationship between the input data for SERA and the algorithms applied to them in order to compute the delivered cost of hydrogen. The infrastructure networks are optimized using a simulated annealing algorithm that explores the large set of potential build-out plans that meet the input requirements for hydrogen delivery at cities over time. The hydrogen transport computations are based on graph-theoretic algorithms for determining optimal flows in networks. The cash flow computations rely on standard discounting approaches. Figure 2 shows sample SERA output in the form of an optimized hydrogen infrastructure network.

Results

The software development work on enhancing SERA's interoperability with HyDRA resulted in several new technical capabilities in SERA: SERA can now retrieve map layers from HyDRA via Web feature services (WFS), can style map layers using symbology consistent with HyDRA (e.g., consistent colors and shapes for visual representations), and can retrieve regional cost data from HyDRA via WFS. Conversely, HyDRA can now ingest analysis results output from SERA: (i) hydrogen infrastructure networks, by year and (ii) delivered hydrogen costs, by year.

Additionally, we enhanced the SERA cost models by substituting current delivery cost curves with H2A...
delivery components built inside the SERA model. This allows us to use H2A standards, but achieve maximum flexibility in constructing pathways (e.g., mixed pathways) within the analyses.

We completed a preliminary study that examines the relative cost-effectiveness of supplying hydrogen refueling stations via CHHP or on-site SMR for a large urban area, under three FCEV penetration scenarios. The major conclusions of this work are: (i) CHHP-based hydrogen production for use in nearby hydrogen refueling stations typically only has cost advantages over on-site SMR hydrogen production at some of those refueling stations, particularly for the early years of FCEV penetration scenarios where hydrogen demand and station sizes are initially low; (ii) variations in SMR or CHHP facility and energy-input costs can dramatically affect the overall cost of hydrogen, but they do not affect the mix of CHHP and SMR deployment as strongly; and (iii) for these scenarios and this study region, hydrogen costs typically drop from slightly above $6/kg in early years to below $5/kg in later years.

In conjunction with the CHHP work, we implemented a spatiotemporal station placement technique that produces realistic spatial, temporal, capacity distributions for hydrogen refueling stations. This station network expansion algorithm is based upon empirical data for existing gasoline stations, simulations of how those networks have evolved over time, and the resulting station size distributions.

Other SERA efforts involved the construction of a new, highly detailed FCEV rollout scenario that matches the standard NAS scenarios [4] in terms of FCEV introduction, FCEV stock, vehicle-miles traveled, and hydrogen demand on a year-by-year basis in addition to matching the city-specific schedule in the study. Analysis of these scenarios using SERA indicates that the more accelerated demand scenarios have lower delivered costs of hydrogen, time-averaged delivered costs ranging ~$3.5/kg to ~$5/kg, and that the details of infrastructure choice are quite sensitive to feedstock costs and the infrastructure cost models.

Finally, we completed a preview study of the SERA biogas capability: this involved (i) provisionally incorporating the latest NREL biogas systems characterization into SERA, (ii) performing an illustrative analysis of infrastructure build-out highlighting the significance of biogas pathways, and (iii) developing insights for future in-depth studies involving biogas pathways. SERA uses cost estimates from the H2A biomethane systems model in conjunction with those from the H2A production model to evaluate the delivered cost of biogas-originated hydrogen. In the sample analysis that we performed (on a test case of Midwestern cities), the optimal choice of infrastructure often hinges upon the difference between biogas and natural gas prices: when the biogas price, plus the processing cost to biomethane, is less than the natural gas price, the biogas pathways have lower costs. In general, the most competitive biogas scenario is where a single large biogas plant supplies a dozen or more (typically small) on-site SMR plants.

Conclusions and Future Direction

In summary, SERA is an effective, integrated, cross-cutting model for optimization-analysis studies of hydrogen infrastructure build-out compatible with the H2A models: it searches for optimal combinations of hydrogen production and transmission infrastructure to meet time-varying demand in urban areas over a region.

The next steps for SERA are to take the lessons learned in recent applications of the tool and to further exercise its analysis capabilities with ever more realistic input data sets in computing and visualization environments that allow thorough exploration of the cost issues around regional hydrogen infrastructure build-out. We are also iteratively improving the detail and accuracy of the cost models in SERA in order to support more complex scenarios. In particular, we plan to examine price points between competing technologies, such as delivered “drop-in” tanks vs. on-site SMR and electrolysis production. These price points will be resolved geographically and temporally as demand increases across multiple cities in a given region. Future SERA work will also address questions about stakeholder behavior and consumer preferences will be examined (e.g., preference for station availability, fuel costs, green hydrogen): to this end, we are planning to couple SERA to a discrete-choice model for hydrogen demand.

FY 2010 Publications/Presentations

References

Objectives

- Develop models of interdependent energy infrastructure systems.
- Analyze the impacts of widespread deployment of a hydrogen fueling infrastructure.
- Analyze the impacts of stationary fuel cell systems for distributed power.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Future Market Behavior
(B) Stove-piped/Siloed Analytical Capability
(E) Unplanned Studies and Analysis

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achievement of the following DOE milestones from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 5**: Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for technology readiness. (4Q, 2010)
- **Milestone 7**: Analysis of the hydrogen infrastructure and technical target progress for the hydrogen fuel and vehicles. (2Q, 2011)
- **Milestone 8**: Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for technology readiness. (4Q, 2014)

Accomplishments

Sandia National Laboratories developed a dynamic tool for analyzing the potential impact of an emergent hydrogen fuel infrastructure on the existing energy infrastructures.

- Developed models of the market behavior of natural gas (NG), refined petroleum, hydrogen, and electricity generation in California.
- Incorporated a vehicle adoption model for hydrogen-fueled vehicles, plug-in hybrid electric vehicles, and a new generation of conventional vehicles that meet the Corporate Average Fuel Economy (CAFE) regulation through the 2016 ruling.
- Incorporated a model for the impact of stationary fuel cell systems with distributed generation of electricity by combined with the provision of heat or cooling to a building, and potential co-production of hydrogen for vehicles.

Introduction

The DOE Hydrogen Program envisions the transition to hydrogen vehicles will begin by using the existing infrastructure for NG to produce hydrogen by steam-methane reforming (SMR). In addition, the transition to widespread use of hydrogen in fuel cells is expected to benefit from development of the market for stationary fuel cells (SFCs). Previously, we developed a model for the adoption of hydrogen-fueled vehicles (HFVs) and plug-in hybrid electric vehicles (PHEVs). The model showed that adoption of either of these alternative fuel vehicles (AFVs) effectively couples transportation to the markets for hydrogen, electricity, and NG.

The present work investigates the coupling of hydrogen and electricity further by adding the adoption of SFC distributed to buildings. The model is now able to examine the reduced load on the grid from distributed SFC, as well as the potential benefits of combined heat (or cooling) and power. Lastly, the application of high-temperature SFC systems allow for the potential co-production of hydrogen, for local refueling of HFVs.
Approach

We use the system dynamics approach to simulate the adoption of SFCs for a selection of buildings within the state of California, which is expected to lead the adoption of HFVs. The adoption of SFCs is specified based upon estimates of the potential for applying combined heat and power (CHP) provided by the California Energy Commission [1]. The penetration of SFCs is not modeled as a competitive adoption based on economics, so the model serves to estimate the potential impact that SFC systems can have on the electricity and fueling infrastructure.

The simulated operation of the SFC follows daily load profiles for the electricity, heating, and cooling for various buildings taken from the DOE database [2]. The hourly loads for the buildings are combined with the total electricity load for the state from California Independent System Operator data [3]. The distributed electricity provided by the SFC reduces the total state demand, which is filled by a simple dispatch model developed previously [4]; the model approximates the state electricity mix for baseload power, but assumes that all marginal electricity is provided by NG generation. Consequently, distributed electricity reduces the demand for NG generation.

The SFCs are sized for buildings and homes to operate with about a 75% capacity factor. A daily load profile for a type of building—large office, for example—is considered for each of the four seasons; the simulation timestep is a quarter of the year, so the integrated operation over a day in each season represents an average for the quarter. When the SFC can meet the building electric load, its electricity reduces the demand on the grid. When the building load exceeds the SFC capacity, the excess load is taken from the grid. Similarly, the useful heat provided by the SFC in CHP mode offsets NG demand for a combustion-driven heater. In combined cooling and power (CCP) mode, the waste heat from the SFC is used in an absorption chiller to provide cooling, thereby offsetting electricity that would have otherwise provided the air-conditioning.

The details of the SFC operation are summarized in Table 1. The model considers two types of SFCs: large, high-temperature systems and small, low-temperature proton exchange membrane fuel cells (PEMFCs). The high-temperature systems have sufficient waste heat to operate either in CHP or CCP mode, depending on which mode the building load demands for the season of year. In addition, the model allows the potential to provide combined heat and hydrogen production (CHHP mode) for fueling HFVs. For the CHHP mode, the electrical efficiency is reduced from 47% to 40%, consistent with the operational data of an example molten carbonate fuel cell system [5].

Results

The projected impacts of SFCs and vehicles on the overall CO$_2$ emissions (including all sectors) for California (CA) are shown in Figure 1. Starting from the top-most curve, the solid curve shows the continuation of existing electricity generation and vehicle travel. The business-as-legislated (BAL) curve shows the impact of two regulations: the CA Renewable Portfolio Standard (33% by 2020) and the CAFE regulation (35.5 mpg by 2016). These two existing regulatory changes will reduce CO$_2$ emissions by 18% below the unregulated emissions by mid-century.

The next simulation adds the impact of SFC to the BAL scenario to see that there is only a minor effect—about 2% further reduction in CO$_2$ emissions. The impact is small because the SFCs displace NG plants with distributed generation that is only marginally
more efficient. The large SFC systems operate with an electrical efficiency that is about 7% better than conventional generation (~40%). The PEMFC systems have approximately the same electric efficiency as the conventional NG generation. The combined benefits of heat or cooling are marginal, because on average only about one-half of the available heat is matched to the daily heating or cooling demand; the other heat is not useable, due to mismatch in the timing of the electricity load and the heating load. Figure 2 shows the fraction of the total electricity supplied to the state by the SFCs. By mid-century, the SFC systems provide 16% of CA’s electricity. The total SFC capacity is 10 GW for the state load that varies from 30 to 70 GW.

Turning now to the impact of AFVs—both PHEVs and HFVs—which replace conventional and CAFE-compliant gasoline vehicles as shown in Figure 3. The penetration of HFVs and PHEVs were adjusted previously [4] to reflect the projections by Greene et al. [6]. The performance assumptions for vehicle performance are listed in Table 3. The impact of the large number of AFVs entering the state on-road fleet is much larger than that of the SFCs, adding a further 14% reduction from the SFC scenario. Since hydrogen from SMR without sequestration brings about the same CO₂ per energy content as gasoline, the gain from HFVs is due to the greater fuel economy.

While the SFC systems do not provide a large impact on CA’s CO₂ emissions, there is the potential for distributed co-production of hydrogen for vehicles. In the AFV scenario, the hydrogen demand grows to 3 billion kg per year, of which the large-scale SFC could potentially provide 11%, or enough to fuel about 2 million vehicles per year. Early market-adoption of SFCs could potentially help support the initial HFV refueling infrastructure.

Conclusions and Future Directions

The dynamic model for the CA infrastructure shows a limited impact of an optimistic penetration of stationary fuel cell systems on the overall CO2 emissions. The benefits of CHP are also limited by the matching of local building loads for electricity and heat (or cooling). However, the adoption of AFVs—primarily HFVs, but also PHEVs—brings a CO2 reduction nearly equivalent to the expected impact of existing regulations. The potential for CHHP to supply HFV in the state is significant if the SFC adoption occurs concurrently with the vehicles.

These conclusions regarding the impact of SFC with CHP are limited to the state of CA. Future work will apply the model to a region of the country where coal-fired electricity generation is dominant. Preliminary simulations suggest that the effect of SFC will be significant. Further development of the model will engage industry and utility partners to enhance the fidelity of the electricity dispatch model.

FY 2010 Publications/Presentations

References

Objectives

- Explore the chicken-or-egg problem: co-development of the hydrogen production and delivery infrastructure and the user base which supports it.
- Understand how the system works rather than provide one forecast of system development.
  - How do different policies affect the transition?
  - How sensitive is growth to factors beyond the control of policy makers?
  - What role do consumer attitudes and behavioral characteristics play?
- Consider in a complex adaptive system the interactions between:
  - Hydrogen fuel producers and suppliers.
  - Consumers of hydrogen fuel and fuel cell vehicles (FCVs).
  - Manufacturers of FCVs.
- Extend the current agent-based model to include limited-service combined hydrogen, heat and power (CHHP) facilities as well as the regular distributed production hydrogen fueling stations (HFSs) currently modeled.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Future Market Behavior
- Stove-piped/Siloed Analytical Capability
- Inconsistent Data, Assumptions and Guidelines

Technical Targets

This project addresses the following Systems Analysis objectives:

- Develop and utilize a macro-system model of the hydrogen fuel infrastructure to support transportation systems.
- Identify and evaluate early market transformation scenarios consistent with infrastructure and hydrogen resources.

Approach

We develop a computer simulation of the transition from petroleum-based to hydrogen-based personal transportation, focused on the Los Angeles, California metropolitan area. The technique we employ is Agent-Based Modeling and Simulation (ABMS), one in which the overall system behavior emerges from the simulation of the decisions, actions, and interactions of individual players, or “agents.” Driver agents represent consumers of vehicles and fuel. They are characterized by attributes such as home location and income level, and take simulated trips around the roadway network purchasing fuel when necessary. Drivers’ vehicle purchase decisions are based on cost, the availability of fuel, their attitudes towards new technology, and interactions with other drivers. Investor agents represent the builders of the hydrogen fueling infrastructure. They assess the suitability of various sites to locate HFSs based on traffic past the site and their estimates of competition and future growth in hydrogen sales, and build HFSs accordingly. A manufacturer agent controls the supply and selling price of FCVs.

The existing model must undergo modifications and enhancements in order to be able to examine questions dealing with CHHP facilities. After implementing the necessary changes we will use the model to analyze various scenarios under the premise that owners of CHHP plants may sell limited amounts of hydrogen to consumers via hydrogen dispensing facilities (HDFs). We will explore how owners of CHHP facilities might expand the hydrogen refueling infrastructure by adding
HDFs, and how the presence of HDFs might affect the overall transition.

**Accomplishments**

The project was initiated in March 2010. At the time of the 2010 Annual Merit Review Meeting, the following model enhancements had been completed:

- Increased the granularity of the roadway network topology to allow more refueling locations and more realistic trip routing.
- Added a simple manufacturer agent to limit the supply of vehicles during the early phase of the transition.
- Based on literature estimates and discussions with an automotive market research firm, improved the calibration of driver “personalities” (attitudes towards new technology and “greenness”) to the actual distribution in the population and stated willingness to pay.
- Provided driver agents with multiple personalities to help the agents better reflect the diversity in a modeled population 1,000 times larger.
- Calibrated driver trip distances to latest National Household Travel Survey data.
- Improved investor agents’ method of estimating and projecting hydrogen sales.

**Future Directions**

- Identify candidate locations for CHHP facilities.
- Develop simplified cost structure for CHHP facilities.
- Develop algorithms for driver agents to register/purchase from HDFs based on their proximity to home/work, the agent’s mileage driven, and perhaps other factors.
- Extend driver personalities to incorporate attitudes towards FCVs influenced by the inconvenience of purchasing fuel at HDFs (e.g., lack of full-service amenities, possible registration requirement).
- Develop algorithms for driver actions in the event of a HDF running out of fuel, and the resulting costs to the driver in inconvenience.
- Conduct scenario analyses and summarize findings in a report.

**FY 2010 Publications/Presentations**

VII.4 HyTrans Model: Analyzing the Potential for Stationary Fuel Cells to Augment Hydrogen Availability in the Transition to Hydrogen Vehicles

Objectives

- Develop and maintain a computer model for simulation of the dynamic market transition from petroleum to hydrogen-powered motor vehicles and for combined heat and power (CHP).
- Identify and evaluate early market transition scenarios for the transition to hydrogen vehicles and analyze conditions that could lead to a sustainable long-term transition.
- Analyze the ultimate potential for hydrogen and fuel cell vehicles through 2050, addressing resources, hydrogen production, infrastructure, cost and benefits.
- Develop scenarios and analyze the potential for stationary combined heat-and-hydrogen power (CHHP) to increase the availability of hydrogen fuel during the early transition.

Technical Challenges

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Future Market Behavior
(B) Stove-piped/Siloed Analytical Capability

Contribution to Achievement of DOE Systems Analysis Milestones

This project is contributing to achievement of the following DOE milestones from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 5: Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for various hydrogen scenarios. (4Q, 2009)
- Milestone 7: Complete analysis of the hydrogen infrastructure and technical target progress for the hydrogen fuel and vehicles. (2Q, 2011)
- Milestone 26: Annual model update and validation. (4Q, 2010)

Accomplishments

- Developed the first integrated market scenarios of the transition to hydrogen vehicles, measuring vehicle manufacturers’ “valley of death,” excess costs of fuel infrastructure, and establishing the sustainability of the transition if DOE technology goals are met.
- Updated HyTrans model to latest H2A models, latest Annual Energy Outlook (AEO) projections and updated vehicle technology characterizations.
- Completed analysis of potential synergies between deployment of stationary CHHP fuel cells and fuel availability during the early stages of a transition to hydrogen vehicles.

Introduction

Making a transition from petroleum-powered internal combustion engine vehicles to a hydrogen-powered system involves decisions by consumers, governments, and industry. HyTrans integrates all key components in a computer model that simulates market decision making from the present to 2050. Consumers choose among competing advanced technologies based on vehicle prices and energy costs, fuel availability and the diversity of makes and models offered. The cost and performance of advanced technology vehicles
change over time affected by cumulative experience producing vehicles, economies of scale and research and development (R&D). Energy suppliers decide what resources and conversion processes to use to produce hydrogen. Key metrics include petroleum consumption and fuel cycle greenhouse gas emissions. HyTrans was used to produce DOE’s first integrated scenarios of the transition to hydrogen vehicles [1].

In this study, the HyTrans model was used to analyze the potential for stationary fuel cells producing combined heat and electric power for buildings to serve as sources of hydrogen for motor vehicles during the early stages of a hydrogen transition. Stationary fuel cells convert a fuel such as natural gas to hydrogen, generating electricity and heat. Depending on the cycle of demand for heat and electricity, the ability to sell electricity to the grid and other factors, stationary fuel cells may also be able to produce hydrogen at relatively low cost for use by motor vehicles. Because stationary fuel cells will be co-located with large buildings and institutions, they could serve as small-scale distributed sources of hydrogen for motor vehicles thereby greatly increasing hydrogen availability in the critical stages of an early transition to hydrogen vehicles.

Approach

The analysis comprised three steps, defining scenarios of CHHP deployment, modifying and updating the HyTrans model to include hydrogen supply via CHHP, running the model and analyzing the results. The three hydrogen fuel cell vehicle market penetration scenarios of DOE’s hydrogen transition analysis [1] were used to estimate the effects of greater hydrogen availability via CHHP.

Three national scenarios of CHHP deployment were created based on a study by the California Energy Commission and the Electric Power Research Institute [5]. The scenarios were intentionally designed to be optimistic about CHHP deployment to determine whether it could potentially affect hydrogen fuel availability and hydrogen vehicle market success. The California scenarios were extrapolated to the U.S. market by scaling the California CHP penetration estimates by residential and commercial energy demand by Census Region. The Base Case reflects expected future gas and electricity prices, existing and expected emissions standards, and existing CHP cost and performance with evolutionary improvement over time. The Base Case does not, however, include the existing California Self Generation Incentive Program (SGIP).

The High-R&D + Incentives Case accelerates progress on fuel cells by three years and adds the California SGIP nationwide. The SGIP incentive for fuel cells, $2,500/kW is much higher than for other technologies and is critical to the uptake of fuel cell CHP units. The High Deployment Case accelerates technological progress for fuel cells by another two years and assumes that a larger fraction of the market is willing to consider CHP and that they will accept a longer payback period. In the reference assumptions half of potential customers require a payback in two years or less. In the High Deployment Case half will accept a three-year payback period.

The HyTrans model was then recalibrated to the 2009 AEO American Recovery and Reinvestment Act Reference Case, updated with vehicle technology characterizations from DOE’s Multi-Path Transportation Futures Study [5] as well as hydrogen production and distribution technologies from the H2A model and greenhouse gas emissions coefficients from the Greenhouse gases, Regulated Emissions and Energy use in Transportation model. Three sizes of CHHP units were represented: (1) 150 kW producing 56 kg/day, (2) 250 kW producing 93 kg/day, and (3) 1 MW producing 340 kg/day. The H2A model includes one representation of hydrogen delivery for CHHP: a short pipeline to a nearby refueling station. We added another option, collection of hydrogen from CHHP sites via tube trailer and trucking to a refueling within five miles of the CHHP site. The latter option was intended to allow greater flexibility in the quantities and timing of hydrogen production by CHHP units, as well as in the location and size of hydrogen refueling stations.

Results

The SGIP incentive has a large impact on the number of fuel cell CHP units projected for the year 2020. In the Base Case there are fewer than 2,000 fuel cell CHP units installed (Figure 1). With the SGIP nationwide almost 40,000 fuel cell CHP units are in service in 2020 in the High R&D Case, and over 60,000 in the High Deployment Case. All could potentially be CHHP units; however the actual number of CHHP units is determined by the demand for hydrogen in a given HyTrans model run. Substantial cumulative subsidies are required to achieve these levels of fuel cell deployment: $23 billion in the High R&D + Incentives Case and $43 billion in the High Deployment Case, compared with $0.5 billion in the Base Case.

Without any availability of hydrogen from CHHP, hydrogen is provided almost exclusively by distributed steam methane reforming (SMR) stations during the early transition. By 2020 there are less than 1,000 SMR stations nationwide (Figure 2). This compares with approximately 160,000 gasoline refueling stations.

In the High R&D and SGIP Case, the number of locations at which motorists can refuel with hydrogen exceeds 6,000 in 2020 and 14,000 by 2025, nearly 10% of all refueling outlets (Figure 3). The vast majority are supplied by midsize CHHP units. This reflects both the
numbers of CHHP units by size and the strong economies of scale in producing and delivering hydrogen from CHHP units. In general, hydrogen from the 250 kW units costs half as much as hydrogen from 150 kW units. Although it is still cheaper to produce hydrogen at the 1 MW units, there are far fewer of them. While the large majority of stations are supplied by CHHP in this Case, the majority of the hydrogen is supplied by larger (1,500 kg/day) distributed SMR stations.

Lack of hydrogen availability poses an extra cost for owners of fuel cell vehicles in terms of added time to access hydrogen fuel and concern about running out. The HyTrans model attempts to measure the cost of lack of availability in $/kg of hydrogen. Without the added hydrogen availability due to CHHP stations, hydrogen availability costs outside of the core regions of Los Angeles and New York remain high ($1 to $4/kg) even in 2020; availability costs in the rest of the U.S. are far higher ($4 to $9/kg). With increased hydrogen fuel availability provided by dispersed CHHP units, the cost of availability falls below $1/kg, even in the medium and low density portions of the Pacific and Northeast Census Regions (Figure 4). After 2020 availability costs are below $2/kg in all regions of the country.

Conclusions and Future Directions

Like any analysis of this kind, the results are strongly dependent on premises and assumptions. Nonetheless, the following conclusions are likely to be robust to alternative assumptions.

- Distributed production and delivery of hydrogen from CHHP units of between 250 kW and 1 MW in size could greatly reduce the costs of hydrogen fuel availability during the early stages of a transition to hydrogen.
- The fuel availability benefits of CHHP units are especially strong in areas that are not centers of hydrogen vehicle penetration.
- Insuring a sufficient number of potential sources of CHHP hydrogen will require large subsidies to fuel cell CHP installations, on the order of $20 billion to $40 billion cumulative to 2025, nationwide.
- Even with large numbers of CHHP units providing hydrogen, the greatest quantities of hydrogen are likely to be produced by distributed SMR during the first two decades or so of the transition.

FIGURE 2. Numbers of Distributed Retail Hydrogen Refueling Stations Assuming no CHHP

FIGURE 3. Number of Distributed Retail Hydrogen Refueling Stations in the High R&D and SGIP Scenario.
The highest priority areas for further analysis are: (1) developing scenarios of national CHP penetration that better represent regional factors affecting the competitiveness of fuel cell CHP, and (2) developing alternative H2A models of hydrogen delivery from CHHP installations.

E-mail: Fred.Joseck@ee.doe.gov

Project Start Date:  August 15, 2009
Project End Date:  September 30, 2010

Objectives

- Develop a cost-analysis tool for biomethane production from biogas and delivery of biomethane based on the H2A Production and H2A Delivery models, respectively.
- Collect Geographical Information System (GIS) data on select biogas resources—dairy farms, landfills, and sewage treatment plants—in California and cost data on biogas upgrading systems.
- Perform techno-economic analyses for scenarios involving production of biomethane from dairy digester biogas and delivery of the product gas to natural gas pipeline or another end-use site.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section (4.0) of the Fuel Cells Technologies Program’s Multi-Year Research, Development and Demonstration Plan [1]:

(B) Stove-piped/Siloed Analytical Capability
(C) Inconsistent Data, Assumptions and Guidelines
(D) Suite of Models and Tools

Contribution to Achievement of DOE Systems Analysis Milestones

This project contributed to achievement of the following DOE milestones from the Systems Analysis section (4.0) of the DOE Fuel Cell Technologies Program’s Multi-Year Research, Development and Demonstration Plan:

- Milestone 5: Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for various hydrogen scenarios. (4Q, 2009)
- Milestone 8: Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for technology readiness. (4Q, 2014)
- Milestone 11: Complete environmental analysis of the technology environmental impacts for the hydrogen scenarios and technology readiness. (2Q, 2015)
- Milestone 26: Annual model update and validation. (4Q, 2010)
- Milestone 41: Annual Analysis Conference for the hydrogen community. (4Q, 2010; 4Q, 2011)

Accomplishments

- Based on the H2A Production and H2A Delivery models, developed the H2A Biomethane, cost analysis model for biomethane production and delivery. The model determines the levelized cost of biomethane at the production site and point of delivery. It also estimates the energy consumption and emissions for the biogas upgrading system, the upstream processes, and downstream pressure-boosting compressors.
- Using GIS analysis tools, collected and evaluated geo-spatial data for biogas potential from landfills, dairy farms, and sewage treatment plants in the state of California.
- Performed a techno-economic analysis to (1) address the impact of biogas feed capacity (flow rate) on unit cost of biomethane, (2) evaluate economic feasibility of transporting the biomethane product to a natural gas pipeline, and (3) determine the critical cost components and identify opportunities for cost reduction.
- Determined that (1) the levelized cost of biomethane is greatly influenced by the wide variations in the costs of biogas and biomethane transport to a natural gas pipeline, and (2) biomethane produced from dairy-farm biogas can be economically competitive with natural gas for large-scale systems.

☆ ☆ ☆ ☆ ☆ ☆
Introduction

Production of biomethane (predominantly methane) from biogas presents an opportunity to reduce emissions and augment the natural gas supply. Along with these attributes, the evolving requirements of renewable portfolio standards, environmental regulations, and the available incentives are among the drivers for biomethane production and utilization. To determine the energy, economic, and environmental potential of biomethane, analysis tools, GIS data, and cost data are required, forming the premise of this project. Although biogas can be extracted from a variety of bio wastes and energy crops, stranded biogas from dairy farms, landfills, and sewage treatment plants is the primary focus here.

As a primary objective of this project, a cost-analysis model, H2A Biomethane, was developed to help perform technoeconomic analyses of scenarios involving production of biomethane from biogas and pipeline connection to the natural gas network or another demand site. Inclusion of the grid-connection feature was based on the realization that export of biomethane to the natural gas grid can expand the market for the potential biogas producers and consumers. Geo-spatial data on biogas resources (dairy farms, landfills, and sewage treatment plants) were collected for the state of California and analyzed using GIS mapping to evaluate the biogas potential in conjunction with the current natural gas consumption. Using the H2A Biomethane model, along with the GIS and cost data, “what-if” analyses were performed for scenarios focusing on biomethane production from biogas and its transport for injection into the natural pipeline.

Approach

The new analysis tool, H2A Biomethane, was developed based on the vetted H2A Production and Delivery models [2,3] that are intended to be transparent with respect to the key assumptions and procedures for calculation of the costs, energy consumption, and emissions. The methodology described in reference [4] was applied for estimating the energy requirements and emissions associated with dairy digester biogas. Reference [5] was also consulted in developing a data set for biomethane (natural gas) pipeline construction. The new model offers versatility in characterizing the upgrading process and the pipeline for transportation of the product biomethane to the natural gas grid or to another end-use site. To determine reasonable default values for the input variables/parameters of the model, cost data were collected from vendor, literature, and real-world projects involving biomethane production from biogas. Use of these sources of data helped develop validated default values with reasonable accuracy.

The preliminary techno-economic analyses conducted in this project are intended to demonstrate the capabilities of the new cost-analysis tool and to provide an insight on the cost structure for biomethane production and delivery. These analyses focus on the relative significance of the various cost components (e.g., costs of feed biogas, upgrading/cleanup process, and delivery pipeline) and explore their variation with the feed biogas capacity. Efforts are made to maintain consistency between the delivery component of this model and the H2A Delivery model in handling the pipeline extension and compression. The results of these and future analyses can lend themselves to stakeholders, including dairy farm owners, municipalities, and policymakers. This notion, coupled with the need for realistic data and practical considerations, prompted formation of a panel discussion with the stakeholders at an early stage of the project.

Results

GIS Analysis

Figure 1 presents the GIS map for the three biogas resources—dairy farms, landfills, and sewage treatment plants—in the state of California. The estimates for the total biomethane potential of these resources and the corresponding stranded gas are provided in Figure 2. At about 73% of the total potential, the aggregated...
landfills have the dominant share followed by the dairy farms at approximately 22%. However, considering that only about 50% of the biomethane potential from the landfills in that state is stranded compared to nearly 100% for the dairy farms, the dominance of the landfills lessens for future implementation. (Another potentially limiting factor for landfill gas may have to do with the lack of protocols/guidelines for permitting injection of biomethane produced from landfill gas into natural gas network.) The total biomethane potential comprises about 5% of the natural gas consumption in California.

Technoeconomic Analysis

An analysis was conducted to determine the levelized cost of biomethane production and pipeline delivery to the natural gas grid for a range of feed biogas capacity based on the following assumptions.

- Biomethane production site is about 16 km (10 miles) from the natural gas transmission line whose operating pressure is 40 bar (600 psia).
- Biogas containing 60% methane (by volume) enters the upgrading/cleanup system at the atmospheric pressure.
- Pipeline-quality biomethane leaves the upgrading system with 97% methane (by volume) at about 7 bar (105 psia) and compressed for injection into the transmission line.
- The life span for the entire system (upgrading system and extension pipeline) is 20 years.
- The investment rate of return is 10% and the inflation rate is 1.9%.
- Biogas cost is $5/GJ of the biomethane product. This cost is closer to the lower limit of the range reported in a United States Department of Agriculture report [6].

Presented in Figure 3 are the total levelized cost of biomethane and its constituents as functions of the feed biogas capacity. Considering that the biogas output capacity of the largest dairy farms rarely exceeds 400 Nm$^3$/h (based on the GIS analysis), potential local/regional clustering of the farms is the basis for the range of the feed biogas capacities covered in this analysis. Examination of these results (Figure 3) leads to the following observations.

- The total levelized cost of biomethane delivered to the natural gas grid is about $35/GJ and $11/GJ corresponding to feed biogas capacities of 250 Nm$^3$/h and 3,000 Nm$^3$/h, respectively. These results are indicative of strong dependency of the biomethane cost on the system size.

- For feed biogas capacities below 2,000 Nm$^3$/h, the pipeline transport cost is the dominant cost component. At higher capacities, the contributions of the biogas upgrading and transporting costs are about equal.

- At the assumed cost of $5/GJ, the feed biogas takes on a greater significance than the upgrading and pipeline transport constituents for biogas capacities exceeding 2,000 Nm$^3$/h.

Although all of the cost results are subject to uncertainties, the pipeline transport cost is additionally influenced by the proximity of the production site to the natural gas pipeline, a variability that is not captured in Figure 3. For example, if injection of biomethane into a distribution pipeline is permissible, a shorter extension line and less pressure-boosting compression for grid connection can ensue, resulting in a markedly lower cost.

FIGURE 2. Estimates of Total Biomethane Potentials and Stranded Amounts

FIGURE 3. Cost Analysis of Biomethane Production and Delivery
lower transport cost. Consequently, the ranking of the transport and upgrading costs may even be reversed at low biogas capacities.

The cost of biogas also has a critical role, particularly in larger systems, given its wide range stemming from the availability of various anaerobic digestion types implemented in dairy farms [6]. The total biomethane cost trend in Figure 3, coupled with the notion that the price of natural gas (residential) is approximately $9.5/GJ for the state of California and $11.7/GJ for the U.S. average [7], the biomethane production for on-site utilization (not involving transport) can be economically competitive for biogas capacities (greater than 500 Nm³/h) evaluated in Figure 2. More favorable economics can be expected when less costly biogas becomes available (e.g., biogas from covered lagoons in mild climates or from landfills). However, the cost of grid connection limits the economic competitiveness of the delivered product gas to large systems only (not accounting for any available state/federal incentives for renewables).

The results shown in Figure 3 do not include storage or any other unforeseen ancillary costs (e.g., sequestration and/or faring of the waste stream from the biogas upgrading process). Based on a report by Krich et al. [8], inclusion of a storage system for two day’s worth biomethane production can increase the cost by about $1.3 to $3 per GJ. For the case of clustered farms, the additional cost of transporting biogas (or bio waste) from the individual farms to a central location for upgrading is not addressed in this analysis either. A comprehensive and more accurate cost analysis requires details that are specific to each given project/scenario.

For cases where biomethane is produced for on- or near-site utilization and the feed biogas cost is available at low prices, the pipeline transport cost vanishes and, consequently, the upgrading cost takes on greater significance. In such scenarios, knowledge of the cost breakdown for the upgrading system can be valuable in identifying opportunities for cost reduction. Figure 4 illustrates the variation of the relative contributions of the key cost components with the feed biogas capacity. This figure suggests an increasing role of the variable costs (primarily utilities) as larger systems are considered.

Based on the emissions results of the H2A Biomethane model, the greenhouse gas emissions arising from the biogas upgrading and the upstream processes are approximately 1.84 kg/kg biomethane and -1.75 kg/kg, respectively, resulting in a net amount of 0.092 kg/kg biomethane. The emission for the biogas upgrading system is a function of the system energy efficiency and the biomethane recovery rate, which is assumed to be 99%.

The newly developed tool, along with analyses similar to the preceding, can assist the DOE Fuel Cell Technologies Program with evaluation of the economic and environmental benefits of using renewable biogas for on-site power generation with fuel cell systems. Other stakeholders, including biogas producers, can also benefit from these in the case-by-case decision making process.

Conclusions and Future Direction

- The newly developed H2A Biomethane model can lend itself to cost analysis of producing biomethane from biogas for on-site utilization or export to natural gas grid or another end-use application site. The model also allows calculation of the energy consumption and emissions for the biogas upgrading system and the upstream processes.
- Price of biogas, feed biogas capacity, distance between the production site and point of delivery, and the delivery pressure influence the levelized cost of biomethane.
- By taking advantage of the economy of scale for biogas upgrading process (biogas capacity greater than about 2,000 Nm³/h) and assuming purchase of dairy digester gas at $5/GJ, the levelized cost of biomethane production for on- or near-site utilization can be as low as $7/GJ. Therefore, biomethane produced from dairy digester biogas can be economically competitive with natural gas in certain circumstances even without applying any financial incentives.
- Achieving economy of scale for biomethane production from dairy digester biogas can be challenging because dairy farms offer relatively small feed biogas capacities (compared to landfills). Therefore, participation of near-by dairy farms in implementing a central system may be imperative if cost reductions are to be realized from the economy of scale.
Based on the predefined scope of the project, dissemination of the results at a conference or workshop is the only remaining activity. The following list outlines additional activities recommended for future work.

- Addressing oxidization and/or sequestration of the waste streams from the biogas upgrading process.
- Investigating the impact of biogas impurity level on the cost of the upgrading process.
- Performing analyses for nascent and existing installations/field studies.

E-mail: Fred.Joseck@ee.doe.gov

Project Start Date: October 2008
Project End Date: Project continuation and direction determined annually by DOE

Objectives
- Evaluate the economic viability of hydrogen for utility-scale energy storage applications compared with other electrical energy storage technologies.
- Explore the cost and greenhouse gas (GHG) emissions impacts of the interaction between hydrogen energy storage and variable renewable electricity resources.

Technical Barriers
This project addresses the following technical barriers from the Systems Analysis section (4.5) of the Fuel Cell Technologies Program’s Multi-Year Research, Development and Demonstration Plan:
(B) Stove-piped/Siloed Analytical Capability
(D) Suite of Models and Tools
(E) Unplanned Studies and Analysis

Contribution to Achievement of DOE Systems Analysis Milestones
This project contributes to achievement of the following DOE milestones from the Systems Analysis section of the Fuel Cell Technologies Program’s Multi-Year Research, Development and Demonstration Plan:
- Milestone 26: Annual model update and validation. (4Q, 2010)

Accomplishments
- Analyzed the levelized cost of energy (LCOE) for hydrogen energy storage versus competing technologies, finding that hydrogen is competitive with batteries and could be a cost-effective alternative to compressed air energy storage (CAES) and pumped hydro in locations that are not suitable for these technologies.
- Analyzed a hydrogen energy storage system with 1,400 kg/day excess hydrogen, finding an LCOE of $4.69/kg, not including tanker truck transport and dispensing (which compares with about $4/kg for the production portion of an electrolysis forecourt hydrogen station).
- Analyzed a hydrogen energy storage system with 12,000 kg/day excess hydrogen, finding an LCOE of $3.33/kg, not including tanker truck transport and dispensing (which compares with about $7/kg for electrolysis at a centralized hydrogen production facility of the same size).
- Analyzed energy storage system sensitivity to electricity price, finding that sensitivity to electricity price is roughly inversely proportional to energy storage system roundtrip efficiency and that efficiency improvements to a hydrogen energy storage system, especially the fuel cell, would have a larger positive impact on LCOE than similar improvements to competing technologies.
- Performed an initial study of the amount by which hydrogen energy storage reduces the amount of wind-generated electricity that must be curtailed and reduces the LCOE of the electricity delivered.
- Preliminarily analyzed the effect of obtaining financial credits for avoided carbon emissions on the LCOE of wind-generated electricity with and without hydrogen energy storage, finding that carbon credits can reduce the wind LCOE below the grid LCOE, with the addition of hydrogen energy storage providing lower LCOE than wind without storage.

Introduction
As renewable electricity becomes a larger portion of the electricity-generation mix, new strategies will be required to accommodate fluctuations in energy generation from these sources. Energy storage has been one of the primary strategies proposed for integrating large amounts of renewable energy onto the grid. Energy storage can absorb excess electricity-generating...
capacity during times of low demand and/or high rates of generation and then reconvert the stored energy into electricity during periods of high demand and/or low renewable generation. The use of hydrogen for energy storage also creates a potential bridge between the electricity and transportation sectors: excess hydrogen generated by energy storage systems could be used to provide fuel for hydrogen-powered vehicles.

In Task 1, the LCOE of the most promising and/or mature energy storage technologies was compared with the LCOE of several hydrogen energy storage configurations. In addition, the cost of using the hydrogen energy storage system to produce excess hydrogen was evaluated. In Task 2, the use of hydrogen energy storage in conjunction with an isolated wind power plant—and its effect on electricity curtailment, credit for avoided GHG emissions, and LCOE—was explored.

**Approach**

For Task 1, a simple energy arbitrage scenario was developed for a hydrogen energy storage system consisting of a 500-MWh nominal storage capacity that is charged during off-peak hours (18 hours on weekdays and 24 hours on weekends) and discharged at a rate of 50 MW for 6 peak hours on weekdays. The system electrolyzes water to produce hydrogen, which is stored in compressed gas tanks or underground geologic formations and reconverted into electricity using a polymer electrolyte membrane fuel cell or hydrogen expansion combustion turbine. The lifecycle LCOE resulting from each hydrogen storage scenario was compared with the lifecycle LCOE resulting from use of several battery systems (nickel cadmium, sodium sulfur, and vanadium redox), pumped hydro, and CAES. The analyses were performed for the same energy arbitrage scenario, and with consistent financial and operational assumptions, using the National Renewable Energy Laboratory’s HOMER model (https://analysis.nrel.gov/homer). In addition, the cost of using the hydrogen energy storage system to produce 1,400 and 12,000 kg/day of excess hydrogen was analyzed.

For Task 2, three scenarios were modeled for an isolated wind power plant in North Dakota that transmits electricity to Chicago: 1) a base case in which electricity from a 1,000-MW wind plant with a capacity factor of about 50% is transmitted via a dedicated 750-MW capacity transmission line to the grid with no energy storage, 2) a storage-constrained case in which the wind plant is combined with a 400-MT hydrogen energy storage system at the wind plant location, and 3) a transmission-constrained case in which the wind capacity is combined with 2,600 MT of hydrogen energy storage but only 500 MW of transmission capacity is available. The LCOE and electricity curtailment resulting from these scenarios were evaluated.

**Results**

In Task 1, modeling suggested that the LCOE of hydrogen energy storage is competitive with batteries and could be a cost-effective alternative to CAES and pumped hydro in locations that are not suitable for these technologies (Figure 1). For each technology, high-cost, mid-range, and low-cost cases were analyzed, and sensitivity analyses were performed to generate a range of possible costs for each case. In Figure 1, the bottom of the bars represents the low end of the range for the low-cost cases, and the top of the bars represents the high end of the range for the high-cost cases. The numbers shown are the nominal values of the mid-range cases and can be considered an estimate for LCOE for a 3–5 year future time frame.

The range of costs for each system reflects the range found in the literature and estimates of potential cost reductions as technologies develop. The hydrogen fuel cell scenario cost range reflects the comparative immaturity of fuel cell technologies for this application. It is anticipated that costs for fuel cells will decrease as the technology matures. Cost considerations aside, hydrogen has some advantages over competing energy storage technologies. It has a very high energy density (170 kWh/m³ versus 2.4 kWh/m³ for CAES [1] and 0.7 kWh/m³ for pumped hydro [2]), which allows for the potential economic viability of aboveground storage. Also, hydrogen combustion turbines could prove to be viable for energy storage applications and could provide additional flexibility to utilities through co-firing of mixtures of natural gas and hydrogen.

The sensitivity analyses showed electricity price to be one of the most important factors influencing LCOE for each storage technology. Further analysis
showed that sensitivity to electricity price is roughly inversely proportional to the roundtrip efficiency of the energy storage technologies (Figure 2). Improvements in the efficiency of hydrogen storage system equipment, especially the fuel cell, would have a larger positive impact on LCOE than similar improvements for competing technologies.

Using the hydrogen energy storage system to produce 1,400 kg/day of excess hydrogen reduces the overall LCOE for this scenario by about 6% compared with the purely energy arbitrage scenario, and the excess hydrogen is produced for $4.69/kg. Excess hydrogen produced in this way is still not competitive with hydrogen produced in a dedicated, distributed electrolysis process with the same daily output of hydrogen ($4.00/kg). However, producing 12,000 kg/day of excess hydrogen to feed into a hydrogen pipeline results in a cost of $3.33/kg, substantially less expensive than the $6.86/kg for a dedicated, centralized 12,000-kg/day hydrogen electrolysis facility.

In Task 2, the preliminary analysis suggested that combining hydrogen energy storage with electricity from an isolated wind power plant reduces the amount of wind-generated electricity that must be curtailed and reduces the LCOE (Table 1). This preliminary analysis also suggested that combining wind power with hydrogen energy storage enhances the reduction in LCOE resulting from instituting a credit for avoided carbon emissions (Table 1).

**Conclusions and Future Direction**

The modeling analyses performed in Fiscal Year (FY) 2009 and FY 2010 suggested that hydrogen energy storage is economically competitive with batteries and could be a cost-effective alternative to CAES and pumped hydro in locations that are not suitable for these technologies. Excess hydrogen could be produced for the transportation market. In addition, preliminary analyses suggested that using hydrogen energy storage in conjunction with an isolated wind power plant could reduce electricity curtailment and LCOE for the wind plant. Additional work is needed to elucidate the impact of hydrogen storage on GHG emissions and credits for avoided emissions, especially in comparison to CAES. Future work may include the following:

- Further explore the costs and benefits of dual-use hydrogen energy storage systems in which hydrogen is used for electricity storage and fuel for vehicles.
- Develop a methodology for optimizing the size of the storage system components and transmission to minimize costs for an isolated wind or solar installation.
- Analyze an isolated solar installation with hydrogen energy storage.
- Compare GHG emissions/carbon tax implications for hydrogen energy storage and CAES.

Start Date: Fiscal Year (FY) 2007
Project End Date: Project continuation and direction determined annually by DOE

Objectives

• Quantify the impact of water (cost, quality, scarcity) on a future hydrogen economy.
• Quantify the impact of a future hydrogen economy on national and regional water resources.
• Document best practices for hydrogen stakeholders in system design and feedstock management with respect to water.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Future Market Behavior
(D) Feedstock Issues
(E) Unplanned Analyses

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achievement of the following DOE milestones from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 5:** Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for various hydrogen scenarios. (4Q, 2009)
- **Milestone 11:** Complete environmental analysis of the technology environmental impacts for the hydrogen scenarios and technology readiness. (2Q 2015)
- **Milestone 27:** Complete the 2nd version of the Macro-System Model to include the analytical capabilities to evaluate the electrical infrastructure. (2Q, 2011)

Accomplishments

- Concluded that under foreseeable price regimes, water management is unlikely to add more than $0.05 to the cost of a kilogram of hydrogen via analysis of water withdrawal and consumption for hydrogen process and cooling water.
- Determined most economic cooling and water treatment technologies under variable water purchase and disposal price regimes.
- Created a national map of water stress by watershed through collaborations with the National Energy Technology Laboratory (NETL) and Sandia National Laboratories.
- Identified potential hydrogen markets with high risk factors (beyond water price) for water impacts.

Introduction

Water is a critical feedstock in the production of hydrogen. Major changes in the energy infrastructure (as envisioned in a transformation to a hydrogen economy) will necessarily result in changes to the water infrastructure.

Water is used as a chemical feedstock for hydrogen production and as a coolant for the production process. There are multiple options for water treatment and cooling systems, each of which has a different profile of equipment cost and operational requirements. The engineering decisions that are made when building out the hydrogen infrastructure will play an important role in the cost of producing hydrogen, and those decisions will be influenced by the regional and national policies that help to manage water resources.
**Approach**

This project takes a narrowly-scoped lifecycle analysis approach. We begin with a process model of hydrogen production and calculate the process water, cooling, electricity and energy feedstock demands. We expand beyond the production process itself by analyzing the details of the cooling system and water treatment system.

The narrow scope of the lifecycle analysis enables economic optimization at the plant level with respect to cooling and water treatment technologies. As water withdrawal and disposal costs increase, more expensive, but more water-efficient technologies become more attractive. Some of the benefits of these technologies are offset by their increased energy usage. We use the H2A hydrogen production model to determine the overall cost of hydrogen under a range of water cost and technology scenarios.

At the regional level, we follow the hydrogen roll-out scenarios envisioned by Greene and Leiby [1] to determine the impact of hydrogen market penetration on various watersheds. In collaboration with Sandia National Laboratories and NETL, we determine the level of water stress in each of the potential hydrogen markets, as well as the competing industrial water demand. We also analyze water purchase and discharge prices at the regional level to identify economic impacts of water on hydrogen at the regional level.

**Results**

As of this progress report, the final report for the hydrogen/water analysis is undergoing final revisions. An economic optimization of technologies for water management related to hydrogen production has been completed, and a regional analysis of water stresses and impacts on hydrogen production has been conducted.

Table 1 conveys the results of the techno-economic analysis. Multiple water treatment and cooling were analyzed. The three that were generally resulted in the lowest cost of hydrogen are arrayed on the right hand side of the table. For various combinations of water purchase and discharge prices (and assuming that other costs, such as labor and electricity, in the H2A model remained constant) the resulting hydrogen prices are shown in the center. As purchase and discharge prices rise, the least-cost water-management technologies shift. Because water purchase and discharge prices may be uncorrelated (Figure 1), the least-cost water option may not simply be the lowest withdrawal option.

Figure 2 shows the results of the water stress analysis that was performed for the entire nation at the watershed level. The blue “pinpoints” represent metropolitan areas highlighted in previous analyses as likely to have significant hydrogen vehicle penetration within the next 15 years. Table 2 lists these areas and provides quantitative metrics of risk to hydrogen rollout. Water stress, in this analysis, is defined as the total water

**Table 1.** The price of central steam methane reformed hydrogen, in $/kg-H₂, as calculated by H2A spreadsheets modified to account for water purchase and discharge prices and the varying capital and operating costs of different cooling and water treatment systems. The cells colored red indicate the lowest hydrogen price from among the three water-technology options.
withdrawal within a watershed divided by the total annual flow into that watershed (including precipitation, groundwater influx and runoff from other watersheds). A water stress greater than unity does not necessarily indicate unsustainable water usage because a significant fraction of all withdrawn water is discharged within the watershed from which it was withdrawn. However, the most highly stressed areas are, without a doubt, using water beyond their local means, either from “fossil” water resources (aquifers that are being depleted) or from water imports. High water-stress areas likely to be impacted by more severe water policies in the near-term.

**Conclusions and Future Directions**

- Water is an important issue for hydrogen stakeholders to monitor because the areas anticipated to have the earliest hydrogen rollout (particularly the Los Angeles area) are some of the most highly water-stressed. Hydrogen producers in these areas may be faced with limited ability to procure a water permit.
- Although permitting may be an issue, water is inexpensive and abundant on a national scale. Under all reasonable water-price scenarios, the total cost of water to hydrogen producers (including the capital cost of treatment and cooling systems) is unlikely to exceed $0.05/kg-H₂
- Hydrogen will not be adopted “in a vacuum.” Hydrogen will displace other fuels, each of which has its own water footprint. Therefore, the net impact of hydrogen on water resources will be somewhat lower than this engineering/economic analysis shows.

**FIGURE 1.** Water discharge (sewer) prices plotted against water purchase prices for 34 different municipalities. There is wide variability in water prices and little correlation between purchase and discharge prices.

**FIGURE 2.** A Google Earth™ map of the United States showing 329 watersheds. The watersheds are color-coded by the levated withdrawals (ground plus surface water) divided by the total water influx (precipitation plus stream inflow). Red regions are more highly stressed. The metropolitan areas expected to see early hydrogen rollout are labeled.
TABLE 2. Metropolitan areas likely to roll out hydrogen with their relevant watersheds. Water stress is calculated as the sum of total water supply (ground and surface) in all relevant watersheds divided by the sum of total water withdrawal in those same watersheds. Water used for hydrogen was calculated by using the number of predicted 1,500 kg/day stations [2] in each metro area and multiplying by a water intensive SMR-based hydrogen production technology (8.5 gallons withdrawal per kg hydrogen). The percent of supply used for hydrogen is calculated by dividing the water used for hydrogen by the total surface and groundwater supplies in the relevant watersheds. The percent increase in industrial water use is calculated by dividing the amount of water used for hydrogen by the watershed(s)-wide industrial use of water. Zero-discharge and dry cooling technologies are capable of reducing these figures by a factor of 4.

Subcontractors:
IDC Energy Insights, Farmington, MA

Project Start Date: September, 2009
Project End Date: September 2010

Objectives

The objective of this project is to revise the H2A Fuel Cell Power model to suit the analytic needs of business and financial decision makers and model end-users. To meet this objective, a Business Tab will be developed within the Fuel Cell Power excel model. It is not expected that the Business Tab will replace in-house financial models used to assess investment options, but it will extend the capability to do financial and business analysis using the model. This will prove especially valuable for tri-generation systems due to multiple stakeholders and energy product revenue streams. Understanding and fulfilling this objective will require significant stakeholder feedback on the decisions making process in question and tab design criteria.

Technical Barriers

This project addresses the following technical barriers from the 4.5 section of the Fuel Cell Technologies Program’s Multi-Year Research, Development and Demonstration Plan (MYPB):

- (B) Stove-piped/Siloed Analytical Capability
- (D) Suite of Models and Tools
- (E) Unplanned Studies and Analysis

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achievement of the following DOE milestones from the Systems Analysis section of the MYPP:

- Milestone 8. Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for technology readiness.

Accomplishments

- Reviewed H2A model structure to identify possible extensions.
- Outlined a theoretical tab format and “to-do” list of potential revisions.
- Collected feedback from internal NREL Business Review Team, including staff from the Strategic Energy Analysis, Deployment and Commercialization, and Federal Energy Management centers.
- Presented the FC Power model and proposed Business Tab design features to the California Hydrogen Business Council (CHBC), the Hydrogen Utility Group (HUG), and the California Fuel Cell Partnership (CaFCP), and collected feedback from each group on analytic capability priorities.
- Received feedback from industry representatives through an online questionnaire developed and administered in collaboration with IDC Energy Insights.
- Revised Business Case tab design accordingly.

Introduction

Stationary fuel cell systems configured to provide heat and power to building can also be configured to provide hydrogen as a third energy product. As depicted in Figure 1, these distributed energy systems would displace power provided by the electricity grid, heat provided by burning natural gas and hydrogen produced from a pathway such as conversion of natural gas via steam methane reforming onsite at a fueling station. Installation of a tri-generation combined, heat, hydrogen and power (CHHP) fuel cell system would involve a large number of stakeholders, including building owners and operators, natural gas and electric utilities, project financiers, fleet managers, fuel cell vendors, fueling station owners and operators, and (potentially) third party developers. The successful initiation of this type of
The project will depend upon rapid identification of benefits to each of the involved stakeholders. The Fuel Cell Power model (FCPower), developed by the National Renewable Energy Laboratory for the Department of Energy, is an analytic tool that can facilitate this process by providing a first-cut estimate of project costs and benefits [1]. The FCPower model is a publicly available, financial model, programmed in Excel™, that can be tailored to a particular building application by importing site-specific information such as hourly building energy demands, feedstock costs, fuel cell system costs and operating characteristics, and various financial assumptions.

The goal of this project is to design a Business Tab within the FCPower model that caters to the analytic needs of a business decision maker. The Business Tab consolidates all the key questions and analytic capabilities pertinent to a business end user in one location within the model. The FCPower model is based upon the discounted cash flow framework of the DOE H2A Models, which were originally designed for a technical rather than business end-user [2]. With addition of the Business Tab, it is anticipated that an interested stakeholder, such as a building owner/operator, would rely upon technical personal to set up and calibrate the model to represent a proposed fuel cell project, and then the model would be passed on to a financial analyst within the same organization to explore strategic business “what-if” questions and financial metrics. Versions of the FCPower model tailored to a specific combined heat and power (CHP) or CHHP building project can also be circulated among multiple project stakeholders to communicate and reach agreement on basic project assumptions. Designing a Business Tab for a new end user required collection of information on the decision making processes most likely to be involved in this early project screening phase. The following sections describe the process undertaken to collect this input from key stakeholders as well as some of the resulting design criteria.

**Approach**

The approach to designing the Business Tab involved collecting input from experts internal and external to NREL. Internal input was received from a Business Review Team consisting of NREL staff in the Strategic Energy Analysis, Deployment and Commercialization, and Federal Energy Management centers. Key external stakeholders included staff from the CaFCP, the HUG and the CHBC. Short multi-choice forms were circulated at these meetings to gauge priority or emphasis placed upon different financial metrics (see examples). Additional input was provided from external stakeholders on an ad hoc basis through hydrogen and fuel cell meetings and conferences. Based upon preliminary suggestions and design criteria provided by these internal and external experts, a questionnaire was developed and administered in collaboration with IDC Energy Insights (www.idc-ei.com) and administered to 100 stakeholders from pertinent organizations, including utilities, accounting
or financial, hospitals, hotels, big box stores, car dealers, hotels, convention centers, government facilities, transportation and warehousing, etc. Sections of the questionnaire inquired into the decision making process of the particular organization, and asked focused questions on the types of financial metrics typically relied upon to reach decisions about large capital investments. A typical list of potential metrics is shown below.

a. Net Present Value (NPV)
b. Internal Rate of Return (IRR)
c. Payback Period
d. Total Capital Cost
e. Maintenance Cost/Savings
f. Energy Cost/Savings
g. Revenue Opportunity
h. Vendor Brand Name Recognition
i. Vendor Financial Stability
j. Efficiency/energy improvements for Corporate Social Responsibility or Sustainability Goals
k–m. Other (please specify)

These and other proposed enhancements to the FCPOWER model are based upon a review of the model capabilities and possible extensions to the discounted cash flow calculations. In most cases only minor modifications are required to enable these capabilities due to the detailed existing H2A financial framework. In addition to identifying priority decision metrics, specific analytic capabilities were discussed, such as the capability to specify hydrogen, heat or electricity price and subsequently calculating IRR (a new capability not included in the original H2A models).

Results

Feedback received through the process described above was compiled, organized by type, prioritized, and associated with specific Tab designs and analytic capabilities. Examples of some of these suggestions are listed in the following, including Big Picture suggestions and Detailed Suggestions.

Big Picture Suggestions

• Make costs and benefits prominent. To keep stakeholders engaged in the project as additional information is collected and analyzed, a clear line of sight is needed to keep potential benefits prominent. This prominence provides motivation to endure transaction costs during the formative screening stage of the project.
• Provide access to technological information. Stakeholders can often be at a disadvantage due to an information imbalance among multiple parties, especially with adoption of new technologies. Providing links to information resources can help even out this imbalance and build confidence for key decision makers.

Detailed Suggestions

• Provide one-sheet printout for executive reading.
• Enable IRR as output and as function of various “what if” assumptions.
• Allow solving for hurdle rates, as stakeholders will know their own hurdle rates.
• Facilitate spot checking of basic financial assumptions.
• Include significant flexibility on treatment of tax credits.
• Allow exploration of alternative future feedstock prices (e.g., natural gas).
• Include a visual display of how hourly and peak demand would be offset.

The general structure of the Business Case Tab, developed in response to these and other suggestions, is indicated in Figure 2. The sections of the worksheet shown are accessible by scrolling down the worksheet. Upon opening the Business Tab, an end user will first see the key results and variables associated with the costs and benefits of the stationary fuel cell CHP or CHHP installation. Scrolling down to the next section, an end user would find a number of commonly used “what if” financial questions. These have been identified as typical inquiries of a business-oriented end user through the outreach activities described previously. Users will also find a section with links to external resources providing additional information on the core technology, fuel cells, in order to familiarize them with the technology and therefore reduce any information imbalances among stakeholders. Subsequent sections include results and input cells associated with taxes and incentives, a detailed balance sheet and cash flows, system performance, utility and feedstock assumptions, and additional advanced or less-common analytic capabilities.

Conclusions and Future Direction

A first-cut analysis of the costs and benefits of installing a stationary fuel cell system in CHP or CHHP configuration at a building can provide key decision makers with project screening criteria. The FCPOWER model, based upon the detailed H2A discounted cash flow framework, is cable of providing these criteria after being calibrated to a particular facility installation. However, the H2A models were originally designed with a technical end user in mind. A Business Tab has therefore been developed to make the FCPOWER model
more useful for a business-oriented end user. Extensive input was collected, both internal and external to NREL, to determine design criteria and priority analysis capabilities for the Business Tab. Having collected and categorized these criteria and design suggestions, the Business Tab will be included in the next release of the FCPower model. If deemed appropriate, similar tabs will be integrated into future versions of some H2A production and delivery models, especially those focused on infrastructure components subject to financial scrutiny by multiple stakeholders, such as onsite steam methane reforming or electrolysis systems.

VII.9 Fuel Quality in Fuel Cell Systems

Objectives

- Study the impact of impurities on fuel cell systems.
- Identify the key impurities of concern.
- Recommend research and development (R&D) strategies to mitigate the effect of the impurities.

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(B) Stove-piped/Siloed Analytical Capability

(D) Suite of Models and Tools

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achieving the following DOE Systems Analysis milestones from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development, and Demonstration Plan:

- Milestone 8: Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for technology readiness. (4Q, 2014) The study described here analyzes the quality of resources/feedstock, their conversion to reformate, and subsequent purification to identify the technology readiness and ability to sustain the operation of reformate-based fuel cell systems.

Accomplishments

A database has been set up to document the impurities encountered in stationary fuel cell systems by reviewing the literature and other public domain information:

- The impurities encountered in these systems have been identified.
- The effect of the impurities on the fuel processor components and their management options are being studied.
- The tolerance of the various fuel cells to the impurities is being documented.

Introduction

Fuel cell systems are being deployed in stationary applications for the generation of electricity, heat, and hydrogen. These systems comprise a variety of fuel cells ranging from the low temperature polymer electrolyte fuel cell (PEFC) to the high temperature solid oxide fuel cell (SOFC). Depending on the application and location, these systems are being designed for, or operate on reformate or syngas produced from various fuels that include natural gas, biogas, coal gas, etc. All of these fuels contain species that can potentially damage or pose a hazard for the fuel cell anode or other unit operations and processes that precede the fuel cell. These effects include loss in performance or durability and require additional components to reduce, if not eliminate, the impurity concentrations to tolerable levels. These impurity management options increase the complexity of the process and add to the capital and operating costs (regeneration, replacement and disposal of spent material, maintenance, etc.)

This project reviews the various impurities encountered in fuel cell systems with the objective of identifying which components (e.g., reformer, heat exchanger, fuel cell, etc.) in the system are affected, the extent of the deleterious effect, the impurity management options being practiced in the field and their effectiveness. For example, the presence of sulfur can lead to poisoning of the reforming catalyst which then results in coke formation and rapid failure of the reformer. To avoid this scenario the plant manager will install a sulfur-removal process. The decision on the desulfurization process (e.g., hydrodesulfurization or ambient sorbent bed and its size, etc.) will be made by considering the tradeoffs between the cost and complication of the process against the loss in productivity (hydrogen yield, power output) and other
considerations (e.g., deactivation rate, cost of disposing the spent sorbent, frequency of maintenance, etc.).

**Approach**

- Information relating to impurities and their impact on fuel cell systems are being collected from the literature and through personal communication with fuel cell developers. Data from the literature and from other public domain sources are being incorporated into a database, which classifies the information in terms of type of application, the type of impurity species encountered and their effect on the system, the technologies that are used for their removal or abatement, and the level at which a fuel cell can tolerate the impurity.
- The data will be analyzed to identify the impurities with respect to their pervasiveness, the difficulty of removal, and cost burdens. Ideally, it will be preferable to translate these factors in terms of cost impact, since this will allow a comparison across different systems and applications.

**Results**

A database has been set up to document and study the effect of fuel quality on fuel cell systems. Table 1 shows data from a demonstration project at the Penrose Power Station in Sun Valley, CA [1], where landfill gas was cleaned, reformed and then fed into a phosphoric acid fuel cell (PAFC) to generate 137 kW of electric power.

Landfill gas contains sulfur, halides, siloxanes, and hydrocarbons. For the Penrose plant, a number of clean-up units were installed to reduce the impurity concentrations to acceptable levels, which were reported to be 3 ppm for sulfur and halides. In order to understand the impact of the impurities and compare them against other applications, it is desirable to know what the clean-up process adds to the cost of the electric power that is generated.

A closer look at landfill gas [1-6] shows (Table 2) that the impurity species that are present at low concentrations can be classified into paraffins, sulfur, cyclics, aromatics, halides, and organic silicon. Hydrogen sulfide is the predominant sulfur species with concentrations that can approach 400 ppm. The organic silicon species include a large number of species each of which can be as high as 15 mg/Nm$^3$.

The presence of siloxanes in landfill gas pose challenges for fuel processing since these species react at higher temperatures to produce silica which then deposits on the surfaces of catalysts and heat exchangers. Siloxanes can be removed with sorbents such as silica gel, bentonite, etc. However, the gravimetric capacity of these sorbents tends to be low and is adversely affected by the presence of other species. For example, silica gel’s capacity for siloxane uptake [6] drops from 10%
for dry gas to less than 1% when the relative humidity is increased to 50%. Similarly, the presence of volatile organic compounds prevents the adsorption of siloxanes on carbon.

Sulfur is present in almost all the feedstocks used for power generation and plagues the fuel cell industry because of their ability to poison heterogeneous and electrochemical catalysts. Some sulfur species can be removed with sorbents such as activated carbon, while others require more reaction based processes such as the Claus process or hydrodesulfurization. The latter reaction produces H$_2$S and COS, which then have to be reacted with other reagents such as ZnO or other sorbents. These processes are complex because of the effects of temperature, competition of sorption sites with H$_2$O, kinetics, and low gravimetric capacities of the sorbents. Table 3 shows some of the media that are used for the removal of H$_2$S [7,8].

Other methods that are employed for the removal of impurities from the reformate stream include phase change to condense out species such as metal vapors from coal syngas, separation membranes, etc. The most comprehensive method for hydrogen enrichment is the pressure swing adsorption which can produce very high purity hydrogen and is very effective for the removal of sulfur and ammonia. Unfortunately, these units require pressurization of the gas stream which is energy intensive, and the operation of the multiple beds tends to be complex.

The data available in the literature on the effect of impurities on fuel cell systems covers a range of systems and conditions [9-13]. Although comparison on a common basis is difficult, some trends and contributing factors are evident. For example, the higher temperature fuel cells show greater tolerance to impurities – the SOFC can tolerate orders of magnitude higher concentrations of ammonia and sulfur than the low temperature PEFCs. Even for a particular type of fuel cell, the performance loss is affected by the nature and concentration of the impurity, the current density, the composition of the fuel, the exposure time, etc.

As an example, introduction of 2 ppm H$_2$S into a natural gas reformed syngas causes the voltage in a button-size SOFC cell to drop sharply by 10%. Increasing the H$_2$S concentration to 5 ppm doubles the performance loss to 20% [15]. The database being assimilated in this project includes similar data on a host of impurities tested at various conditions in fuel cells with varying anode compositions. Analysis of performance data, however, can be much more coherent when the tests are coordinated to address specific questions on similar hardware under consistent conditions.

**Conclusions and Future Directions**

- A database is being set up to document the impurity levels and their management in stationary fuel cell applications:
  - The data are being classified on the basis of the unit operations and processes of the system.
- The key impurities in the feedstock fuel and the fuel gas to the anode have been identified:
  - The concentrations of these impurities are being documented.
- Sulfur and siloxanes have detrimental effects on fuel cells and components that precede them.
- The higher temperature fuel cells demonstrate higher tolerance to impurities such as sulfur, carbon monoxide, and sulfur.
- The database will be analyzed to identify trends and key technical challenges faced by the stationary fuel cell industry. This will be followed by recommendations on R&D needs.

VII.10 Macro System Model

Objectives

- Develop a macro-system model (MSM):
  - Aimed at performing rapid cross-cutting analysis.
  - Utilizing and linking other models.
  - Improving consistency between models.
- Support decisions regarding programmatic investments through analyses and sensitivity runs.
- Support estimates of program outputs and outcomes.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Future Market Behavior
(B) Stove-piped/Siloed Analytical Capability
(C) Inconsistent Data, Assumptions and Guidelines
(D) Suite of Models and Tools

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achievement of the following DOE milestones from the System Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 5: Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for various hydrogen scenarios. (4Q, 2009)
- Milestone 27: Complete the 2nd version of the Macro-System Model to include the analytical capabilities to evaluate the electrical infrastructure. (2Q, 2011)

Accomplishments

- Completed Version 1.0 of the MSM and used it for programmatic analysis.
- Linked H2A Production cases with the Hydrogen Delivery Scenario Analysis Model (HDSAM), the Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) Model, and physical property information from the Hydrogen Analysis Resource Center (HyARC) and validated the use of those models and the results generated using them.
- Developed a flexible, comprehensive Web-based user interface so that many members of the analysis community can use the MSM.
- Completed a user guide for the MSM.
- Added stochastic (Monte Carlo) capabilities to the MSM.
- Upgraded the MSM to the latest versions of H2A Production (V.2.1), HDSAM (V 2.0) and GREET (V 1.8c).
- Linked with geospatial model HyDRA to add the spatial dimension to the MSM.
- Integrated MSM with the temporal pathway evolution assessment tool HyPro.

Introduction

At the DOE Hydrogen Program’s behest, we are developing an MSM to analyze cross-cutting issues because no existing model sufficiently simulates the entire system, including feedstock, conversion, infrastructure, and vehicles, with the necessary level of technical detail. In addition, development of the
MSM exposes inconsistencies in methodologies and assumptions between different component models so that they can be identified and corrected when necessary.

Version 1.0 of the MSM has been developed and is available to the hydrogen analysis community. It links H2A Production, HDSAM, GREET, and physical property information from HyARC to estimate the economics, primary energy source requirements, and emissions of multiple hydrogen production/delivery pathways. A Web-based user interface has been developed so that many users have access to the MSM; stochastic capabilities have been added to it to provide uncertainty ranges around the results. The MSM has been used for several analyses to compare pathways and to understand the effects of varying parameters on pathway results.

**Approach**

The MSM is being developed as a tool that links or federates existing models across multiple platforms. This approach was chosen because the task of building a single monolithic model incorporating all of the relevant information in the existing models would have been overwhelming because the necessary expertise to do so was spread among half a dozen DOE laboratories and a dozen or more universities and private contractors. Linking models allows model users that depend on data from component models to continue using their models while retrieving data from component models in a less labor-intensive manner. In addition, it provides a common platform for data exchange necessary to update integrated models when the component models have been updated.

The MSM is being built on a framework inspired by an example of the federated object model (FOM). FOMs also link together models and are exemplified by the Department of Defense high level architecture [1]. The general MSM framework provides a common interlingua that is extensible (accommodates new models with a minimum of difficulty), distributable (can be used by multiple people in different areas of the country), and scalable (to large numbers of participating models). Version 1.0 of the MSM uses Ruby and Ruby interfaces to Microsoft Excel and other platforms to collect, transfer, and calculate data.

**Results**

Levelized hydrogen costs, primary energy requirements, and emissions have been estimated for multiple pathways using H2A 2.1 [2], HDSAM V2.0 [3], and GREET V1.8c [4]. Thus, Figure 1 [5] shows the levelized cost of the hydrogen pathways. The levelized cost of hydrogen is calculated directly in the H2A model for the distributed hydrogen production cases because the H2A distributed hydrogen production model includes the forecourt station capital and operating costs. For central production cases, the levelized cost of hydrogen is the sum of levelized production cost calculated in H2A, levelized delivery cost calculated in HDSAM, and the cost of excess production due to losses in delivery. For distributed production, the costs of compression, storage, and dispensing (CSD) are about $1.88/kg and are included in the production cost. For central production, the CSD costs are included in the delivery cost and depend upon the delivery technology (gas in pipelines vs. liquid from trucks). Note that the delivery costs are $2-$3/kg hydrogen; delivery costs may need to be reduced to make central production technologies competitive with distributed production technologies.

Connecting hydrogen production and other costs with associated emissions is one of the advantages that the MSM provides by linking together different models. Figure 2 shows the levelized hydrogen fuel cost per mile and the well-to-wheels (WTW) greenhouse gas (GHG) emissions for each of the seven pathways assessed based on U.S. average fuel costs and fuel cycle energy requirements. For comparison, it also shows the projected 2009 market price per mile (in 2005 dollars) and GHG emissions for gasoline-, diesel-, and E85-fueled vehicles. The levelized fuel cost was put onto a per-mile basis. The projected fuel cost per mile for most of the hydrogen pathways (based on projected, mature fuel cell electric vehicle markets) is similar to that for gasoline in a traditional vehicle and corn ethanol as E85 fuel in a flexible-fuel internal combustion engine (ICE) vehicle. The fuel costs per mile for gasoline in a hybrid electric vehicle (HEV) and diesel in a conventional diesel ICE vehicle are lower. The dotted green cloud in the figure represents the stochastic analysis results obtained based on input distributions for the forecourt steam methane reforming (SMR) production option [6]. The dispersion of the data points well surpasses the differences between the central (with pipeline delivery)
and distributed SMR production options. This relates to both the per-mile cost of hydrogen and the WTW GHG emissions. Similarly, the blue cloud shows the stochastic analysis result for the central biomass case. For the latter, as seen in the figure, the data point distribution is less significant when compared with the differences incurred by switching from pipeline to liquid truck delivery.

As key MSM inputs are sometimes region-specific, it is important to add the geospatial dimension into the range of the MSM features. Bilateral links with the online geospatial tool HyDRA [7] have been developed that allow the MSM user to easily apply regional electricity and natural gas (NG) feedstock data as MSM inputs and, conversely, update the HyDRA database and maps with the latest MSM version outputs. As an example, Figure 3 shows the results obtained for a selected (from HyDRA interface) region. For every county in the region, HyDRA supplies the MSM with the electricity grid mix and price data, and the MSM calculates hydrogen production (via electrolysis) costs and associated WTW GHG emissions. (The interaction between the models is implemented via internet.) As a result, regions with both lower hydrogen production cost and lower WTW GHG emissions can be easily selected.

The transition to high-market-penetration levels for hydrogen fuel cell vehicles will likely involve several hydrogen production/delivery/dispensing pathways. To facilitate this analysis and to involve the temporal dimension, the temporal pathway evolution assessment tool HyPro [8] is integrated with the MSM. As a result, HyPro inputs are updated via MSM (Figure 4) with latest current H2A Production and HDSAM models, and the MSM facilitates probing into the effect of any of the HyARC, HDSAM, or H2A Production model parameters on the potential evolution of hydrogen production/delivery/dispensing pathways.

**Conclusions and Future Directions**

- By linking production/delivery/dispensing models, the MSM is a tool for rapid cross-cutting comparative analysis of various production/delivery pathways.
- The U.S. region-specific data are readily available as MSM inputs via live MSM/HyDRA links.
As a result of linking HyPro with MSM, pathway evolution is examined in a manner consistent with latest versions of H2A and HDSAM.

Future directions:

- Include vehicle production and maintenance in the MSM analysis.
- Add combined heat and power as a production option.
- Expand delivery and distribution options to include the 700-bar storage, cryo-compressed and tube trailer delivery.
- Continue updating the MSM links to new model versions as they are released.

Objectives

- Conduct fuel-cycle analysis of stationary fuel cell (FC) systems (to help development of hydrogen production and FC technologies).
- Engage in discussions and dissemination of energy and environmental benefits of FC systems and applications.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development, and Demonstration Plan:

(C) Inconsistent Data, Assumptions and Guidelines
(D) Suite of Models and Tools
(E) Unplanned Studies and Analysis

Contribution to Achievement of DOE Systems Analysis Milestones

This project contributes to achievement of the following DOE milestone from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development, and Demonstration Plan:

• Milestone 11: Complete environmental analysis of the technology environmental impacts for the hydrogen scenarios and technology readiness (2Q 2015).

Accomplishments

- Conducted energy use and greenhouse gas (GHG) emissions analysis of FC systems for combined heat and power (CHP) and combined heat, hydrogen, and power (CHHP) generation, which showed that CHP and CHHP FCs offer significant reduction in energy use and GHG emissions compared to distributed combustion generation technologies.
- Conducted criteria pollutants emissions analysis of FC systems for CHP and CHHP generation, which showed that CHP and CHHP FCs offer reductions in criteria pollutant emissions compared to distributed combustion generation technologies.
  - FC systems for CHP and CHHP provide significantly less carbon monoxide (CO), particulate matter (PM), and oxides of nitrogen (NOx) emissions than conventional combustion generation technologies.
  - Utilization of byproduct heat is critical to the fuel-cycle emission performance of FC systems for distributed power generation.
  - CHHP FC systems provide better utilization of byproduct heat compared to CHP FC systems when heat is utilized for producing additional amounts of hydrogen.

Introduction

The pathway to the application of FCs in hydrogen vehicles will be assisted by the introduction of FCs in markets with fewer technical challenges than automobiles. Distributed power generation and forklifts are near-term markets in which FCs can be successful. One of the issues associated with transforming the market of FCs to these early markets is their potential fuel-cycle energy use and emissions benefits – this issue is important because many sectors of the U.S. economy are becoming increasingly subject to reduction of energy use and emissions of GHGs and air pollutants. An earlier study by ANL examined the fuel-cycle energy use and GHG emissions of FCs for forklift propulsion systems and distributed power generation. In addition to polymer electrolyte membrane (PEM), FC technologies suitable for distributed power generation include phosphoric acid FCs (PAFCs) and molten carbonate FCs (MCFCs). The application of FCs to distributed power generation has the potential to produce excess hydrogen at a relatively low cost for local utilization. The excess hydrogen may be stored locally and used for
the refueling of FC forklifts in a nearby facility or for the generation of supplemental electricity to satisfy a facility's electric load during peak demand periods. The availability of a hydrogen co-product may also overcome one of the barriers to introducing hydrogen FC vehicles (FCVs) to some early FCV market places by facilitating a distributed source of hydrogen while effectively employing the primary energy source and the initial capital investment of the FC to serve a facility's demand for electric and heat energy.

This analysis evaluates the fuel-cycle criteria pollutant emissions, in addition to GHG emissions, associated with the application of PAFCs and MCFCs to CHP and CHHP generation. It also evaluates the fuel-cycle GHG and criteria pollutant emissions of other combustion technologies for CHP, such as internal combustion engines (ICEs) and microturbines (MTs). These FC and combustion technologies are compared against the conventional technologies that supply buildings with electricity and heat, such as the local grid generation mix and the combustion technologies typically used to meet the facility's heating demand. Three facility types, representing a hospital, a large office building, and a warehouse located in two different climatic regions (Chicago and Los Angeles), were evaluated for their carbon footprint and criteria pollutants emissions. The Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model has been expanded to address the fuel-cycle GHG emissions and criteria pollutant emissions associated with the application of FCs to CHP and CHHP generation.

Approach

Fuel-cycle analysis of various power-generation technologies in this study calculates the energy use and emission occurrences per unit of consumed energy at end-use. These occurrences include the initial recovery, processing, and transportation of the primary fuels, as well as the generation of heat, hydrogen, and electricity. The energy use and emissions primarily depend on the energy conversion efficiency of each process in the fuel cycle pathway. Efficiency and emissions data for the distributed generation technologies of interest to this analysis are extracted from testing data reported by U.S. Environmental Protection Agency, as well as data provided by California Air Resource Board and industry sources. For CHP and CHHP FC systems, the efficiency data are extracted from the H2A power model developed by National Renewable Energy Laboratory, which simulates the hourly FC performance based on actual (load-following) performance data. These efficiencies, as shown in Table 1, are generally lower than those obtained from steady-state testing at peak performance or rated power due to performance degradation as a result of typical duty cycles and unsteady operation in the field.

The reported thermal efficiencies in Table 1 assume that the entire amount of recoverable waste-heat is utilized.

Two different approaches for fuel-cycle analysis of CHP and CHHP applications have been considered in this analysis: a total demand approach and a displacement approach. The total demand approach compares the impact of various technologies in satisfying a facility's demand for electricity, hydrogen and heat. It accounts for the energy use and emissions associated with the on-site generation of power, heat, and hydrogen, as well as the energy use and emissions associated with the generation of supplemental heat, hydrogen, and grid power. The system boundary for this approach includes the FC and the supplemental systems that satisfy the building's excess electricity and heat demands. The energy use and emissions for this approach are evaluated per one million Btu (mmBtu) of combined electric, heat, and hydrogen demand. The displacement approach compares different technologies for the on-site generation of electricity and hydrogen, and calculates credits for the heat byproduct. The system boundary for this approach only includes the distributed generator system and assumes full utilization of any heat byproduct. The energy use and emissions for this approach are evaluated per one million Btu of net electricity and hydrogen generation. The credit of by-product heat is calculated from the displacement of equivalent amount of heat from a typical standalone heating system. The displaced heat is assumed to be produced from a natural gas (NG)-fired heater with 90% efficiency. A major difference between the two fuel cycle approaches is the percentage utilization of the heat byproduct. In the displacement approach, the entire amount of heat available from the generators is assumed to displace conventional heat production from NG-fired burners, although a significant amount of heat could be rejected by the facility because generators often produce more heat than required by the instantaneous demands, and the facility is assumed not to have a heat storage tank. Thus, while the effect of heat utilization (HU) is properly captured in the total demand approach, the displacement approach assumes 100% utilization of heat byproduct. The fuel-cycle results presented below are based on the displacement approach.

Results

The fuel-cycle results for various distributed generation technologies were examined based on estimates of efficiency and emission factors shown in Table 1. Figures 1-5 show the fuel-cycle GHG and criteria pollutant emissions associated with different generation technologies using the displacement approach. The relative benefits of the CHP and CHHP systems compared to other generation technologies depend on the efficiency and carbon intensity of the displaced grid mix. In general, CHHP FCs are shown
to provide more reduction in energy use and GHG emissions compared to CHP fuel cell systems due to the better utilization of byproduct heat in making hydrogen (Figure 1). Criteria pollutant emissions are comparable for CHP and CHHP FC systems, but are significantly less than those for all other generation systems (Figures 2-5). The amount of displaced heat for the different generators is critical to their overall performance. This is apparent in Figure 2 for CO emissions where the displaced heat results in negative emissions for FC systems (i.e., a net credit). The credit for CHHP FCs is less compared to CHP FCs due to the utilization of the coproduced heat to make hydrogen, and thus less heat byproduct is produced and displaced. FC systems produce an order of magnitude less NOx compared to combustion generation technologies as shown in Figure 3. They also produce significantly less PM compared to other distributed generation technologies and grid generation mix in U.S. and California (Figure 4). All distributed generation technologies powered by NG produce much less oxides of sulfur (SOx) compared to the grid generation mix in the U.S. and California, mainly due to the much low sulfur content of NG (Figure 5).

Conclusions and Future Directions

Conclusions

FC systems for distributed power generation in CHP or CHHP achieve significant reductions in criteria pollutant emissions:

- FC systems for CHP and CHHP provide significantly less CO, PM, and NOx emissions compared to conventional generation technologies.
- Utilization of byproduct heat is critical to the fuel-cycle emission performance of FC systems for distributed power generation.
- CHHP FC systems provide better utilization of byproduct heat compared to CHP FC systems.

Future Work

- Complete fuel-cycle analysis of FC CHHP systems for criteria pollutants as well as energy use and GHGs.

FY 2010 Publications/Presentations

Objectives

- Perform analysis of topics of interest to the Fuel Cell Technologies (FCT) Program related to projected CO₂ benefits of fuel cell applications.
- Provide additional analytical support to the FCT Program to respond to departmental data requests and other needs.

Technical Barriers

(A) Future Market Behavior
(C) Inconsistent Data and Assumptions
(E) Unplanned Studies and Analysis

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to the achievement of the following DOE milestones from the Systems Analysis section of the FCT Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 22: Completed the modification of the MARKAL model to include hydrogen analysis. (4Q, 2007)

Accomplishments

- Examined the impact of changes in various Program cost assumptions for fuel cell costs, cost of onboard storage, hydrogen distribution costs and carbon prices on market penetration of fuel cell vehicles and carbon emissions. The analysis was presented to the FCT Program.

- Analyzed the benefits of biomass-to-hydrogen in deep CO₂ emission reduction scenarios. This analysis demonstrated that the use of biomass-to-hydrogen with carbon capture and sequestration (CCS) can greatly reduce the cost of meeting deep carbon emission reduction goals. A paper has been written based on the results and will be submitted to a journal for publication.

Introduction

The goal of this analysis is to explore the role that hydrogen technologies can play in reducing carbon emissions. Our analysis for the last two fiscal years include a sensitivity analysis of fuel cell vehicle market penetration to changes in production, distribution and vehicle costs and CO₂ prices, as well as analysis to examine the benefits of biomass-to-hydrogen in deep CO₂ emission reduction scenarios.

Approach

MARKAL Sensitivity Analysis

Our primary analytical tool is the 10 Region U.S. MARKAL model developed by BNL. The model was calibrated to the Energy Information Administration's (EIA's) 2009 Annual Energy Outlook. The first analysis under this project is the sensitivity analysis that we performed in Fiscal Year (FY) 2009 using our 10 Region U.S. MARKAL model. Our goal was to examine the impact of changes in various Program cost assumptions.

The cost assumptions we looked at included: hydrogen distribution cost where we looked at the program goal of $1.00 per kg, as well as $1.50 and $2.00. The next cost sensitivity was the cost of the fuel cell for vehicle applications where we tested the Program goal of $30 per kW, as well as costs of $40, $50 and $60 per kW. We also looked at the cost of on-board storage and the impacts of a ten year delay in the commercialization of fuel cell vehicles. Finally, we tested the impact of a range of carbon prices from $0 to $100 per tonne of CO₂, to see the impact of carbon prices on fuel cell vehicle market penetration, the desired hydrogen feedstocks and total CO₂ emissions.

Role of Biomass-to-Hydrogen in Deep CO₂ Emission Reduction Scenarios

The second analysis under this project is an analysis of the benefits of biomass to hydrogen in deep CO₂ emission reduction scenarios. This analysis also used
the 10 region U.S. MARKAL model. For this analysis, we have two sets of technology scenarios. The first set is based primarily on the EIA assumptions, with the exception of light-duty vehicles where we have included the research and development (R&D) improvements from the Vehicle Technologies Program research in light weighting, hybridization and battery technologies. We then have a second technology scenario where we include the FCT Program’s R&D goals for hydrogen production, distribution and stationary and mobile fuel cells. We used the CO₂ cap from the Waxman-Markey bill that was passed by the House of Representatives in 2009. We only modeled provisions directly related to the CO₂ cap and trade provisions. Other provisions, such as national renewable portfolio and appliance standards were not modeled. Since we wanted to explore the impacts of hydrogen technologies under more stringent carbon caps, we decided to look at what might happen if the domestic or international offsets were excluded from the legislation.

Results

MARKAL Sensitivity Analysis

The key results for the sensitivity analysis relate to impacts of carbon prices on the MARKAL model’s choice of hydrogen production technologies and the impacts of increased fuel cell and onboard storage costs on fuel cell vehicle market penetration. As shown in Table 1, without a carbon price, the model primarily chooses to use central coal and distributed gas reforming to produce hydrogen. However, with increased prices of carbon, the model rapidly switches to using more biomass with CCS.

With respect to the impacts of alternative costs of vehicle fuel cells and on board storage, increasing the cost of either component will reduce overall market penetration of fuel cell vehicles. However, the impacts of changing the cost of onboard storage has a relatively minor effect, while increasing the cost of the fuel cell to $50 or more per kW has a dramatic impact on fuel cell vehicle market share (Figure 1).

Role of Biomass-to-Hydrogen in Deep CO₂ Emission Reduction Scenarios

The Waxman-Markey cap and trade provision is a market-based program for reducing greenhouse gas emissions. The ultimate goal is to reduce emissions by 83% below 2005 levels by 2050. However, small utilities are exempt from the regulation and covered entities can secure permits by purchasing domestic and international carbon offsets. Overall, up to 2 giga-tonnes of CO₂ offsets can be used annually. Also, banking and trading of permits is permitted. The net effect of the allowing offsets and exempting small utilities is that the effective CO₂ emissions cap is much higher than advertised. Since we wanted to explore the impacts of hydrogen
technologies under more stringent carbon caps, we decided to look at what might happen if the domestic or international offsets were excluded from the legislation.

A total of eight cases were run. They are:

- Reference Case: Ref. Case
- Reference with Carbon Cap: Ref. w/CC
- Reference with Carbon Cap Without International Offsets: Ref. w/CC w/o IO
- Reference with Carbon Cap Without Any Offsets: Ref. w/CC w/o AO
- FCT Program: FCTP Case
- FCT Program with Carbon Cap: FCTP w/CC
- FCT Program with Carbon Cap Without International Offsets: FCTP w/CC w/o IO
- FCT Program with Carbon Cap Without Any Offsets: FCTP w/CC w/o AO

Comparing the Reference Case with the FCT Program Case without a carbon policy, there is a 37% reduction in direct transportation sector emissions. However, this is partially offset by an increase in industrial sector emissions, where we account for the direct emissions from producing hydrogen. Overall, there is a 10% reduction in carbon emissions relative to the reference case (Figure 2).

When we add the Waxman-Markey CO₂ cap, we see a significant difference between the reference and hydrogen technology scenarios. With the FCT Program assumptions, there is a dramatic reduction in transportation and industrial emissions due to efficient fuel cell vehicles and the “negative” carbon emissions from biomass-to-hydrogen with CCS. Figure 3 shows that the 2050 carbon emissions from the power generation sector are higher than with the reference technology scenario. With the increased savings in the industrial and transportation emissions other sectors can emit more and still comply with the overall CO₂ cap. In this case, the model finds that the biomass-to-hydrogen technology has much lower marginal cost than some of the power sector technologies that were chosen in the Reference with Carbon Cap case.

Looking at 2050 carbon emissions by sector for the two technology scenarios and under the different carbon caps, Figure 4 shows a significant reduction in transportation and industrial carbon emissions for the advanced hydrogen cases on the right side of the chart, than for the reference case technology cases on the left.
You can also see total carbon emissions are lower for the FCT cases due to a reduced use of offsets and banking of carbon credits.

With the introduction of the Waxman-Markey cap (with offsets), there is a significant increase in use of biomass in both cases. With the FCTP assumptions, we get a significant increase in the overall consumption of biomass, due to the use of biomass to hydrogen with CCS. However, under the more stringent carbon caps where we don’t allow international or any offsets, the reference technology set biomass consumption catches up with the advanced hydrogen technology cases. The primary difference is that under the reference technology set, the model relies on biomass-to-liquids with CCS, where the FCT Program cases use both biomass-to-liquids and biomass-to-hydrogen with CCS (Figure 5).

**Conclusions and Future Directions**

- The use of biomass-to-hydrogen with CCS can greatly reduce the cost of meeting deep carbon emission reduction goals.
- Biomass-to-liquids with CCS generates “negative” CO₂ emissions, however, the hydrogen pathway generates deeper reductions per ton of biomass used.
- Under the two most stringent CO₂ caps, both biomass-to-liquids with CCS and hydrogen with CCS are needed.
- While the transport sector may be a more difficult sector to achieve deep CO₂ emission reductions, with a successful R&D program, deep CO₂ emission reductions can be achieved with a significant reduction in cost of meeting the CO₂ cap.
FY 2010 Publications/Presentations

VII.13 Pathways to Commercial Success: Technologies and Products Supported by the FCT Program

Objectives

This objective of this project is to provide a retrospective assessment of Fuel Cell Technologies (FCT) Program benefits by tracking commercial successes of FCT-developed technologies (and technologies developed by FCT predecessors) and estimating the business impacts, when possible. Tracking technologies helps determine the impacts of research and development (R&D) undertaken by the program, develop lessons learned, and guide future program developments. Technology tracking also allows for more effective management of R&D projects and budget defense, and the database developed serves as the institutional memory for the program.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section (4.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(C) Inconsistent Data, Assumptions and Guidelines
(E) Unplanned Studies and Analyses

Contribution to Achievement Systems Analysis Milestones

This project does not contribute to achievement of any specific milestones listed in the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan. However, it supports the following subtask in Table 4.6.1: “Provide other support to the program and other organizations” (under Task 3).

Accomplishments

- Produced a report entitled, “Pathways to Commercial Success: Technologies and Products Supported by the Hydrogen, Fuel Cells & Infrastructure Technologies Program,” describing patents, commercialized technologies, and emerging technologies that have emerged from the FCT Program and its predecessor programs.
- Updated the FCT technology tracking database containing information on commercial and emerging technologies.

Introduction

The FCT Program and its predecessor programs have been conducting a wide range of hydrogen and fuel cell R&D projects, some of which have resulted in patents and/or products now available in the commercial marketplace. This project focused on identifying and describing both patents and commercialized technologies resulting from Energy Efficiency and Renewable Energy (EERE) hydrogen and fuel cell program activities, as well as technologies likely to be commercialized in the near future (called “emerging” technologies).

Once they were identified, PNNL gathered information on the commercialization status of EERE-developed hydrogen and fuel cell technologies that are on the market, and, when possible, quantified the business impacts (e.g., number of units sold) of these successfully commercialized technologies. Working with the technology vendors, PNNL documented product characteristics, history, applications, capabilities, and benefits.

Approach

To identify and document the commercial and near-commercial (emerging) hydrogen and fuel cell technologies and products that benefited from EERE support, PNNL undertook several efforts simultaneously. The first effort was a patent search and analysis to identify hydrogen and fuel cell related patents that are associated with FCT-funded projects (or projects conducted by DOE-EERE predecessor programs) and
to ascertain the patents' current status, as well as any commercial products that may have used the technology documented in the patent.

The second effort was a series of interviews and document reviews to identify and characterize commercial and emerging technologies that have directly benefited as a result of direct funding from the FCT Program (or funding from EERE predecessor programs) or from grants under programs such as Small Business Innovation Research and Small Business Technology Transfer.

Data gathered about the technologies were then entered into a FCT Program Technology Tracking Database, a Lotus Notes database that is updated and available on the DOE system. For each of the commercial and emerging hydrogen technologies in the database, a summary description was prepared, edited, and sent it to the industry/research organization point of contact for review and subsequent approval before sending it to FCT Program personnel to review.

**Results**

The patent search and analysis, identified 198 patents: 99 fuel cell patents, 74 production/delivery patents, and 25 storage patents. Figure 1 shows the patents awarded in each year, starting with pre-2000 patent awards through 2010. As the figure shows, 2006 had significantly more patents than the other individual years. The storage patent awards are spread out over the entire period, with a peak of four awards in 2004, while fuel cell and production/delivery patents peaked in 2006 with 12 patents in each category.

Three types of organizations received the patents: national laboratories (100 patents), private companies (76 patents), and universities (22 patents). The national laboratories had patent awards for fuel cell and production/delivery technologies that were almost equal to those awarded to private companies in these two areas. The national laboratories had 68% of the awards in the storage area. While the universities received fewer total patent awards, they had 59% of their patents in the production/delivery area. The national laboratories and private companies both received more than half of their patents in the fuel cell area.

Figure 2 shows the patent award status by use. As the figure shows, six patents are used in commercial products and 36 are part of research now taking place on emerging technologies identified on the technology tracking list compiled. In addition, 84 awarded patents are still being used in research that is more than three years from a commercial product. Of the 198 patents reviewed, 36% are no longer being used in research. In the production/delivery area, 73% of the patents are still actively being pursued through use in continuing research, emerging technologies, or commercially available products. The storage and fuel cell areas also have a majority of their patents being actively pursued.

In the second effort PNNL identified 28 commercial technologies that have entered the market including five using patents identified in the first effort. Figure 3 shows the cumulative number of commercial technologies entering the market. Of the 28 technologies, 27 are still commercially available. Years 2000–2006 showed a steady addition of technologies entering the market of one to three per year. In 2007, and 2008, five and seven technologies entered the market respectively. For 2009 and 2010 the rate of technologies entering the market returned to one to three per year. This effort also identified 52 emerging technologies. Figure 4 shows the distribution of the emerging technologies in the FCT research areas. The number of fuel cell technologies is more then half of the total number of emerging technologies.

A total of 52 emerging and 28 commercial technology descriptions are being prepared and will be included in the updated report.

**Conclusions and Future Directions**

Commercialization of technologies that were cultivated in a government R&D program is generally viewed as a measure of success. In addition, technology tracking can support:

- Effective management of R&D programs
- Budget defense
- Strategic planning
- Portfolio management
- Institutional memory.

The report and technology tracking database will help organizations highlight the impacts and benefits of their products, potentially expanding their markets. It will also help publicize emerging technologies to interested commercialization partners.

The information presented on commercial and emerging technologies fulfills the primary objective – to assess the commercialization status of EERE-developed hydrogen and fuel cell technologies and provide information on the business impacts. Insights about pathways to successful introduction of hydrogen and fuel cell technologies are beginning to emerge from this analysis, but this topic has not yet been fully explored.

VII.14 Fuel Cell Power Model: Evaluation of CHP and CHHP Applications

Objectives

- Accurately model performance of stationary fuel cells in combined heat and power (CHP) and combined heat, hydrogen, and power (CHHP) applications.
- Combine detailed performance information with a comprehensive discounted cash flow methodology to evaluate lifecycle costs.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section (4.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(B) Stove-piped/Siloed Analytical Capability
(C) Inconsistent Data, Assumptions and Guidelines
(E) Unplanned Studies and Analysis

Contribution to Achievement of DOE Systems Analysis Milestones

This project will contribute to achievement of the following DOE milestones from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 26: Annual model update and validation. (4Q, 2010)

Accomplishments

- Published Version 1.2 of the Fuel Cell Power Model.
- Provided presentations, webinars, and one-on-one guidance to train Fuel Cell Power Model users.
- Used the Fuel Cell Power Model in support of a wide range of actual and proposed fuel cell installations as well as theoretical research projects.
- Analyzed the effect of additional fuel for CHHP system hydrogen overproduction, finding that using additional fuel to boost hydrogen production reduces hydrogen cost.
- Compared fuel cell CHHP and steam methane reforming (SMR) hydrogen production strategies, finding that hydrogen production from CHHP is less expensive than from SMR for small-scale systems.
- Modeled a case study of a system combining dairy farm digester gas and fuel cell CHP, finding a payback time of about 7 years with an 8.5% internal rate of return (IRR) and emissions savings of about 750 g CO₂eq/kWh electricity generated.

Introduction

The U.S. Department of Energy’s H2A platform is a Microsoft Excel–based economic analysis model that provides transparent, consistent, and comparable results for DOE’s hydrogen modeling efforts. H2A hydrogen production and delivery models geared toward use of hydrogen as a vehicle fuel have been in use for several years. However, stationary fuel cell systems that produce electricity, heat, and hydrogen—known as “tri-generation” systems—also offer potential advantages: lower hydrogen production cost, inherently distributed hydrogen production, lower fossil energy use and greenhouse gas (GHG) emissions, reduced electricity transmission congestion, lower capital investment risk, and backup power functionality. DOE views tri-generation systems as critical for early fuel cell market transformation and requires modeling to evaluate the potential costs and benefits. This need resulted in creation of the Fuel Cell Power Model. Because the Fuel Cell Power Model is based on the H2A platform, it can be used for cross-cutting analysis in conjunction with other DOE tools, including the H2A production and delivery models, H2A Delivery Scenario Analysis Model (HDSAM), Macro System Model (MSM), Hydrogen Demand and Resource Analysis (HyDRA), and Scenario Evaluation, Regionalization and Analysis (SERA).
The Fuel Cell Power Model analyzes the technical and economic aspects of high-temperature fuel cell–based tri-generation systems in CHP and CHHP applications. This type of system would provide onsite-generated heat and electricity to large end users such as hospitals and office complexes. The hydrogen produced could be used for fueling vehicles or stored for later conversion to electricity. In the model, users select which technologies are used in the system—such as hydrogen fuel cells, photovoltaic panels, and electrolyzers—and define each technology’s cost and performance parameters (Figure 1). Users also select fuel costs and, for the phosphoric acid fuel cell system, demand priority (i.e., whether the system follows electricity or heat demand) and can accept default financial parameters or enter custom parameters. Hourly electricity, heat, and hydrogen demand profiles and renewable energy supply profiles can be entered or selected from databases. The model uses the inputs, default values and calculations, and a standard discounted cash flow rate of return methodology to determine the cost of delivered energy, with reference to a specified after-tax IRR. It also determines the amount and type of energy input and output and the associated GHG emissions. Version 1.2 of the Fuel Cell Power Model was completed in Fiscal Year (FY) 2010. Training was provided to Fuel Cell Power Model users, and the model was used to analyze a variety of CHP and CHHP applications.

Approach

The potential advantages of a fuel cell–based tri-generation system depend on numerous variables, including the type of building/application using the system, geographic location, utility grid interaction, financial assumptions, and economic incentives. To evaluate the cost of producing electricity, heat, and hydrogen accurately, the Fuel Cell Power Model analyzes energy supply and demand for each hour over the course of a year. Case studies demonstrate the model’s functionality and value for modeling various applications and tri-generation regimes. The enhancements to Version 1.2 of the model enable financial decision-makers to evaluate the business case for a CHP or CHHP installation using a variety of financial metrics.

Results

Version 1.2 of the Fuel Cell Power Model was completed, which included the following enhancements:

- A single simple-to-use home for business case analyses, including calculating: cost without IRR, simple payback period, solutions for different variables (e.g., IRR, net present value), total lifecycle cost, benefit-to-cost ratio, and savings-to-investment ratio.
- Enhanced presentation of financial output from the model.
- More accurate evaluation of the “baseline” system (building energy costs prior to installation of the fuel cell system).
- Enhanced differentiation between technical operating and cost parameters and financial parameters, providing financial analysts with a more streamlined user interface dedicated to financial analysis.

Training and support was provided to Fuel Cell Power Model users, including presentations, webinars, and one-on-one guidance. Market transformation analyses were completed for several commercial and government entities. In addition, a variety of organizations used the Fuel Cell Power Model to support a wide range of actual and proposed fuel cell installations as well as theoretical research projects, including the following:

- National Renewable Energy Laboratory campus
- NASA Ames Research Center
- Los Alamitos Military base
- U.S. Postal Service Distribution Facility, San Francisco
- Materials and Systems Research, Inc.
- Sandia National Laboratories/Lawrence Livermore National Laboratory campus
- Three stores in a large grocery chain
- Five large food-processing facilities
- DOE generic scenario studies
- Spatial model development for deployment in conjunction with SERA
- Biogas case studies

Among the DOE studies conducted using the Fuel Cell Power Model was an analysis of the effect of additional fuel for CHHP system hydrogen.
overproduction; the study found that using additional fuel to boost hydrogen production reduces hydrogen cost. Another study compared fuel cell CHHP and SMR hydrogen production strategies, finding that hydrogen production from CHHP is less expensive than from SMR for small-scale systems (Figure 2).

A case study was developed for a system combining dairy farm digester gas and fuel cell CHP (Figure 3).

Input data included capital costs, operation and maintenance costs, expected life, and performance of the digester, gas cleanup, and fuel cell components; applicable government incentives; on-site energy demands; and energy costs. Using these data, the Fuel Cell Power Model showed a payback time of about 7 years with an 8.5% IRR. It also showed a GHG emissions reduction of about 750 g CO₂eq/kWh electricity generated, primarily owing to less GHG-intensive manure management and displacement of grid electricity (Figure 4).

Conclusions and Future Directions

In FY 2010, Fuel Cell Power Model efforts focused on three areas: improving the model’s analytical capabilities (including the completion of Version 1.2), training and supporting the model’s user community, and performing analyses using the model. Future work may include the following:

- Enhance the Fuel Cell Power Model in response to needs identified through its user community.
- Enhance the model’s business case analysis capabilities using experience from the business community.
- Develop additional case studies, with data from actual fuel cell installations for comparison.
VII. Systems Analysis

- Use the Fuel Cell Power Model to evaluate early hydrogen transition scenarios and the potential effects on electricity systems and GHG emissions.
- Add analysis capabilities for solid oxide fuel cells and residential-sized systems to the Fuel Cell Power Model.
- Integrate the Fuel Cell Power Model with DOE’s MSM and SERA.

Contract Number: DE-AC36-08GO28308
Project Start Date: May 28, 2009
Project End Date: November 30, 2010

Objectives

- Develop a tool to allow users to compare hydrogen production pathways and policy options within a single common framework.
- Identify low-cost hydrogen production pathways at demand centers across the U.S.
- Perform scenario analysis to characterize the effect of factors such as the price of carbon, hydrogen demand, and feedstock costs on hydrogen price, resource utilization, and carbon dioxide (CO₂) emissions.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section (4.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Future Market Behavior
(B) Stove-piped/Siloed Analytical Capability
(D) Suite of Models and Tools

Contribution to Achievement of DOE Systems Analysis Milestones

This project contributes to achievement of the following DOE Systems Analysis milestones from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 5**: Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for various hydrogen scenarios (4Q, 2009). The Hydrogen Logistics Model enables geographic analysis of hydrogen supply, demand, delivery and selling price.

- **Milestone 11**: Complete environmental analysis of the technology environmental impacts for the hydrogen scenarios and technology readiness (2Q 2015). The Hydrogen Logistics Model helps quantify the impact of hydrogen production pathways and carbon policy on greenhouse gas emissions from hydrogen production.

Accomplishments

- Developed a user-interactive tool to allow scenario analysis comparison between hydrogen production pathways and policy options within a single common framework.

- Identified the least-cost hydrogen production pathways at demand centers across the United States under a variety of demand, carbon tax, and resource price scenarios. Results indicate that coal, natural gas, and biomass-based production pathways dominate the supply over a robust set of input assumptions.

- Estimated hydrogen cost contributions, carbon mitigation cost, and resource utilization under several different scenarios. The average delivered cost of hydrogen was estimated to range from $4.60/kg to $5.45/kg depending on the level of demand, availability of carbon capture, and the cost of CO₂.

Introduction

A number of hydrogen production, delivery, and storage options are being investigated that could eventually meet the demands of future hydrogen vehicles. Hydrogen production options include natural gas steam methane reforming, coal gasification, high-temperature nuclear electrolysis or thermochemical water splitting, and renewable options (e.g., biomass gasification, solar- and wind-based water electrolysis, solar thermochemical water splitting). The cost and availability of these resources varies widely based on the geographic location of demand and the size of the production facilities.
To help understand the economics of different hydrogen production pathways, TIAX developed a tool to estimate the price of delivered hydrogen to major demand centers across the U.S., as well as the associated resource utilization that is required to meet this demand. Hydrogen price and resource utilization were estimated by determining the location-specific combination of resources that minimizes the cost of delivering hydrogen. The present effort extends prior work [1] by incorporating additional conventional supply resources, carbon capture and sequestration (CC&S), and improving the compatibility between the Hydrogen Logistics Model inputs and outputs and other hydrogen crosscutting analysis models recently developed or currently under development for the DOE Hydrogen Program.

### Approach

A hydrogen production and infrastructure modeling tool (the Hydrogen Logistics Model) was developed to investigate the resource constraints and fuel cost of a future hydrogen fueling infrastructure in the U.S. The Hydrogen Logistics Model is an interactive tool that uses geographic information system (GIS) data to optimally deploy hydrogen production resources. The inputs to the Logistics Model include location, quantity, and cost information for hydrogen production feedstocks, and the location and size of demand centers. Data was gathered from a variety of publically available sources, notably the National Renewable Energy Laboratory’s (NREL’s) GIS database [2], the DOE’s Energy Information Administration [3], and H2A Production case studies [4]. A linear optimization algorithm uses these inputs to select the combination of hydrogen production resources that minimizes the average price for hydrogen at individual demand centers across the U.S. To account for the geographical variation in hydrogen resource feedstock supply and projected hydrogen demand, the model deconstructs the U.S. into a grid of discrete nodes, each with an associated resource supply and hydrogen demand. Using these inputs, the model projects the resources, infrastructure, and delivered price of hydrogen to each demand center. Ten different hydrogen production pathways were evaluated: coal gasification, natural gas, nuclear electrolysis, nuclear thermochemical hydrogen, biomass gasification, wind electrolysis, solar thermochemical, concentrating solar powered electrolysis, solar photovoltaic powered electrolysis, and landfill gas (LFG).

The Hydrogen Logistics Model was used to analyze a base case plus several sensitivity scenarios that vary factors such as demand, the price of CO₂, technology availability, and cost assumptions.

### Results

The results of scenario analysis performed using the Hydrogen Logistics Model indicate that if CC&S is available, hydrogen is produced primarily from fossil-based production pathways – even with carbon taxes as high as $100 per ton – although biomass and LFG also make an important contribution. If CC&S is not available, biomass becomes the dominant production pathway. Other resources – notably wind, nuclear, or solar thermochemical hydrogen – become widely adopted only when CC&S is unavailable and using favorable cost assumptions. The average delivered price of hydrogen was estimated to vary from $4.60 per kg under a high demand scenario with no carbon tax to $5.40 per kg under a high demand scenario with $100 per ton carbon tax and no CC&S available.

In the base case scenario, which assumes a $25 per ton carbon tax and that CC&S is utilized and does not include LFG, hydrogen is produced primarily from fossil resources (~80% of supply), with biomass accounting for the remaining 20% at an average delivered price of approximately $4.90/kg H₂. A summary of these base case results is shown in Table 1.

The dominant contributor to the price of hydrogen is the delivery cost, which averages $3.25/kg H₂ (nearly 70% of the selling price), and does not vary appreciably with the production pathway (Figure 1). Analysis of the variable (per-mile) and fixed delivery costs showed a large price impact, but relatively minor shifts in resource utilization. Carbon mitigation costs (carbon taxes plus the cost of CC&S) account for less than 5% of the selling price in the base case, but reduce emissions by 93% compared to a scenario with no carbon constraints. An illustrative map of the geographical distribution of the delivered price of hydrogen to demand centers is

VII. Systems Analysis

1238

DOE Hydrogen Program

Kromer – TIAX, LLC

As shown in Figure 2; alternative maps showing details such as the location and type of production plants and the delivery infrastructure may also be generated. As shown, hydrogen prices range from a low of $4.50 to a high of $5.95 per kg; a primary determinant of this price variation is the population density.

In addition to the base case, sensitivity scenarios that vary hydrogen demand (low, medium, and high); size of CO2 tax ($0, $25, and $100 per ton); availability of CC&S technology; and the cost and availability for individual production pathways (favorable wind, favorable nuclear, favorable solar thermochemical, and including landfill gas) were evaluated. Figure 3 shows the resource utilization and average hydrogen selling price using four different sets of carbon constraints at three different levels of demand. This set of scenarios uses the same cost assumptions as those used in the base case. As shown, only coal, natural gas, and biomass resources are utilized, although the distribution between the three varies across the scenarios. In particular, increasing the cost of carbon causes a shift from coal to natural gas and biomass, while increasing demand tends to favor fossil resources over biomass. These scenarios do not include LFG-to-hydrogen pathway, which was included as a sensitivity scenario. If it is included, its market share ranges from 30% at low demand to 4% at high demand with a modest downward effect on the price of hydrogen.

Other hydrogen production pathways – wind electrolysis, nuclear electrolysis, nuclear thermochemical, and solar thermochemical – are adopted only when more favorable cost assumptions are included in combination with high carbon taxes ($100 per ton) and assuming that carbon capture is not available. Figure 4 shows the effect of these more favorable cost assumptions at three different demand levels.

Additional calculations were performed to estimate the CO2 emissions impact and CO2 mitigation cost (in dollars per ton of CO2 avoided). These calculations show that if CC&S is available, CO2 emissions can be reduced by upwards of 95% at a cost of $15 to $20 per ton of CO2 avoided compared to a case with no carbon constraints. If CC&S is not available, CO2 emissions reductions range from 80 to 100% with costs ranging from $20 to $50 per ton. The cost and efficacy of CO2 mitigation is strongly influenced by demand if CC&S is not available, and weakly influenced if it is. These results suggest that at low demand, CO2 emissions can be avoided at relatively low cost across a robust set of scenario, but that the feasibility and widespread deployment CC&S is a critical element to low-cost and efficacious CO2 mitigation at high demand.

Conclusions and Future Directions

TIAX developed the Hydrogen Logistics Model to allow comparison between hydrogen production
pathways and to perform scenario analysis on future hydrogen fueling infrastructure. Key conclusions from this scenario analysis include:

- If carbon capture and sequestration is available or if the price of carbon is low, hydrogen is produced primarily from fossil-based production pathways, although biomass and LFG also make an important contribution, accounting for up to 30% of supply.
- LFG and biomass are the most economic non-fossil production pathways, and are adopted under a robust set of input assumptions. Other low carbon pathways are only adopted when favorable cost assumptions are included in combination with high carbon taxes.
- The average delivered price of hydrogen ranges from $4.60/kg to $5.45/kg. The efficacy of carbon capture and the level of demand are the key factors influencing this price variation.
- Using base case assumptions, the average delivered price of hydrogen is $4.90. This price varies geographically from $4.50 to $5.95 per kg. The dominant contribution to the hydrogen price is the delivery cost; population density is the primary determinant of the geographic variation in the price of hydrogen.
- The cost and efficacy of CO₂ mitigation is strongly influenced by demand if CC&S is not available and weakly influenced by demand if it is. Carbon mitigation costs range from $15 to $25 per ton of CO₂ avoided if carbon capture is available, but rise to as high as $50 per ton under high demand scenarios without carbon capture. From a policy perspective, this suggests that at low demand, CO₂ emissions can be avoided at relatively low cost, regardless of the costs and availability of technologies such as CC&S, nuclear-to-hydrogen, or low cost wind. However, the feasibility and widespread deployment CC&S is a critical element to low-cost and efficacious CO₂ mitigation as demand rises.

The current project has been completed. However, several additional areas for further work are proposed:

- Include distributed production pathways in the analysis: allows comparison of centralized and distributed production within the same framework.
- Further integrate inputs and outputs with existing Hydrogen Program tools (HyDRA, Macro-System Model, etc) or GIS tools (e.g., ArcGIS).
- Use a design-of-experiments approach to model hydrogen infrastructure transition and evolution over time.
- Introduce additional policy constraints – e.g., renewable portfolio standards, low carbon fuel mandates, production tax credits.
- Model competition with alternative end-uses (e.g., electricity).
- Characterize high sensitivity parameters using Monte Carlo analysis.

VII.16 HyDRA: Hydrogen Demand and Resource Analysis Tool

Objectives

- Develop a Web-based geographic information system (GIS) tool to allow analysts, decision makers, and general users to view, download, and analyze hydrogen demand, resource, and infrastructure data spatially and dynamically.
- Provide a repository for hydrogen spatial data inputs and model results.
- Display and aggregate the results of spatial analyses.
- Support interoperability between HyDRA and similar applications in other domains of energy infrastructure research.

Technical Barriers

This project addresses the following technical barriers from the Systems Analysis section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(B) Stove-Piped/Siloed Analytical Capability
(C) Inconsistent Data, Assumptions, and Guidelines
(D) Suite of Models and Tools

Contribution to Achievement of DOE Systems Analysis/Integration Milestones

This project will contribute to achievement of the following DOE milestones from the System Analysis and System Integration sections of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 5 (System Analysis): Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for various hydrogen scenarios. (4Q, 2009)
- Milestone 8 (System Analysis): Complete analysis and studies of resource/feedstock, production/delivery and existing infrastructure for technology readiness. (4Q, 2014)
- Milestone 27 (System Analysis): Complete the 2nd version of the Macro-System Model to include the analytical capabilities to evaluate the electrical infrastructure. (2Q, 2011)
- Milestone 15 (System Integration): MSM analysis test cases. (4Q, 2006; 3Q, 2009; 4Q, 2010)

Accomplishments

- Completed the Macro System Model (MSM) dynamic integration that can, at the user’s request, produce six data layers based on user specified parameters and load them into HyDRA for visualization and querying.
- Initial interoperability between HyDRA and the Scenario Evaluation, Regionalization and Analysis (SERA) model was achieved in Fiscal Year (FY) 2010:
  - External datasets from multiple locations are available within the HyDRA interface.
  - Worked with SERA leadership to finalize the initial data input and delivery needs for SERA which will be supported by HyDRA.
- The strategy will also support interoperability between HyDRA and other systems, models, and analysis applications including the Bioenergy Knowledge Discovery Framework (BKDF).
- Interaction with the BKDF:
  - Enhancements on the BKDF project resulted in several data services being made available to HyDRA in the fourth quarter of FY 2010.
- Increased the number of spatial data layers related to hydrogen resource, infrastructure, and demand to over 90 layers. These datasets are comprised of background data, model input data, and results spatial analyses and modeling efforts.
- A diverse group of 257 users from 62 countries accessed the HyDRA application over 2,000 times in FY 2010.
Introduction

The HyDRA tool was developed to conduct dynamic geographic analysis of hydrogen processes in Web-based environment. This capability is important as resource, demand, and infrastructure will vary regionally for hydrogen production, delivery, and dispensing. HyDRA provides a repository for storing spatial data used by hydrogen analyses and tools, and allows analysis results from multiple domains of research to be explored and compared from within a single interface.

Approach

The HyDRA tool is a state-of-the-art, Web 2.0 application that has the look, feel, and functionality of a traditional client-based GIS application. It provides the capability to view hydrogen data and how they vary across the United States on a regional basis. HyDRA provides analysis results in the form of maps that can be queried to access the numbers behind the visualization. It is available at http://maps.nrel.gov. Users can view spatial hydrogen data and interact with the maps to create custom analyses. Data can be downloaded from the application and used in other analyses. To ensure HyDRA's usability, NREL recently redesigned it from its original code base to provide an easier to use, more intuitive interface. Users can create their own spatial datasets and provide them to the HyDRA application to create a completely customizable and dynamic analysis tool.

The capability to explore and query spatial data layers is a core capability of the HyDRA application. There are currently more than 90 datasets available in the system including resource cost and availability, hydrogen production potential, hydrogen production cost, resource consumption, hydrogen demand, infrastructure, and results from integration with other hydrogen models. The ability to access externally hosted datasets and also to run the MSM model from within the HyDRA application will provide access to a significant number of additional datasets. Additionally, dynamic data acquisition services will provide up-to-date versions of data that change over time.

Results

The major HyDRA efforts that we completed this year involve the integration of HyDRA with the MSM, developments to support interoperability between HyDRA and SERA, and preliminary development of spatial analysis and complex querying within HyDRA.

The development of the HyDRA/MSM integration allows for an MSM job to be initiated from an MSM tab in the HyDRA interface. Users can submit a job to the MSM for any state and specify various parameters within their request. Users are limited to running jobs on a state basis due to the time each MSM run requires. MSM jobs take over five minutes per county to run, so larger states that include a sensitivity analysis on electricity cost can take several days. As a result the MSM jobs are submitted in a batch format so that users can send their MSM jobs from HyDRA and then continue using the application while the jobs run in the background. Status information is available in the MSM tab within the HyDRA application.

At this time the forecourt electrolysis MSM scenario can be run from within HyDRA. The interface provides a form for the entry of the required parameters and sends these to the MSM along with the electricity cost and grid mix for every county in the state. The MSM generates a resultant hydrogen cost, greenhouse gas emissions, total energy usage, fossil energy usage and petroleum energy usage for every county in the state. These data are accessible to the user through an interface in the HyDRA application along with the specific parameters entered by the user in the request (Figures 1). Additionally, a preliminary design was completed to support querying of HyDRA data by the MSM.

The NREL HyDRA team built a Web service (a specific uniform resource locator [URL] that allows computers to exchange data) that includes user authentication to allow MSM to access data contained in the HyDRA database such as the electricity and natural gas rates for specific counties (Figure 2). A Web
service specification was created that will allow the MSM team and the HyDRA team to develop in parallel which. This integration was completed early in the third quarter of FY 2010.

The effort to support interoperability between HyDRA and SERA is being implemented in such a way as to support interoperability between HyDRA and a number of other applications as well (Figure 3). This development effort allows users to specify external datasets that can be dynamically loaded into the HyDRA interface and also to load some HyDRA data directly within other applications. A prototype of this capability is shown in Figure 4 by displaying live weather data, which is an external data source, over the MSM greenhouse gas emissions.

As new datasets are ingested into HyDRA which support analysis and modeling efforts, such as the SERA model, HyDRA will become a venue for results of analysis and modeling applications. Users are able to load these results directly into HyDRA along with the existing HyDRA data layers and external data from applications such as the BKDF.

Conclusions and Future Directions

HyDRA provides a single point of reference for spatial data related to hydrogen. Improvements to the user interface and functionality provides an intuitive user experience. Additionally, the enhanced interoperability of HyDRA simplifies the direct use of this data in analysis and modeling and places HyDRA at the center of many other applications and research efforts. In the future HyDRA will:

- Develop a process for automatically updating SERA input data in the HyDRA application on a regular basis.
- Develop an interface to explore, visualize and display complex temporal and multivariate datasets.
- Provide an interface to dynamically create, print, and export images of maps and charts.
- Allow users to customize map classification and dynamically manipulate charting variables.
- Formalize data interoperability relationships and data exchanges between other spatial data analysis and visualization applications in other domains of research.
- Continue to develop the capability to generate dynamic layers in the HyDRA application from user and model provided data.
- Develop and deploy basic analysis functions such as graphing, changing underlying assumptions, and buffering.
- Continue to integrate with other hydrogen models and analyses to develop new data input layers and display model results using manual and dynamic integration.
- Create case studies to ease user analysis, similar to H2A cases.
FY 2010 Publications/Presentations

VIII. TECHNOLOGY VALIDATION
VIII.0 Technology Validation Sub-Program Overview

**Introduction**

The Technology Validation sub-program has been focused on conducting learning demonstrations that emphasize co-development and integration of hydrogen infrastructure with hydrogen fuel cell-powered vehicles to permit industry to assess progress toward technology readiness. Technology Validation tests, demonstrates, and validates hydrogen fuel cell technologies and infrastructure and uses the results to provide feedback to the Program’s research and development (R&D) activities.

**Goal**

Validate—under real-world operating conditions—the status, relative to Program targets, of integrated hydrogen and fuel cell technologies that will be used in both the transition and early market periods for transportation, infrastructure, and electric power generation.

**Objectives**

- **2014:** Validate a stationary fuel cell system that co-produces hydrogen and electricity at 40% efficiency, with 40,000-hour durability.
- **2015:** Validate fuel cell vehicles achieving 5,000-hour durability (service life of vehicle) and a 300-mile driving range between fueling.

**FY 2010 Technology Status**

In 2010, the National Learning Demonstration—a government-industry cost shared project initiated in 2004 with four automobile and energy company teams—continued to provide data for evaluating the technology status with respect to fuel cell durability, driving range, and power park demonstrations. Data collected during the past five years has been analyzed. Thus far, more than 2.8 million miles have been traveled by the fuel cell vehicles in the project and 130,000 kg of hydrogen has been either produced or dispensed, with some of this hydrogen being used in vehicles not in the Learning Demonstration. Demonstrated fuel cell durability has exceeded 2,500 hours, and the vehicle driving range has exceeded the goal of 250 miles. Fuel cell system efficiency data at about 25% net power is 53–59% which is close to the DOE target of 60%.

In June 2009, the National Renewable Energy Laboratory (NREL) and Savannah River National Laboratory (SRNL) verified that Toyota’s FCHV-adv fuel cell vehicle can achieve a driving range of 430 miles without refueling (Figure 1). The report and related video on range estimates for the Toyota FCHV-adv have been issued.¹

**FY 2010 Accomplishments**

National Learning Demonstration

- Learning Demonstration projects by Ford and Chevron were completed in Fiscal Year (FY) 2010, and DOE expects final reports soon.
- Generation-2 vehicles continued to be operated by customers, and data was provided to the Hydrogen Secure Data Center at NREL (Figure 2).
- Figure 3 shows all of the major key performance metrics that have been reported in the National Hydrogen Learning Demonstration.

FIGURE 2. Learning Demonstration Project Teams and their Two Generations of Vehicles
Fuel Cell Bus Evaluation

- Data has been collected on nine fuel cell buses at five sites. Overall, the buses have traveled more than 395,000 miles. Fuel economy results of the fuel cell buses were 39% to 141% better than diesel and compressed natural gas buses.

Hawaii Hydrogen Power Parks

- Selection of a contractor has been made, all agreements have been executed, and the hydrogen station is due to be delivered to Hawaii in FY 2010.
- The selected system is from PowerTech which produces 12 kg of hydrogen per day and allows rapid-fill to 350 bar with flexibility to expand output.
- At the Volcanoes National Park site, hydrogen is to be produced through electrolysis powered by renewable electricity from Hawaii Electric Light Company.
- Specifications for the shuttle buses were developed by the Hawaii Volcanoes National Park and the Hawaii Center for Advanced Transportation Technologies.
- The PowerTech fueling station will be deployed at the Marine Corps base in Hawaii to support General Motors Equinox fuel cell vehicles until vehicles at Volcanoes National Park are ready for deployment.

Energy Station at Fountain Valley

- Air Products and FuelCell Energy shipped the fuel cell system to Fountain Valley, California, and completed the installation at the Orange County Sanitation District. Initial operation will use natural gas, in order to obtain baseline information to compare with the system’s operation prior to shipment.

**FIGURE 3.** Summary of Key Performance Metrics for the Learning Demonstration
The funding portfolio for Technology Validation addresses the need to validate integrated hydrogen and fuel cell technologies for transportation, infrastructure, and electric power generation in a systems context, under real-world operating conditions. In FY 2010, $13 million in funding was appropriated for the Technology Validation sub-program. The President’s FY 2011 request includes $11 million for Technology Validation activities.

FIGURE 4. Concept for the Energy Station at Fountain Valley, California

Budget

The funding portfolio for Technology Validation addresses the need to validate integrated hydrogen and fuel cell technologies for transportation, infrastructure, and electric power generation in a systems context, under real-world operating conditions. In FY 2010, $13 million in funding was appropriated for the Technology Validation sub-program. The President’s FY 2011 request includes $11 million for Technology Validation activities.
FY 2011 Plans

In FY 2011 the final two National Learning Demonstration projects (General Motors and Mercedes-Benz North America) will conclude and final reports will be prepared.

The Program’s validation activities also encompass fuel cell buses. The Technology Validation sub-program collaborates with the Department of Transportation to validate fuel cell and hydrogen technologies in transit bus demonstrations conducted by the Federal Transit Administration, and to harmonize data collection efforts with other fuel cell buses demonstrations worldwide.

In FY 2011, the power park at Volcanoes National Park will begin operation, supplying electricity to the visitors’ center and hydrogen fuel to the plug-in hybrid fuel cell shuttle buses.

The Hydrogen Energy Station at Fountain Valley will be fully operational in FY 2011 and data will be collected on electric power and heat generation, hydrogen production, and vehicle refueling.

Within its Market Transformation activities, the Program has collaborated with the Department of Defense (DOD) Defense Logistics Agency (DLA) on the demonstration of fuel cell forklifts. As the main provider of fuel and supplies for the DOD as well as several civilian agencies, DLA supports a vast infrastructure of distribution centers across both the United States and abroad. By introducing fuel cell forklifts into their distribution centers, DLA capitalizes on an excellent opportunity for testing fuel cells under real world conditions and providing feedback to manufacturers. As part of this effort, NREL will collect and analyze the operation and performance data of the forklifts.

E-mail: John.Garbak@ee.doe.gov
Objectives

- By 2008, validate that hydrogen vehicles have a greater than 250-mile range without impacting passenger or cargo compartments.
- By 2009, validate 2,000-hour fuel cell durability in vehicles and hydrogen infrastructure that results in a hydrogen production cost of less than $3.00/gallons of gasoline equivalent (gge) (untaxed) delivered and safe and convenient refueling by drivers (with training).
- Assist DOE in demonstrating the use of fuel cell electric vehicles (FCEVs) and hydrogen infrastructure under real-world conditions, using multiple sites, varying climates, and a variety of sources for hydrogen.
- Analyze detailed fuel cell and hydrogen data from vehicles and infrastructure to obtain maximum value for DOE and industry from this “learning demonstration.”
- Identify the current status of the technology and its evolution over the project duration; generate composite data products (CDPs) for public dissemination.
- Provide feedback and recommendations to DOE to assist hydrogen and fuel cell research and development (R&D) activities and assess technical progress.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section (3.6.4) of the Fuel Cell Technologies (FCT) Program’s Multi-Year Research, Development, and Demonstration Plan:

(A) Lack of Fuel Cell Vehicle Performance and Durability Data
(B) Hydrogen Storage
(C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data
(D) Maintenance and Training Facilities
(E) Codes and Standards
(H) Hydrogen from Renewable Resources
(I) Hydrogen and Electricity Co-Production

Contribution to Achievement of DOE Technology Validation Milestones

Throughout the duration of this project, researchers are gathering data and providing technical analysis that is contributing to achieving the following DOE technology validation milestones from the FCT Program’s Multi-Year Research, Development, and Demonstration Plan:

- **Milestone 2:** Demonstrate FCEVs that achieve 50% higher fuel economy than gasoline vehicles (Q3, FY 2005). This milestone was achieved.
- **Milestone 3:** Decision for purchase of additional vehicles based on projected vehicle performance and durability and hydrogen cost criteria (Q4, FY 2006). This milestone was achieved.
- **Milestone 4:** Operate fuel cell vehicle fleets to determine if 1,000 hour fuel cell durability, using fuel cell degradation data, was achieved by industry (Q4, FY 2006). This milestone was achieved.
- **Milestone 5:** Validate vehicle refueling time of 5 minutes or less for a 5 kg tank [1kg/min] (Q4, FY 2006). At the time of the milestone, we had analyzed over 2,000 vehicle refueling events and had calculated an average rate of 0.69 kg/min and median rate of 0.72 kg/min, with 18% of the events exceeding the 1 kg/min target. Updates 3.5 years later, data from over 25,000 refueling events showed improved results with an average rate of 0.77 kg/min with 22% of refueling events exceeding 1 kg/min. This milestone was achieved.
- **Milestone 7:** Validate refueling time of 5 minutes or less for 5 kg of hydrogen (1 kg/min) at 5,000 psi through the use of advanced communication technology (Q4, FY 2007). Currently, the data show that communication fills can refuel at a higher rate (up to 1.8 kg/min) and have an average fill rate 30% higher than non-communication fills (0.86 kg/min vs. 0.66 kg/min). This milestone was achieved.
• Accomplishments
  • Received and processed data from a total of 436,000 individual vehicle trips, amounting to over 98 GB of on-road data, since inception of the project.
  • Created and published 80 CDPs (the ninth and largest set of public results) representing results from analyzing almost five years of Learning Demonstration data.
  • Documented and archived each quarter's analysis results in the Fleet Analysis Toolkit (FAT) graphical user interface.
  • Milestone 8: Fuel cell vehicles demonstrate the ability to achieve a 250-mile range without impacting passenger cargo compartment (Q4, FY 2008). This milestone was achieved in 2008 using data from the Learning Demonstration results, with range between 196–254 miles. In June 2009, an on-road driving range evaluation was performed in collaboration with Toyota and Savannah River National Laboratory. The results indicated a 431-mile on-road range was possible in southern California using Toyota’s FCHV-adv fuel cell vehicle. This milestone was achieved.
  • Milestone 10: Validate FCEVs 2,000-hour fuel cell durability using fuel cell degradation data (Q4, FY 2009). On-road fuel cell voltage data from second-generation fuel cell systems were analyzed and published in the Fall 2009 CDP results. Results indicate that the highest projected team average to 10% voltage degradation for second-generation systems was 2,521 hours, with a four-team average of 1,020 hours. The Spring 2010 results only slightly increased the average (to 1,062 hours) and the highest team remained the same at 2,521 hours. This milestone was achieved.
  • Milestone 23: Total of 10 stations constructed with advanced sensor systems and operating procedures (Q1, FY 2008). This milestone was achieved.
  • Milestone 24: Validate a hydrogen cost of $3.00/gge (based on volume production) (Q4, FY 2009). Cost estimates from the Learning Demonstration energy company partners were used as input to an H2A analysis to project the hydrogen cost for 1,500 kg/day early market fueling stations. Results indicate that on-site natural gas reforming would lead to a range of $8-$10/kg and on-site electrolysis would lead to $10-$13/kg hydrogen cost. While these results do not meet the $3/gge cost target, two external independent panels concluded that distributed natural gas reforming could lead to $2.75-$3.50/kg [1] and distributed electrolysis could lead to $4.90-$5.70 [2]. This milestone was achieved outside of the Learning Demonstration project.

Introduction

The primary goal of this project is to validate vehicle/infrastructure systems using hydrogen as a transportation fuel for light-duty vehicles. This means validating the use of FCEVs and hydrogen refueling infrastructure under real-world conditions using multiple sites, varying climates, and a variety of sources for hydrogen. Specific targets for 2009 were hydrogen vehicles with a range greater than 250 miles, 2,000-hour fuel cell durability, and $3/gge hydrogen production cost (based on modeling for volume production). We are identifying the current status of the technology and tracking its evolution over the project duration, particularly between the first- and second-generation fuel cell vehicles. NREL's role in this project is to provide maximum value for DOE and industry from the data produced by this “learning demonstration.” We seek to understand the progress toward the technical targets, and provide information to help move the FCT R&D activities more quickly toward cost-effective, reliable hydrogen FCEVs and supporting refueling infrastructure.

Approach

Our approach to accomplishing the project’s objectives is structured around a highly collaborative relationship with each of the industry teams, including Chevron/Hyundai-Kia, Daimler/BP, Ford/BP, General Motors/Shell, and Air Products (through the DOE California Hydrogen Infrastructure Project). We are receiving raw technical data from both the hydrogen
vehicles and refueling infrastructure that allows us to perform unique and valuable analyses across all teams. Our primary objectives are to feed the current technical challenges and opportunities back into the DOE FCT R&D Program and assess the current status and progress toward targets.

To protect the commercial value of these data for each company, we established the Hydrogen Secure Data Center to house the data and perform our analysis. To ensure value is fed back to the hydrogen community, we publish CDPs twice a year at technical conferences to report on the progress of the technology and the project, focusing on the most significant results. Additional CDPs are being conceived as additional results and results of interest are identified, and as we receive requests from DOE, industry, and the codes and standards community. We also provide our detailed analytical results (not public) on each individual company's data back to them to maximize the industry benefit of NREL's analysis work and to obtain feedback on our methodologies.

Results

The results in Fiscal Year (FY) 2010 came from analyzing an additional year of data (January – December 2009), creating a total of 80 new or updated CDPs, and presenting these results at many technical conferences. To accomplish this, we continued to improve and revise our in-house analysis tool, FAT. Since there are so many technical results from the project, they cannot all be listed here or be fully presented during brief conference presentations. Therefore, in 2007 NREL launched a new Web page at http://www.nrel.gov/hydrogen/cdp_topic.html to provide the public with direct access to the results. Portions of these results have also been presented publicly at conferences in the last year as two distinct sets of results (labeled “Fall 2009” and “Spring 2010”). Since all 80 of the results are now available on the Web site, this report will just include some of the highlights over the last year. Figure 1 shows the cumulative number of vehicles that have been deployed by quarter and hydrogen storage system type. A total of 144 vehicles were deployed through March, with 127 of those vehicles retired from the project and 17 still on the road. By fall 2010, there should be roughly 40 vehicles on the road with a cumulative 160 vehicles deployed since project inception.

- **Real-World Vehicle Driving Range:** In FY 2008, the driving range of the project’s FCEVs was evaluated based on fuel economy from dynamometer testing and on-board hydrogen storage amounts and compared to the 250-mile target. Since that time, significant on-road data have been obtained from second- and first-generation vehicles. This allowed us to evaluate the distribution of real-world driving ranges of all the vehicles in the project. The data show (Figure 2) that there has been a 45% improvement in the median real-world driving range.
range of second-generation vehicles (81 miles) as compared to first-generation (56 miles), based on distances driven between over 25,000 refueling events. Obviously the vehicles are capable of two to three times greater range than this, but the median distance travelled between refuelings is one way to measure the improvement in the vehicles’ capability and the way in which they are actually being driven. The Toyota on-road FCHV-adv range evaluation (discussed in the milestone section) was an additional way to see how far FCEVs could be driven in everyday typical use in southern California through a one-day test with two vehicles.

**Fuel Cell Durability:** Fuel cell stacks will need roughly a 5,000-hour life to enter the market for light-duty vehicles. Preliminary durability estimates were first published in the fall of 2006 when most stacks at that time only had a few hundred hours of operation or less accumulated on-road. NREL developed a methodology for projecting the gradual degradation of the voltage based on the data received to date. This involved creating periodic fuel cell polarization curve fits from the on-road stack voltage and current data and calculating the voltage under high-current conditions. This enabled us to track the gradual degradation of the stacks with time and do a linear fit through each team’s data. The methodology was subsequently improved to include a two-segment linear fit and also use a weighting algorithm to come up with a more robust fleet average.

In the past three and a half years since the first fuel cell durability evaluation, many more hours have been accumulated on the fuel cell stacks. The maximum number of hours a first-generation stack has accumulated without repair is 2,375, which is the longest stack durability from a light-duty vehicle FCEV in normal use published to date. Now that the data submissions are complete on first-generation stacks, we can make some conclusions. The initial power degradation is steeper in the first 200 hour hours and flattens out after that (see Figure 3 for the maximum fuel cell power loss as a function of operating hours, with an overall red trend line added). We also needed around 1,000 hours of data accumulated to determine the slope of the more gradual degradation. Finally, with significant drops in power observed at 1,900–2,000 hours, it appears as though this is a solid upper bound on first-generation stack durability. For second-generation fuel cell stacks, the range of maximum hours accumulated from the four teams is now ~800 to over 1,200 hours, with the range of team average hours accumulated of ~300 to 1,100 hours. Relative to projected durability, the Spring 2010 results indicate that the highest average projected team time to 10% voltage degradation for second-generation systems was 2,521 hours, with a multi-team average projection of 1,062 hours.
Therefore, the 2,000-hour target for durability has been validated.

- **Factors Affecting Fuel Cell Durability – Voltage Transients:** In the Spring 2010 results, there were several new results that quantified fuel cell voltage transients from multiple different angles. NREL used a 3-step process where we 1) defined a voltage transient cycle by a drop in voltage, followed by a rise, and finally a steady-state period; 2) identified the voltage transient cycles during all data we had accumulated; and 3) categorized and collected transient cycle details for subsequent analysis. One of the highlights from this analysis was that we observed a significant reduction in the voltage transients for second-generation systems from the first-generation systems (a factor of four reduction in voltage cycles per mile for one team). This comes from a combination of hybridization and control strategy improvements, and should help to improve overall durability. In the coming year, NREL will evaluate whether or not an effect on durability from voltage cycling can be determined based on an expanded multivariate analysis.

- **Fuel Cell Efficiency:** The baseline fuel cell system efficiency was measured from selected vehicles on a vehicle chassis dynamometer at several steady-state points of operation. DOE’s technical target for net system efficiency at one-quarter-power is 60%. Data from the four Learning Demonstration teams showed a range of first-generation net system efficiencies from 51% to 58%, which is very close to the target. Results are now available for the second-generation systems, which revealed slightly improved efficiency at one-quarter-power of 53% to 59%. These results are significant because they show that the system efficiency has not been sacrificed in order to achieve improved durability and freeze capability. In addition to the efficiency at one-quarter-power, we have updated CDP 8 to include the range of system efficiency as a function of power, sweeping from 5% power up to 100% power, as shown in Figure 4.

- **Summary of Performance against Major Project Targets:** Since there are so many results for the two generations of vehicles in this project, we have summarized the key performance numbers and compared them to DOE targets in Table 1. The table shows that this project has exceeded the expectations established in 2003 by DOE, with all of the key targets being achieved except for on-site hydrogen production cost, which would have been difficult to

1 Gross stack power minus fuel cell system auxiliaries, per DRAFT SAE J2615. Excludes power electronics and electric drive.
2 Ratio of DC output energy to the lower heating value of the input fuel (hydrogen).
3 Individual test data linearly interpolated at 5,10,15,25,50,75, and 100% of max net power. Values at high power linearly extrapolated due to steady state dynamometer cooling limitations.

*Outside of this project, DOE independent panels concluded at 500 replicate stations/year: Distributed natural gas reforming at 1500 kg/day: $2.75-$3.50/kg (2006)
Distributed electrolysis at 1500 kg/day: $4.90-$5.70 (2009)
demonstrate through this project. Additional data accumulated and analyzed in 2010–2012 will assess the latest generation of FCEV technology, which includes improvements over the second-generation systems included in the results to date. It will also include data analysis from many new hydrogen stations being commissioned in California, all of which will have 700-bar fueling capability.

Conclusions and Future Direction

- Completed the first five years of the seven-year project with 144 vehicles deployed in fleet operation, 23 project refueling stations constructed, and no major safety barriers encountered.
- Analyzed data from 436,000 individual vehicle trips covering 2.5 million miles traveled and 130,000 kg hydrogen produced or dispensed.
- Verified that high fuel cell system efficiency was maintained from Gen 1 to Gen 2 systems, with Gen 2 efficiency at quarter-power ranging from 53 to 59%, close to the 60% DOE target.
- Published 80 CDPs to date and made them directly accessible to the public from an NREL Web site.
- Expanded fuel cell system degradation analysis to include detailed transient voltage study and metrics.
- We will create new and update CDPs based on data collected through June 2010 (Fall 2010 CDPs) and present results for publication at 2010 Fuel Cell Seminar.
- We will support original equipment manufacturers, energy companies, and state organizations in California in coordinating early infrastructure plans.
- We will gather and analyze data from a relatively large hydrogen station in Burbank, California, along with many new stations that are being opened in California in the next year.
- NREL will continue to identify opportunities to feed findings from the project back into Vehicle Technologies and Fuel Cell Technologies programs and industry R&D activities to maintain the project as a “learning demonstration.”
- We will continue to gather data from FCEVs and hydrogen stations through 2011, and publish the Spring 2011 and Fall 2011 CDPs and potentially one final set of results in Spring 2012.
- As the last deliverable from this project, we will write a final comprehensive summary report for publication.

Contract Number: DE-FC36-04GO14286

Subcontractors:  
• Hyundai Motor Company (HMC) - Seoul, South Korea  
• Kia Motors Corporation (KMC) - Seoul, South Korea  
• Hyundai-KIA America Technical Center Inc. (HATCI) - Chino, CA  
• UTC Power (UTC) - South Windsor, CT  
• Alameda-Contra Costa Transit (ACT) - Oakland, CA  
• Southern California Edison (SCE) - Rosemead, CA

Start Date: January 15, 2004  
Projected End Date: December 31, 2009

Objectives

Validate performance targets:
• Fuel cell stack durability: >2,000 hours  
• Vehicle range: >250 miles  
• Hydrogen cost: <$3.00/gasoline gallon equivalent (gge)  
• Safe and convenient refueling by drivers (with training)

Demonstrate a variety of hydrogen generation technologies including:
• Auto-thermal reformation of natural gas  
• Low pressure steam reformulation of natural gas  
• High pressure steam reformulation of natural gas  
• Electrolysis of water

Technical Barriers

This project addressed the following technical barriers from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Fuel Cell Vehicle Performance and Durability Data  
(B) Hydrogen Storage  
(C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data  
(D) Maintenance and Training Facilities

Contribution to Achievement of DOE Technology Validation Milestones

This project contributed to achievement of the following DOE milestones from the Controlled Hydrogen Fleet and Infrastructure Demonstration and Validation Project of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

• Milestone 10: Validate FCVs 2,000 hour fuel cell durability, using fuel cell degradation data. (4Q, 2009)
• Milestone 12: Validate cold start capability at -20 C. (2Q, 2011)
• Milestone 14: Validate achievement of a refueling time of 3 minutes or less for 5 kg of hydrogen at 5,000 psi using advanced communication technology. (2Q, 2012)
• Milestone 22: Five stations and two maintenance facilities constructed with advanced sensor systems and operating procedures. (4Q, 2006)
• Milestone 23: Total of 10 stations constructed with advanced sensor systems and operating procedures. (1Q, 2008)

Accomplishments

• All 32 vehicles entered the project  
• One additional vehicle was added to the project  
• Five infrastructure stations provided safe operation for the duration of the project  
• Two maintenance facilities provided safe vehicle operation  
• Safe and convenient refueling by drivers was demonstrated
VIII. Technology Validation

- Cold weather vehicles testing completed
- Survey of fuel cell vehicle (FCV) drivers conducted

Introduction

As a result of President Bush’s Initiative, the DOE detailed a strategy to develop a hydrogen economy that emphasized co-developing hydrogen infrastructure in parallel with hydrogen fuel cell-powered vehicles to allow a commercialization decision by 2015. In the past, efforts to introduce new energy technologies in the transportation sector have been thwarted by the classic “chicken and egg” dilemma of which comes first, in this case, hydrogen infrastructure or hydrogen vehicles. The Controlled Hydrogen Fleet and Infrastructure Demonstration and Validation project was an important first step towards achieving the above strategy because the selected consortia developed a complete system solution(s) that addressed all elements of infrastructure and vehicle development.

The goals were accomplished by developing hydrogen infrastructures and hydrogen-powered vehicles at selected U.S. locations. This Technology Validation project provided an opportunity to participate in a cost-shared demonstration of hydrogen infrastructure and vehicle technologies.

Approach

CTV and its project team of HMC, HATCI, UTC and the site hosts operated a fully integrated fueling and fleet operation consisting of 32 FCVs, (including two different generations) while developing a database of operational experience under a wide variety of conditions including, for the stations, different technology and feed stocks, and for the vehicles, differing driving patterns and ambient temperatures. This data was collected in a manner that allowed ‘consumer’ (including station operators, fuelers, drivers and maintenance workers) feedback to be recognized and incorporated into lessons learned.

Learning’s from the early phases of this project were incorporated into later phases in a way that allowed performance improving technologies to be tested in the most cost-effective and efficacious manner.

Results

In support of DOE’s objective “By 2009, validate 2,000-hour fuel cell durability in vehicles . . . “, vehicles were operated at the cold-weather station in Selfridge, Michigan and were subject to cold starts in the winter of 2008/2009 to validate cold-start capability. Vehicles were left outside overnight prior to starting (Figure 1). Hyundai addressed the barrier of “Lack of facilities for maintaining hydrogen vehicles” by operating three maintenance facilities including the training of operators to maintain the vehicles (Figure 2). Training was also conducted for first responders at all stations. Refresher training was offered each year to local first responders to support the training of new responders to the communities around the hydrogen stations. In addition, hypothetical fire response drills were held at the stations (Figure 3).

In support of DOE’s objective “By 2009, . . . safe and convenient refueling by drivers (with training),” Chevron trained drivers to conduct fueling of the FCVs. Drivers performed hundreds of safe refueling events at several infrastructure stations 24/7 (Figure 4).
Chevron operated five stations in support of DOE’s objective “By 2009, . . . validate hydrogen infrastructure that results in a hydrogen production cost of less than $3.00/gge (untaxed) delivered”. Data from operating these stations was provided to NREL and is stored at the Hydrogen Secure Data Facility in Golden, Colorado. A hydrogen energy station operated at HATCI in Chino, California. This station demonstrated the on-site auto-thermal reformation of natural gas. The Chino site served as the commissioning site for all project vehicles as well as one of the project’s fleet operators. The station, as all stations in the project, was designed to utilize state-of-the-art remote monitoring and operation systems and incorporates advanced hydrogen and fire sensors. A hydrogen energy station operated at ACT in Oakland California. This station was only partially funded by the DOE project but the data from the station was shared with NREL. This station demonstrated the use of on-site low-pressure and high-pressure steam methane reforming.

A hydrogen energy station was installed at the Progress Energy site in Orlando, Florida. This station was not funded by DOE but CTV reported the station data to NREL. A hydrogen energy station operated at the SCE site in Rosemead, California. This site demonstrated on-site production of hydrogen using electrolysis. A cold-weather hydrogen energy station operated at the Selfridge Air National Guard site in Selfridge, Michigan.

Conclusions and Future Directions

Thirty-two vehicles were entered into the project. One additional vehicle was added to the project. Four vehicles remain in operation at HATCI in Chino, California. The other vehicles have been retired. Five hydrogen infrastructure stations have completed operation for the project.

FY 2010 Publications/Presentations

Objectives

- Record, collect and report data from fuel cell vehicles (FCVs) and the hydrogen fueling operations to validate DOE targets:

<table>

</tbody>
</table>

- Demonstrate the safe installation of hydrogen fueling stations and fuel cell service facilities as well as the safe operation of all FCVs.
- Continuously update safety manuals and provide training.
- Participate in various working groups to ensure continuous progress towards establishing codes and standards essential for FCV commercialization.
- Raise public awareness of hydrogen technology and demonstration projects.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Fuel Cell Vehicle Performance and Durability Data
(B) Hydrogen Storage
(C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data
(D) Maintenance and Training Facilities
(E) Codes and Standards
(H) Hydrogen from Renewable Resources

Contribution to Achievement of DOE Technology Validation Milestones

This project will contribute to achievement of the following DOE technology validation milestones from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 7**: Validate vehicle refueling time of 5 minutes or less for a 5 kg of hydrogen (1 kg/min) at 5,000 psi through the use of advanced communication technology. (4Q2007)
- **Milestone 8**: Fuel cell vehicles demonstrate the ability to achieve 250 mile range without impacting passenger cargo compartment. (4Q2008)
- **Milestone 10**: Validate FCVs 2,000 hour fuel cell durability using fuel cell degradation data. (4Q2009)
- **Milestone 12**: Validate cold start capability at -20°C. (2Q2011)

Accomplishments

- Externally operated Gen II vehicles for the sixth consecutive year although the vehicles were designed for a 2-year operation.
- Submitted over 100 DVDs of raw data to the National Renewable Energy Laboratory (NREL).
- Finalized internal operation and testing of Gen II pre-production vehicles.
- Preparing for Gen II deployment with external customers and dealership.
- Improved equipment reliability and maintained operation of the DTE refueling station.
Participated in various working groups to ensure continuous progress with regards to codes and standards.

Introduction

The primary goal of this project is to validate fuel cell technologies for infrastructure, transportation as well as assess technology/commercial readiness for the market. The Mercedes Team, together with its partners, have been testing the technology by operating and fueling hydrogen FCVs under real world conditions in varying climate, terrain and driving conditions. Vehicle infrastructure data has been collected to monitor the progress toward the hydrogen vehicle and infrastructure performance targets of $2.00–3.00/gasoline gallon equivalent (gge) hydrogen production cost and 2,000-hour fuel cell durability. Furthermore, progress has been made to validate cold-start capability at -20°C. Finally, to prepare the public for a hydrogen economy, outreach activities have been designated to promote awareness and acceptance of hydrogen technology.

Approach

To achieve the project goals, the Mercedes Team deployed 30 Gen I vehicles into customer hands for real-world operations in three climatic regions of the United States. The Team is also providing data from Gen II vehicles under similar operations as Gen I vehicles to compare technology maturity during the project duration. All vehicles have been equipped with a data acquisition system that automatically collects statistically relevant data for submission to NREL, which monitors the progress of the FCVs against the DOE technology validation milestones. The energy partners have installed an infrastructure to provide hydrogen to the Mercedes Team’s FCVs and to evaluate the technologies which have the potential to achieve the DOE hydrogen cost targets.

To raise public awareness of hydrogen technology and demonstration projects, the Mercedes Team aligned its communication activities with the goals of the DOE. In addition, project safety was maintained through continued inter-team communication, vehicle and infrastructure training, employee and customer education, and emergency responders training.

Results

Gen I FCVs

Although the Gen I FCV fleet was designed for a 2-year operation, A-Class FCVs have outperformed engineering expectations as the vehicles have been in full operation for over six consecutive years. Since the inception of this demonstration project, customers have fuelled and driven the vehicles in a variety regions providing a complete range of climate and traffic conditions from congested city driving to open road highways (see Figure 1) to rural roads. All Gen I vehicles have been equipped with extensive data acquisition and reporting capability, allowing the Mercedes Team to generate over 100 DVDs of vehicle raw data for submission to NREL.

Gen II Technical Accomplishments

As the Gen I FCVs have been driven for over six years, the Mercedes Team is gradually transitioning the operation from Gen I A-Class FCVs to Gen II B-Class FCVs. Gen II FCVs have been tested and internally operated in a wide range of terrains, driving conditions and climates including diverse temperature, humidity and ambient air pressure. For example, the B-Class FCVs were operated under real-life winter conditions at double-digit, below-zero temperatures where cold-start capability was subjected to thorough scrutiny and FCVs repeatedly started with frozen fuel cell systems (see Figure 2). B-Class FCVs were also
driven in deserts during the harsh summer months when temperatures may reach up to 122°F (Figure 3). To expedite mileage accumulation and expeditiously provide DOE with on-road data, Gen II vehicles were operated by test operators on routes specifically selected to simulate real-world conditions. These durability tests demonstrated the reliable vehicle configuration and uncompromising performance of the Mercedes Gen II FCV. To complement on-road testing, the Mercedes Team performed dynamometer tests showing that Gen II vehicles exceed the 2009 DOE range targets and attain best-in-class fuel economy.

Not only has the Mercedes Team finalized the assembly and manufacturing of all B-Class FCVs designated for external operations through an assembly process similar to traditional vehicles, but authorized Mercedes-Benz dealership are being selected for Gen II fuel cell market in southern California. These dealers will act as the handover point, and make the transaction to customers. These dealers will also provide all customer interfaces for service and maintenance activities, as well as the turn-in point at lease end. The Mercedes Team is in the process of selecting initial customers from a compiled list of inquiries received via normal channels, previous partners in the A-Class FCV project and specific fuel cell related inquiries.

Codes and Standards

The Mercedes Team participated in various working groups to support and assist in the development of codes and standards necessary to commercialize FCVs. Of particular note is Society of Automotive Engineers (SAE) J2601, “Fueling Protocols for Gaseous Hydrogen Surface Vehicles,” the first worldwide published guideline that established a fueling baseline for hydrogen FCVs. It is anticipated that future stations funded by the California Air Resources Board (CARB) and the California Energy Commission (CEC) will adhere to J2601. The SAE Fueling Interface Group has also made strides with J2600, “Compressed Hydrogen Surface Vehicle Fueling Connection Devices” and is currently determining whether the guideline should follow the proposed H70 geometry from the corresponding International Organization for Standardization (ISO) document. A revised draft of J2719, “Information Report on the Development of Hydrogen Quality Guideline for Fuel Cell Vehicles” is expected by June of 2010 in which the report will incorporate the proposed changes from corresponding ISO documents. The SAE Safety Working Group has made continued efforts to update J2578, “Recommended Practice for General Fuel Cell Vehicle Safety” and J2579, “Technical Information Report for Fuel Systems in fuel Cell and Other H2 Vehicles.”

The Mercedes Team began its initial involvement with Canadian Standards Association (CSA) America 4.3 (“Temperature Compensation systems”) and ISO Working Group 5 in which the members are actively involved in Draft International Standard 17268, “Gaseous Hydrogen Land Vehicle Refueling Connection Devices.”

NextEnergy

NextEnergy continued to work on the National Fire Protection Association 2 Standard, intended to provide clarity to the infrastructure design process and to streamline permitting. NextEnergy is a voting member of the technical committee which has been instrumental in developing this extraction code for the industry. Being a voting member continues indefinitely but NextEnergy believes that it is vital to continue participation through the initial release and the first modification cycle of the document.

NextEnergy Center also held a Hydrogen Codes and Standards Conference which attracted first responders, local officials, hydrogen industry experts, and national code development organizations that provided updates on the latest developments of national and international hydrogen codes and standards. This conference featured updates from such organizations as SAE, American Society of Mechanical Engineers, CSA America, Compressed Gas Association, International Code Council, and the ISO.

Safety and Health

The process of fully commissioning the Burbank Station was completed. As a part of this process, a number of test fills were performed by the Mercedes Team to ensure that all of the safety and communication systems were fully operational. Additionally, fueling training was provided to employees of Mercedes, California Fuel Cell Partnership and City of Burbank.

Despite the novelty of 70 MPa fueling, the Mercedes Team determined that the technology was mature.
enough to remove the personal protective equipment requirements at the City of Burbank Station for both 35 MPa and 70 MPa fueling.

The Incident Management Plan is receiving a major overhaul, as it is revised to fit the 2010 customer model. While the Plan is still in development, select dealers will play an active role in some safety relevant communications. In addition, the Safety Plan was updated to reflect the new company structure.

Outreach and Media

Mercedes-Benz FCVs were on display at several national shows over the course of 2009 and 2010. The year began with a presence at the Detroit Auto Show where the Concept BlueZero with its battery and fuel cell electric drive models was presented along with video material about the next generation B-Class F-Cell. The F-Cell was incorporated into the Mercedes-Benz exhibit at the Washington Auto Show in Washington, D.C. in February. The following month in Columbia, South Carolina, the Mercedes Team organized a presence at the National Hydrogen Association meeting where the 700 bar A-Class F-Cell was part of a ride-n-drive and the F600 cutaway model attracted participants in the exhibition hall. Finally, at the Los Angeles Auto Show in December, the B-Class F-Cell was presented for the first time in North America as part of a sustainability platform at the Mercedes-Benz exhibit booth.

The largest FCV-specific outreach event was the Hydrogen Road Tour in which seven auto manufacturers including Daimler participated. The convoy drove over 1,400 miles in nine days starting near the Mexican border in Chula Vista, CA and ending in Vancouver, Canada with a ride-n-drive finale at the Hydrogen and Fuel Cells 2009 Conference. The Team participated with two 700 bar A-Class FCVs. The A-Class F-Cells performed well and capably held their own vis-à-vis the newer FCV models of the other manufacturers.

Fueling Stations and Co-Production Facilities

DTE Hydrogen Technology Park

DTE Energy completed the installation of the replacement electrolyzer/dispenser, and as a result, the site equipment has run the best of any year thus far. DTE Energy has had a number of tours of the DTE Energy Hydrogen Technology Park both from industry, educational institutions and the general public (Figure 4). On Thanksgiving Day, the Park was shown on local television featuring solar, hydrogen and green economy. Not only was remote data collection added to collect dispenser data at the site, but modifications were also made to the dispenser to support fast-fill communications with 700 bar vehicles. Final technical report for the Technology Validation portion of the project has been finished with Lawrence Technological University graduate students and has been sent to the State of Michigan.

Preparing for Fueling Infrastructure

As FCVs transition from a demonstration phase to commercialization, the development of well-established hydrogen fueling station network is critical and, as a result, the Mercedes Team has been actively collaborating with other auto manufacturers, government officials and energy partners to build a hydrogen fueling infrastructure:

- Supported CARB/CEC by recommending station specifications, site locations and supplier qualification guidelines.
- Provided commitment letters to appropriate suppliers requesting government funding and meeting Mercedes-Benz Research & Development North America requirements.
- Worked with the California Fuel Cell Partnership to develop an action plan detailing strategy for deploying hydrogen fuelling stations and FCVs.
- Collaborated with other auto manufacturers to determine and coordinate locations of future fueling stations.

Summary and Future Directions

Summary

- Improved equipment reliability and maintained operation of the DTE hydrogen fueling station.
- Continued mileage accumulation of Gen I vehicles.
- Finalized internal operation and testing of Gen II pre-production vehicles.
- Preparing for Gen II deployment with external customers and dealerships.
• Participated in various working groups to ensure continuous progress with regards to codes and standards.
• Continued data collection, analysis and reporting.

Future Work

• Prepare for Gen II demonstrations.
• Maintain and finalize smooth operation of Gen I FCVs with on-going service, maintenance and customer support.
• Begin customer operations of production-level Gen II vehicles.
• Maintain the high quality of technical vehicle and infrastructure data reporting to NREL.
• Enlist support of corporate communications for a more expansive national outreach in addition to ongoing community and industry related events.

Lessons Learned

Deploying FCVs and placing a hydrogen fueling station is a unique experience that breaks new ground. Based on the experiences and lessons learned, the following conclusions and recommendations are made:

• Extensive real world experience provided by DOE’s Demonstration and Validation Project has shown that vehicles are ready for the commercialization phase.
• Customers need public, customer-friendly fueling stations with no access agreements.
• Older, strategically located hydrogen fueling stations need to be updated with 700 bar fast-fill fueling standards, such as “SAE J2601 (A70), to enable safe, fast and effective fueling for all vehicles.
• Auto manufacturer, energy company and government agency coordination is important for optimal selection of sites.
• Continued DOE funding and political support is essential.
Objectives

General Motors and energy partner Shell Hydrogen, LLC, will deploy a system of hydrogen fuel cell electric vehicles (FCEVs) integrated with a hydrogen refueling infrastructure to operate under real world conditions. With this deployment General Motors and Shell Hydrogen will:

- Demonstrate progressive generations of fuel cell system technology.
- Demonstrate multiple approaches to $\text{H}_2$ generation and delivery for vehicle refueling.
- Collect and report operating data.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section (3.6.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Fuel Cell Electric Vehicle Performance and Durability Data

(C) Lack of Hydrogen Fueling Infrastructure Performance and Availability Data

(D) Maintenance and Training Facilities

(E) Codes and Standards

Contribution to Achievement of DOE Technology Validation Milestones

This project contributes to the achievement of the DOE Technology Validation milestones listed below from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 2**: Demonstrate FCEVs that achieve 50% higher fuel economy than gasoline vehicles. (3Q, 2005)

- **Milestone 4**: Operate fuel cell vehicle fleets to determine if 1,000-hour fuel cell durability, using fuel cell degradation data, was achieved by industry. (4Q, 2006)

- **Milestone 22**: Six stations and two maintenance facilities constructed with advanced sensor systems and operating procedures. (4Q, 2006)

Accomplishments

General Motors has accomplished the following project milestones:

- Deployed 60 vehicles demonstrating two generations of GM’s proprietary fuel cell technology in various terrains, driving conditions, and climates (see Figure 1).

- Constructed and utilized first-class maintenance and training facilities located in Ardsley, NY, Ft. Belvoir, VA and Burbank, CA with a satellite hub located in Lake Forest, CA.
VIII. Technology Validation

Established retail and retail-like hydrogen stations for public fueling:
- Six fueling stations in operation spreading across the eastern and western regions.
- Different types of hydrogen generation/delivery options are demonstrated such as delivered compressed gas and on-site electrolysis.
- Two stations are infrared capable and able to fast-fill 3+ vehicles back-to-back.
- Hydrogen quality testing has been completed in both eastern and western regions, among the first stations in the U.S. to be tested at 700 bar.

Shell Hydrogen opened new stations in the New York City metropolitan area at the John F. Kennedy International Airport and in Bronx during 2009. They also commissioned a station in Culver City, California (Los Angeles). These stations utilize hydrogen compressed gas delivered by truck and dispense hydrogen at 700 bar utilizing equipment supplied by several companies.

Gathered comprehensive feedback on all elements of customer experience and vehicle performance to guide future FCEV and infrastructure development.

Collected vehicle and station data using automated logbook entry and automated wireless data transfer from vehicles to a data server.

Conducted and verified extensive cold weather performance testing; additionally, vehicles were deployed in the north east U.S. through several winters and performed as customers expected (see Figure 2).

GM continues to operate and maintain 10 baseline Phase 2 (Gen2) FCEVs through 2011 or until failure.

Ten additional Phase 2 FCEVs equipped with technology developed during the initial part of Phase 2 were added in 2010 in order to extend learnings. These “Technology Insertion” vehicles were deployed and are accumulating miles (see Figure 3).

Three fuel cell systems were instrumented with the same hardware as the Technology Insertion vehicles and are running accelerated durability tests on test stands.

Introduction

Over the five-year period to date, the project has made significant progress in support of the long-term goals of DOE’s Technical Validation sub-program. GM has deployed eight Phase 1 FCEVs and 42 of its commercially-developed Phase 2 FCEVs and has maintained them through the use of two primary maintenance and training hubs and two additional satellite locations.

For the rest of the project, GM will continue to operate and maintain 10 baseline Phase 2 FCEVs. These baseline Phase 2 FCEVs will continue to operate through 2011 or until failure. The purpose is to demonstrate long stack durability with extended vehicle operating hours (see Figure 4). In addition, 10 new Phase 2 FCEVs have been equipped with the most recent materials and controls technology in order to demonstrate the progress made in the project to date.
These “Technology Insertion” vehicles are currently deployed and are accumulating miles and generating data for submission to DOE according to the National Renewable Energy Laboratory (NREL) data reporting templates.

In order to accelerate the learnings on the most recent technology stack design, three fuel cell systems were instrumented with the same hardware as the Technology Insertion vehicles and are running accelerated durability cycles on test stands. These fuel cell systems operate under a stressful, accelerated protocol in order to capture early learnings.

Shell Hydrogen will no longer participate in the rest of this project. GM will continue to utilize the Shell Hydrogen stations and other hydrogen refueling stations outside of the project to provide fuel for the demonstration vehicles.

**Approach**

- Demonstrate FCEVs:
  - Deploy FCEVs in various terrains, driving conditions, and climates including cold weather.
  - Demonstrate two generations of fuel cell technology.
- Insert Technology with recent advances to test Phase 2 learnings.
- Establish retail-like hydrogen stations for public fueling:
  - Install and operate total of six fueling stations on east and west coasts.
  - Explore hydrogen generation/delivery options such as electrolysis.
- Set up maintenance and service operations in support of FCEVs:
  - Train personnel in maintenance, fueling, technical support, safety.
- Generate and report data required:
  - Capture vehicle on-road and dynamometer test data.
  - Capture hydrogen infrastructure production/fueling data.
- Evaluate vehicle performance against targets:
  - Vehicle range, stack durability, cold-weather performance.

**Results**

Phase 2 FCEVs were launched in the fourth quarter of 2007 in the eastern and western regions. All 42 Phase 2 vehicles were deployed by the end of the third quarter of 2008. Thirty-two vehicles completed their deployment at the end of the third quarter of 2009, and 10 baseline Phase 2 vehicles will continue to report data through the third quarter of 2011 or until failure in order to support stack durability estimates. All 10 Technology Insertion vehicles were deployed by the end of the second quarter of 2010.

Beginning-of-life chassis dynamometer testing was conducted for a “Technology Insertion” vehicle in June 2010.

Accelerated fuel cell system durability testing will continue through 2010.

GM continues to submit infrastructure data templates for Ardsley, NY, Clean Energy LAX, CA and Culver City, CA. The 10 baseline and the 10 “Technology Insertion” vehicles continue to utilize many stations for refueling including Monroe County, NY, Honeoye Falls, NY, West Point, NY, Ft. Belvoir, VA and Burbank, CA.

The hydrogen orientation program for emergency first responders continues to be delivered on request in cities where GM’s DOE vehicles operate totaling over 1,500 people trained.

NextEnergy Center chaired task groups made up of a consortium of industry experts on hydrogen to provide feedback on the National Fire Protection Agency (NFPA) hydrogen codes. Task Groups completed their review of the latest NFPA revision. NextEnergy Center has successfully transferred hydrogen permitting database tools to new Web site. They coordinated with DOE and its partners to transfer the databases’ layout and functionality to DOE ownership, for public benefit.

**Conclusions and Future Directions**

- FCEVs fully meet all functional needs for day-to-day use by individual customers.
- FCEVs are fully functional in sub-freezing cold weather conditions.
- Fuel cell stack durability rapidly increased and is expected to meet or exceed the DOE target of 2,000 hours during the completion of this project.
- GM is taking a significant step by introducing elements of our next generation fuel cell stack and system into a small group of Equinox FCEVs for continued Gen2 operation/demonstration during 2010 and 2011. GM believes that the learnings from the demo project so far have helped enable materials and operating controls within the fuel cell system that will clearly demonstrate the ability of the Gen2 vehicles to meet and exceed the demo project stack durability goal of 2,000 hours.
- Furthermore, GM looks forward to a continued relationship and collaboration with NREL in the areas of fuel cell stack and FCEV data analysis methods. GM believes that this work is helping establish a strong foundation for future work
throughout the fuel cell industry to develop universally accepted metrics for assessing the performance of fuel cells and FCEV.

- GM will continue to provide data for baseline and Technology Insertion vehicles that are deployed and operating.
- Provide lab data from accelerated durability testing to enhance understanding of fuel cell durability.

**FY 2010 Publications/Presentations**

2. An onsite review meeting with NREL, DOE, and GM personnel is planned for August 2010.
VIII.5 Validation of an Integrated Hydrogen Energy Station

Objectives

Demonstrate the technical and economic viability of a hydrogen energy station using a high-temperature fuel cell designed to produce power and hydrogen.

- Complete a technical assessment and economic analysis on the use of high-temperature fuel cells, including solid oxide and molten carbonate, for the co-production of power and hydrogen (energy park concept).
- Build on the experience gained at the Las Vegas Hydrogen Energy Station and compare/contrast the two approaches for co-production.
- Determine the applicability of co-production from a high-temperature fuel cell for the existing merchant hydrogen market and for the emerging hydrogen economy.
- Demonstrate the concept at a suitable site with demand for both hydrogen and electricity.
- Maintain safety as the top priority in the system design and operation.
- Obtain adequate operational data to provide the basis for future commercial activities, including hydrogen fueling stations.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section (3.5.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data
(I) Hydrogen and Electricity Co-Production

Contribution to Achievement of DOE Technology Validation Milestones

This project will contribute to achievement of the following DOE technology validation milestones from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 37**: Demonstrate prototype energy station for 6 months; projected durability >20,000 hours; electrical energy efficiency >40%; availability >0.80. (4Q, 2008)
- **Milestone 38**: Validate prototype energy station for 12 months; projected durability >40,000 hours; electrical energy efficiency >40%; availability >0.85. (1Q, 2014)

Accomplishments

- Completed shop validation test of hydrogen energy station at FuelCell Energy’s facility in Danbury, CT, including >7,000 hours of integrated operation, producing 2 to 4 kilograms per hour of hydrogen (total in excess of 2,350 kilograms of hydrogen) and >200 kW-net alternating current (AC) power, and performing a 7-day continuous operation test. Fuel used was pipeline natural gas.
- Operated Hydrogen Energy Station on simulated digester gas by addition of carbon dioxide to the methane supply. System performance matched predictions for power and hydrogen production. Verified ability to switch between anaerobic digester gas and natural gas.
- Developed operating map (cycle time vs. feed rate) for hydrogen pressure swing adsorption (PSA) system.
- Tested and validated programming for automated integration and de-integration of PSA system from fuel cell and anode exhaust gas processing skid.
- Ordered new fuel cell stack for 3-year demonstration program at Orange County Sanitation District (OCSD), with funding also
provided by CA Air Resources Board and South Coast Air Quality Management District.

- Began packaging hydrogen energy station for shipment to OCSD.
- Extended DOE cooperative agreement to 31 March 2011, with additional funding toward procurement of fuel cell stack for operation at OCSD.

**Introduction**

One of the immediate challenges in the development of hydrogen as a transportation fuel is finding the optimal means to roll out a hydrogen-fueling infrastructure concurrent with the deployment of hydrogen vehicles. The low-volume hydrogen requirements in the early years of fuel cell vehicle deployment make the economic viability of stand-alone, distributed hydrogen generators challenging. A potential solution to this “stranded asset” problem is the use of hydrogen energy stations that produce electricity in addition to hydrogen. To validate this hypothesis, a four-phase project is being undertaken to design, fabricate and demonstrate a high-temperature fuel cell co-production concept. The basis of the demonstration will be a FuelCell Energy DFC®-300 Molten Carbonate Fuel Cell modified to allow for the recovery and purification of hydrogen from the fuel cell anode exhaust using an Air Products-designed hydrogen purification system.

The DFC® technology is based on internal reforming of hydrocarbon fuels inside the fuel cell, integrating the synergistic benefits of the endothermic reforming reaction with the exothermic fuel cell reaction. The internal reforming of methane is driven by the heat generated in the fuel cell and simultaneously provides efficient cooling of the stack, which is needed for continuous operation. The steam produced in the anode reaction helps to drive the reforming reaction forward. The hydrogen produced in the reforming reaction is used directly in the anode reaction, which further enhances the reforming reaction. Overall, the synergistic reformer-fuel cell integration leads to high (~50%) electrical efficiency.

The baseline DFC® power plant (electricity only) is designed to operate at 75% fuel utilization in the stack. The remaining 25% of fuel from the anode presents a unique opportunity for low-cost hydrogen, if it can be efficiently recovered from the dilute anode effluent gases. The recovery and purification of hydrogen from the anode presents several challenges:

- The anode off-gas is a low-pressure, high-temperature gas stream that contains ~10% hydrogen by volume.
- The anode exhaust stream must be heat integrated with the fuel cell to ensure high overall system efficiency.
- The parasitic power used for purification must be optimized with the hydrogen recovery and capital cost to enable an economically viable solution.

**Approach**

A hydrogen energy station that uses a high-temperature fuel cell to co-produce electricity and hydrogen will be evaluated and demonstrated in a four-phase project. In Phase 1, Air Products completed a feasibility study on the technical and economic potential of high-temperature fuel cells for distributed hydrogen and power generation. As part of the Phase 1 analysis, three different high-temperature fuel cells were evaluated to determine the technology most suitable for a near-term demonstration. FuelCell Energy’s DFC®-300 technology was selected for concept development. In Phase 2, a process design and cost estimate were completed for the hydrogen energy station that integrates the high-temperature fuel cell with a PSA system selected and designed by Air Products. Economics were developed based on actual equipment, fabrication, and installation quotes as well as new operating cost estimates. High-level risks were identified and addressed by critical component testing. In Phase 3, a detailed design for the co-production system was initiated. The system was fabricated and shop tested. Prior to shipping to the field, the entire system was installed at FuelCell Energy’s facility in Danbury, CT for complete system check-out and validation. In Phase 4, the system will be operated on municipal waste water derived biogas at OCSD, Fountain Valley, California, under a 3-year project. DOE will receive 6 months of data from the initial operating phase to validate the system versus DOE and economic performance targets.

**Results**

Figure 1 shows the process flow diagram for the hydrogen energy station. Methane (in this case, from natural gas) is internally reformed at the fuel cell anode to hydrogen and carbon dioxide. The fuel cell operates near 600°C and uses molten carbonate electrolyte as the charge carrier. Heated air is combined with the waste gas from the hydrogen purification system and oxidized. These resultant waste gases are fed to the cathode. The fuel cell cathode converts waste gas carbon dioxide to the carbonate charge carrier to complete the fuel cell circuit. The fuel cell stack generates direct current voltage, which is then converted to AC by an inverter in the electrical balance of plant. The system produces 480 VAC, 60 Hz, and a nominal 300 kW without hydrogen co-production. Excess carbon dioxide and
About 70 to 80% of the hydrogen is converted to power, and some hydrogen remains available for recovery. The anode exhaust gas is cooled and sent to a water-gas shift catalytic reactor to convert most of the carbon monoxide present in the stream to hydrogen and carbon dioxide. After an additional cooling step, this gas stream is then compressed and sent to the PSA system. The PSA uses adsorbents to remove carbon monoxide, carbon dioxide, and water to produce a high-purity hydrogen stream. The waste gas from the PSA is catalytically oxidized and returned to the cathode. The PSA system can also be placed in stand-by mode to stop hydrogen production and allow for maximum power production by the DFC® system, thereby improving the system efficiency and economics.

In late 2008, the hydrogen energy station was installed at FuelCell Energy's facilities in Danbury, CT for a system check-out and validation of performance on natural gas. A photograph of the hydrogen-ready DFC®300 is provided in Figure 2, and a photograph of the anode exhaust processing and hydrogen purification system is provided in Figure 3. This testing had several key objectives, including the demonstration of variable production of both electricity and hydrogen, optimization of the process control system and overall controls philosophy, and testing and development (if needed) of systems that respond to upset conditions.

Figure 4 shows the main results of the shop validation test of the hydrogen energy station. During initial testing in March/April 2009, the system was operated in hydrogen coproduction mode for the first time; in order to better understand the dynamics and interaction of the fuel cell with the PSA system, limitations were placed on the rate of change in key control parameters surrounding the extraction and processing of anode exhaust gas from the DFC®300. Programming was then added to the control system to further automate the Hydrogen Energy Station to allow for unattended operation, and the process was restarted in July 2009. The operation and control of the system, including automated integration and de-integration of the PSA from the balance of plant, was excellent.

The feed gas to the fuel cell was then modified by the addition of sufficient carbon dioxide to simulate the anticipated concentration in anaerobic digester gas. The system performed well, and the map for cycle time as a
function of feed gas flowrate was developed. The design hydrogen production rate (2 to 4 kilograms per hour) and purity (less than 0.2 parts per million by volume (ppmv) carbon monoxide and less than 2 ppmv carbon dioxide) were achieved at all operating conditions tested during the Danbury phase of the project.

Conclusions and Future Direction

- The shop validation test for the hydrogen energy station was completed during the reporting period. Excellent results were achieved that met or exceeded the expected performance of the unit.
- The hydrogen energy station is being shipped to OCSD. Following installation and commissioning, operation will begin on natural gas to compare performance with the results of the shop validation test. Digester gas from the wastewater treatment facility will then be introduced to the system to demonstrate the production of renewable electricity and hydrogen. The hydrogen fueling station (sized at 100 kilograms per day) and a gas cleanup skid to remove contaminant species such as sulfur from the anaerobic digester gas supply will be installed under a second DOE project (Cooperative Agreement No. DE-FC36-05GO85026).
- The current DOE project includes operation of the Hydrogen Energy Station for up to 6 months.

Phone: (303) 275-4795  
E-mail: James.Alkire@go.doe.gov  

Contract Number: DE-FC36-05GO85026  

Subcontractor and Working Partner:  
• University of California, Irvine (UCI), Irvine, CA  
• National Fuel Cell Research Center (NFCRC), Irvine, CA  

Project Start Date: August 1, 2005  
Project End Date: December 31, 2010  

Objectives

• Demonstrate a cost-effective infrastructure model in California for possible nationwide implementation:  
  – Collect and report infrastructure data.  
  – Document permitting requirements and experiences.  
  – Validate expected performance, cost, reliability, maintenance, and environmental impacts.  
• Implement a variety of new technologies with the objective of lowering costs of delivered H₂:  
  – New Delivery Concept (NDC).  
  – High-pressure/high-purity clean-up equipment.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section (3.6.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:  
(C) Hydrogen Refueling Infrastructure  

Contribution to Achievement of DOE Technology Validation Milestones

This project will contribute to achievement of the following DOE Technology Validation milestones from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:  
• **Milestone 23**: Total of 10 stations constructed with advanced sensor systems and operating procedures. (1Q, 2008).

Accomplishments

• Continued operation of permanent station (350 and 700 bar gaseous hydrogen) opened at UCI.  
• Began construction of hydrogen pipeline fueling station (350 and 700 bar dispensing) in Torrance, CA.  
• Began 6-month deployment of 350 bar mobile station (HF-150) in Placerville, CA.  
• Submitted permit application for renewable hydrogen fueling station (350 and 700 bar dispensing) in Fountain Valley, CA.

Introduction

Air Products and Chemicals, Inc. is leading a comprehensive, multiyear project to demonstrate a hydrogen infrastructure in California. The specific primary objective of the project is to demonstrate a model of a “real-world” retail hydrogen infrastructure and acquire sufficient data within the project to assess the feasibility of achieving the nation’s hydrogen infrastructure goals. The project will help to advance hydrogen station technology, including the vehicle-to-station fueling interface, through consumer experiences and feedback. By encompassing a variety of fuel cell vehicles, customer profiles and fueling experiences, this project is obtaining a complete portrait of real market needs. The project is also opening its stations to other qualified vehicle providers at the appropriate time to promote widespread use and gain even broader public understanding of a hydrogen infrastructure. The project is engaging major energy companies to provide a fueling experience similar to traditional gasoline station sites to foster public acceptance of hydrogen.
Approach

Work over the course of the project was focused in multiple areas. With respect to the equipment needed, technical design specifications were written, reviewed, and finalized. Both safety and operational considerations were a part of this review. After finalizing individual equipment designs, complete station designs were started including process flow diagrams and systems safety reviews. Material quotes were obtained, and in some cases, depending on the project status and the lead time, equipment was placed on order and fabrication was started. Consideration was given for expected vehicle usage and station capacity, standard features needed, and the ability to upgrade the station at a later date.

In parallel with work on the equipment, discussions were started with various vehicle manufacturers to identify vehicle demand (short- and long-term needs). Discussions included identifying potential areas most suited for hydrogen fueling stations, with focus on safe, convenient, fast-fills. These potential areas were then compared and overlaid with suitable sites from various energy companies and other potential station operators. Work continues to match vehicle needs with suitable fueling station locations. Once a specific site has been identified, the necessary agreements can be completed with the station operator and expected station users.

Detailed work can begin on the site drawings, permits, safety procedures and training needs. Once stations are brought online, infrastructure data will be collected and reported to DOE using Air Products’ eRAM system. Feedback from station operators will be incorporated to improve the station user’s fueling experience.

Results

The first of the hydrogen fueling stations within the California Hydrogen Infrastructure Project continued operation at the NFCRC at UCI. The capability for fueling vehicles with gaseous hydrogen at 350 bar, involving the installation of a 1,500 gallon horizontal liquid hydrogen tank, 2 kg/hr compressor skid, storage for 50 kg of hydrogen, and a dual dispenser for both 350 and 700 bar hydrogen was brought online in August of 2006. The 700 bar system, including the installation of a booster compressor, was commissioned in February of 2007. Based on a 50% compressor on-stream factor, the station has the capacity to dispense 24 kg/day or approximately six cars per day. When starting with full storage, four to five cars can be filled in succession. The station continues to see increasing use over time, with average station throughout having doubled over the past 12 months. A photograph of the dispensing system is provided in Figure 1.

The world’s first fueling station supplied by a hydrogen pipeline began construction in February 2010 to demonstrate a low-cost, reliable supply of hydrogen. A site in the Torrance, CA area in proximity to an existing Air Products hydrogen pipeline is under development by Shell Hydrogen. A 4 kg/hr compressor skid and a total of 100 kg of high-pressure hydrogen storage are being provided. Hydrogen purification technology will be deployed for the first time in this application to demonstrate the production of an ultra-pure hydrogen stream from the industrial-grade pipeline supply. Two dual dispensers for both 350 and 700 bar hydrogen are being provided. Based on a 50% compressor on-stream factor, the station will have the capacity to dispense 48 kg/day or approximately 12 cars per day. When starting with full storage, six cars can be filled in succession. The design of the station is intended to provide the ability to double storage capacity in the future. A photograph of the dispenser area is provided in Figure 2. Station commissioning is expected to begin in August 2010.

The HF-150 (shown in Figure 3) is ideal for small fleet fueling and offers the advantages of being a highly reliable, cost-effective, and automated fueling system that can be easily installed. The HF-150 maintains about 150 kg of gaseous hydrogen at 6,600 psig. It can dispense approximately 80 to 90 kg before needing to be refilled. In March 2010, Air Products began a 6-month deployment of an HF-150 mobile fueler at the District Office of the U.S. Forest Service in Placerville, CA.

Air Products was selected under California Air Resources Board Solicitation 06-618, “Establish
Demonstration Hydrogen Refueling Stations,” to install a renewable-based hydrogen fueling station and cleanup system for anaerobic digester gas at Orange County Sanitation District in Fountain Valley, CA. Hydrogen will be produced utilizing the Hydrogen Energy Station concept being developed under a second DOE project (Cooperative Agreement No. DE-FC36-01GO11087). The hydrogen dispenser will be co-located with an existing compressed natural gas fueling island; Figure 4 shows a photograph of the existing dispenser and the proposed location for the hydrogen fueling equipment. A modification to the Cooperative Agreement was executed on 30 September 2009 to include a no-cost time extension and to modify the Statement of Work for the procurement and installation of a hydrogen fueling station (sized at 100 kilograms per day) and of a gas cleanup skid to remove contaminant species such as sulfur from the anaerobic digester gas that will be fed to the Hydrogen Energy Station. Construction of the fueling station will begin pending final approval by the City of Fountain Valley of the construction permit application. Station commissioning is expected to commence in September 2010.

Conclusions and Future Directions

Planned future work includes:

- UCI Fueling Station – Continue operation of gaseous dispensers.
- Torrance Pipeline Fueling Station – Commission both 350 and 700 bar systems.
- Fountain Valley Renewable Station – Acquire necessary permits, install and commission both 350 and 700 bar systems.
- Hydrogen Fueler (HF-150) – Complete second deployment in northern California.
- Infrastructure data acquisition, analysis and delivery – report data to DOE.

E-mail: John.Garbak@ee.doe.gov

Subcontractor:  
Kevin Chandler, Battelle, Columbus, OH

Start Date: March 2001  
Projected End Date: Projected continuation and direction determined annually by DOE

Objectives

- Determine the status of fuel cell bus (FCB) technologies in transit applications by evaluating them in real-world service.
- Coordinate with the Department of Transportation’s Federal Transit Administration (FTA) on the data collection for the National Fuel Cell Bus Program and with international work groups to harmonize data-collection methods and enable the comparison of a wider set of vehicles.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section of the Fuel Cell Technologies Program’s Multi-Year Research, Development, and Demonstration Plan:

(A) Lack of Fuel Cell Vehicle Performance and Durability Data  
(C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data  
(D) Maintenance and Training Facilities

Contribution to Achievement of DOE Technology Validation Milestones

Milestone 18: Validate fuel cell durability of 3,500 hours, 300+ mile range and fuel cell stack power density of 1.5kW/L. (4Qtr 2012) Two of the five current-generation FCBs evaluated in this project have achieved more than 6,000 hours on the fuel cell system with no major repairs. One of these systems has logged more than 7,000 hours in service. Based on in-service fuel economies between 5 and 7 miles per kilogram, hybrid FCBs can achieve a range between 250 and 350 miles per fill. This efficiency depends on duty-cycle. There are no major issues with lost cargo/passenger space on transit buses because the tanks are typically mounted on the roof; however, the added weight of the system limits the number of standing passengers allowed on the buses.

Accomplishments

- Completed collection and analysis of current-generation performance and operational data on five full-size hybrid FCBs in revenue service in the United States.
- Began data collection on next-generation fuel cell system in revenue service at three transit agencies.

Introduction

Transit agencies continue to aid the FCB industry in developing and optimizing advanced transportation technologies. These in-service demonstrations are necessary to validate the performance of the current generation of fuel cell systems and to determine issues that require further development. Using fuel cells in a transit application can help accelerate the learning curve for the technology because of the high mileage accumulation in short periods of time. During the last year, major progress has been made in improving fuel cell durability; however, more work is needed to improve reliability, increase durability to meet the needs of transit agencies, lower capital and operating costs, and transition maintenance to transit staff.

Approach

NREL uses a standard evaluation protocol to provide:

- Comprehensive, unbiased evaluation results of advanced technology vehicle development and operations.
- Evaluations of hydrogen infrastructure development and operation.
- Descriptions of facility modifications required for the safe operation of FCBs.
- Detailed results on fuel cell systems for buses and the requisite hydrogen infrastructure to complement...
the light-duty demonstrations and further DOE goals.

The evaluation protocol includes two levels of data: operation and maintenance data on the bus and infrastructure, and more detailed data on the fuel cell, system, and components. The first set of data is considered non-sensitive and is obtained mainly from the transit fleet. The analysis, which consists of economic, technical, and safety factors, focuses on performance and use, including progress over time and experience with vehicle systems and supporting infrastructure.

The detailed data are collected with cooperation from the bus/fuel cell system manufacturers and are considered highly sensitive. Results include aggregate data products that protect each manufacturer’s specific data. To date, NREL has collected this type of data from two fuel cell manufacturers. Aggregate results will be published if and when enough data are available to protect each company’s identity and source data.

Results

During Fiscal Year 2010, NREL collected data on current-generation FCB demonstrations at three transit agencies in the United States: SunLine Transit Agency in Thousand Palms, California; Connecticut Transit (CTTRANSIT) in Hartford, Connecticut; and AC Transit in Oakland, California. The first two of these evaluations were funded by DOE, and the third evaluation was covered by funding from FTA. Under DOE funding, NREL also began collecting data on next-generation FCBs at three agencies: City of Burbank, California; AC Transit; and SunLine. NREL published results from the current-generation FCBs. A summary of selected results is included in this report, followed by an overview of the next-generation FCBs being evaluated.

The current-generation FCBs in service at AC Transit, CTTRANSIT, and SunLine are all of the same basic design: Van Hool 40-foot buses with ISE Corp. hybrid-electric drives and UTC Power fuel cell power systems. During the early demonstration period, the manufacturer partners used the performance data to validate the systems and further develop the product and components. Beginning in November 2007, UTC Power replaced the fuel cell power systems in each of the five buses with newer versions that were developed incorporating many of the lessons learned from the previous operation of these fuel cell buses. NREL collected operational and performance data on these FCBs and conventional baseline buses at each agency. Table 1 provides a summary of results from the operation at each agency after the new fuel cells were installed. Data from the baseline buses are included in the table.

Figure 1 shows the fuel economy of the buses at each location in miles per diesel gallon equivalent. (Note that the baseline buses at SunLine are compressed natural gas [CNG] buses – SunLine does not operate diesel buses.) The FCBs at the three locations showed fuel economy improvement ranging from 48% to 123% when compared to diesel and compressed natural gas baseline buses. This figure also illustrates the variability of the results from fleet to fleet. The results are affected by several factors,
including duty-cycle characteristics (average number of stops, average speed, and idle time). Also, the diesel buses at AC Transit do not have air conditioning but the fuel cell buses do. The CTTRANSIT diesel buses operate at twice the average speed of the FCB operating on the Star Shuttle Route, which causes significantly lower fuel economy for the FCB compared to the fuel economies at the other two agencies.

One measure of reliability for the transit industry is miles between roadcall (MBRC). A roadcall is the failure of an in-service bus that causes the bus to be replaced on route or causes a significant delay in schedule. NREL typically reports MBRC for the entire bus and for the propulsion system separately to show the reliability of the FCBs. Over time, these FCBs have been shown to have propulsion system MBRCs that are much lower than MBRCs for the baseline buses. This is not necessarily due to the fuel cell power system, but instead has mostly been because of traction battery issues. To illustrate the improvement in reliability of the fuel cell power system in the buses, Figure 2 tracks the combined monthly fuel cell system MBRC since the buses went into service. The shading in the middle of the chart marks the time during which all five FCBs had the newer version fuel cell systems installed. The average fuel cell system MBRC shows an upward trend and has increased by 21% with the newer version system. In fact, two of these fuel cell systems accumulated significant hours without any major repairs (one is over 7,000 hours and a second is over 6,000 hours).

Another measure of reliability for the transit industry is availability—the percentage of days a bus is planned for service compared to the percentage of days the bus is actually available. When a bus is unavailable, NREL reports the cause by one of several categories. To show the improvement in fuel cell system reliability over time, Figure 3 tracks the percentage of time by month that the buses are unavailable because of the fuel cell system. As in Figure 2, the shaded area denotes the period of time when the newer version fuel cells were installed. The chart shows a marked improvement for the new fuel cell systems.

NREL began collecting data on several next-generation FCBs at the following three transit agencies:

- City of Burbank – one battery dominant, plug-in hybrid FCB developed by Proterra using Hydrogenics fuel cells and lithium titanate batteries.
- SunLine – one New Flyer 40-ft FCB with an ISE hybrid system, Ballard fuel cells, and lithium ion batteries.
- AC Transit – 12 next-generation Van Hool FCBs with a hybrid system integrated by Van Hool and UTC Power fuel cell power system.

NREL also began data collection on another Proterra FCB in Columbia, South Carolina, under the FTA project.

Conclusions and Future Direction

Over the last two years, first-generation fuel cell propulsion systems in buses have shown progress, although they are still considered prototypes in the early stages of technological development. Manufacturers have learned from the results of these first-generation demonstrations and have incorporated design improvements into next-generation fuel cell systems that are now beginning field demonstrations. There are still challenges to overcome, and more data are needed on these new systems just being introduced. Remaining challenges include:

- Lowering costs of purchasing, operating, and maintaining buses and infrastructure.
- Increasing durability/reliability of the fuel cell systems and other components to match transit needs.
- Transferring all maintenance to transit personnel.
Future work by NREL includes:

- Collecting, analyzing, and reporting on performance data for next-generation hydrogen-fueled vehicles in service at the following sites:
  - Bay Area FCB demonstration led by AC Transit
  - SunLine
  - City of Burbank
  - Additional sites as funding allows
- Investigating reliability, durability, and life cycle of FCBs as a part of ongoing evaluations; these efforts complement the DOE light-duty fuel cell electric vehicle demonstrations.
- Coordinating with FTA to ensure harmonized data-collection efforts for the National Fuel Cell Bus Program.
- Coordinating with national and international FCB demonstration sites.

**FY 2010 Publications/Presentations**

Objectives

- Install hydrogen fueling station infrastructure at Hawaii Volcanoes National Park (HAVO) on the Big Island of Hawaii.
- Support the operations of the National Park Service (NPS) hydrogen plug-in hybrid electric vehicle (PHEV) shuttle buses for 24 months through December 2013.
- Conduct engineering and economic analysis of HAVO bus operations on different routes, grades, elevations and climatic conditions.
- Validate fuel cell system performance in harsh environments including high SO₂ concentrations.
- Position HAVO as an alternative fuel vehicle test bed for the NPS.
- Attract new partners and applications for the Big Island hydrogen infrastructure.
- Conduct outreach to local authorities and the general public regarding hydrogen infrastructure.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Fuel Cell Vehicle Performance and Durability Data

(C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data

(H) Hydrogen from Renewable Resources

Contribution to Achievement of DOE Technology Validation Milestones

This project will contribute to the following Technology Validation milestones from the Multi-Year Research, Development and Demonstration Plan:

- Milestone 34: Complete power park demonstrations and make recommendations for business case economics (2Q, 2008). Our HAVO system will generate hydrogen utilizing an electrolyzer powered by renewable energy resources delivered over the grid. Data will be collected to evaluate cost and technical performance.

Accomplishments

- Signed an implementation agreement with the State of Hawaii (DOE funds via State Energy Office) contracting HNEI as the project “Implementing Partner” on behalf of the State of Hawaii.
- Secured State of Hawaii $1.2 million cost share funds via Kolohala Holdings LLP.
- Completed a hydrogen station specification. Compressor, storage and dispenser sized to support increased production capacity.
- Issued a request for proposal for the supply of “turn-key” fueling station.
- Applied for and received a special research and development energy supply agreement from the Hawaiian Electric Light Company through the State of Hawaii Public Utilities Commission.
- Obtained KMC approval and support as the site of the fueling station.
Hawaii Volcanoes National Park superintendent approved Categorical Exclusion for siting and operation of the fueling station.

Completed background sounds survey at the KMC site.

Assisted HAVO to develop an aggressive acoustic specification for the fueling station. Extensive acoustic data analysis by NPS Natural Sounds Program department. Acoustic level specification not to exceed 35 dba at 75 meters based on proximity of closest sleeping quarters;

Assisted HAVO to secure bus funding ($1 million) from the Federal Transit Administration via the Department of Interior. These buses to serve as the primary vehicles for the Power Park project.

Assisted HAVO to secure $600,000 in cost share funding from the Hawaii Hydrogen Investment Capital Special Fund (Hydrogen Fund) to support the HAVO bus conversion funding.

Issued a contract to Powertech for the supply of a “turn-key” fueling station due for completion by the end of July 2010 and delivery by the end of August 2010.

Developed a fueling station site plan layout.

Introduction

The Hawaii Hydrogen Power Park (Power Park) was established to support the DOE Hydrogen Program Technology Validation sub-program. Funded by the DOE through the Department of Business, Economic Development and Tourism’s Strategic Industries Division, in its role as the Hawaii State Energy Office, with the University of Hawaii’s HNEI as the implementing partner, the Power Park conducts engineering and economic validation of pre-commercial hydrogen technologies. The Power Park is supporting the testing and validation of hydrogen fueling system technologies on the big island of Hawaii including production utilizing renewable energy, compression, storage, delivery, and dispensing to hydrogen vehicles. In parallel, HAVO is planning to acquire initially two battery-dominant fuel cell plug-in hybrid electric vehicle shuttle buses. The source of HAVO funds is from the Department of Transportation through the NPS Alternative Transportation in the Parks and Public Lands Program. It is intended to support HAVO's hydrogen fueling requirements with the infrastructure developed in the Power Park.

Approach

- Procure a turn-key H\textsubscript{2} fueling station designed for ease of installation:
  - Modular design and installation plan to greatly reduce installation timeline, cost, and risk.
  - Conduct a factory acceptance trial prior to shipping the system.
  - Supplier to provide detailed infrastructure template with precisely located module connection points. These are precisely replicated on the site prior to shipping.
  - System modules craned into place and connected to utilities. Estimate ~4 days installation effort.

- Use fuel cell PHEVs to maximize the electrical efficiency of a new park shuttle bus service at Hawaii Volcanoes National Park.

- Collaborate with existing data analysis groups at the national labs (SNL and NREL) to compare system data under different operating conditions (fueling station and vehicles).

- Evaluate the effect of different grades, climatic zones, and air quality conditions including SO\textsubscript{2} on vehicle performance.

- Identify areas that require further technical development such as air filtration systems.

- Transfer results to industry and government agencies.

- Produce hydrogen using an electrolyzer powered by renewable electricity from the Hawaii Electric Light Company at a special research rate.

- Design the initial installation to produce 10-20 kg of hydrogen per day @ 350 bar with the flexibility to expand production.

- Site the fueling station at KMC:
  - Department of Defense recreational facility located within HAVO.
  - KMC to provide shuttle bus operators.

Results

Contract Issued for the Supply of a “Turn-Key” Hydrogen Fueling Station

A major accomplishment this year was issuing a contract to Powertech for the supply of a “turn-key” hydrogen production and fueling station. The challenges involved included working closely with the Natural Sounds Program department of the NPS to develop an acoustic level specification for the system. The lack of industry data required a major effort by the project to conduct in-field acoustic measurements on existing equipment and extrapolate the results to develop a
specification for HAVO. This required almost six months of effort and delayed the request for proposal process by a like time frame. The benefit of the effort is that an aggressive acoustic specification of 35 dba at 75 meters (illustrated in Figure 1) was developed and our supplier can meet it. This will have application in the future to the overall hydrogen program as hydrogen production and fueling system will start moving from industrial to urban sites. In particular, cooling fans and compressors in particular will need to meet these reduced acoustic levels.

Identified Fuel Cell PHEV Shuttle Bus Market Gap

Working with HAVO, the Power Park team identified a market gap for shuttle bus-sized fuel cell PHEVs. The lack of a suitable off-the-shelf vehicle requires HAVO to convert an existing internal combustion engine shuttle bus and this is proving to be very costly and time-consuming. The project team assisted HAVO in obtaining addition funding ($600,000) from the State of Hawaii Hydrogen Investment Capital Special Fund (Hydrogen Fund) to help pay for non-recurring engineering for the bus conversions. This will result in a set of engineering designs that can be used to convert additional buses for other projects.

Progressed Multi-Party Legal Agreements

While the involvement of several agencies and organizations is highly desirable for outreach across many agencies, the requirement to negotiate suitable agreements among all the parties is time-consuming and has become a serious barrier to the timely implementation of the project. While considerable progress had been made in execution of a 4-way Memorandum of Understanding, and bilateral Memoranda of Agreement among the various federal and state agencies it, remains outstanding after almost a year of negotiations.

Utilize HAVO as Test Bed for Testing and Mitigating the Effects of $SO_2$ on Vehicle Performance

A significant advantage of the HAVO test site is the opportunity to test fuel cell vehicles in challenging environmental conditions and particularly in high $SO_2$ conditions. This is a challenge that must be addressed as fuel cell vehicles are introduced into general use. As illustrated in Figures 2 and 3, HAVO has extensive monitoring and data collection capabilities for $SO_2$. This
provides the opportunity to develop and test fuel cell vehicle air filtration systems.

**Conclusions and Future Directions**

- Based on unanticipated delays by HAVO in acquiring its shuttle buses, the Power Park team is developing alternative plans to deploy the hydrogen fueling station to support the October 2010 deployment of GM Equinox vehicles at Marine Corps Base Hawaii on Oahu until HAVO shuttle buses are ready. Preliminary discussions with both DOE and the State have been positive. Efforts will commence once written approval is obtained from both funding agencies.
- Subject to a new timetable for HAVO vehicles including availability in January 2012, complete KMC site prep in November 2011.
- Install the Power Park fueling station at HAVO – target: December 2011.
- Collect and analyze fueling station and vehicle data.
- Seek opportunities for expansion of fleet and/or additional hydrogen infrastructure.

**FY 2010 Publications/Presentations**

Objectives

- Quantify how much excess wind energy is available at the existing wind-diesel plant on St. Paul Island and how much is needed to power transportation, in addition to heat and lights.
- Optimize the use of wind energy to produce fuel for transportation.
- Demonstrate the technical and economic feasibility and commercial availability of appropriate technology for non-fossil fuel forms of transportation on St. Paul Island.

Introduction

St. Paul Island is a remote speck in the Bering Sea 300 miles west of the Alaskan mainland, in the heart of America’s last rich fishing grounds. It is increasingly expensive, logistically challenging, and sometimes impossible to import fossil fuels to this location. The island has a class 7 wind resource and three Vestas 225 kW wind turbines that operate at a 47% capacity factor. TDX Power owns, operates and maintains the wind farm for the corporation, producing electricity and utilizing excess power for heat to a large industrial complex at the airport. TDX Power is in final negotiations with the City of St. Paul to sell wind energy to the city-owned electric utility, which now uses diesel to provide power for the 396 residents. TDX wants to stretch wind energy’s power to transportation and then add more wind turbines.

TDX evaluated the prospect of using wind energy to produce hydrogen for use in transportation, particularly the small buses used in our tourism business that take...
visitors to bird watching sites and northern fur seal rookeries. We researched the technical feasibility, commercial availability, environmental benefits, climate and geographic challenges, costs, additional applications for hydrogen, training needs and opportunities, operations and maintenance requirements, and the economic offset of diesel.

**Approach**

St. Paul Island has enough excess wind resource to produce fuel for transportation. Hydrogen could be the fuel of the future. TDX wanted to determine if hydrogen technology was ready for our remote location. We made site visits to two active hydrogen fueling stations and public transportation projects to collect real data and stories. We felt there were lessons to be learned by visiting facilities, site managers, fueling attendants, bus drivers, and bus riders face to face that cannot be found on project web pages. Our technical contractor visited the wind to hydrogen electrolysis project at the National Renewable Energy Laboratory to interview Kevin Harrison regarding the status of that project.

TDX contracted with ACEP to do a procurement study and produce a vendor and price list for the components we would need for a hydrogen demonstration project on St. Paul Island. TDX considers community education a critical piece of this project and conducts workshops and school events in St. Paul to present our findings and future plans.

**Results**

St. Paul Island has a class 7 wind resource and 47% availability for its one 225 kW Vestas wind turbine now in operation. Once interconnection of the two additional 225 kW turbines is complete, there will be a considerable amount of excess electricity available. Although plans are in process to tie two of the wind turbines into the city-owned community electric grid, there will still be excess power available. There is also a plan and space available to add three more wind turbines to the Petroleum Offshore Survey Support (POSS) Camp Wind Farm. St. Paul could become the first all-electric community run by wind energy.

The POSS Camp wind farm will produce an abundance of excess electricity when the two newest V27 wind turbines come on line [1]. Current power and production can be seen in Table 1.

According to the study completed by ACEP, the cost per mile driven of a hydrogen vehicle is considerably more than existing diesel technology (see Figure 1) [2]. Battery-powered electric vehicles are more expensive than diesel – at current prices – but show the most promise for near-term commercial availability. Battery technology is progressing rapidly.

Originally funded to demonstrate hydrogen technology, TDX opted to modify the grant to demonstrate plug-in electric vehicle (PEV) technology (see Table 2). Although the modification is not yet complete, TDX did invest in a Barefoot Motors ATV, introducing the vehicle to the community at the Wind Festival in September 2009.

The ATV does not perform as advertised, due to the more challenging environment on St. Paul Island. But the ATV works well enough that TDX is optimistic about the potential to expand the use of wind energy on island with PEV technology.

Currently, the POSS Camp uses the energy from only one of the three V-27 wind turbines. A plan is in progress to sell the energy from the other two to the City of St. Paul electric utility. The wind farm has space available for three more turbines. TDX assumes there will be a minimal increase in daily energy use for the demonstration project [3].

One concern is that the lowest wind resource months coincide with the height of tourist season (see Figure 2). TDX is prepared to add more wind turbines as use of PEVs becomes more widespread to solve this problem [4].

![Figure 1. Estimated Cost Per Mile Driven by Vehicle Type](image)
Conclusions and Future Directions

- PEV technology is available today, advancing rapidly, and looks to be economically feasible.
- TDX, with community input, chose to modify the existing grant to focus our demonstration efforts on PEVs.

- TDX has purchased a Barefoot Motors plug-in electric ATV, has ordered a Polaris plug-in electric ATV, and plans to contract with Miracle Energy Systems, Inc. to purchase or custom build an appropriate plug-in electric van or small truck.

Objectives

- To advance commercialization of hydrogen-powered transit buses and supporting infrastructure.
- To provide public outreach and education by showcasing the operation of a 22-foot fuel cell hybrid shuttle bus and Texas's first hydrogen fueling infrastructure.
- To showcase operation of zero-emissions vehicle for potential transit applications.

Technical Barriers

This project addresses the following technical barriers from the Technology Validation section (3.6) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Fuel Cell Vehicle Performance and Durability Data
(B) Hydrogen Storage
(C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data

(D) Maintenance and Training Facilities
(E) Codes and Standards

Contribution to Achievement of DOE Technology Validation Milestones

This project will contribute to achievement of the following DOE milestones from Section 3.6: Technology Validation of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 11: Decision to proceed with Phase 2 of the learning demonstration (2Q, 2010)
- Milestone 14: Validate achievement of a refueling time of 3 minutes or less for 5 kg of hydrogen at 5,000 psi using advanced communication technology. (2Q, 2012)
- Milestone 24: Validate a hydrogen cost of $3.00/gge (based on volume production). (4Q, 2009)
- Milestone 25: Validate refueling site compression technology provided by the delivery team (4Q, 2012)
- Milestone 26: Validate refueling site stationary storage technology provided by the delivery team. (4Q, 2012)
- Milestone 32: Validate the ability to produce 5,000 psi hydrogen from natural gas for $2.50/gge, untaxed and with large equipment production volumes (e.g. 500 units/year) for 1,000 hours. (3Q, 2011)

Approach

This project was originally developed in 2004 to show that a skid-mounted, fully-integrated, factory-built and tested hydrogen fueling station could help simplify and lower the cost of fueling infrastructure for fuel cell vehicles. The initial project approach was to design, engineer, build, and test the integrated fueling station at the “factory”; install it at a site that offered educational and technical resources; and provide an opportunity to showcase both the fueling station and advanced hydrogen vehicles. Through the five years of project development (2004 to 2008), in coordination with various public and private sector sponsors, the site selected for a fuel cell bus and fueling station was Austin, Texas. Project participants are using these hydrogen technology assets in this current project (Texas Hydrogen Highway) to inform Texas target audiences on hydrogen and fuel cell applications. The assets in Austin are illustrating the potential for commercialization of hydrogen-powered transit buses, fueling infrastructure and related technologies. The project also showcases
modeling techniques that can be used to design hydrogen vehicle and fueling solutions for other locations and applications.

The station and bus are housed at the J.J. Pickle Research Center, University of Texas at Austin located in north Austin (Figures 1 and 2). The hydrogen fueling station is operated by the University of Texas technical staff, under the supervision of GTI personnel. In addition to the fueling station, the project showcases a plug-in hybrid electric fuel cell transit bus that can operate in a real-world commercial application. It serves to validate the potential for transit agencies (and others) to operate similar vehicles thereby reducing emissions and the nation’s dependency on foreign sources of energy for transportation fuels.

Accomplishments

- Commissioning of the fuel station in February 2010:
  - The project team expended considerable effort for start-up of the station in Austin.
  - Performance and safety checks were conducted on the system during initial start-up which resulted in resolution of the following issues:
    - Pressure fluctuations in the system during automated start-up have led to on-site adjustment of the system controls.
    - Communications network link problems at the University of Texas led to a station computer system crash and subsequent need to reprogram the hydrogen station automated controls.
  - The hydrogen station storage and dispensing system have been purged with hydrogen and test “fills” have been accomplished from the station to the fuel cell bus.
- Station commissioning trials were completed and hydrogen was generated on-site for use by the fuel cell bus. All systems were deemed operational March 15, 2010.
- Completed and submitted fueling station safety plan to DOE.
- Held station showcase events for limited, invited visitors, which included bus rides and station tours.
- Conducted four Texas showcase events in Fall 2009 and early 2010 in coordination with various target groups. Conducted transit staff briefing and training in conjunction with these showcase events.
- Conducted briefing on the project for Texas legislative staff.
- Transit agency personnel from Capital Metropolitan Transportation Authority conducted interface meetings at both Capital Metro and UT-CEM to discuss hydrogen bus and fueling station operation and maintenance (March 24-25, 2010).
- Completed final Powertrain Systems Analysis Toolkit (PSAT, a vehicle simulation software package developed at Argonne National Laboratory) modeling of transit routes to verify vehicle suitability for deployment.
- Collaborated on fuel cell bus and electrified transportation modeling.
  - UT-CEM collaborated with the University of Texas Department of Mechanical Engineering and Georgia Tech on advanced energy storage and modeling techniques of electrified vehicles, including PSAT model development of the Ebus and studies of ultracapacitor assisted batteries.
  - UT-CEM assisted Georgia Tech on battery modeling method in PSAT for advanced, electrified transportation.
- Submitted grant request to Texas Commission on Environmental Quality to support hydrogen station operation as part of the U.S. Department of Transportation/Federal Transit Administration National Fuel Cell Bus Program, April 2010.
Future Directions

- Continue monitoring and evaluation of station and bus operations.
- Plan and conduct final outreach and showcase event in Austin with state and local government officials.
- Compile report on project milestones.

FY 2010 Publications/Presentations

Objectives

Develop Florida’s hydrogen and fuel cell infrastructure by:

- Creating partnerships for applied technology demonstration projects throughout the state.
- Sponsoring research and development in the production, storage and use of hydrogen and in the use and application of fuel cells.
- Facilitating technology transfer between the public and private sectors to create, building and strengthen high-growth potential, high technology companies.
- Developing industry support or potential for widespread applications.
- Developing unique hydrogen/fuel cell university level education programs.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen, Fuel Cells and

Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

From the Fuel Cell section:

(C) Performance
(E) System Thermal and Water Management
(G) Start-up and Shut-down Time and Energy/Transient Operation

From the Education section:

(A) Lack of Readily Available, Objective, and Technically Accurate Information
(B) Mixed Messages
(E) Regional Differences

From the Technical Validation section:

(C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data

Contribution to Achievement of DOE Technology Validation Milestones

This project will contribute to achievement of the following DOE milestones from the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 24 (Technology Validation): Validate a hydrogen cost of $3.00/gge (based on volume production). (4Q, 2009)

Accomplishments

- Project has solicited proposals to conduct research, development and demonstrative work.
- New program management in October 2009.
- Solicited new projects in October 2009.
- Selected three new projects in January 2010. Received DOE approval.
- Solicited additional new projects by issuing request for proposals in April 2010.
- Preliminary selection of five additional new projects made in May 2010.
Introduction

The contract for operation and management of the Florida Hydrogen Initiative (FHI) project was transferred from the FHI, a not-for-profit corporation, to the University of Central Florida (UCF) in October 2009. UCF’s Office of Research and Commercialization and UCF’s Finance and Accounting Division manages the contractual and financial aspects of the project and the issuance of subcontracts, per established procedures. Ms. Ashuantay Houston is in charge of the contractual and financial aspects of the project. Project management and technical oversight is provided by UCF’s principal investigator, Dr. David Block of UCF’s Florida Solar Energy Center (FSEC).

Approach

Following the change in operation and management of FHI, the project managers began the process of allocating the remaining funds (~$2.5 million) to new projects and finishing and/or completing old projects. Each of the FHI sub-project activities are designated as a Task number within the project. At the present time, there are nine tasks. The first six tasks are old projects. Tasks 1, 3, 4, 5, and 6 are now completed. Task 2 is continuing and Tasks 7, 8, and 9 are new tasks. The active tasks, including the two completed this year, are as follows:

• Task 3. Assessment of Public Understanding of the Hydrogen Economy through Science Center Exhibits, Hydrogen Exhibit, Orlando Science Center. This project is complete and final report submitted.
• Task 5. On-Site Reformation of Diesel Fuel for Hydrogen Fueling Station Applications, FSEC/UCF and Chevron Technology Ventures. The project is complete and a final report written.
• Task 7. Chemochromatic Hydrogen Leak Detectors for Safety Monitoring, FSEC. New project.
• Task 9. Understanding Mechanical and Chemical Durability of Fuel Cell Membrane Electrode Assemblies, FSEC. New project.

Individual Project Descriptions

As stated above, FHI has funded individual projects which conduct the research, development and demonstration activities. Each of the individual projects are approved by DOE before work can begin. During the past year, one project was a continuing effort, two were completed, three new projects were approved and a request for proposal was issued. With this background, each of the six past year projects are described in the following sections.

The only active old task is Task 2 being done by Michael Fuchs of EnerFuel, Inc., 561-868-6720, x239. The project activities conducted in the past year are:

• Examined three new demonstration sites. Selected and received approval for a demonstration site of an electric vehicle charging station at Florida Atlantic University (FAU) in Boca Raton, FL. Secured the support of FAU to design, construct and evaluate the charging station and developed required documentation for DOE approval.
• New site activities include designing charging station using existing fuel cells and inverters and secured all permits necessary to begin construction phase and successfully incorporated the existing inverter/fuel cell systems into the design of the charge station.
• Future actions are to construct fuel cell demonstration site, operate charge station for period of three months, determine overall electrical efficiency, document system transient response to load changes, and determine overall performance and effectiveness of charging station.

Task 3. Assessment of Public Understanding of the Hydrogen Economy through Science Center Exhibits, Orlando Science Center, FL.

The H2Now exhibit has completed software and hardware ‘shakedown’ that resulted in a streamlined interface and communication and is functioning at 100% in the Orlando Science Center (OSC). The exhibit is so popular that exit intercept surveys that OSC regularly conducts have revealed that visitors like the exhibit and wish that there was more to it. In response, OSC has added a video presentation produced by the H2Now exhibit designers, IDEAS, Inc., titled “I Am Hydrogen” and developed a panel exhibit on other alternative energy resources. Future plans for H2Now include developing an interactive instructional video game based on hydrogen and other renewable energy sources. The video game was developed using a grant from Progress Energy Foundation. OSC has submitted its final report “Summative Evaluation Findings H2Now: (submitted with the 2009-01 Quarterly Report to DOE).

The learning objectives established for H2Now were established so that after participating in the exhibit, visitors would be able to:
VIII. Technology Validation

- Explain what hydrogen is, where it comes from, and some of its possible uses.
- Distinguish between truth and myth about hydrogen as an alternative energy source, and give specific examples.
- State a benefit and a challenge of hydrogen as an alternative energy source.
- Give an example of how hydrogen power is created, and how it can affect everyday life.
- Comment on a possible impact of hydrogen power on the future state of the world.

Evaluations to determine the extent to which H2Now meets educational objectives revealed that:
- 77% of the visitors surveyed either loved or liked the exhibit.
- 64% indicated that they ‘learned something’ or found the exhibit informative in the word choice section of the interview.
- 32% found the exhibit ‘interesting’ indicating that both cognitive and affective learning has clearly taken place.
- 65% indicated that they found out something they didn’t know before. This finding is a clear indication of both cognitive gain and a change of attitude, i.e., compare this to the 44% who, when given the choice to select “I learned something new”.

Task 6. On-site Reformation of Diesel Fuel for Hydrogen Fueling Station Applications

This project was conducted by N.Z. Muradov, A. T-Raissi, C. Linkous, K.K. Ramasamy, C. Huang, and F. Smith of the Florida Solar Energy Center, jointly with the Chevron Technology Ventures, LLC, Dr. James Stevens, Technical Advisor. The project was started in January 2008 and was completed in January 2010. The final report was submitted to DOE in April 2010.

The objective of the project was to develop a new on-demand forecourt hydrogen production technology by catalytically converting high-sulfur hydrocarbon fuels to an essentially sulfur-free gas. The removal of sulfur from reformate is critical since most catalysts used for the steam reformation have limited sulfur tolerance. The FSEC’s responsibilities included building, operating and validating the performance of a diesel pre-reformer as well as developing and demonstrating a small-scale desulfurization unit. Chevron Technology Ventures provided catalysts and know-how for the design and fabrication of the pre-reforming reactor. The pre-reformer was coupled with a regenerable Fe2+/Fe3+ redox/electrolysis system used for hydrogen sulfite removal from the pre-reformer effluent.

Results from laboratory tests showed that electrolysis of acidic FeSO₄ aqueous solution was highly efficient with a coulombic efficiency of 100% at a cell potential of 1.0 V and that the electrolytic process can be made to operate with a Pt-free anode to oxidize ferrous to ferric ions, thereby reducing the cost of the electrolytic scrubber. FSEC researchers have also developed a robust bi-functional catalyst for accomplishing the pre-reformation of the high-sulfur fuels (sulfur content as high as 5,240 ppmw) to short chain hydrocarbons (C1-C4, mostly propane) at an average yield of about 97%. Furthermore, results showed that after100 hours of continuous operation, the combined Fe2+/Fe3+ redox/electrolyzer H₂S scrubber and pre-reformer could achieve desulfurization efficiencies greater than 95% and removed sulfur down to less than 5 ppmv in the pre-reformer effluent. The project results were the development of a novel process for converting high-sulfur diesel to a mixture of light molecular weight hydrocarbons that can be readily reformed with steam to fuel cell grade hydrogen gas.

New Projects Approved during Past Year

Beginning in October 2009 and ending in February 2010, a request for letters of interest (LOI) was issued to select three new projects for submission to DOE. The LOI request resulted in five proposal submittals that were evaluated by a proposal evaluation team of six technical experts.

The results of the evaluation team and discussions on each project’s merit with DOE resulted in selection of the following three new projects:

Task 7. Chemochromic Hydrogen Leak Detectors for Safety Monitoring – Dr. N. Mohajeri and Dr. N. Muradov, FSEC. The aim of this project is to develop and demonstrate a cost-effective, high specific chemochromic (visual) hydrogen leak detector for safety monitoring at any facility engaged in handling and use of hydrogen. The work will lead to a new generation of versatile chemochromic hydrogen detectors that employ “smart” materials that cost less, possess fast discoloration kinetics, are user-friendly, are reliable and have superior field worthiness.

Task 8. Development of High-Efficiency, Low-Cost Electrocatalysts for Hydrogen Production and Proton Exchange Membrane (PEM) Fuel Cell Applications – Dr. C. Huang, FSEC. The objectives of this project are to develop highly active metal alloys with low Pt loading and metal-metal oxide-based electrocatalysts having nanosized grains. The project will conduct research and development for enhanced hydrogen evolution at low cost. The new catalysts will be evaluated for their activity toward hydrogen evolution via electrolysis of water as well as applications for PEM fuel cells.

Task 9. Understanding Mechanical and Chemical Durability of Fuel Cell Membrane Electrode Assemblies – Dr. D. Slattery, FSEC. The objective of this project...
is to increase the knowledge base of the degradation mechanisms for membranes used in PEM fuel cells. Approaches to mitigate membrane degradation can be classified into three areas: membrane composition changes; radical quenching; and platinum band formation mitigation.

**Issuing of RFP for Final Projects**

The final activity of the year was the release of a request for proposals (RFP) for the remaining funds of $1,427,910. The RFP was released on March 17, 2010 with applications due by April 23, 2010. The RFP e-mail stated that FHI had about $1.5 million in funds that are to be awarded in competitive solicited projects and the RFP was sent to a large number of potential responders. Following the receipt of 19 proposals, a six-member review committee was established. The review committee met in May 2010 and a recommendation for the funding of five new projects has been submitted to DOE. Final DOE documentation material is now being developed.

**Conclusions and Future Directions**

The FHI project results have produced a stabilized project management, the completion of two projects, the continuation of one project, the awarding of three new projects and the preliminary selection of five additional new projects. At this time, the funding should be totally allocated. The future work will continue the monitoring and conducting of the eight new projects. There are no open issues.

**Patents Issued**

**FY 2010 Publications/Presentations**

IX. SAFETY, CODES & STANDARDS
Introduction

The Safety, Codes & Standards sub-program supports research and development (R&D) that provides critical information needed to define requirements and close gaps in codes and standards and safety to enable the widespread commercialization and safe deployment of hydrogen and fuel cell technologies. In FY 2010 the sub-program focused on continuing to identify risk management measures to reduce the risk and mitigate the consequences of potential incidents that could hinder the commercialization of these technologies.

The sub-program continues to promote collaborative activity among government, industry, standards development organizations (SDOs), universities, and national laboratories in an effort to harmonize regulations, codes and standards (RCS) both internationally and domestically. Communication and collaboration among codes and standards stakeholders is emphasized by the sub-program to maximize the impact of its efforts and activities in international RCS.

In addition to R&D, the sub-program’s safety activities focus on development of information resources and best practices. The sub-program utilizes extensive external stakeholder input—from the fire-protection community, academia, automobile manufacturers, and the energy, insurance, and aerospace sectors—to create and enhance safety knowledge tools for emergency responders and authorities having jurisdiction. Continual availability of safety knowledge tools, distributed via an array of media outlets to reach the largest number of safety personnel possible, is a renewed priority. The sub-program also supports the development and implementation of best practices and procedures to ensure safety in the operation, handling, and use of fuel cell and hydrogen technologies for Hydrogen Program-funded projects.

Goals

The sub-program’s aim is to provide the validated scientific and technical basis required for the development of codes and standards and to implement safety practices and procedures to allow for the safe deployment of hydrogen and fuel cell technologies. The goals are to:

- Conduct and facilitate the appropriate R&D for the development of scientifically and technically sound codes and standards that enable the safe use of hydrogen and fuel cell technologies.
- Facilitate the development and harmonization of domestic and international RCS by seeking the consensus of all major stakeholders via the sub-program’s continued support of R&D that produces critical data and information needed to define requirements and fill gaps in codes and standards.
- Ensure that safety is a critical priority in research, technology development, and market deployment of hydrogen and fuel cell technologies.
- Develop and implement safety practices and procedures that will ensure the safe operation, handling, and use of hydrogen and fuel cell technologies, and utilize these practices and lessons-learned to promote the safe use of hydrogen and fuel cell technologies in Hydrogen Program-funded projects.
- Promote widespread sharing of safety-related information, procedures, and lessons-learned with first responders, authorities having jurisdiction, and other stakeholders.
- Understand and mitigate risk, to facilitate the safe use and insurability of hydrogen and fuel cell technologies.

Objectives

The sub-program’s objectives are to:

- Support and facilitate the promulgation of essential codes and standards by 2015 to enable the widespread commercialization and market entry of these technologies.
Facilitate uniform implementation of requirements in codes and standards throughout the United States by 2015.

Support and facilitate the completion of all essential domestic and international RCS by 2020.

FY 2010 Technology Status

The sub-program continues to support R&D to provide the technical basis for codes and standards development with specific projects in a wide range of areas such as fuel specification, separation distances, materials and components compatibility, and hydrogen sensor technologies. Utilizing the results from this R&D, the sub-program continues to actively participate in discussions with SDOs such as the National Fire Protection Association (NFPA), International Code Council (ICC), Society of Automotive Engineers (SAE), Canadian Standards Association (CSA), and International Organization for Standardization (ISO) to promote domestic and international collaboration and harmonization of RCS. Figure 1 gives an overview of codes and standards development work:

![FIGURE 1. Overview of Codes & Standards Development Work](image)

The sub-program also utilizes the expertise of the Hydrogen Safety Panel to evaluate the safety plans and practices of Hydrogen Program-funded R&D projects. This activity provides recommendations on the safe conduct of project work and lessons learned/best practices that can be of broad benefit to the Program. The Hydrogen Safety Panel has taken the lead in reviewing fuel cell deployments under the American Recovery and Reinvestment Act (ARRA) by forming a team to conduct reviews of ARRA project safety plans, safety reviews, and site visits. As high-profile examples of early market deployments, it is especially important these projects are conducted in a safe and effective manner.

After initial pilot deployments of the advanced-level, prop-based course for first responders, the official course was rolled out to first responders in FY 2010. This rigorous eight-hour course uses a hydrogen fuel cell vehicle burn prop to provide first responders with hands-on experience and training. The course was developed with input from a steering committee made up of representatives from automobile manufacturers, energy companies, and the fire safety community. The course was deployed in three locations in August and September 2010.
The sub-program actively participates in the International Partnership for Hydrogen and Fuel Cells in the Economy Regulations, Codes and Standards Working Group and the International Energy Agency Hydrogen Implementing Agreement, both of which have been engaged in hydrogen safety work. Additionally, DOE continues to work with the Department of Transportation (DOT) to support its role as the U.S. representative to the UN ECE-WP29/GRPE to develop a global technical regulation for hydrogen-fueled vehicles.

**FY 2010 Accomplishments**

In FY 2010, the sub-program:

- Developed the technical basis for assessing the safety of hydrogen-based systems, which will be used in the development and modification of relevant codes and standards. This technical basis has introduced a risk-informed approach that enabled NFPA2 to update bulk gas storage separation distances in the 2010 edition of NFPA55.
- Completed additional materials and components compatibility work, including updates to the Technical Reference for Hydrogen Compatibility and completed testing to enable the deployment of 100-MPa stationary storage tanks; also supported the development of codes and standards for forklifts, including tank lifecycle testing, for use by the CSA Hydrogen Powered Industrial Truck Committee.
- Developed and published the “H₂ Safety Snapshot,” a quarterly newsletter promoting safety best practices.
- Developed and published a Web-based educational course addressing Hydrogen Safety Training for Researchers—the four-hour course has six modules and highlights best practices for the safe use of hydrogen in a research setting.
- Engaged members of the building code and fire safety community in the development of safety information tools for the permitting of hydrogen fueling stations and hydrogen fuel cells for telecommunications backup power—this includes the expansion of the Permitting Compendium for Hydrogen Facilities.
- Conducted hydrogen permitting workshops, which have reached over 250 code and permitting officials.
- Expanded outreach to code officials through four in-person workshops, an updated Introduction to Hydrogen Safety for Code Officials Web-based training course, and case studies documenting the permitting process for two early market fuel cell installations in conjunction with the Education sub-program. The codes and standards workshops, held in collaboration with local fire department and government organizations, were expanded to include additional modules on electric vehicles and infrastructure. The electronic learning package was updated with material on indoor hydrogen fueling to support the increasing number of fuel cell material handling equipment deployments. To support Market Transformation, the Education and Safety, Codes and Standards sub-programs were asked to evaluate, assist with and document the permitting of a backup-power fuel cell system and a fleet of fuel cell forklifts at two Department of Defense sites. The results were published as case studies to assist code officials and project developers in understanding the codes and standards and safety evaluations for similar early market installations.
- Continued to deploy the advanced-level, prop-based course for first responders in coordination with the Education sub-program. Two pilot sessions of the prop-based course were held at the

---

4 [http://www.h2bestpractices.org/](http://www.h2bestpractices.org/)
Hazardous Materials Management and Emergency Response training center in 2009. The course was conducted three times in the state of California in 2010. More than 300 students from 18 states have been trained.

- Expanded the reach of the Web-based educational course *Introduction to Hydrogen Safety for First Responders.* This multimedia tutorial acquaints first responders with hydrogen, its basic properties, and how it compares with other fuels. The Web-based course has received over 17,000 unique visitors and is averaging 300–500 unique visitors each month from almost every state and many countries.

- Co-hosted, with the DOT, an international workshop for compressed natural gas (CNG) and hydrogen in December 2009. The workshop included participants from national laboratories and industry as well as international representatives from Brazil, India, Canada, China, and the United States. The workshop promoted the exchange of information among experts in CNG and hydrogen for vehicles, facilitated the sharing of lessons-learned from the deployment of these vehicles, and identified opportunities for international R&D collaboration.

- Held an Early Market Fuel Cell Technologies Workshop in April 2010 at Sandia National Laboratories (SNL). The workshop promoted the exchange of information among industry, government, national laboratories, SDOs, and other relevant stakeholders to enable the early market deployment of fuel cell technologies.

- Held a Vehicular Tank Workshop in April 2010 at SNL, which included participants from industry, government, national laboratories, SDOs, and other relevant stakeholders to coordinate R&D and RCS to enable the deployment of hydrogen storage tanks.

**Budget**

The sub-program received an appropriation of $8.8 million for FY 2010. This allowed for sustained progress in R&D, codes and standards development, and safety. The President’s FY 2011 budget request is $9 million, as shown below.

---

FY 2011 Plans

The Safety, Codes & Standards sub-program will continue to work with codes and standards organizations to identify and address gaps to develop new hydrogen-specific codes and standards. To address these challenges, the sub-program will continue to support its rigorous technical R&D program.

In FY 2011, the sub-program will perform a technology status assessment of hydrogen sensors and their related targets. In addition, insurability for fuel cell and hydrogen technologies will be assessed through an international forum. In FY 2011 and beyond, the sub-program will continue to focus on critical safety R&D, such as assessment of materials compatibility for component designs, high-pressure tank cycle testing, and promoting a quantitative risk assessment approach to ensure the development of technically sound codes and standards. The sub-program will continue to promote the domestic and international harmonization of RCS.

• Smart Chemistry, Sacramento, CA
• Sloane Solutions, Oxford, MI
• CSA Standards, Cleveland, OH
• MorEvents, Englewood, CO
• GWS Solutions, Tolland, CT

Project Start Date: 1995
Project End Date: Project continuation and direction determined annually by DOE

Objectives

- Conduct research and development (R&D) needed to establish sound technical requirements for hydrogen and fuel cell codes and standards.
- Support code development for the safe use of hydrogen and fuel cell technologies.
- Advance safety, code development, and market transformation issues through collaborations with appropriate stakeholders.
- Facilitate the safe deployment of hydrogen and fuel cell fuel technologies.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Codes and Standards section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Limited Government Influence on Model Codes
(B) Competition among SDOs and CDOs (Standards Development Organizations, Code Development Organizations)
(C) Limited State Funds for New Codes
(D) Large Number of Local Government Jurisdictions (approximately 44,000).
(E) Lack of Consistency in Training of Officials
(F) Limited DOE Role in the Development of International Standards
(G) Inadequate Representation at International Forums
(H) International Competitiveness
(I) Conflicts between Domestic and International Standards
(J) Lack of National Consensus on Codes and Standards
(K) Lack of Sustained Domestic Industry Support at International Technical Committees
(L) Competition in Sales of Published Standards
(N) Insufficient Technical Data to Revise Standards
(P) Large Footprint Requirements for Hydrogen Refueling Stations
(Q) Parking and Other Access Restrictions

Contribution to Achievement of DOE Safety, Codes & Standards Milestones

This project will contribute to achievement of the following DOE milestones from the Hydrogen Codes and Standards section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

<table>
<thead>

</tbody>
</table>
Accomplishments

NREL has accomplished the following in support of section 3.7 of the DOE Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Vehicle codes and standards gap analysis: performed an analysis of codes and standards for all six alternative fuel vehicle fuels. The analysis gave background information on the history of fuel usage, the existing codes and standards structure, gaps in the existing codes and standards structure, and research projects or other work needed to fill these codes and standards gaps. This report was published as a NREL technical report in FY 2010.
- Chemical sensor testing and validation: continued collaborations with key stakeholders; completed formal agreement with the European Commission’s Joint Research Centre (JRC) laboratory for testing hydrogen safety sensors and began round-robin testing with the JRC; continued testing commercially available sensors; participated on International Organization for Standardization (ISO) TC197 WG15 to develop a hydrogen sensor standard.
- Component testing: conducted validation testing of high-pressure release devices (HPRD). This work has been used to develop a HPRD standard by CSA America and will be complete in FY 2010. Also initiated compressed natural gas nozzle failure project, which could give useful information on designing hydrogen nozzles.
- Fuel quality specification: worked with ISO on technical specification 1 4687-2; coordinated testing and modeling to understand the effects of contaminants on fuel cell performance. Continued to support the promulgation of ASTM standards required to test contaminants to show compliance with the ISO standard.
- Codes and standards development: worked with CDOs and SDOs to develop codes, identify gaps, and provide R&D support; participated on National Hydrogen and Fuel Cell Codes and Standards Coordinating Committee, DOE Codes and Standards Technical Team, and Hydrogen Industry Panel on Codes; added significant subcontracting responsibilities to support individuals and organizations responsible for codes and standards development.

Introduction

It is essential to develop and promulgate codes and standards in order to provide for the safe use of hydrogen and fuel cell technologies. With the help of key stakeholders, the DOE Fuel Cell Technologies Program and NREL are coordinating a collaborative national effort to prepare, review, and promulgate codes and standards for all hydrogen and fuel cell technologies.

Approach

The Fuel Cell Technologies Program recognizes that domestic and international codes and standards must be established to enable the timely commercialization and safe use of hydrogen and fuel cell technologies. The lack of codes and standards applicable to hydrogen and fuel cell technologies is an institutional barrier to deploying...
these technologies. It is in the national interest to eliminate this potential barrier. As such, the Hydrogen Codes and Standards sub-program works with domestic and international SDOs to facilitate the development of performance-based and prescriptive codes and standards. These standards are then referenced by building and other codes to expedite regulatory approval of hydrogen and fuel cell technologies. This approach ensures that U.S. consumers can purchase products that are safe and reliable, regardless of their country of origin, and that U.S. companies can compete internationally.

**Results**

The Safety Codes and Standards work is divided into three major areas:

1. National Template Implementation
2. Codes and Standards Research
3. Codes and Standards Training and Outreach

This report addresses the National Template Implementation

National Template Implementation, shows both the hierarchy for enforcing codes and standards and some of the progress made in promulgating the codes and standards required to implement hydrogen and fuel cell technologies (Figure 1).

In FY 2010 good progress was made in this implementation effort. National Fire Protection Association (NFPA) 2 Hydrogen Technologies Code was published as a Report on Proposal draft and the Hydrogen Technology Technical Committee met at NREL to act on comments to the draft. A final document will be issued in either December 2010 or July 2011 depending on whether there are any challenges to the document. NREL has supported the development of NFPA 2 in several ways including:

- Acting as a principal member of the technical committee.
- Funding subcontractors actively participating in the development of the document such as FP2 Fire Protection Engineering.
- Hosting meetings.

Another key codes and standards development area is the development of hydrogen fueling station component and system standards being performed by Canadian Standards Association (CSA) Standards. These H-4 series of documents consists of nine component standards and one system standard that address hydrogen dispensing. An NREL subcontractor is participating as a member of the CSA technical committee drafting these documents.

NREL continues to support the National Hydrogen and Fuel Cell Codes and Standards Coordinating Committee. This effort, which is coordinated and directed by NREL, holds monthly meeting where SDOs, DOE laboratories, industry representatives, DOE and other interested parties are given topical information on codes and standards development activities.

**Conclusions and Future Directions**

NREL will continue to support the development of codes and standards by:

- Working with DOE to implement a national template for vehicle codes and standards development.
- Continuing R&D support of the key technologies required to close the gaps identified in the codes and standards development process.
• Continuing R&D collaborations with national and international stakeholders on vehicle codes and standards activities.
• Performing outreach work to distribute information on hydrogen and fuel cell technologies to code officials, project developers, and other interested parties.
• Coordinating domestic codes and standards and international standards to ensure consistent requirements.

E-mail: Antonio.Ruiz@ee.doe.gov

Subcontractors:
• American Society of Mechanical Engineers (ASME), New York, NY
• Society of Automotive Engineers (SAE), Troy, MI

Project Start Date: Fiscal Year (FY) 2008
Project End Date: Project continuation and direction determined annually by DOE

Objectives

- Support development of new codes and standards required for commercialization of hydrogen technologies.
- Create code language that is based on the latest scientific knowledge by providing analytical, technical and contractual support.
- Participate directly on codes and standards committees to identify technology gaps, then work to define research and development needs required to close those gaps.
- Conduct laboratory testing to provide a basis for improved code language.
- Collaborate with industry, university and government researchers to develop improved analytical and experimental capabilities.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Codes and Standards section (3.7.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration (RD&D) Plan:

(A) Limited Government Influence on Model Codes
The code development process is voluntary, so the government can affect its progression, but ultimately it is up to the code development organizations (CDOs).

(B) Competition among SDOs and CDOs
The competition between various organizations hinders the creation of consistent hydrogen codes and standards. (SDO = standards development organization)

(C) Limited State Funds for New Codes
Budget shortfalls in many states and local jurisdictions impact the adoption of codes and standards because they do not always have the funds for purchasing new codes or for training building and fire officials.

(F) Limited DOE Role in the Development of International Standards
Governments can participate and influence the development of codes and standards, but they cannot direct the development of international standards.

(G) Inadequate Representation at International Forums
Participation in international forums and meetings is voluntary and, to date, has been limited by budgetary constraints.

(H) International Competitiveness
Economic competition complicates the development of international standards.

(I) Conflicts between Domestic and International Standards
National positions can complicate the harmonization of domestic and international standards.

(J) Lack of National Consensus on Codes and Standards
Competitive issues hinder consensus.

(K) Lack of Sustained Domestic Industry Support at International Technical Committees
Cost, time and availability of domestic hydrogen experts have limited consistent support of the activities conducted within the international technical committees.

(N) Insufficient Technical Data to Revise Standards
Research activities are underway to develop and verify the technical data needed to support codes and standards development, retrofitting existing infrastructure and universal parking certification, but are not yet completed.

Contribution to Achievement of DOE Codes & Standards Milestones

This project will contribute to achievement of the following DOE milestones from the Hydrogen Codes and Standards section of the Fuel Cell Technologies
Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 18: Implement research program to support new technical committees for the key standards including fueling interface and fuel storage. (4Q 2007)
- Milestone 20: Draft standards for hydrogen detectors in stationary applications. (4Q, 2008)
- Milestone 21: Completion of necessary codes and standards needed for the early commercialization and market entry of hydrogen energy technologies. (4Q, 2012)

Accomplishments

- Completed validation testing of high-pressure composite overwrapped pressure vessel with induced flaws in support of ASME Boiler and Pressure Vessel code development.
- Completed validation testing of thermodynamic modeling used to generate SAE J2601 fill tables for hydrogen vehicle dispensing.
- Defined component level hydrogen compatibility testing being used to validate Canadian Standards Organization (CSA) hydrogen pressure relief device (HPRD) draft standard and initiated test program.
- Completed design/build/operations activities for NREL’s Sensor Testing Laboratory and initiated testing program responsible for supporting sensor development and commercialization.
- Established sensor test laboratory collaboration partners both domestically and internationally, entering into a long term agreement to develop sensor test protocol, conduct round robin test method validation and provide sensor commercialization support with European Joint Research Centre laboratory.

Introduction

Development of codes and standards has been identified as a key area needing support for the commercialization and growth of hydrogen technologies. NREL is providing research and development support to these codes and standards organizations through validation testing, analytical modeling, and product commercialization efforts. NREL has been tasked with these responsibilities as defined in the DOE multi-year RD&D plan.

Approach

NREL is participating on relevant codes and standards committees to help identify gaps and define research and development (R&D) needs to close those gaps. Working at the committee level allows us to quickly identify areas that need R&D support and to work directly with the technical experts in planning a path forward. This process is instrumental in avoiding delays and setbacks in the development of new codes and standards and in the revision of existing codes and standards. By providing support from a national lab we are able to help establish codes and standards language with solid technical basis.

Hydrogen safety sensors are a key component to commercialization of hydrogen technologies. NREL is tasked with building capability to test sensors for this growing market. By developing standard test methods and measuring sensor performance of a wide range of sensors of different designs and from a many different manufacturers, NREL will characterize the sensor market and identify gaps relative to the DOE targets. With this information we will be able to work closely with sensor manufacturers so that they can better understand the performance of their sensor relative to the needs of hydrogen stationary applications. This work will be directed toward sensor R&D, such that sensor manufacturers, utilizing the resources of a national lab, can expedite their product development life cycle. In addition, the sensor market expertise gained will be used to support commercialization through development of representative codes and standards for safety sensor certification. Commercialization support will include collaboration with key stakeholders as well as direct participation on the relevant codes and standards committees.

Results

NREL has been working on identifying gaps and supporting R&D efforts for developing new and improved hydrogen codes and standards. Results reported here are for efforts specifically directed at component level standards. There are four subject areas addressed in this report where significant achievements have been made during FY 2010. A summary of the four subject areas and corresponding gaps identified are presented in Table 1.

- Tanks: ASME Boiler and Pressure Vessel Code – ASME has developed new requirements that address the certification of tanks designed for stationary hydrogen storage applications. In developing these standards, new language has been developed for composite overwrapped pressure vessel (COPV) designs defining required testing to insure survivability in the event of material flaws. Flaw testing is based on best engineering
knowledge, however there was a need for validating these test methods. NREL worked with ASME in identifying the need and defining a series of validation tests. This work was subsequently conducted at Lincoln Composites. Testing included subjecting tanks to pressure cycling followed by a burst test to determine residual strength. Flaws were cut at depths up to 40% of the wall thickness in both longitudinal and transverse directions. Results of the testing are shown in Figure 1. Post test burst data show that current design COPV tanks are able to maintain better than a two times safety factor with a worst case flaw.

![FIGURE 1. ASME Flawed Cylinder Testing, Burst Pressure vs. Cycling and Depth of Flaw](image)

---

Interface: SAE J2601 Fueling Protocol – SAE standards for fueling rates in non-communication fill scenarios have been developed and are incorporated into the SAE J2601 standard, recently released as a technical information report. These fill rates are needed to insure against overfilling or exceeding temperature limits in the COPV tank. Fill tables have been developed based on thermodynamic modeling provided by a team of automotive manufacturers. The thermodynamic models take into account effects of Joule-Thomson heating, friction heating, thermal mass, pre-cooling and initial thermodynamic state. Validation testing was required to provide a sound basis for the data provided in the tables. NREL and SAE worked on defining a series of tests that include 35 and 70 MPa tanks, -20°C and -40°C pre-cooling and tank sizes ranging from 1.4 liter up to 9.8 liter internal volume. Fill cycle testing was conducted at Powertech labs. Results were shared with the SAE interface committee and it was determined that results showed good correlation and that there was no further modification to the tables required.

**PRD: CSA HPRD1 Pressure Relief Device** – Pressure relief devices have been identified as a key safety component on hydrogen storage systems. Inadvertent opening can result in a failure mode where there is a release of the entire contents of the storage vessel. Component standards for HPRD certification testing are being put in place to insure that these components have end of life reliability. NREL and CSA have worked toward defining scope of supply required to validate hydrogen service suitability testing as part of the CSA HPRD1 draft standard. Testing includes pneumatic cycle testing in hydrogen on three valves of three different designs. Also included in the test program are three surrogate designs made from materials that are known to show poor performance in hydrogen service. Post test metallurgical examination will be conducted to determine the extent of hydrogen related material degradation. Test components have been procured and testing has started. Completion of the contracted test program is scheduled for the end of FY 2010.

Hydrogen Safety Sensors – DOE has published performance targets for hydrogen safety sensors in the multi-year RD&D plan. NREL is working toward characterization of sensor performance relative to the DOE targets by testing commercially available sensors and near-term developmental sensors. Through research on the sensor market, over 140 different sensor technologies have been identified. Information on each of these designs is being compiled in spreadsheet format. This data resource includes manufacturer information, product specifications, contact lists and links to communication logs and test data. NREL has completed the design and build of a new custom test apparatus with capability for an expanded range of environmental test conditions and capacity to test
multiple sensors concurrently. Figure 2 shows the new test apparatus.

NREL is currently working directly with sensor manufacturers, testing both commercially available product and near term prototype designs. In order to validate our test methods we have started a round robin test program with our sensor lab collaboration partner, the Joint Research Centre lab in the Netherlands. Selected sensors are being tested in both labs in order to show sensor performance is independent of any facility to facility differences. NREL is also collaborating with other national and international partners, including national laboratories, universities and codes and standards development organizations.

Conclusions and Future Directions

NREL has completed (or is near completion of) validation testing in support of ASME, SAE and CSA standards and will continue to work closely with codes and standards development organizations to close gaps and promulgate codes and standards that are based on the latest technical knowledge.

In addition to continuing to support component level codes and standards development, NREL will undertake a number of initiatives including:

• Identifying gaps to hydrogen technology commercialization.
• Developing national laboratory capabilities needed to provide a sound basis for component level codes and standards content.
• Focusing efforts toward working directly with sensor manufacturers in order to reach performance targets defined in the DOE multi-year RD&D plan.
• Expanding sensor laboratory capabilities to test over a wider range of environmental conditions and to add long-term exposure and response time test apparatus.
• Further our efforts on national and international collaboration in order to provide a path toward commercialization of hydrogen components.

FY 2010 Publications/Presentations

IX.3 Codes and Standards Training and Outreach and Education for Emerging Fuel Cell Technologies

Objective

- Conduct research and development (R&D) needed to establish sound technical requirements for hydrogen and fuel cell codes and standards.
- Support code development for the safe use of hydrogen and fuel cell technologies.
- Advance safety, code development, and market transformation issues through collaborations with appropriate stakeholders.
- Facilitate the safe deployment of hydrogen and fuel cell fuel technologies.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Codes and Standards section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Limited Government Influence on Model Codes
(B) Competition among SDOs and CDOs (Standards Development Organizations, Code Development Organizations)
(C) Limited State Funds for New Codes
(D) Large Number of Local Government Jurisdictions (approximately 44,000).
(E) Lack of Consistency in Training of Officials
(F) Limited DOE Role in the Development of International Standards
(G) Inadequate Representation at International Forums
(H) International Competitiveness
(I) Conflicts between Domestic and International Standards
(J) Lack of National Consensus on Codes and Standards
(K) Lack of Sustained Domestic Industry Support at International Technical Committees
(L) Competition in Sales of Published Standards
(N) Inadequate technical data to revise standards
(O) Affordable insurance is not available
(P) Large footprint requirements for hydrogen refueling stations
(Q) Parking and other access restrictions

Contribution to Achievement of DOE Safety, Codes & Standards Milestones

This project will contribute to achievement of the following DOE milestones from the Hydrogen Codes and Standards section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

<table>
<thead>
<tr>
<th>Milestone</th>

</table>
Accomplishments

NREL has accomplished the following in support of section 3.7 of the DOE Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

1. Codes and standards workshops: expanded codes and standards workshops from Fiscal Year (FY) 2009 to cover more subject matter, including a new module on electric vehicles and infrastructure requirements for electric vehicles. Presented four workshops in FY 2010 partnering with local fire departments and government organizations.
2. Web-based information compendium: expanded compendium to include other vehicle fuels and to include updated code official training course that includes material on indoor hydrogen fueling.

Introduction

It is essential to develop and promulgate codes and standards in order to provide for the safe use of hydrogen and fuel cell technologies. With the help of key stakeholders, the DOE Fuel Cell Technologies Program and NREL are coordinating a collaborative national effort to prepare, review, and promulgate codes and standards for all hydrogen and fuel cell technologies.

Approach

The Fuel Cell Technologies Program recognizes that domestic and international codes and standards must be established to enable the timely commercialization and safe use of hydrogen and fuel cell technologies. The lack of codes and standards applicable to hydrogen and fuel cell technologies is an institutional barrier to deploying these technologies. It is in the national interest to eliminate this potential barrier. As such, the subprogram works with domestic and international SDOs to facilitate the development of performance-based and prescriptive codes and standards. These standards are then referenced by building and other codes to expedite regulatory approval of hydrogen and fuel cell technologies. This approach ensures that U.S. consumers can purchase products that are safe and reliable, regardless of their country of origin, and that U.S. companies can compete internationally.

Results

The Safety Codes and Standards work is divided into three major areas:

1. National Template Implementation
2. Codes and Standards Research
3. Codes and Standards Training and Outreach

This report will address codes and standards outreach.

Codes and Standards Training and Outreach

NREL has several active training and outreach projects in FY 2010 including the following:

- Codes and Standards workshops.
- Update of code official on-line training course.
- Analysis of two emerging fuel cell technology projects (funded through the Education subprogram).

NREL conducted four Codes and Standards workshops in FY 2010. These workshops were held in Tampa, FL, New Orleans, LA, San Francisco, CA and Los Angeles, CA. All four were held in collaboration with local fire service departments or organizations. These workshops were targeted at code officials and project developers who would be working on fuel cell or hydrogen technology projects.
The proceedings from these workshops are posted at the Hydrogen Program Safety, Codes and Standards Web page. Generally, the workshops have been effective at getting information to individuals who will be directly involved in hydrogen and fuel cell projects. These individual proceedings include plan reviews for officials of fire departments and project managers responsible for getting hydrogen and fuel cell projects built.

The Code Official training course that was placed on-line in FY 2009 was amended to include material on indoor fueling operations. Indoor fueling is a special concern because of the developing use of hydrogen-fueled forklifts that are typically fueled indoors.

Another key project is two case studies that address emerging fuel cell technologies. The first project is an evaluation of codes and standards and safety issues associated with a fuel cell system used to supply backup power at a military base and the second is an evaluation of indoor fueling and forklift operations at a military storage facility. The analysis and findings from these projects will be published as an NREL technical report that would assist code officials and project developers in codes and standards and safety evaluations in similar projects.

Figure 1 shows the how the work done in the outreach activities feeds into the research projects and codes and standards development work.

**Conclusions and Future Directions**

NREL will continue to support the development of codes and standards by:

- Working with DOE to implement a national template for vehicle codes and standards development.
- Continuing R&D support of the key technologies required to close the gaps identified in the codes and standards development process.

![FIGURE 1. Structure of Safety, Codes and Standards Work at NREL](image-url)
• Continuing R&D collaborations with national and international stakeholders on vehicle codes and standards activities.
• Performing outreach work to distribute information on hydrogen and fuel cell technologies to code officials, project developers, and other interested parties.
• Coordinating domestic codes and standards and international standards to ensure consistent requirements.

IX.4 Hydrogen Safety Sensors

Objective

- Develop a low-cost, low-power, durable, and reliable hydrogen safety sensor for vehicle and infrastructure applications.
- Demonstrate working technology through application of commercial and reproducible manufacturing methods and rigorous life testing results guided by materials selection, sensor design, and electrochemical research and development investigation.
- Recommend sensor technologies and instrumentation approaches for engineering design.
- Disseminate packaged prototypes to DOE laboratories and commercial parties interested in testing and fielding advanced commercial prototypes while transferring technology to industry.

Multi-Year Program Plan Technical Barriers from the Hydrogen Safety section (3.8) of the Fuel Cell Technologies Program

- Liability Issues: Potential liability issues and lack of insurability affecting the commercialization of hydrogen technologies: Need for reliable H₂ safety sensor.

(G) Expense of Data Collection and Maintenance

Technical Targets

- Sensitivity: 1 vol% in air.
- Accuracy: 0.04-4% ± 1%.
- Response Time: <1 min at 1% and <1 sec at 4%; recovery <1 min.
- Temperature: -40°C to 60°C.
- Durability: 5 years without calibration.
- Cross-Sensitivity: Minimal interference to humidity, H₂S, CH₄, CO, and volatile organic compounds.

Accomplishments

- New zirconia-based mixed potential sensor with 0-4 vol% hydrogen sensitivity was demonstrated utilizing a machined, dense indium-tin oxide (ITO) working electrode (In₂O₃: SnO₂; 90%: 10%), a Pt wire counter electrode, and porous yttria-stabilized zirconia (YSZ) electrolyte were prepared using ceramic tape casting methods. The response of these devices to hydrogen concentrations up to 2% in air was studied from 600 to 740°C.
- Durability testing of over 1,700 hrs was accomplished on pre-commercial tape-cast sensors.
- Potential manufacturing platform were investigated for early prototypes.
- Developed a miniaturized, low-power, robust H₂ sensor prototype conducive to commercialization.
- Stable response over time achieved in the sensor prototype by modifying Pt morphology.
- Completed long-term testing of H₂ sensor (4,000 hrs) including 100 hrs of accelerated stress testing.
- Evaluated sensor electrode materials and design to further improve long-term stability and prevent sensor-aging effects.
- Investigated the suitability of lanthanum strontium manganate (LSM) as a pseudoconuter electrode to replace Pt electrode for long-term stability and reliability.
- Explored alternate modalities such as impedancemetric detection for H₂ screening.
Introduction

Recent developments in the search for renewable energy coupled with the advancements in fuel cell powered vehicles have augmented the demand for hydrogen safety sensors [1]. There are several sensor technologies that have been developed to detect hydrogen, including deployed systems to detect leaks in manned space systems and hydrogen safety sensors for laboratory and industrial usage. Among the several sensing methods electrochemical devices [2-8] that utilize high temperature-based ceramic electrolytes are largely unaffected by changes in humidity and are more resilient to electrode or electrolyte poisoning. The desired sensing technique should meet a detection threshold of 1% (10,000 ppm) H₂ and response time of ≤1 sec [9] targets for infrastructure and vehicular. Further, a review of electrochemical hydrogen sensors by Korotcenkov et al. [10] and the report by Glass et al. [11] suggest the need for inexpensive, low-power, and compact sensors with long-term stability, minimal cross-sensitivity, and fast response. As part of the Hydrogen Code and Standards sub-program, Los Alamos National Laboratory (LANL) and Lawrence Livermore National Laboratory (LLNL) are working together to develop and test inexpensive, zirconia-based, electrochemical (mixed potential) sensors for H₂ detection in air. Previous work conducted at LLNL showed [8] that ITO electrodes produced a stable mixed potential response in the presence of up to 5% of H₂ in air with no response to CO₂ or water vapor. The sensor also showed desirable characteristics with respect to response time and resistance to aging, and degradation due to thermal cycling.

In this investigation, the development and testing of an electrochemical H₂ sensor prototype based on ITO/YSZ/Pt configuration is detailed. The device fabricated on an alumina substrate integrates a resistive Pt heater to achieve precise control of operating temperature while minimizing heterogeneous catalysis. Targeting fuel cell-powered automotive applications, the safety sensor was subjected to interference studies, temperature cycling, operating temperature variations, and long-term testing over 4,000 hrs. The sensor responded in real time to varying concentrations of H₂ (1,000 to 20,000 ppm). Among the interference gases tested such as NO, NO₂, NH₃, CO, and propylene (C₃H₆), the sensor showed cross-sensitivity to C₃H₆. Analyzing the overall device performance over 4,000 hrs of testing for 5,000 ppm of H₂, (a) the sensitivity varied between 0.135 to 0.17 V with a minimum low of 0.12 V, (b) the baseline signal ranged from 0 to 0.04 V, and (c) the response rise time fluctuated between 3 to 47 s.

The salient features of the H₂ sensor prototype developed by LANL are (a) the low power consumption, (b) compactness to fit into critical areas of application, (c) simple operation, (d) fast response, (e) a direct voltage read-out circumventing the need for any additional conditioning circuitry, and (f) conducive to commercialization.

Approach

The sensor design approaches from LANL and LLNL were used to develop devices with superior performance.

LANL Design: Controlled Electrode/Electrolyte/Gas Interface

At LANL, electrochemical potentiometric modality is utilized for designing the sensors. Mixed potential sensors are a class of electrochemical devices that develop an open-circuit electromotive force due to the difference in the kinetics of the redox reactions of various gaseous species at each electrode/electrolyte/gas interface, referred to as the triple phase boundary [12]. Therefore these sensors have been considered for the sensing of various reducible or oxidizable gas species in the presence of oxygen. Based on this principle, a unique sensor design was developed. The uniqueness of the LANL sensor [13] derives from minimizing heterogeneous catalysis (detrimental to sensor response) by avoiding gas diffusion through a catalytically active material and minimizing diffusion path to the 3-phase interface (electrode/electrolyte/gas referred to as tripe phase boundary). Unlike the conventional design of these devices that use a dense solid electrolyte and porous thin film electrodes (similar to the current state-of-the-art zirconia-based sensors and fuel cells), the LANL design uses dense (either metal wires, oxide pellets or thin film) electrodes and porous electrolytes (bulk or thin film). Such a sensor design facilitates a stable and reproducible device response, since dense electrode morphologies are easy to reproduce and are significantly more stable than the conventional porous morphologies. Moreover, these sensors develop higher mixed potentials since the gas diffusion is through the less catalytically active electrolyte than the electrode. Further, the choice of electrodes is primarily based on their O₂ reduction kinetics. Sensors fabricated at LANL will typically involve one electrode with fast (Pt) and another with slow (Au or LaCrO₃) O₂ reduction kinetics aimed to improve the sensitivity.

LLNL Design

In the LLNL design, a new impedance-based measurement technique, originally developed for electrochemical NOₓ sensors, was shown to generate more stable sensor responses and may be able to offer a way to compensate for cross-sensitivity effects. The technique is based on the measurement of parameters related to the complex impedance of the sensor in the frequency range of 1 Hz to 10 kHz. Measurements
are typically made at a single frequency selected to maximize the desired sensitivity, although measurements performed at additional frequencies have been shown to be useful for correcting the response to interfering gases. LLNL has also found in the NOx sensor studies that it may be possible to use a wider variety of electrodes for the sensor in impedance-based sensing. Additional possible advantages included better tolerance to mechanical defects (such as delamination) and better longer-term stability.

Results

(a) Potentiometric Sensing

Figure 1 shows the schematic of the fabricated sensor with integrated Pt heater. The plan and cross-sectional view of the sensor schematic along with the four post (two electrodes, two heater pads) metal connections are shown in the top and bottom part of Figure 1, respectively. After obtaining the sensor platform from ESL Electro-Science Laboratories (fabricated using a patented LANL design), the ITO electrode was deposited.

The ITO working electrode was sputter deposited onto the sensor body using a commercially available 2" diameter radio frequency magnetron sputtering target (Alfa, In2O3: SnO2; 90%: 10%) in an off-axis orientation. After ITO deposition, the YSZ electrolyte layer was prepared using e-beam evaporation. Tosoh-8z YSZ powder was pressed into a pellet, which was then sintered at 1,200°C for 6 hrs. The sintered pellet was used as the evaporation source. An alumina platform with four metal posts connecting the sensor electrodes and heater was housed in a low volume quartz tube with a gas inlet and outlet. Humidity was added to the system by passing the gas through a bubbler. The heater voltage was set to 6.5 V, which corresponded to an operating temperature of approximately 535°C following a polynomial trend, \( Y = 4.941 \times 2 + 45.85 \times + 28.16 \) (\( Y \) represents the operating temperature in degrees and \( x \) represents the heater voltage).

The ITO and Pt electrode achieve different steady-state redox potentials when exposed to a mixture of \( \text{H}_2 \) and \( \text{O}_2 \) determined by the kinetic balance of the following electrochemical reactions:

\[
\frac{1}{2} \text{O}_2 + 2e^- \leftrightarrow \text{O}^{2-} \quad (i)
\]

\[
\text{H}_2 + \text{O}^{2-} \leftrightarrow \text{H}_2\text{O} + 2e^- \quad (ii)
\]

The electrode that favors the second reaction over the first develops a large non-Nernstian potential. However, the non-electrochemical oxidation (heterogeneous catalysis) of \( \text{H}_2 \) lowers the differential voltage developed between the electrodes signifying the importance of materials selection and localized heating.

In this investigation, the alumina substrate is integrated with a screen-printed Pt heater for precise control over the operating temperature. In addition, the use of metal oxide electrode enables a higher mixed potential. The derived the mixed potential equation for a \( \text{H}_2 \) sensor as a function of air/hydrogen concentration as:

\[
E_m = E_o + mAlnC_{\text{H}_2} - nAlnC_{\text{O}_2} \quad (iii)
\]

\( E_m \) is the developed mixed potential, \( E_o \) is the electrode potential at equilibrium, \( m \) and \( n \) are constants, \( A \) is a constant associated with the catalytic activity of the electrode material through their dependence on the charge-transfer coefficient and the standard rate constant, and \( C \) stands for the concentration of \( \text{H}_2 \) or \( \text{O}_2 \). As inferred from equation (iii), the mixed potential linearly relates with logarithmic concentrations of \( \text{H}_2 \). Such an observation is noticed in this investigation.

Figure 2a shows the staircase sensor response with varying concentrations of \( \text{H}_2 \). The sensor response was seen to linearly vary with logarithmic concentrations of \( \text{H}_2 \) and seems to follow a mixed potential device behavior.

For interference studies, 100 ppm of gases such as NO, NO2, CO, NH3 and C3H6 were used as analytes. Figure 2b shows the cross-sensitivity response indicating a strong signal from 100 ppm of C3H6. The concentration of C3H6 was further increased to 500 ppm to observe any augment in the undesired signal. Absence of any
significant increase in the C\textsubscript{3}H\textsubscript{6} response with higher concentration suggests that the tested concentration range of C\textsubscript{3}H\textsubscript{6} must have coincided with the saturation region of the device (characterized by the logarithmic flat sensor response). Also, the occurrence of a non-electrochemical heterogeneous process rather than electrochemical oxidation of C\textsubscript{3}H\textsubscript{6} cannot be ruled out.

Life cycle characterization of the sensor was initiated since the device exhibited the appropriate sensitivity and selectivity to H\textsubscript{2}. Table 1 summarizes the different sensor testing conditions over 4,000 hrs. The variation in the sensor response (Figure 3) subjected to different thermal treatments can be attributed to thermal expansion mismatch between the electrodes (ITO, Pt) and the electrolyte (YSZ). For a typical ceramic-metal system involving high-temperature applications, the recommended rule for materials selection involves the

use of metal, that have similar and/or smaller thermal expansion coefficients than that of the ceramic. Though intermediate layers (such as an insulator or metal composites) have been added in the past to match the coefficient of thermal expansion (CTE) of the metal and the ceramic, certain applications that involve charge transfer process demand a direct ceramic-metal contact. Considering the materials specific to this application, the thermal expansion coefficients of ITO, 8z-YSZ, and Pt from published literature were found to be 6.2 x 10-6/°C, 9.6 x 10-6/°C, and 10.53 10-6/°C respectively. The CTE of both ITO and Pt electrode deviate from that of YSZ. Such a variation in CTE of the materials may be responsible for the different levels of sensor response observed in Figure 3. The variation in the sensor response subjected to different thermal treatments is also shown in Figure 3. As the response time of the device is governed by the speed of the competing oxygen reduction and electrochemical oxidation reactions, it is postulated that surface stress on ITO due to CTE mismatch and H2 oxidation slows down the reaction represented in equation (ii) upon different thermal treatments.

Analyzing the overall device performance from 0 to 4,000 hrs upon exposure to 5,000 ppm of H2, (a) the sensitivity varied between 0.135 to 0.17 V with a minimum low of 0.12 V, (b) the baseline signal ranged from 0 to 0.04 V, and (c) the response rise time fluctuated between 3 to 47 s. It should be noted that the rise time includes the time constant of the test set-up, which is calculated as 1 s. The absence of any dramatic deterioration in the sensor response over time is attributed to a stable three-phase interface (electrode/electrolyte/gas). As the interfacial regions contain the electrochemically active sites, it is vulnerable to microstructural changes during sensor operation as these regions are also the sites for mass transport and diffusion. These microstructural changes (for example, due to annealing/heating) can be a major factor inducing sensor drift. Even well designed interfaces contribute to the electrical losses of devices and hence limit the overall sensor performance. Hence, it is critical to engineer the interface through materials selection and processing for the development of a reliable and stable sensor.

(b) Impedancemetric Sensing

Based on preliminary results, impedance-based response was evaluated using a test cell with a stacked electrode configuration consisting of a porous ITO sensing electrode on the bottom, porous YSZ electrolyte, and dense LSM counter electrode on the top. Results of impedance-based testing indicated reasonably stable performance to over 150 hrs of testing with resolution of 0.25, 0.5, 1, and 2 vol% H2. However, the sensitivity for the impedance-based method was lower than that of the potentiometric signal. Nevertheless, another important result of the impedance-based sensing experiments was characterizing the overall influence of applied signals (alternating and direct current, ac and dc) on the stability of the sensor response during long-term testing. Further investigation is necessary to understand how applied signals may temporarily influence sensing behavior, and the development of a novel strategy using electrical measurement and conditioning protocols, both alternating current and direct current, will be explored to improve sensor performance.

Conclusions

- Improved electrode materials with potentially better performance were investigated where dense electronically conducting oxide (LSM) counter electrode showed better long-term stability.
- An alternate impedancemetric sensing modality was explored to evaluate improvements in long-term performance and stability.
- A pre-commercial H2 sensor prototype was fabricated on an alumina substrate with ITO and Pt electrodes and YSZ electrolyte with an integrated Pt heater to achieve precise operating temperature and minimize heterogeneous catalysis.
- During the initial 4,000 hrs of long-term testing for the prototype with optimized platinum electrode, the sensor response to 5,000 ppm of H2 varied at a maximum of ca. +10%/-7% from its original value of 0.135 V (0 hrs). The response rise time fluctuated between 3 to 47 s.
- The extended sensor response stability over time may be attributed to a stable, engineered three-phase interface.
- The salient features of the investigated H2 sensor prototype include (a) conducive to commercialization, (b) low power consumption, (c) compactness to fit into critical areas, (d) simple transduction mechanism, and (e) fast response.

Future Directions

- Postmortem analysis of H2 prototype sensor tested for 4,000 hrs (Aug. 2010 - Oct. 2010).
- Fabrication and lifetime performance evaluation (minimum 5,000 hours) of advanced prototypes (Aug. 2010 - Feb. 2011).
  - Investigation of composite electrode compositions with novel impregnation technique for improved stability. Such a rationale is based on controlling properties at the interface between the electrode and electrolyte. The composite electrode compositions, containing both electrode and electrolyte material may decrease...
thermal expansion mismatch at the interface and improve stability. Further, the novel impregnation technique uses an already sintered backbone of electrolyte material where the electrode material is added in a separate low-temperature process step (previous work has shown this approach to not only improve thermal expansion matching (as anticipated with a composite structure), but also improve electronic/ionic conduction paths).

- Cross-sensitivity studies, stability evaluation using LSM electrodes in advanced prototypes (Sep. 2010 - Dec. 2010).
  - Need to configure radio frequency magnetron sputter system and optimize deposition conditions for lanthanum strontium manganese oxide (LSMO) thin film deposition. This material will replace Pt as a sensor pseudo-reference counter electrode. Then, sputter masks (for low- and high-temperature depositions) needs to be prepared for sensor electrode and electrolyte film patterning during deposition. Also, a modified mount needs to be machined to fix position of sensor substrate relative to mask. This will permit a high degree of reproducibility for placement of electrodes/electrolyte from sensor to sensor. Finally, several ITO and LSMO calibration runs needs to be performed to characterize rates/structure/morphology/conductivity.

- Characterize and understand the sensing mechanism(s) in various modalities and apply to future devices and optimize next generation of pre-commercial prototypes (Sept. 2010).

- Investigate and identify packaging schemes for field and laboratory testing (Nov. 2010 - Jan. 2011).

- Independent testing and comparison of the performance of packaged prototype $H_2$ sensor with a commercial device (Feb. 2011 - May 2011).
  - Initiate and pursue collaboration and independent testing work with Dr. William Buttner from National Renewable Energy Laboratory. Then, acquisition of best available technology $H_2$ sensor (thermal conductivity detector-based technology, $\$2000.00$ unit cost) for comparison performance/stability testing with the low-cost LANL/LLNL device needs to be completed.
  - Further, a new, customized test chamber assembly needs to be constructed to test $H_2$ sensors (both experimental and commercial) under diffusion conditions while permitting continuous sampling and measurement of $[H_2]$ local to sensors using gas chromatography.

Start Date: Fiscal Year (FY) 2003
End Date: Project continuation and direction determined annually by DOE

Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

Technical Barriers
This project addresses the following technical barriers from the Codes and Standards section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:
(F) Limited DOE Role in the Development of International Standards
(I) Conflicts between Domestic and International Standards
(N) Insufficient Technical Data to Revise Standards

Contribution to Achievement of DOE Codes and Standards Milestones
This project will contribute to achievement of the following DOE milestones from the Codes and Standards section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

Milestone 21: Completion of necessary codes and standards needed for the early commercialization and market entry of hydrogen energy technologies (4Q, 2012). This project enables the development and implementation of codes and standards by providing expertise and data on hydrogen compatibility of structural materials.

Accomplishments

- Completed cutting-edge measurements and report on fracture threshold measurements of tank steels in H2.
- Testing completed on stationary tank materials to meet immediate needs for market transformation.
- Testing performed on forklift tank materials to meet immediate needs for market transformation.
- Measurements performed to illuminate pathway to optimization of procedures in American Society of Mechanical Engineers (ASME) Article KD-10 standard.
- Updated “Technical Reference for Hydrogen Compatibility of Materials” to include single-phase nickel alloys.
- Initiated testing and analysis effort to evaluate the cycle-life of steel tanks and inform the design qualification standards for hydrogen-powered industrial trucks (e.g. forklifts).
Introduction

A major barrier to the deployment of hydrogen technologies is the lack of validated safety codes and standards. The purpose of this project is to provide the technical basis for assessing the safety of hydrogen-based systems with the accumulation of knowledge feeding into the development or modification of relevant codes and standards. The materials compatibility effort focuses on developing optimized materials qualification methodologies and assembling a resource entitled the Technical Reference on Hydrogen Compatibility of Materials. This effort is driven by the need for a materials guide, as identified in the Multi-Year Research, Development and Demonstration Plan (Table 3.7.5). The content of the Technical Reference is developed by identifying and documenting materials data from journal articles and institutional reports. Voids in the database uncovered during the process of composing the Technical Reference are addressed through a materials testing activity. Results from this materials testing illuminate the pathways to optimize materials qualification methods, enabling efficient, high-quality testing to support rapid technology deployment.

Approach

The focus of the Materials and Components Compatibility project is to optimize materials characterization methodologies, generate benchmark data for materials to enable technology deployment, and compose the Technical Reference on Hydrogen Compatibility of Materials. Two activities proceed in parallel: generating new data and understanding through materials testing, and identifying and compiling existing data from technical documents. The high-priority structural materials featured in these activities are low-alloy and carbon steels, austenitic stainless steels, and aluminum alloys. The materials testing activity emphasizes high hydrogen gas pressures (>100 MPa), fracture mechanics methods, and material fabrication and service variables (e.g., welds, temperature). The data from materials testing are critically reviewed to identify pathways to improve the test methods and to ensure the data are suitable for implementation in structural design. The qualification methods developed in this program are then validated on real components to enable effective incorporation into codes and standards.

As part of codes and standards advocacy, Sandia personnel are actively engaged in the codes and standards development process through direct participation in standards development organizations such as ASME, Canadian Standards Association (CSA), Society of Automotive Engineers, and the International Organization for Standardization. This participation ensures that the standards development organizations have the most current technical information on structural material compatibility. Sandia personnel provide guidance in the development of both component design standards as well as materials testing standards.

Results

Technical Reference

The Technical Reference is an evolving document, where individual chapters are published via Web site (http://www.ca.sandia.gov/matlsTechRef/) and updated as information is collected. In addition, a formal report (SAND2008-1163) has been distributed to stakeholders and will be revised periodically. When available, the data featured in the Technical Reference are those that enable application of design standards such as ASME Article KD-10 and ASME B31.12. In addition, permeability data are needed to calculate the rate of hydrogen release from containment structures. There are currently 22 material-specific chapters whose content has been informed by input from stakeholders including industry and standards development organizations. In FY 2010, a new chapter on single-phase nickel alloys was incorporated. The data contained in this reference is often used for materials selection in technology design and for standards development and will continue to be an enabling product of the Codes and Standards program element.

Material Measurements

Efforts in FY 2010 focused on improving methods for measuring fatigue crack growth rates of structural metals in high-pressure hydrogen gas and generating high-demand fatigue crack growth data to enable the implementation of ASME Article KD-10 for short-term technology deployment. We developed and evaluated a new load cell capable of operation in high-pressure hydrogen gas. The performance of the load cell was then assessed by conducting a fatigue crack growth test on the line pipe steel X52 in high-pressure hydrogen gas. In this case, the fatigue crack growth test was conducted using control software that required a feedback signal from the load cell. The test was successfully conducted, and the resulting fatigue crack growth (da/dN) vs stress-intensity factor range (AK) data from the test are displayed in Figure 1. Test systems capable of measuring fatigue crack growth rates under high-pressure hydrogen are rare, and the implementation of this platform at Sandia establishes a valuable capability that will be leveraged to generate critical data for hydrogen service materials.

The need to determine the cycle-life of steel hydrogen storage tanks on lift trucks emerged as a high priority during FY 2010. In response, a new activity was initiated to establish cycle-life prediction methodologies
FIGURE 1. Fatigue crack growth rate data measured for X52 line pipe steel in 3,000 psi (21 MPa) hydrogen gas at a load cycle frequency of 1 Hz and load ratio of 0.5. This fatigue crack growth test represents the successful performance of the new strain gauge-based load cell in the test system.

and support standards development for lift-truck tanks. One of the cycle-life prediction methodologies explored in this lift-truck tank activity is based on structural analysis, i.e., ASME Article KD-10. This analytical framework for calculating the cycle life of steel hydrogen pressure vessels requires measurements of fatigue crack growth data for the steel in hydrogen gas. Since one objective of the Materials and Components Compatibility activity has been to measure fatigue crack growth rates for pressure vessel steels in hydrogen gas, this activity is well positioned to contribute critical data for the lift-truck tank effort. The lift-truck tanks are fabricated from the DOT 3AAX (4130X) steel, which we evaluated previously while measuring the sustained-load cracking thresholds of pressure vessel steels. The parameters for the fatigue crack growth tests were developed in consultation with several industry partners. Based on these interactions, the hydrogen gas test pressure and initial stress-intensity factor range were selected as 6,500 psi (45 MPa) and about 9 MPa m\(^{1/2}\), respectively, for the fatigue crack growth tests. Two variables that are known to affect measured fatigue crack growth rates in hydrogen gas are the load cycle frequency and the load ratio, i.e., ratio of minimum applied load to maximum applied load (R). Since the rationale for specifying values of load cycle frequency and load ratio are still being developed for fatigue crack growth testing in hydrogen gas, it was decided to test the 4130X over a range of load cycle frequencies and load ratios.

A summary of the fatigue crack growth test matrix, the measured fatigue crack growth rate (da/dN) vs. stress-intensity factor range (ΔK) curves, as well as the status for each test on the 4130X steel are provided in Table 1 and Figure 2. The table indicates that three heats of 4130X are included in the test matrix, in which each steel heat was supplied by a different industry partner. Results in Figure 2 show that the fatigue crack growth rates in hydrogen gas exhibit a complex dependence on the applied stress-intensity factor range. The fatigue crack growth rate relationships (da/dN vs. ΔK) are being used, along with data generated in the full-scale tank tests, to better understand crack initiation in hydrogen gas and to validate the engineering analysis method for design and qualification of steel tanks for use in hydrogen, especially the lift-truck application. Heats 2 and 3 in Table 1 represent specimens taken from the tanks that are being tested in the full-scale tests.

Fatigue crack growth testing of ASME SA-372 Grade J in hydrogen gas at 100 MPa pressure has also been a recent focus of testing activities. Results from this testing directly impact market transformation, since our industry partner will use the data to qualify a stationary hydrogen tank design for a refueling station. Sandia was approached by the industry partner since no commercial test facilities exist in North America with capabilities to execute the testing required by the ASME Article KD-10 code at the service pressure of 100 MPa. Our testing is designed to meet the requirements of the ASME code for hydrogen tanks: three heats of steel tested at a frequency of 0.1 Hz. The low specified test frequency is intended to accommodate the kinetics of hydrogen transport in the steel, but the resulting extended test durations can present a challenge. Table 1 summarizes the matrix for the SA-372 Grade J fatigue testing, and includes the durations for tests completed on both the SA-372 Grade J as well as the 4130X. The da/dN vs. ΔK relationships from the completed test matrix on the SA-372 Grade J steel are plotted in Figure 2. Fatigue crack growth tests in air can be characterized by a power law relationship over a wide range of ΔK, which is represented by a line in a log-log plot such as Figure 2.

Component Testing and Codes and Standards Advocacy

Members of the Sandia Materials and Components Compatibility team were actively involved in the development of standards for lift truck tanks, CSA Hydrogen Powered Industrial Trucks (HPIT) 1. An experimental and analysis project was initiated in FY 2010 to perform hydrogen pressure-cycle testing and engineering analysis of commercial Type 1 hydrogen pressure vessels to build consensus for design methodologies and code development processes for high-frequency refueling applications. The effort provides the technical basis for CSA HPIT 1. The project addresses fatigue crack initiation and growth in steel tanks used in high-cycle applications. The tanks under test are sourced from two fuel cell forklift partner companies and tank manufacturers. We are developing design methodologies for steel tanks in this environment and validating the methodologies with experiments that emulate the real environment of the storage tank.

FIGURE 2. Fatigue crack growth rate (da/dN) vs. stress-intensity factor range (√K) relationships measured for 4130X tank steel (Heat 1) in 6,500 psi (45 MPa) hydrogen gas and for SA-372 Grade J tank steels (Heats 1-3) in 15,000 psi (103 MPa) hydrogen gas.
IX. Safety, Codes & Standards

A tank cycling apparatus was developed in a high-pressure facility at Sandia (Figure 3). This is a closed-loop cycling manifold that allows efficient hydrogen utilization. The system has the engineering and administrative controls in place to accommodate tank failure, which is desired in order to understand life-cycles of steel pressure vessels. A periodic pressure profile involves a 2 minute fill to 6,350 psi, a 2 minute hold, and a 2 minute vent which was deemed appropriate by the CSA HPIT 1 Materials working group. This accelerated fatigue cycling allows for up to 250 cycles per day. The test manifold is designed to operate up to 10 tanks in parallel. A test plan was developed in conjunction with the CSA HPIT 1 Materials working group. Two different tanks are under test from two separate manufacturers. Both as-manufactured tanks as well as tanks with engineered defects are tested to understand how cracks imitate and grow through the tank walls. Output from this project provides data in the area of crack initiation in components and validation of performance-based design qualification methods as will be codified in CSA HPIT 1 and the GTR.

Conclusions and Future Directions

In FY 2010:

- A report was completed on fracture threshold measurements of tank steels in hydrogen gas. The data has enabled revision of the ASME Article KD-10 tank standard.
- Fatigue crack growth testing was conducted on tank steels in hydrogen gas following ASME Article KD-10 to meet immediate needs for technology deployment in refueling stations and forklifts.
- We determined that the application of the ASME Article KD-10 standard indicates a path for optimization by establishing fatigue crack growth test frequencies that shorten test duration without compromising data quality.

Future Work:

- Update “Technical Reference” chapters on ferritic steels with new data.
- Establish ability to test properties of materials at variable temperature and pressure.
- Complete and distribute report on results from fatigue crack growth and fracture threshold testing of SA372 Grade J tank steel in hydrogen.
- We will complete fatigue crack growth testing of forklift tank steels in hydrogen to provide data for tank testing activity and enable standards development.
- Establish optimum load cycle frequencies for fatigue crack growth testing of steels in high-pressure hydrogen to enable standards revision.
- Complete first phase of materials qualification standard development for vehicle components (i.e., fittings, regulators, etc.) in collaboration with international partners.
- Conduct testing on additional materials (e.g., aluminum) that impact market transformation (FY 2011–2012).
- Complete materials qualification standard development for vehicle components (i.e., fittings, regulators, etc.).

IX.6 Hydrogen Safety Knowledge Tools

Linda Fassbender
Pacific Northwest National Laboratory (PNNL)
P.O. Box 999
Richland, WA 99352
Phone: (509) 372-4351
E-mail: Linda.Fassbender@pnl.gov

DOE Technology Development Manager: Antonio Ruiz
Phone: (202) 586-0729
E-mail: Antonio.Ruiz@ee.doe.gov

Project Start Date: March 2003
Project End Date: Project continuation and direction determined annually by DOE

Objectives

- **Hydrogen Safety Best Practices** - Capture the vast knowledge base of hydrogen experience and make it publicly available. The best practices online manual is a “living” document that provides guidance for ensuring safety in DOE hydrogen projects, while serving as a model for all hydrogen projects and applications.

- **Hydrogen Incident Reporting and Lessons Learned** - Collect information and share lessons learned from hydrogen incidents and near-misses, with the goal of preventing similar safety events from occurring in the future.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Safety section of the Fuel Cell Technologies (FCT) Program Multi-Year Research, Development and Demonstration Plan:

(A) Limited Historical Database
(B) Proprietary Data

Contribution to Achievement of DOE Safety, Codes & Standards Milestones

This project has already met the following DOE milestones from the Hydrogen Safety section of the FCT Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 18: Publish safety bibliography and incident databases (3Q, 2006).

Accomplishments

Hydrogen Safety Best Practices

- We enhanced the best practices content for outdoor storage of hydrogen cylinders in the Laboratory Safety/Laboratory Design section.
- We made Management of Change (MOC) more visible by adding a new page on the Web site and adding links to that page from three other Web pages.
- We drafted a new section called Hydrogen Properties that is focused on hydrogen combustion and liquid hydrogen expansion.
- We updated the Hydride Storage and Handling Section of Laboratory Safety/Laboratory Operations to cover the risks related to large-scale experiments with metal hydrides.
- We added approximately 50 links to safety event records in the Incident Reporting and Lessons Learned database to illustrate the kinds of incidents and near-misses that can occur if hydrogen safety best practices are not followed.

Hydrogen Incident Reporting and Lessons Learned

- We added 37 new safety event records, for a total of 177 records currently in the database. The new records came from DOE projects, private companies, and member countries of the International Energy Agency (IEA) Hydrogen Implementing Agreement (HIA) Task 19 (Hydrogen Safety).
- We created a new feature on the Web site called the Lessons Learned Corner to analyze and present hydrogen safety themes illustrated with database content.

Introduction

PNNL has developed and continues to improve two software tools to support the Hydrogen Safety, Codes and Standards Sub-Program. This report covers the Hydrogen Safety Best Practices online manual (http://

Approach

Hydrogen Safety Best Practices - There are many references and resources that deal with the safe use of hydrogen, and our intent is to organize and compile relevant information in an easy-to-use Web-based manual without duplicating existing resources. PNNL teams with hydrogen safety experts at Los Alamos National Laboratory (LANL), Sandia National Laboratories (SNL), the Hydrogen Safety Panel, and other subject matter experts to compile hydrogen-specific best practices from a variety of references. Links to Web-based resources and actual PDF files are provided on the Web site.

Hydrogen Incident Reporting and Lessons Learned - The purpose of “H2Incidents.org” is to facilitate open sharing of lessons learned from hydrogen safety events to help avoid similar incidents in the future. Our approach to this task includes encouraging DOE-funded project teams and others to voluntarily submit incidents and near-misses and to provide specific lessons learned. We continue to pursue the addition of new records by actively seeking news reports on hydrogen incidents and searching existing databases and other sources for hydrogen-related safety event records. We contact private-sector companies who experience hydrogen-related safety events to solicit their permission to publish such records. We continue to maintain a mechanism for online submission of records. Specific safety event records are linked to Best Practices online manual content to emphasize safe practices for working with hydrogen and avoiding future incidents. Expert review of all safety events and lessons learned is provided by PNNL subject matter experts and the Hydrogen Safety Panel.

Results

Hydrogen Safety Best Practices – We enhanced the best practices content for outdoor storage of hydrogen cylinders in the Laboratory Safety/Laboratory Design section. The Hydrogen Safety Panel identified the need for more detailed content and recommendations as the result of conducting a number of safety review site visits to facilities and discussing safe practices for outdoor cylinder storage.

MOC content is now more visible because we added a new page on the Web site and provided links to that page from three other pages (Safety Culture/Formalized Procedures; Equipment Maintenance and Integrity; and Development of Operating Procedures). Multiple references are provided on the new MOC page, including publications by the American Institute of Chemical Engineers Center for Chemical Process Safety and the U.S. Chemical Safety and Hazard Identification Board. Links to incidents in our Incident Reporting and Lessons Learned database are provided to illustrate what can happen if MOC procedures aren’t rigorously followed.

Hydrogen Incident Reporting and Lessons Learned - We added 37 new records to the database during the past year from DOE projects, private companies, and member countries of IEA HIA Task 19 (Canada, France, Germany, Italy, Japan, The Netherlands, Norway, Switzerland, the U.K., and the U.S.). We now have 177 records in the database, and about 15 more are pending approval by the organizations involved. PNNL staff, the Hydrogen Safety Panel, and others provided technical review of all records, with emphasis on fully capturing lessons learned.

Conclusions and Future Directions

Hydrogen Safety Best Practices - Our future work includes improving existing Web site content as well as drafting new content. Ideas for new content come from the Hydrogen Safety Panel, other national laboratories, technical reviewers at the DOE Annual Merit Review, and actual Web site users. For example, a new section on indoor refueling of forklifts is planned.
It has been suggested that we should consider the needs of end-user communities with less engineering and technological expertise. In response to this suggestion, we are drafting a new section that is focused on technicians and young engineers with limited or no knowledge of hydrogen properties and behavior. This new section will be practical and concise, formatted as a series of bullets showing what to do and what not to do, and include lots of photos and graphics to enhance the material. It will be highlighted on the Web site with a link that says “Starting Point for Those Not Familiar with Hydrogen” and will cover Hydrogen Basics, Hydrogen Hazards, and Design and Operation of Hydrogen Systems. It will also include links to existing Web site sections for further information.

We are also adding new content on working safely with chemical hydrides (analogous to the metal hydride section discussed earlier). The section has been drafted and reviewed by PNNL research staff working with chemical hydrides, and a revised version will be reviewed by Hydrogen Safety Panel members.

PNNL continues to monitor website usage and respond to user feedback. Users have submitted many requests for additional information and guidance through the Web site’s comment submittal feature. We routinely seek guidance from one or more Hydrogen Safety Panel members in crafting our responses to these requests. Web site utility is enhanced by continuing to link the content to safety event records in the Hydrogen Incident Reporting and Lessons Learned database and by adding photos, graphics, and videos to complement the text.

Hydrogen Incident Reporting and Lessons Learned - Our future work will focus on increasing the number of records in the database, in part through identifying additional sources of hydrogen safety event data and lessons learned. A significant part of our effort involves working with the national laboratories, universities, and private-sector firms that experience hydrogen incidents and near-misses to help them communicate what happened, what the primary causes and contributing factors were, and most importantly, what lessons were learned by their organizations that could benefit others if they were freely shared. We are planning to incorporate graphical software to enable the display of the database contents in graphical format. We will continue to monitor Web site usage and respond to user feedback.

We will also continue to encourage all DOE-funded projects, universities, private-sector organizations, and others to voluntarily submit records of their hydrogen incidents and near-misses. Success requires that people use the database and submit information without fear of negative consequences from reporting and publicizing safety events. We will continue to maintain confidentiality for the organizations that voluntarily submit safety event records.

Project Start Date: October 1, 2006
Project End Date: September 30, 2011

Objectives

- Test the effects of critical constituents (NH₃, CO, and H₂S) on fuel cell performance and provide data sets to fuel cell modelers to establish predictive mechanistic models.
- Provide guidance to other test facilities to expedite International Organization for Standardization (ISO) TC197 Working Group 12’s experimental results.
- Collaborate with international experts to determine levels of constituents for the development of an international standard for H₂ fuel quality.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Codes and Standards section (3.7) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(I) Conflicts between Domestic and International Standards
(N) Insufficient Technical Data to Revise Standards

Contribution to Achievement of DOE Codes and Standards Milestones

This project will contribute to achievement of the following DOE milestone from the Codes and Standards sub-program section of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

Milestone 26 - Revised (Society of Automotive Engineers/ISO) hydrogen quality guidelines adopted. (4Q, 2010)

Accomplishments

- Developed baseline test procedures for commercial membrane electrode assemblies (MEAs).
- Continued providing data sets to and interacting with fuel cell modelers.
- Performed multiple experiments using both common commercially-available and LANL ‘in-house’ MEAs.
- Tested critical constituents (NH₃, CO, and H₂S) and presented data sets to the working group and interacted with fuel cell modelers at various meetings.
- Participated in the development of the North American Team’s perspective on the levels of the critical constituents in the hydrogen fuel specification.

Background

LANL scientists have continued their support of the DOE/Energy Efficiency and Renewable Energy Office of Fuel Cell Technologies, in the Safety, Codes and Standards sub-program, through their expertise in the various disciplines such as materials physics and applications, chemistry, and modeling.

There has been an on-going effort to harmonize at the international level, a standard for hydrogen fuel quality, specifically for vehicle applications. This effort is being coordinated by the ISO Technical Committee on Hydrogen (TC197) in Working Group 12 (WG-12). They have maintained a lead role in the collaborative development and implementation of international performance-based codes, standards and regulations based on actual fuel cell performance.

Approach

We attempt to address two important concerns as the standard is being developed and finalized. The first is to recall that the current level of the constituents in the hydrogen fuel specification was based on detection limits. Since the specification origination, analytical techniques have improved considerably, inherently lowering these detectable limits. And, the other concern is that experimental data were collected using different membrane electrode assemblies (MEAs).
This was mainly due to the lack of a commercial supplier to provide platinum loadings desired by the WG-12. We previously developed and performed baseline test protocols for the commonly agreed upon commercial MEAs. Our previous results with the most deleterious critical constituents (NH₃, CO, and H₂S) employed LANL's MEAs and showed unacceptable performance losses. These tests were conducted at the original specification levels. More recently, the WG-12 tentatively agreed to lower both H₂S and CO levels in the fuel specification. Our results shown reflect test with both LANL and the common MEAs at the initial and reduced levels. Table 1 shows the initial and reduced critical constituents taken from the fuel specification.

</tbody>
</table>

**Results**

Test using NH₃, CO, and H₂S as isolated contaminants, in addition to testing combinations of these contaminants were continued. Experiments were conducted using 0.1 mg Pt/cm² at the anode and 0.2 and 0.4 mg Pt/cm² at the cathode electrodes for LANL and the common MEAs, respectively. We used 50 cm³ hardware from Fuel Cell Technologies (Albuquerque, NM) with Nafion® (NRE212) as the membrane and our catalyst was 20% Pt/C (ETEK) for the LANL cell and commercial MEAs were provided by W.L. Gore & Associates. In each result shown we operated the cell in constant current mode at 80°C with 85% utilization for the hydrogen and 50% for the air. In Figures 1 and 2, fuel cells with the common MEA were exposed to 4 ppb H₂S and the ISO critical contaminant mixture (NH₃, CO, and H₂S) in the anode feed stream while operating at 100% relative humidity (RH), respectively. After approximately 100 hours of exposure to H₂S, the voltage decay begins and slowly increases over time. This is consistent with an accumulative effect that has been observed with sulfur-platinum interactions. A similar phenomenon occurs in Figure 2, except after 100 hours the decay rate is higher than a fuel cell operating with just a sulfur containing compound. This indicates that the critical contaminants as a mixture are more detrimental to fuel cell performance.

We also probed the impact of RH on fuel cell behavior in the presence of these critical contaminants. Figure 3 illustrates the results of varying the level of humidification. Clearly, the left graph show a slower voltage decay rate and the extent of performance losses is much lower. This implies that the local water will definitely play a major role in the fuel cell behavior operating in the presence of the more soluble impurities.

As mentioned earlier, the initial specification was reduced and tests at those levels (see Table 1) are currently underway. Our preliminary results are shown in Figure 4. Parallel testing with both LANL and the common MEA are being investigated. Results shown are not conclusive, however, they show promise.
FIGURE 3. LANL MEA tested with 4 ppb H₂S, 100 ppb NH₃, and 200 ppb CO at 80°C in a fuel cell operating at 0.8 A/cm² with (a) 50% RH and (b) 100% RH.

FIGURE 4. Results using the common MEA with 1 ppb H₂S combined with 100 ppb NH₃ (left figure) and 200 ppb CO (right figure) at 80°C for a fuel cell operated at 1 A/cm².

Project Start Date:  2004  
Project End Date:  Project continuation and direction determined annually by DOE

Objectives

• Provide expertise and guidance to DOE and assist with identifying safety-related technical data gaps, best practices and lessons learned.  
• Help DOE integrate safety planning into funded projects to ensure that all projects address and incorporate hydrogen and related safety practices.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Safety section (3.8) of the Fuel Cell Technologies (FCT) Program Multi-Year Research, Development and Demonstration Plan:

(A) Limited Historical Database  
(B) Proprietary Data  
(C) Validity of Historical Data  
(D) Liability Issues  
(E) Variation in Standard Practice of Safety Assessments for Components and Energy Systems  
(F) Safety is Not Always Treated as a Continuous Process  
(G) Expense of Data Collection and Maintenance  
(H) Lack of Hydrogen Knowledge by Authorities Having Jurisdiction  
(I) Lack of Hydrogen Training Facilities for Emergency Responders

Contribution to Achievement of DOE Hydrogen Safety Milestones

This project contributes to achievement of the following DOE milestones from the Hydrogen Safety section of the FCT Program Multi-Year Research, Development and Demonstration Plan:

• Milestone 8: Complete investigation of safe refueling protocols for high pressure systems. (1Q, 2012)  
• Milestone 20: Update peer-reviewed Best Practices Handbook (4Q, 2008/ongoing)

Related milestones in Task 3 (Failure Modes), Task 5 (Safety of DOE R&D Projects), Task 6 (Hydrogen Safety and Incidents), Task 7 (Best Practices Handbook) and Task 8 (Hydrogen Safety Props) of the above reference have all been achieved with support from the Hydrogen Safety Panel.

Accomplishments

• Reviewed 50 safety plans since July 1, 2009 for projects in hydrogen storage, fuel cells, production and delivery and manufacturing and updated the DOE/Panel-prepared safety planning guidance resource [1].  
• Conducted safety review site visits for two hydrogen storage projects; completed and submitted five safety evaluation reports for site visits previously conducted [2-6]; conducted nine follow-up interviews for previously issued safety evaluation reports and submitted interview reports.  
• Provided technical guidance, source material and review for the Hydrogen Incident Reporting and Lessons Learned database (www.h2incidents.org), the Hydrogen Safety Best Practices Web site
Introduction

Safety is an essential element for realizing the "hydrogen economy" – safe operation in all of its aspects from hydrogen production through storage, distribution and use; from research, development and demonstration to commercialization. As such, safety is given paramount importance in all facets of the research, development, demonstration and deployment work of the DOE FCT Program Office.

Recognizing the nature of the DOE program and the importance of safety planning, the Hydrogen Safety Panel was formed in December 2003 to bring a broad cross-section of expertise from the industrial, government and academic sectors to help ensure the success of the program as a whole. The experience of the Panel resides in industrial hydrogen production and supply, hydrogen research and development and applications, process safety and engineering, materials technology, industrial liability and facility insurance, risk analysis, accident investigation and fire protection. The Panel provides expertise and guidance on safety-related issues and technical data gaps, reviews individual DOE-supported projects and their safety plans and explores ways to bring best practices and lessons learned to broadly benefit the DOE program.

Approach

The Panel strives to raise safety consciousness most directly at the project level. Safety should be driven at the project level by organizational policies and procedures, safety culture and priority. Project safety plans are reviewed in order to encourage thorough and continuous attention to safety aspects of the specific work being conducted. Panel-conducted safety reviews focus on engagement, learning, knowledge-sharing and active discussion of safety practices and lessons learned, rather than as audits or regulatory exercises. Through this approach, DOE and the Hydrogen Safety Panel are trying to achieve safe operation, handling and use of hydrogen and hydrogen systems for all DOE projects.

Results

The Hydrogen Safety Panel was formed in Fiscal Year (FY) 2004 and the first meeting was held in Washington, D.C., December 11-12, 2003. Two meetings of the Panel were held in FY 2010 as noted above. The 13th meeting (Washington, D.C.) included a topical session on fuel cell applications in the materials handling market with presentations by Air Products, Nuvera Fuel Cells and Plug Power. Panel project work in this application is planned (see Conclusions and Future Directions). The 14th meeting (Aiken, SC) included presentations/discussion with participating organizations in the Hydrogen Storage Engineering Center of Excellence lead by SRNL and facility visits to Bridgestone Firestone and GENCO, both employing fuel cell forklifts for materials handling.

Current Panel membership is noted in Table 1.

The Panel conducted safety reviews for the projects noted in Table 2 since the last reporting (safety reviews have been conducted for 41 projects since March 2004). Preliminary reports have been issued for all safety reviews and completed final reports with recommendations are referenced. Final reports were also issued for safety reviews previously conducted [2-6].

The Panel established a follow-up protocol to interview project teams in order to identify actions, findings and conclusions regarding safety review recommendations as one means for measuring the value of this work. Action on report recommendations represents a rich source of safety knowledge that can have broader benefits to others. Table 2 identifies the follow-up interviews that have been conducted and Table 3 summarizes the conclusions for the first eight follow-up interviews.

The Panel concluded that all interviewees have improved the safety aspects of the work they are conducting. Overall, nearly 90% of the
recommendations – 58 in number – have been implemented in some manner or are in progress for the set of eight project interviews. A presentation given at the 2010 World Hydrogen Energy Conference noted that “the mechanism used by the Panel for seamless discussion and knowledge sharing at the project level augments the prime responsibility of any organization to ensure the safe conduct of work” [7].

The Hydrogen Safety Panel contributes to PNNL’s ongoing work in updating and adding new technical content to two safety knowledge tools, the Hydrogen Incident Reporting and Lessons Learned database (www.h2incidents.org) and the Hydrogen Safety Best Practices Web site (www.h2bestpractices.org). For example, the Panel supported work to add content on laboratory safety aspects for hydrogen storage in cylinders, management of change procedures and additional information on hydrogen properties. Panel members also reviewed technical content for the new feature, the Lessons Learned Corner, in the above mentioned database. A second review of “Safety Training for Researchers,” an online training tool developed by Lawrence Livermore National Laboratory, was completed prior to release by DOE.

Conclusions and Future Directions

Being conscious of the need to use safe practices is a necessary first step for the conduct of all work. The work and approaches taken by the Panel will continue to focus on how safety knowledge, best practices and lessons learned can be brought to bear on the safe conduct of project work.

The Panel will undertake a number of additional initiatives in FY 2011 including:

- Safety plan reviews and safety review site visits for American Recovery and Reinvestment Act fuel cell deployment projects in specialty vehicle, auxiliary

Start Date: Fiscal Year (FY) 2002
End Date: Project continuation and direction determined annually by DOE

Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

Objectives

(1) Scenario Analysis, Risk Assessments for Safety:
   – Develop a scientific basis and the associated technical data for modifying or developing new codes and standards for the commercial use of hydrogen.
   – Develop benchmark experiments and a defensible analysis strategy for risk assessment of hydrogen systems.
   – Develop and apply risk-informed decision-making tools in the codes and standards development process.

(2) Hazards Mitigation Technologies for Hydrogen Applications:
   – Determine the effectiveness of ventilation, active sensing, and similar engineered safety features.

(3) Codes and Standards Advocacy:
   – Provide technical program management and support for the Safety, Codes and Standards program element.
   – Participate in the hydrogen codes and standards development/change process.

Technical Barriers

This project addresses technical barriers from the Codes and Standards section of the Fuel Cell Technologies 2007 Multi-Year Research Plan:

(F) Limited DOE Role in the Development of International Standards
(I) Conflicts between Domestic and International Standards
(N) Insufficient Technical Data to Revise Standards
(P) Large Footprint Requirements for Hydrogen Refueling Stations
(Q) Parking and Other Access Restrictions

Contribution to Achievement of DOE Codes and Standards Milestones

This project will contribute to achievement of the following DOE milestones from the Codes and Standards section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 21:** Completion of necessary codes and standards needed for the early commercialization and market entry of hydrogen energy technologies (4Q, 2012).
- **Milestone 8:** Complete investigation of safe refueling protocols for high pressure systems. (1Q, 2012)
- **Milestone 9:** Complete risk mitigation analysis for advanced transportation infrastructure systems. (1Q, 2015)
- **Milestone 12:** Complete research needed to fill data gaps on hydrogen properties and behaviors. (2Q, 2010)

Accomplishments

- We determined that implementation of barriers can be effective in reducing risk and separation distances to the facility lot line.
- Analysis of $\text{H}_2$ releases and delayed ignition deflagration have been performed for partially confined spaces (tunnels).
- Experiments have shown that entrained particulates originating from tanks or piping are likely a source of spontaneous ignition.
- The Sandia turbulent entrainment model for cold hydrogen jets has been validated against high-momentum jet data (from Forschungszentrum Karlsruhe tests).
Introduction

The purpose of this project is to enable risk-informed development of codes and standards for hydrogen fuel cell technology that is based on a traceable, scientific foundation. Our scenario analysis and risk assessment efforts focus on defining scenarios for the unintended release of hydrogen and quantifying the consequences through scientific experimentation and modeling. Quantitative risk assessment (QRA) is used to identify risk drivers and risk mitigation strategies for the commercial use of hydrogen. We combine our validated models with QRA to support risk-informed decision-making in the code development process.

Approach

We develop an understanding of combustion behavior and thermal effects from the unintended releases of hydrogen in the built environment. We consider ignition characteristics, barrier wall interactions, partially confined spaces (tunnels, garages, warehouses), and liquid hydrogen handling. Technical information is disseminated through a variety of public channels and is used by codes and standards developers writing for the International Code Council and National Fire Protection Agency (NFPA). International partnerships for vetting technical data and analysis methods occur through activities such as International Energy Agency Task 19 on Hydrogen Safety and the European HYPER project. Efforts in FY 2010 have focused on developing the basis for regulations and codes and standards development in the area of hydrogen releases in enclosures, ignition mechanisms, and liquefied hydrogen release behavior.

Results

Risk Analysis

Using risk information in the code development process enables rapid and effective hydrogen and fuel cell technology deployment. In FY 2010 we evaluated the use of barrier walls to reduce the risk (and thus separation distances) for hydrogen facilities. The use of properly designed barriers will remove the potential for direct contact with jet flames, reduce the distance of unignited jets, reduce the isosurfaces for various thermal radiation heat fluxes, and not result in any substantial increase in pressure that would harm people or structures. Thus, barriers provide a means to reduce the risk to the public from unintended releases of hydrogen. This reduction in risk also allows for the opportunity to reduce the separation distances at a hydrogen facility. Estimates of the risk reduction potential were generated by using the risk model developed for evaluation of the separation distances selected for incorporation into the NFPA-2 and NFPA-55 hydrogen standards [1] and the consequence results reported in [2,3]. The system configurations and associated leakage frequencies utilized in [1] were utilized in the barrier risk assessment, thus allowing for direct comparison of the risk with and without a barrier. The barrier wall was assumed to be 2.4 m high and separated from the hydrogen equipment by 1.22 m. The barrier wall was assumed to be 2.4 m high and separated from the hydrogen equipment by 1.22 m. Table 1 provides a comparison of the risk to an individual located at the facility lot line from a leak equivalent to a 3% of the maximum flow area in the hydrogen system.

1 Leak diameter corresponds to 3% of the largest flow area in the system.
2 Separation distance specified in NFPA-55, based on selected leak diameter.

As indicated in Table 1, the presence of a barrier can be used to reduce the risk to a person standing at the facility lot line. The use of a barrier can also be used to reduce the separation distances. For a risk level equivalent to the risk without a barrier, the separation distance to the facility lot line can be shortened to approximately 3.5 m for the leak diameters shown in Table 1.

Unintended Releases of Hydrogen in Partially Enclosed Spaces

Code language is being developed for the use of hydrogen in partially enclosed spaces. In FY 2010, we evaluated the release of hydrogen in enclosures to inform the code development processes in NFPA 2, 52, and 502. Experiments were performed in a scaled tunnel test facility (Figure 1) to provide model validation data for release simulations resulting from the venting of the thermally-activated pressure relief device (PRD) on a hydrogen vehicle in a full-scale tunnel. The tunnel test facility had a cross-sectional area that was approximately 1/2.53 that of the full-scale transversely ventilated tunnel. The release diameter was designed to match the scaled mass flow rate versus scaled time tank blow-down curve from the full-scale release. Measurements were made of the hydrogen concentration, flame speed, and ignition delay overpressure in the scaled tunnel resulting from the release produced by activation of three simulated...
PRD vents on the bottom of the scale-model vehicle. As part of the work a dispersion model and deflagration model of the test tunnel and vehicle geometry were developed. These models were used prior to the tests to estimate the placement of concentration and pressure sensors in the tunnel test geometry and to determine the amount of expected overpressure from ignition of the hydrogen releases. Pretest ignition deflagration simulations of the test tunnel geometry using three-dimensional concentration maps from the dispersion simulations indicated that the maximum overpressure would be approximately 0.5 barg and that a peak in the overpressure would occur with increasing ignition delay time as observed in the full-scale tunnel simulations. Figure 1 shows a comparison of the peak overpressures measured in the experiments for different ignition delay times as compared to the model simulations. The ignition overpressure simulations are found to be in good agreement with the experimental data.

The same modeling approach was used in the full-scale tunnel simulations and the pretest simulations of the scaled-tunnel experiments. The good agreement between the scaled-tunnel test experimental data and pretest simulations provide validation of the simulation approach and full-scale tunnel modeling results. Results were reported to NFPA 502 – the standard for road tunnels.

Auto-Ignition of Unintended Hydrogen Releases

Understanding ignition mechanisms and the probability of ignition is a vital aspect of the QRA. Ignition source in a large percentage of reported hydrogen release incidents is not easily identified. Due to this uncertainty, these events are often referred to as auto-ignition events. One of the most likely ignition sources for these events is ignition of the hydrogen/air mixture by electrostatic discharge resulting from the presence of charged particles in the flow. It is known from industrial experience that significant particle charge can develop during the high-speed flow of particle-laden gases through piping. During FY 2010, experiments were carried out to investigate the generation of static charge on iron-oxide particles in hydrogen gas flowing through pipes and the potential for these charged particles to induce an ignition event in the release. The objective of these experiments was to determine whether a static charge accumulation on iron oxide particles entrained in a hydrogen jet release could lead to a spark discharge ignition or a corona discharge ignition. Experiments were performed by adding particles to a high-pressure release of hydrogen gas flowing through a 10 foot steel pipe prior to exiting to ambient air through a nozzle.

A series of tests were performed where a circular ungrounded plate was placed in close proximity to a grounded probe in the particle-laden jet release (see Figure 2). In this configuration the ungrounded plate is charged by induction or particulate impact until the charge is high enough to arc to the nearby grounded probe. In this configuration, six ignitions occurred and in case when only 0.1 gram of iron (III) oxide particles were introduced into the flow ignition occurred in three out of four tests. In the case when no particles were introduced into the flow ignition did not occur. In addition, ignition did not occur when both probes were maintained at comparable floating electrostatic potentials. No corona-discharge events were observed during the test matrix. The results of these tests show that entrained particulates can be a source leading to spontaneous ignition in hydrogen gas releases.

Liquid Hydrogen Releases

Separation distances for liquid hydrogen systems are being specified in codes such as NFPA 2. We have developed an engineering model that can be utilized
to provide the basis for these separation distances. In FY 2010, this model was validated against high-momentum jet data from Forschungszentrum Karlsruhe of Germany. Forschungszentrum Karlsruhe conducted several experiments in which room temperature and 80 K under-expanded jets of hydrogen were vented into still air at ambient conditions. Hydrogen concentration was measured at several locations along the centerline. These jet releases were simulated using the Sandia turbulent entrainment model for cold hydrogen jets. Since the releases were choked, a source model was used to extrapolate choked conditions at the actual leak diameter to a source diameter where the pressure was atmospheric. Predicted centerline concentrations for hydrogen were compared with the Forschungszentrum Karlsruhe measurements as shown in Figure 3. Centerline concentrations for both room temperature and 80 K jets were well-reproduced by the model. The comparison shown in Figure 3 represents a validation for the cold- and ambient-temperature single phase hydrogen jet model and the high momentum source model. Further validation of the model for colder jets in which the release is two-phased will be made as validation data becomes available.

Conclusions and Future Directions

This project provides key understanding to enable the deployment of early-market hydrogen systems. In FY 2010:

- We analyzed the use of barriers to reducing risk and separation distances to the facility lot line.
- We performed analysis of H\(_2\) releases and delayed ignition deflagration for partially confined spaces (tunnels):
  - A preliminary risk analysis indicates that the level of potential risk from H\(_2\) vehicles accidents does not significantly increase the level of individual risk.
  - Tunnel release modeling approach validated with scaled-tunnel experiments.
- We completed experiments that identified entrained particulates as a likely a source of spontaneous ignition.
- We validated the Sandia turbulent entrainment model for cold hydrogen jets against high-momentum jet data (from Forschungszentrum Karlsruhe tests).

This project will continue to enable hydrogen and fuel cell technology deployment through developing the defensible technical basis for codes and standards. We will perform work to:

- Complete risk and consequence analysis of indoor refueling and operation of hydrogen powered industrial trucks.
- Analyze risk of unintended releases involving other confined spaces (e.g. sheds).
- Incorporate data from existing demonstration and projects into the QRA of hydrogen technologies.
• Improve the existing predictive model of ignition in turbulent flames to include sustained flame light-up probability.
• Understand ignition behavior due to environmental particulate entrainment and other mechanisms.
• Develop an understanding of high-momentum low-temperature hydrogen plume behavior in support of NFPA 2 separation distance activities.
• Perform risk analysis of advanced storage materials in support of NFPA 2 activities.

Accomplishments

Provided methods, data, and analytical support to International Organization for Standardization (ISO) technical committee (TC) 197 working group (WG) 11 Task Group 1 for the implementation of a risk-informed approach to determine separation distances for refueling facilities.

✨ ✨ ✨ ✨ ✨ ✨

Introduction

The development of a set of safety codes and standards for hydrogen facilities is necessary to ensure they are designed and operated safely. To help ensure that a hydrogen facility meets an acceptable level of risk, code and standard development organizations (SDOs) are utilizing risk-informed concepts in developing hydrogen codes and standards. Two SDOs, the National Fire Protection Association (NFPA) and the ISO have been developing standards for gaseous hydrogen.
facilities that specify the facilities have certain safety features, use equipment made of material suitable for a hydrogen environment, and have specified separation distances. Under DOE funding, SNL has been supporting efforts by both of these SDOs to develop the separation distances included in their perspective standards. Important goals in these efforts are to use a defensible science-based approach to establish these requirements and to the extent possible, harmonize the requirements. The successful approach to risk-inform the separation distances in the NFPA standards [1] is a model for establishment of additional requirements by NFPA and other SDOs. In fact, ISO has generally adopted the SNL approach to determine the separation distances in ISO 20100, “Gaseous hydrogen – Fuelling stations” [2]. The efforts to support development of the ISO separation distances by providing methods, data, and analytical support to the ISO TC197 WG11 task group on separation distances are described subsequently. Differences between the approaches and data utilized in NFPA and ISO assessments are highlighted.

Approach

The approaches used in establishing the NFPA and ISO separation distances for gaseous hydrogen facilities are very similar but do have some important differences. Both use Quantitative Risk Assessment (QRA) techniques to evaluate the risk from unintended releases of hydrogen. The risk from the operation of a facility is the product of the frequency and consequences of all credible accidents and can be estimated using QRA. A QRA can be used to identify and quantify scenarios involving the unintended release of hydrogen, identify the significant risk contributors, and to identify potential accident prevention and mitigation strategies to reduce the risk to acceptable levels. A key mitigation feature is the use of separation distances. Under DOE sponsorship, SNL developed the data and methods that were used in quantifying both the frequency and consequence portions of the QRAs performed in both the NFPA and ISO analyses.

A significant difference between the NFPA and ISO approaches is that the NFPA approach is risk-informed while the ISO approach is more properly characterized as risk-based. A risk-informed process utilizes risk insights obtained from QRAs combined with other considerations to establish code requirements. Other considerations used in this risk-informed process include the results of deterministic analyses of selected accident scenarios, the frequency of leakage events at hydrogen facilities, and the use of safety margins to account for uncertainties in the data, methods, and scope of the risk evaluation. In contrast, a risk-based approach only utilizes risk to develop the requirements.

The separation distances in both the NFPA and ISO analysis are based on the selection of a hydrogen leak size that if ignited, would result in unacceptable risk to a person, structure, or equipment. It is generally accepted that separation distances should not be used to provide protection against rare events such as large, catastrophic ruptures. Separation distances should be selected to cover leakage events that may be expected to occur during the facility lifetime, especially small leaks that may occur frequently. It is also desirable to establish separation distances that are not too short and consequently result in unacceptable risk levels. In particular, the associated risk from leakage events that would result in consequences beyond the designated separation distances should be acceptable as determined by consensus. The risk-informed process used in the NFPA approach for selecting the separation distances explicitly included consideration of both the frequency of the selected leak size and the risk from larger leaks. In contrast, the ISO approach only included the evaluation of risk from leakage events (the frequency of expected leakage events was implicitly evaluated in the risk assessment but was not used in making any decisions). It is noted that in both analyses, some of the separation distances were not based on risk arguments. For example, in the ISO analysis the separation distances for large volume systems (i.e., >100 kg hydrogen) was based on the subjective argument that the distances should be greater than for the smaller systems.

The ISO risk-based approach utilizes the conceptual framework shown in Figure 1. In this approach, the cumulative risk from different leak diameters resulting in one or more specified consequence are evaluated against the separation distances required to protect people, equipment, or structures from a specified level of harm. The ISO analysis also included risk to structures and components with the potential for structural or component damage assumed to result in a fatality. The accidental releases of hydrogen were limited to leakage events from four types of components

![FIGURE 1. Risk-Based Approach for Establishing Safety Distances](image-url)
(valves, compressors, hoses, and joints – pipes and tanks were excluded because they were not important risk contributors in the NFPA analysis). The consequences in both the ISO and NFPA analyses were limited to the effects of ignited hydrogen jets and exposure to an ignited hydrogen jet was assumed to result in harm to a target independent of the exposure period. In the ISO QRA, two selected risk acceptance criteria were used to establish the risk-based separation distances using the framework in Figure 1. The separation distances were generated for one of two selected consequence parameters that can result from a hydrogen jet: (1) the extent of the 4% hydrogen envelope or, (2) the exposure to an ignited hydrogen flame. Hydrogen leaks resulting in risk values equal to the risk criteria were used to select the separation distances for both consequence parameters.

In contrast, the leak diameter used as the basis for the separation distances in the NFPA approach was selected to encompass at least 95% of possible leakage events in typical hydrogen gas storage facilities. As a second criterion, the leak diameter was selected such that an event would not likely occur during the life time of the facility due to a low occurrence frequency (i.e., approximately 1E-2/yr). Although larger leaks would not be expected to occur, if they did, it would be desirable that the risk from these larger leaks to a member of the public standing at the selected separation distance be acceptable. Thus, the cumulative risk to the public from larger leaks was evaluated and compared to a single risk guideline, as opposed to the two risk criteria in the ISO approach, using the framework depicted in Figure 1. A risk guideline is essentially a soft risk criterion that allows consideration of uncertainty in the risk assessment when selecting the separation distances when using the framework in Figure 1. The NFPA risk evaluation included separate scenarios involving either early and late ignition of a hydrogen jet and added the risk to an individual from both scenarios to determine the separation distances (the ISO analysis only included one or the other scenario to evaluate the separation distances for each target but this was compensated for by using a higher ignition probability that was equal to the average of the early and late ignition probabilities used in the NFPA analysis for a large release).

The risk measure evaluated in the NFPA QRA was the frequency of a fatality to a person assumed to be constantly present at the facility lot line from an ignited hydrogen jet. The fatality risk from all possible leaks in the modeled facility was evaluated and used to help select a single leak size (expressed as a percentage of the largest flow area in the system) that was used to determine the separation distance for all exposures included in the separation table. In contrast, the ISO analysis included the frequency of exposure of structures and equipments to hydrogen jets (to prevent escalation of a leakage event into a major incident; escalation was assumed to result in a human fatality) in addition to the potential for exposure of humans that would result in fatalities. Thus, different leak diameters were evaluated for different exposures and used to establish the resulting separation distances.

The performance of the QRAs in both assessments required selection of risk criteria/guidelines, establishment of needed data (component leakage frequencies and hydrogen ignition probabilities), and selection of a consequence model. Reference 1 provides a survey of fatality risk criteria that was used to select the risk guidelines utilized in the NFPA assessment. The selected fatality risk guideline of 2E-5/yr was based on three inputs: maintaining the risk at an equivalent level to gasoline stations, using a value that is consistent with countries that have established risk criteria, and limiting the risk from hydrogen releases to a fraction of the risk to an average person from accidental causes. The ISO analysis is using a slightly lower fatality risk criteria of 1E-5/yr for some exposures and a lower risk criteria of 4E-6/yr for selected “critical” exposures believed by some in ISO TC197 WG11 task group to require additional protection (e.g., large volumes of flammable liquids and air intakes in occupied buildings). There is no documented basis for the critical exposure criteria. It is also important to note that the ISO analysis used the two fatality risk criteria listed above for the criteria of exposure of equipment and structures to hydrogen jets based on the assumption that equipment damage would result in a fatality.

In both analyses, data and models generated by SNL were utilized. The hydrogen jet model developed by Houf and Schefer [3] was used in both the NFPA and ISO assessment to evaluate the harm distances associated with hydrogen jets. However, there are some differences in the two analysis in the data used in evaluating the frequency of ignited hydrogen jets. For example, different hydrogen ignition probabilities were used. The NFPA utilized ignition probabilities that changed with leak size and whether the ignition occurred immediately or was delayed. The ISO risk model included a single ignition model that was independent of leak size or ignition time. Although the selected ISO ignition probability was conservative, its use skews the actual risk profile and the resulting selection of the separation distances.

The component hydrogen leakage frequencies utilized in the NFPA were generated using a Bayesian statistical approach [4]. A Bayesian statistical method was selected for use in the data analysis for three reasons. First, this approach allows for the generation of leakage rates for different sizes of leaks which is a critical requirement for estimating the size of a leak to use as the basis for establishing separation distances. Second, it also generates uncertainty distributions for the leakage rates that can be propagated through the QRA.
models to establish the uncertainty in the risk results. Finally, it provides a means for incorporating limited hydrogen-specific leakage data with leakage frequencies from other sources (e.g., the nuclear and petroleum industries) to establish estimates for leakage rates for hydrogen components. An example of the generated hydrogen component leakage frequencies is provided in Figure 2. The component leakage distributions utilized in the ISO analysis are linear versions (on a log-log plot) of the values generated by SNL that as depicted in Figure 2 are conservative over the majority of the leak size range. The linearization of the SNL data distributions was performed to simplify the ISO analysis and allow for a method to generate alternate separation distances for facilities that are substantially different than the example facility used to establish the ISO separation distance table. However, the ISO linear leak frequency distributions actually used in the risk analysis were shifted an order of magnitude when used in the ISO risk analysis (illustrated in Figure 2). The shifting of the leak frequency distributions results in underestimating the risk associated with each leak size and under prediction of the resulting separation distances by a factor of 3 (e.g., it uses the risk for 100% leaks to generate the separation distance for 10% leaks).

Both the ISO and NFPA QRAs also require establishment of representative facilities for evaluating the frequencies of hydrogen leaks and the resulting risk. The NFPA analysis was focused on establishing separation distances for gaseous bulk hydrogen storage systems whereas the ISO analysis was for gaseous fuelling stations. A single facility description was used in the ISO evaluation while four configurations were used in the NFPA evaluation. Two operating pressures were evaluated with the ISO model while four pressures (one per model) were evaluated in the NFPA analysis. Thus, the representative facilities and pressures used in the analysis were substantially different. These differences also resulted in different separation distance table formats in the ISO and NFPA standards.

The NFPA example facilities had multiple components with diameters ranging from 7 mm to 52.5 mm. The ISO analysis used a single component (8 mm) in the facility. In addition, the NFPA analysis assumed that the entire facility was collocated while the ISO analysis divided the facility into modules that were assumed to be adequately separated. The risk from leaks for each module was evaluated and compared with the risk criteria. By separating the gaseous fuelling station in this fashion, the risk to an individual can be underestimated for stations that are not separated. These differences in the assumed facility separation result in significant differences in the estimated leak frequencies and associated risk for the facilities. It also makes it difficult to compare the resulting separation distances.

### Results

Comparison of the separation distances generated in the ISO and NFPA analysis is not possible due to the differences in the scope of the application (i.e., bulk storage versus fuelling station) and the differences in the separation distance table format used in the specific standards (pressure ranges and exposures). However, it is informative to compare the leak size, in terms of the percentage of the flow area, used to determine the separation distances. As indicated in Table 1, the fraction of the flow area used to determine the ISO separation distances for both the regular and critical exposures (i.e., based on a 1E-5/yr and 4E-6/yr risk criterion, respectively) are substantially less than the 3% of the flow area utilized by NFPA (calculated using a 2E-5/yr risk guideline). There are several contributors to the difference including different risk criteria, different facility configurations, separation of the gaseous fuelling station into separate modules, different ignition probabilities, and most importantly, the difference in the application of the hydrogen leak frequencies. Table 1 shows that the leak area would increase by an order of magnitude if the linear leak frequency distributions generated by ISO TC197 WG11 task group were not shifted in the ISO risk assessment. The resulting leak sizes for the ISO regular exposures are closer to the value selected for the NFPA standards.

### Conclusions and Future Directions

As indicated above, the efforts to harmonize the ISO and NFPA approaches was generally successful as both used essentially the same risk approach for evaluating separation distances developed by SNL. Similarly, the SNL consequence models and the hydrogen leak frequency distributions were combined to provide an adequate estimate of the risk associated with hydrogen leaks. However, further work is needed to refine the separation distances and to better understand the impact of different factors on the risk associated with hydrogen leaks.
data generated by SNL were used in both evaluations, although generally conservative approximations of the leak frequencies were generated for the ISO analysis. However, the application of the ISO leak frequency distributions in the QRA underestimates the risk and associated separation distances. International harmonization of regulations, codes and standards enables global market penetration of hydrogen and fuel cell technologies. Toward this end, efforts will continue to evaluate the effect of other differences between the NFPA and ISO analyses in order to harmonize the methodologies and the resulting separation distances to the greatest extent possible.

### References

Objectives

The goal of the Hydrogen Safety Task is to survey and analyze effective risk management techniques, testing methodologies, test data, contribute to development of fundamental knowledge on hydrogen related to hydrogen safety and develop targeted information products that will facilitate the accelerated adoption of hydrogen systems.

The specific objectives of this task are to:

• Survey risk assessment methodologies based on case studies provided by collaborative partners;
• Survey available test data, develop recommendations on modeling and testing methodologies, and share future test plans around which collaborative testing programs can be conducted thus avoiding duplication of work among collaborative partners;
• Collect information on the effects of component or system failures of hydrogen systems; and
• Use the results obtained to develop targeted information packages for selected hydrogen energy stakeholder groups.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Safety section (3.8) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Limited Historical Database
(B) Proprietary Data
(C) Validity of Historical Data
(D) Liability Issues
(E) Variation in Standard Practice of Safety Assessments for Components and Energy Systems
(F) Safety is not Always Treated as a Continuous Process
(G) Expense of Data Collection and Maintenance
(H) Lack of Hydrogen Knowledge by Authorities Having Jurisdiction

Contribution to Achievement of DOE Hydrogen Safety Milestones

This project will contribute to achievement of the following DOE milestones from the Hydrogen Safety section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

• Milestone 2: Develop sensors meeting technical targets (4Q, 2012)
• Milestone 7: Complete Risk mitigation analysis for baseline transportation infrastructure systems (1Q, 2012)
• Milestone 8: Complete investigation of safe refueling protocols for high pressure systems (1Q, 2012)
• Milestone 9: Complete risk mitigation analysis for advances transportation infrastructure systems (1Q, 2012)
• Milestone 12: Complete research needed to fill data gaps on hydrogen properties and behaviors (2Q, 2010)

Accomplishments

In 2009, the task continued to compare experimental data with risk analysis methods to validate the models and further close the knowledge gaps identified in earlier work. The subtask also completed the development of the Hydrogen Technical Experimental (HyTEx) database. Starting in late 2009, the populating of the database with data from participating countries was begun. Technical progress
on the development of Risk Informed Approval Criteria for hydrogen projects to provide a solid basis for Risk Informed Codes and Standards was completed.

- Established a list of relevant engineering models that had been used to evaluate the safety of hydrogen systems, categorized them, and performed a comparative analysis with actual testing data.
- Several dispersion models were further developed in 2009 by extending their capabilities to include surface and transient effects (November 2009).
- Developed a more detailed thermal radiation model.
- Completed development of the HyTEX database.
- Task participants presented many papers at technical conferences on subjects that dealt with the collaborative work.
- The International Energy Agency (IEA) Hydrogen Implementing Agreement Co-organized the September 2009 Third International Conference on Hydrogen Safety and Task 19 members presented more than 10 technical papers.

Introduction

Acceptability of new systems is traditionally measured against regulations, industry and company practices and the judgment of design and maintenance engineers, however contemporary practice also incorporates systematic methods to balance risk measurement and risk criteria with costs. Management decisions are increasingly relying on quantitative risk assessment (QRA) for managing the attainment of acceptable levels of safety, reliability and environmental protection in the most effective manner. QRA is being applied more frequently to individual projects and may be requested by regulators to assist in making acceptance and permitting decisions. This task was approved by the executive committee of the IEA Hydrogen Implementing Agreement in October 2004. The Task is currently comprised of 11 participating countries.

Approach

This task, aimed at reducing the barriers to widespread adoption of hydrogen energy systems, is being accomplished within three subtasks:

Subtask A. Risk Management - To survey QRA methodologies and compare assessments of hydrogen systems with conventional fuels to develop recommendations for modeling and testing methodologies around which collaborative testing programs can be conducted. Subtask A Risk Management is concentrating on the following four activities:

- Develop uniform risk acceptance criteria and establish link with risk-informed codes and standards.
- Develop a list of appropriate engineering models and modeling tools. Develop simple but realistic physical effects models for all typical accident phenomena (i.e., jet fires, vapor cloud explosions, flash fires, boiling liquid expanding vapor explosions, pool fires, etc.) for education and training, design evaluation and simplified quantitative risk analysis purposes.
- Develop a methodology for consistent site risk assessment based on the hydrogen quantitative risk assessment (HyQRA) approach.
- Release updates to all published products: risk assessment methodology survey, knowledge gaps white paper and review and comparison of risk assessment studies.

Subtask B. Testing and Experimental Program - To conduct a collaborative testing program to evaluate the effects of equipment or system failures under a range of real life scenarios, environments and mitigation measures. This subtask will summarize and ultimately coordinate and guide the experimental programs being conducted within the 11 countries participating in the task. The approach is to identify such testing programs, the facilities being used, and to coordinate the activities to fill in the data and knowledge gaps for the development of risk informed codes and standards. Subtask B focuses on both testing and experimental data, i.e., testing data as collected by checking the performance of applications and equipment and experimental data as collected by experiments with hydrogen release, ignition, fire, explosions and preventive and protective measures.

Subtask C. Information Dissemination - To disseminate results of the task through targeted information packages for stakeholders. An important aspect of information dissemination is to ensure that the review and vetting of all work products for Task 19 are consistent with the requirements and procedures for producing, approving and distributing various types of IEA reports and other information products. A protocol has been adopted by Task 19 partners and is being applied appropriately for Task 19 work. It is expected that several of these Subtask C products will be updated and enhanced over the course of the period covering Task 19 through October, 2010.

Results

In 2009, the task continued to compare experimental data with risk analysis methods to validate the models and further close the knowledge gaps identified in earlier work. The subtask also completed
the development of the HyTEx database. Starting in late 2009, the populating of the database with data from participating countries was begun. Technical progress on the development of Risk Informed Approval Criteria for hydrogen projects to provide a solid basis for Risk Informed Codes and Standards was completed.

Risk Management

Prior to 2009, the task had established a list of relevant engineering models that had been used to evaluate the safety of hydrogen systems and categorized them. In 2009 they were compared to each other to assess their limitations and validity. Part of this effort was achieved through comparing the engineering models to actual testing data. Several dispersion models were further developed in 2009 by extending their capabilities to include surface and transient effects. A more detailed thermal radiation model was also developed that would account for crosswinds.

Testing and Experimental Program

An inventory of existing testing and experimental data is in progress and the participants have started sharing information during and beyond the Task 19 meetings. This has been extended (and will be in the future activities) by a search by the partners for any data existing in their respective countries and around the world. In order to secure a continuing refinement of the survey, the data and/or references will be stored in the HyTEx database. The Subtask B databases HyTEx, HYPRO and HYTEF will be used as a source of information for any missing data in relation to the knowledge gaps as defined by and resulting from the Subtask A activities. If data is not available this could give rise to recommendations on new testing and experimental programs. The existing data can also be checked on its relevance and completeness. A first set of knowledge gaps has been identified in Subtask A and described in the white paper ‘Knowledge Gaps in Hydrogen Safety.’ Currently identified knowledge gaps are: spontaneous ignition, protective barriers and consequence modeling.

Development of Targeted Information Packages for Stakeholder Groups

The targeting of information packages for selected hydrogen energy stakeholder groups is central to the work and objectives of Task 19, currently focused on risk assessment methodologies and studies, testing and experimental programs, safety training and knowledge resources and hydrogen facility siting. Information packages can take a variety of forms: IEA publications, publicly available Web-based tools, databases and documents for use by Task 19 partners.

Conclusions and Future Directions

The current task is scheduled to be completed in October 2010 and a new task on hydrogen safety is being developed to continue to build on the very effective collaboration of this six-year effort. It is anticipated that one of the major outcomes of this ongoing work will a technical and credible basis for the development of risk informed codes and standards that will not be unnecessarily restrictive. This will eliminate a major barrier to the widespread commercial adoption of hydrogen energy systems. Future work will support this goal by improving hydrogen risk assessment methodologies and quantitative risk analysis and closing knowledge gaps with regard to consequences of hydrogen related accidents and incidents, the effects of mitigation methods, and failure probabilities of system components.

FY 2010 Publications/Presentations

Objectives

- Select and finalize the hydrogen sensor chemistry that possesses the optimum sensitivity, reliability, reproducibility, and aging performance.
- Design and fabricate optoelectronic board for hydrogen leak sensor.
- Assemble and test the optoelectronic interface for the sensor prototype.
- Test and validate the fully packaged prototype performance at the National Renewable Energy Laboratory (NREL).

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Safety section of the DOE Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan (MYRDDP), page 38-7:

(D) Liability Issues: Potential liability issues and lack of insurability are serious concerns that could affect the commercialization of hydrogen technologies.

Barriers addressed by this project from other sections of the MYRDDP include:

- Delivery:
  (I) Hydrogen Leakage and Sensors (page 3.2-20)
- Storage:
  (H) Balance of Plant (BOP) Components (page 3.3-14)
- Manufacturing R&D:
  (F) Low Levels of Quality Control and Inflexible Processes (page 3.5-11)
- Technology Validation:
  (C) Lack of Hydrogen Refueling Infrastructure Performance and Availability Data (page 3.6-8)

Contribution to Achievement of DOE Safety, Codes & Standards Milestones

This project will contribute to the achievement of the following DOE milestones from the Hydrogen Safety/Leak Detection Technology section of the Fuel Cell Technologies Program MYRDDP:

- Milestone 2: Develop sensors meeting technical targets. (4Q, 2012)
- Milestone 3: Develop leak detection devices for pipeline systems. (4Q, 2015)

Accomplishments

This continuation of a project that was initiated on June 1st, 2008 has been extended through November 2010. The initial work focused on exploring a family of colorimetric hydrogen sensor formulations and physical embodiments for different venues and markets. These included porous glass “optrodes” for integration with optical fiber sensors, polymer integrated optic chip sensors, and fully-distributed fiber optic sensors. Work on the latter has been presented by R.G. Zalosh and N.F. Barilo [1] from the Pacific Northwest National Laboratory at the International Hydrogen Conference in France, 2009.

In the past year, IOS has focused on developing and testing an optrode-based point H₂ detector technical accomplishments for the past 12 months are summarized below:

- A process for reproducible fabrication of hydrogen sensor substrates was optimized and tested. The statistical variance in different batches of sensor elements was observed to be (~0.04±0.01) from batch-to-batch.
The development of the optoelectronic readout device was finalized. Two generations of fully functional hydrogen sensor prototype devices were fabricated, tested and optimized.

Signal processing algorithms were developed to linearize optrode response under various environmental conditions. The algorithms are currently undergoing validation and optimization testing before release of the final version.

The hydrogen sensor was tested and validated, for reversibility, repeatability, accuracy, and environmental dependence, confirming IOS results at NREL.

IOS presented a briefing, and a working prototype unit, during the 2010 Hydrogen and Vehicle Technologies Annual Merit Review in Washington, D.C. During this review, we met with a number of parties interested in the hydrogen sensor and its performance.

Introduction

Hydrogen safety is an important key to commercializing hydrogen energy technologies, and to facilitate the use of hydrogen as a green energy source. The principal objective of this DOE project is to integrate IOS’ proprietary hydrogen indicator chemistry with optical and optoelectronic designs, and advanced signal processing, to create a prototype point-sensor system with well-defined sensing characteristics for various markets, including fuel cell-powered passenger vehicles, hydrogen generation and refueling stations, storage locations, and other situations.

Each IOS hydrogen sensor uses an optoelectronic platform to monitor an optically conductive matrix hosting a colorimetric indicator. Upon hydrogen exposure, the sensor element changes color, and the sensor uses the resulting optical signal to calculate hydrogen concentration.

IOS’ hydrogen sensor approach is unique in many aspects. First, it uses an intrinsically safe sensing element that functions without the heat required by many electronic hydrogen sensors, and can be remotely read without any electrical connection. Second, the unit has a faster response time and higher sensitivity levels, over a wide range of environmental conditions (i.e., temperature and humidity) than its counterparts. The sensor module can also be cabled to a readout unit for remote monitoring applications.

Approach

IOS has studied three formats for hydrogen sensors: porous glass substrates (optrodes), evanescent-field polymer-clad silica optical fiber sensors (distributed sensors), and integrated-optic chip sensors.

A comparative evaluation of the three sensor matrices revealed that, overall, the more technologically mature porous glass optrodes performed the best, and thus the optrodes were chosen as the hydrogen indicator matrix for the final product prototype. Sensor prototypes, each designed to accommodate both a hydrogen-sensitized optrode and an undoped porous glass “reference optrode,” were fabricated and tested. The optrode response time is rapid (time to reach 90% of full scale: T90 ≈ 5-8 seconds); software routines have been developed to provide a user-settable detection alarm at low hydrogen levels (down to 0.02% hydrogen in air).

Results

Optrode development focused on optimizing the optrode substrate fabrication steps to achieve the optimum response characteristics, a reproducible fabrication process, longer shelf-life times, and better resistance to chemical gas interferences. The operational specifications are summarized in Table 1.

LOD – limit of detection; RH – relative humidity

The design, fabrication, assembly, and testing of the optoelectronic readout unit resulted in the construction of two hardware generations. After successfully testing and characterizing the first generation development prototype, we then developed the second generation (final prototype) unit shown in Figure 1. Among other requirements, the new version was designed with scaled up manufacturability and mass production in mind. Multiple user-friendly features, such as the replaceable sensor module, were also added. Figure 1 shows the fully functional final prototype in an anodized aluminum enclosure. The new prototype is smaller than the
The new device can be powered with a wall plug adapter, a universal serial bus, or the built-in rechargeable battery. This unit is an ideal handheld device that can also be used as a wall mounted unit. The detachable sensor module is mounted on a printed circuit board that was adapted from the design of a secure digital memory card, which is commonly used in today’s consumer electronics. The sensor module is inserted into the main measuring module using a push-pull locking and removal mechanism. The replaceable sensor module containing a hydrogen-sensitive optrode and a reference optrode is shown in Figure 1.

Repeatability/Reversibility

Excellent signal reversibility and repeatability are now being observed for our optimized optrodes, as illustrated by the test data shown in Figure 2. High degree of reproducibility in sensor fabrication was achieved by controlled sensors preparation protocol. Figure 3 illustrates the signal changes for two various batches, error bars represent the standard deviation from the average value (~0.04±0.01).

Environmental Stability

The detection and quantification of hydrogen was observed under a wide range of humidity and temperature, as shown in Figure 4; some degree of dependence on RH was noted, while at different temperatures, variations in the relative humidity were also observed (from 30 to 45%), and therefore, the sensor signal was not only affected by the temperature, but also by the humidity. Because of this factor, an accurate calibration curve for temperature dependence alone cannot be extracted from these tests; however, we have qualitatively identified the thermal dependence of the sensor.
Reproducible Fabrication/Longevity Studies

Fabricated hydrogen sensor optrodes were placed in long-term longevity studies where the optrodes were exposed to various levels of hydrogen (0.2 and 1.0%) at standard conditions (RH ~40%, and T=25°C). The signal change at a fixed hydrogen concentration showed no noticeable change over an aging period of five months (see Figure 5). We envision that a minimum longevity time of one year can be obtained. The accuracy and precision of hydrogen optrode measurements are listed in Table 2. A high degree of optrode fabrication reproducibility was achieved; data summarizing the inter-batch performance versus the intra-batch performance is shown in Figure 6.

Conclusions and Future Directions

We have developed sensitive, stable, reversible colorimetric hydrogen optrodes, and incorporated them in unique compact, hydrogen sensor units. Future directions include:

- “Map” the temperature/humidity parameter space using formally designed experiments to provide complete coverage.
- Develop, test, and optimize data processing algorithms to fully compensate for environmental effects.
- Perform field tests to validate sensor performance in a variety of environments and applications.
- Explore commercial possibilities for the different hydrogen sensor embodiments.
Special Recognitions & Awards/Patents Issued

An application is currently under examination in the United States Patent Office (USPTO); during this quarter, IOS did not receive any communications from the USPTO on this matter.

Subcontractors:
• Volpentest HAMMER Training and Education Center, Richland, WA
  Dennis McCall, James Bryan, Scott Jones
• California Fuel Cell Partnership (CaFCP), Sacramento, CA
  Jennifer Hamilton

Project Start Date:  October 1, 2004
Project End Date:  Project continuation and direction determined annually by DOE

Objectives

• Support the successful demonstration and deployment of hydrogen and fuel cell technologies by providing technically accurate hydrogen safety and emergency response information to first responders.

• Provide a one-day first responder training course, “Hydrogen Emergency Response Training for First Responders,” that integrates the use of DOE’s mobile hydrogen fuel cell vehicle (FCV) prop (initial offering in Fiscal Year [FY] 2009).

• Continue to support the Web-based awareness-level course, “Introduction to Hydrogen Safety for First Responders,” (initial offering in FY 2007).

• Disseminate first responder hydrogen safety educational materials at appropriate conferences to raise awareness.

Technical Barriers

This project addresses the following technical barriers from both the Education (ED) and Safety (SAF) sections of the Fuel Cell Technologies (FCT) Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Readily Available, Objective, and Technically Accurate Information (ED)

(C) Disconnect Between Hydrogen Information and Dissemination Networks (ED)

(D) Lack of Educated Trainers and Training Opportunities (ED)

(H) Lack of Hydrogen Knowledge by Authorities Having Jurisdiction (SAF)

(I) Lack of Hydrogen Training Facilities for Emergency Responders (SAF)

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education section (3.9) of the FCT Program Multi-Year Research, Development and Demonstration Plan:

• Milestone 6: Update “prop-course” for first responders (4Q, 2011).

• Milestone 7: Update “awareness-level” information package for first responders (4Q, 2012).

• Milestone 9: Update “prop-course” for first responders (4Q, 2014).

• Milestone 10: Update “awareness-level” information package for first responders (4Q, 2015).

In addition, the following milestones were met in previous years:

• Milestone 1: Develop “awareness-level” information package for first responders (4Q, 2006).

• Milestone 3: Develop “prop-course” using hands-on training devices for first responders (4Q, 2008).

• Milestone 4: Update “awareness-level” information package for first responders (4Q, 2009).

Accomplishments

• Prop-Based Course: Three sessions were held at the Hazardous Materials Management and Emergency Response (HAMMER) facility in June 2009, August 2009, and April 2010 to train 66 students from 14 states. Extremely positive feedback reinforced the value of this course.

• Awareness-Level Course: Our Web site still averages 500-500 unique visits per month from almost every state and some foreign countries. We registered the course on the TrainingFinder Realtime Affiliate Network (TRAIN) Web site for broader dissemination to first responders. TRAIN is a central repository for public health training courses.
Almost 30,000 TRAIN users identify themselves as emergency responders [1].

- **Outreach**: Compact discs (CDs) of the awareness-level course, laminated posters, and Firehouse article reprints were distributed through the DOE Energy Efficiency and Renewable Energy Information Center [2]. PNNL and HAMMER hosted booths at two key first responder conferences.

---

**Introduction**

Safety in all aspects of a future hydrogen infrastructure is a top priority, and safety concerns influence all DOE hydrogen and fuel cell projects. Despite the most concerted effort, however, no energy system can be made 100% risk-free. Therefore, for any fuel and energy system, a suitably trained emergency response force is an essential component of a viable infrastructure. The FCT Program Office has identified training of emergency response personnel as a high priority, not only because these personnel need to understand how to respond to a hydrogen incident, but also because firefighters and other emergency responders are influential in their communities and can be a positive force in the introduction of hydrogen and fuel cells into local markets.

This project is employing the Occupational Safety and Health Administration (OSHA) and National Fire Protection Association (NFPA) frameworks for hazardous materials emergency response training to develop a tiered hydrogen safety education program for emergency responders. The overall first-responder education program will be developed over a number of years. The effort started with development and distribution of the awareness-level Web-based course in FY 2006-2007. A more advanced course and materials to facilitate education were developed in FY 2008-2009, complementing the design, construction, and operation of a fuel cell vehicle prop (developed under PNNL’s Hydrogen Safety project). In addition, PNNL has implemented outreach efforts to key stakeholder groups to facilitate delivery of the training to a broad audience.

---

**Approach**

PNNL works with subject matter experts in hydrogen safety and first responder training (e.g., the PNNL Hydrogen Safety Panel, other national laboratories, HAMMER, CaFCP), to develop hydrogen safety course materials. Draft materials are prepared and undergo considerable review and revision before being released. The PNNL team works with DOE to make stakeholder groups aware of training opportunities and to provide “live” training when appropriate. The prop-based course has been given at the HAMMER facility, but plans are in progress to deliver the course at three training centers in California during 2010 in order to reach larger audiences in areas where hydrogen and fuel cell technologies are being deployed.

---

**Results**

**Prop-Based Course**: The focus of the curriculum is on teaching first responders what is the same and what is different about hydrogen and FCVs as compared to conventional fuels and vehicles. Course evaluation forms are distributed and feedback obtained at each class to help us improve the course content and delivery. Based on feedback from the three class sessions held this year (June 2009, August 2009, and April 2010), we concluded that first responders are comfortable with hydrogen and prepared to operate in a safe and effective manner, if a hydrogen incident should occur in their jurisdiction.

The FCV prop (shown in Figure 1) demonstrates potential conditions that could be encountered during the control and suppression of a FCV fire. The prop has been integrated into the “Hydrogen Emergency Response Training for First Responders” course developed by PNNL, HAMMER, and the CaFCP for DOE. The figure shows a team of firefighters responding to a multi-vehicle accident involving a hydrogen FCV and two conventional vehicles.

**Web-Based Course**: Since the online course was launched in January 2007, there have been more than 17,000 unique visitors to the Web site. The site is still averaging 300-500 unique visitors each month from almost every state and many foreign countries. Typical users include the fire prevention/protection community, firefighters, fire department education coordinators, fire marshals, fire plan examiners/inspectors, code officials, law enforcement officials, and representatives from industry, universities, the military, and non-profit organizations. Feedback on the course has been positive.
**Outreach**: To distribute information and raise awareness about hydrogen safety and the DOE-sponsored courses, PNNL and HAMMER staff participated in two major first-responder conferences in FY 2010:

- Fire Department Instructor’s Conference, April 2010, Indianapolis, IN.
- Fire Rescue International, August 2010, Chicago, IL.

Booths were set up to display and disseminate posters, announcements of course offerings, hydrogen safety literature, and awareness-level course CDs.

**Conclusions and Future Directions**

The introductory Web-based course has been quite successful, based on the usage recorded and feedback received. The course is fulfilling a need expressed by the first responder community to receive more information about hydrogen and fuel cells so they will be prepared in the rare event of a hydrogen incident. The in-depth prop-based course builds on that success and is very useful in giving first responders a hands-on experience with simulated FCV incidents that integrates well with classroom training. PNNL will continue to update both courses as needed to reflect current applications and markets for hydrogen and fuel cells.

There is an identified need for the prop course curriculum to achieve a better balance between the vehicles and stationary facilities modules, through the development of some type of prop for stationary applications of fuel cells. A virtual hydrogen fueling station model having dual capabilities to simulate both outdoor fueling of passenger FCVs and indoor fueling of hydrogen forklifts could address that need. We are planning to develop a virtual model with the following capabilities and attributes:

- Visualizations of outdoor and indoor hydrogen dispensing systems.
- Text pop-ups describing the key components of outdoor and indoor hydrogen fueling stations (e.g., compressor, cylinder storage, dispenser).
- Animations of 30-second emergency response scenarios that could occur at outdoor and indoor fueling stations (e.g., various hydrogen leaks and fires).
- Narration of scripts for outdoor and indoor fueling scenarios.

The prop course will be offered at three first responder training facilities in California in FY 2010 (Sunnyvale Public Safety Department in Sunnyvale, Rio Hondo Community College Fire Academy in Santa Fe Springs, and the Orange County Fire Authority in Irvine). The prop will be transported to California in its trailer and left at each site for about a week. Three classes will be given at each site, resulting in a total of ~300 first responders trained. In future years, the prop will be transported to other locations across the country for use in delivery of this course at training centers in areas that have emerging deployments of hydrogen and fuel cell technologies. PNNL will also work with DOE and other stakeholders to determine what, if any, additional types of educational courses and materials are warranted, and to develop and implement plans to provide education to specific groups.

**FY 2010 Publications/Presentations**

**References**

Objectives

- Prepare safety training materials for researchers unfamiliar with hydrogen technology.
- Prepare advanced safety training materials for personnel in charge of hydrogen systems.

Technical Barriers

This project addresses the following technical barriers from the Hydrogen Safety section (3.8) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (H) Lack of Hydrogen Knowledge by Authorities Having Jurisdiction
- (I) Lack of Hydrogen Training Facilities

Contribution to Achievement of DOE Hydrogen Safety Milestones

This project will contribute to achievement of the following DOE milestones from the Hydrogen Safety section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 17. Identify user needs for safety bibliography and incident databases. (1Q, 2006)

Accomplishments

- Delivered a final version of the Web-based class that incorporated reviewers’ comments.
- Started working toward a hands-on safety class for technical personnel.

Introduction

LLNL has been conducting hydrogen research for more than 50 years, starting with national security applications and continuing with hydrogen energy research. For many of these years, LLNL was designated as the pressure safety training facility for the whole DOE complex and other government institutions such as the National Aeronautics and Space Administration. Many technicians and researchers visited LLNL to receive appropriate training on many aspects of pressure safety, including hydrogen technology, cryogenics, leak detection, and vacuum technology.

The national security hydrogen and high-pressure research conducted at LLNL demanded unique testing facilities, and these were built with funding from DOE defense programs. These facilities include a high-pressure laboratory equipped with four hydrogen-compatible test cells, each rated for 80,000 psi, and 4 pounds of trinitrotoluene (TNT) equivalent stored energy. LLNL also has a high explosive test facility (Site 300) for high-energy experiments with many pounds of TNT-equivalent and many kilograms of hydrogen. Experiments in Site 300 are typically conducted in outdoor firing tables and monitored from the safety of a bunker. The remote location of this facility protects employees and property from any hazard.

These unique facilities and the expertise necessary to operate them are now being made available for hydrogen energy research through the development of training materials that may contribute to safe operation within the many institutions working for the Hydrogen Program.

Approach

We are planning to pursue a two-pronged approach to hydrogen safety training:

- Most researchers participating in the Hydrogen Program can benefit from basic training on hydrogen and pressure safety. This Web-based training can be completed in ~2 hours.
- Pressure operators in charge of setting up experimental equipment require comprehensive education on all aspects of hydrogen operation, in addition to the Web-based training on hydrogen fundamentals.
Results

We have developed a Web-based class with basic safety information for hydrogen researchers available through the following link: http://www.h2labsafety.org.

Readers are invited to take the class and submit comments to the authors that may improve the learning experience and/or update the class information.

The class takes ~2 hours for completion, and includes six modules:

- **Introduction** (5 minutes): course description, navigation, study guides.
- **Hydrogen Properties** (20 minutes): buoyancy, dispersion, ignition, flame and leak detection, ventilation, ignition sources, protective equipment.
- **Pressure Safety** (60 minutes): pressurized systems (Figure 1), system components, stored energy considerations and calculations, basic design criteria, material properties, pressure ratings, safety factors, gas cylinder use and storage.
- **Cryogenic Safety** (15 minutes): cryogenic fluid properties, thermal hazards, pressure hazards, expansion charts, asphyxiation, liquid air, safety measures.
- **Emergency Response** (15 minutes): hydrogen posted signs, alarms, emergency crews, emergency instructions.
- **Codes and Standards** (15 minutes): importance, organizations developing codes relevant to hydrogen, applicability, local and external resources.

Each module is followed by a quiz. After successful completion of all module quizzes (85% passing grade) the student will receive class credit. If a module quiz is failed, the student has the opportunity to review the module and retake that quiz.

This is a self-paced course that may take several hours to complete. However, it is not necessary to complete the course at one time. This course will track progress, allowing students to leave the course and continue where they left off when they return.

Navigation through the class is simple: from any location the student can easily jump to different modules at any time by pressing the “menu” button in the upper part of the screen.

The pressure safety module is the longest and most demanding module of the course. To better assist the student in learning the information, this module provides practice questions as a preview of the module quiz. We recommend students to carefully go through these practice questions to be better prepared for the end of module quiz.

In addition to the Web-based fundamentals class, we are also working on the development of a hands-on hydrogen safety class for pressure operators. This comprehensive training includes basic hydrogen safety, regulators, relief devices, leak detection, and cryogenics safety, followed by hands-on assembly and test of a hydrogen pressure system and a final evaluation. Training can be conducted during a three-day session at LLNL or at remote institutions with appropriate facilities.

While work in this more comprehensive “hands-on” class is just starting, we have been able to prepare two working tables and instructional materials including segmented pressure components (regulators, valves, FIGURE 1. A Screen Image from the Pressure Safety Module of the Web-based “Hydrogen Safety Class for Researchers”

Working table  Pressure vessels  Regulator

Relief device  Pressure gauge  CGA fitting

FIGURE 2. A Working Table and Different Pressure Components Cut to Illustrate Internal Structure and Operability
gauges; Figure 2). We anticipate Fiscal Year (FY) 2011 completion and start of instruction.

**Conclusions and Future Directions**

- We are contributing to safe hydrogen operations by developing instructional materials for researchers and operators.
- Web-based class (now complete) addresses the need of laboratory researchers handling small amounts of hydrogen.
- Hands-on class (in process) will present in-depth information for technical personnel tasked with installing and testing hydrogen systems.
- Participation from the hydrogen community will improve the class through suggestions, bug reports, etc.

E-mail: Antonio.Ruiz@ee.doe.gov

Start Date: August 2007
Projected End Date: Project continuation and direction determined annually by DOE

Objectives

- Develop sensing technology that achieves DOE research and development (R&D) targets for hydrogen safety sensors.
- Characterization of response time, recovery time, sensitivity and accuracy within the operating temperature range.
- Demonstrate sensor performance and compliance with safety goals.
- Establish partnership to develop pre-commercial sensor prototype.

Technical Barriers

The project addresses the following technical barriers from the Hydrogen Safety section (3.8.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan (October 2007):

(D) Liability Issues
(E) Variation in Standard Practice of Safety Assessments for Components and Energy Systems

Technical Targets

The long-term project objective is to achieve commercialization and regulatory acceptance of fiber-reinforced polymer pipeline technology for hydrogen transmission and distribution. Accordingly, the project tasks address the challenges associated with meeting the DOE hydrogen delivery performance and cost targets for 2017:

- Measurement Range: 0.1%-10%
- Operating Temperature: -50 to 80°C
- Response Time: under one second
- Accuracy: 5% of full-scale
- Gas environment: ambient air, 10%-98% relative humidity range
- Lifetime: 10 years
- Resistant to interferents (e.g., hydrocarbons)

Accomplishments

- Developed new highly porous nanoparticle palladium-coated microcantilever sensor arrays.
- Developed a new wet chemical Pd film deposition technique on Ag/Cr coated cantilever sensors using a galvanic PdCl₂ exchange reaction.
- Demonstrated that large sensor surface area in comparison with film volume leads to very fast sensor response and recovery times.
- Completed selectivity, sensitivity, response and recovery time and regeneration analyses of the nanoporous Pd coated sensors and demonstrated excellent response characteristics.
- Demonstrated excellent stability, repeatability and life measurements that have been observed during more than a year of operation.
- Fabricated first field portable instrument to demonstrate operational performance of the Pd based sensors.
- Identified sensor commercialization partners and are negotiating commercialization agreements.

Introduction

Utilization of hydrogen as a transportation fuel requires comprehensive safety management during its storage, handling and use. Although safety-by-design and passive mitigation systems are the preferred methods for safety management, it is vitally important to develop technologies that can detect hydrogen releases and alert to system failures. The DOE Fuel Cell Program’s Hydrogen Safety sub-program recognizes the need to develop and commercialize hydrogen sensors that provide the appropriate response time and the sensitivity and accuracy necessary for use in safety applications, thereby reducing risk and helping to establish public confidence in the hydrogen infrastructure.

This project addresses the above needs by developing, proving and commercializing a hydrogen detection device based on nanostructured thin film...
palladium microcantilever arrays. This hydrogen sensor has been shown to provide major performance improvements over existing and other recently developed sensors. The overall objective is to develop sensor technology that achieves DOE R&D targets for hydrogen safety sensors at lower cost and with the potential for wide-area hydrogen gas detection.

**Approach**

Microcantilever-based chemical sensors were first seriously explored as a trace gas sensing technology in 1990s with the first reported use of Pd coated microcantilevers for sensing H2 occurring in 2000. Adsorption of a gas onto a thin film surface can cause large changes in stress and consequent bending of a thin cantilever structure. This bending response can be sensitively detected using piezoresistive, capacitive and optical techniques such that sub part-per-billion (ppb) sensitivities are achievable. Microcantilever-based chemical sensors have been shown to have high sensitivity, wide dynamic range and fast response times. Optically read microcantilever sensors are particularly advantageous in the presence of combustible or explosive gases and vapors (e.g. H2) due the possibility of vapor ignition when using heated or electrically operated sensors. Other advantages of this sensing technique include very low power consumption, and their potential use in distributed wide area sensor networks allowing multiple low cost chemical sensors to be located at storage or processing facilities (e.g. in the H2 fuel economy) or on H2-powered or transportation vehicles [1].

One of the most challenging aspects of detecting and quantifying the amount of a low concentration gas or vapor in the environment is the effect of potential interferents on the gas sensor response. Interferents can lead to false positive responses or suppressed responses to the gas being detected. One approach to overcoming this problem is the use of a multiplexed sensor array, with each sensor having a distinct sensitivity response to the gas or vapor of interest and any potential interferents. A much simpler approach is to use a single sensor, or small array of sensors, to sense a single gas species, as the computational processing of the array responses is much less intensive than for the multiplexed sensor array. The single sensor mode of operation is feasible if a coating can be found that responds primarily to the gas species of interest with minimal response to any potential interferents. Palladium has previously been used as a sensing medium in a number of sensor technologies due to its strong and reasonably unique response to H2. The possibility of using Pd-coated microcantilever sensors to detect H2 leaks has been examined in several previous studies.

Approach

The issue with most previous thin film Pd studies, and reasonably unique response to H2. The possibility of using Pd-coated microcantilever sensors to detect H2 leaks has been examined in several previous studies. The single sensor response and recovery times are far longer than acceptable for most applications; response times for these microcantilever-based H2 sensor studies varied from a few minutes to as long as 1 hour. The long response and recovery times are attributed to the long diffusion time for elemental hydrogen to diffuse into and out of the palladium film to form palladium hydride.

Our approach is to use a new nanostructured Pd/Ag alloy that we developed specifically for the hydrogen sensing application. Microcantilever sensors coated with this alloy have fast, near ideal response characteristics when monitoring low concentration H2 gas. In particular, the response and recovery times measured with these sensors are far shorter (<10 s) than those reported in all previous microcantilever-based H2 sensor studies. The development work performed to optimize the performance of our sensor consisted of efforts to increase the sensitivity and dynamic range, to minimize the response and recovery times, to improve its resistance to interferents, and to increase its accuracy, repeatability and lifetime. We are presently working on the development of a prototype that can be performance-evaluated by third parties and adapting the sensor system for use in wide-area sensing.

**Results**

We conducted sensitivity and performance measurements of the Pd-Ag functionalized, optically read microcantilever using a benchtop setup consisting of the microcantilever in a gas flow cell, an optical readout system, a flow control valve and sample loop, and a LabVIEW®-based data acquisition system. The threshold and dynamic range test results revealed a lower-limit-detection of 0.01% (100 ppm) H2 in argon, with three orders of magnitude dynamic range. Response and recovery times for 4% H2 in argon were <3 s and <10 s, respectively. Over an eight-month period the sensor accuracy and repeatability remained constant within ±2%, indicating that the projected operational lifetime of this early version of the sensor could be as long as several years. Measurements of sensor specificity to common impurities and carrier gases (CO2, CH4, H2O, N2, He, CO) showed that in all cases, the responses from the interferents were an order of magnitude or more smaller than that observed for H2 at similar concentrations (see Figure 1). This degree of discrimination against interfering species will be adequate in all but the most demanding applications.

As illustrated in Table 1, in laboratory tests completed to date, we demonstrated that our microcantilever-based H2 sensors meet all but the most stringent requirements for automotive sensing applications.
We have demonstrated that Pd-Ag functionalized, optically read microcantilever H₂ sensors have nearly ideal attributes required for distributed low cost sensing of hydrogen leaks in many applications. These include high sensitivity, wide dynamic range, adequate response and recovery times and repeatable response. These sensors have been operating in a laboratory environment for more than a year without noticeable changes in sensitivity, specificity and response and recovery times. Work is also progressing on the development of low-cost portable detector prototypes that can be used to validate the expected performance of this potentially lower cost, better performing sensing technique. To this end, we have developed and done preliminary performance studies on two generations of portable instrumentation with encouraging results. We plan to report on these studies at a later date.

**Conclusions and Future Directions**

In the next project year we plan to:

- Improve H₂ sensor response in several areas:
  - Faster response/recovery times: shorten recovery from 3-10 s to <1 sec.
  - Improve specificity by reducing response to water vapor.
  - Continue studies on potential interferents such as CO, EtOH, CH₄, H₂S.
  - Perform studies on multi-component mixtures.
- File patents applications on techniques, methods, coatings, applications.
- Finalize commercialization partnership agreements.

**TABLE 1.** ORNL microcantilever-based H₂ sensor meets all requirements for stationary and automotive applications and possibly exceeds performance of other recent sensors.

X. EDUCATION
Introduction

The Education sub-program seeks to support and facilitate hydrogen and fuel cell demonstration, deployment, and early market introduction by providing technically accurate and objective information to key target audiences that can help transform the market (see Table 1).

TABLE 1. Key Target Audiences for the Education Sub-Program

<table>

The Education sub-program includes the development and dissemination of information resources as well as training. It considers a balanced message to help target audiences become familiar with hydrogen and fuel cell technologies and how they fit in the portfolio of energy and efficiency options. To aid with market introduction, the sub-program helps to develop an accurate understanding of hydrogen safety, to recognize opportunities for deployment in near-term markets, and to understand the role of early markets in facilitating use of hydrogen and fuel cell technologies.

Goals

Educate key audiences about hydrogen and fuel cell technologies to facilitate near-term demonstration and long-term commercialization and market acceptance.

Objectives

- By 2011, expand availability of university curricula developed under Fiscal Year (FY) 2008 solicitation projects and expand availability of case studies for near-term market applications.
- By 2012, complete analysis to identify domestic employment and workforce development opportunities for early market hydrogen and fuel cell applications.

FY 2010 Status

The Education sub-program works in collaboration with the Safety, Codes and Standards sub-program to provide objective and technically accurate information to the safety community—including fire, law enforcement, and emergency medical personnel.

In FY 2010, the sub-program conducted several sessions of a hands-on “prop course” for firefighters. This advanced-level, one-day course builds on a 2007 introductory course, “Introduction to Hydrogen Safety for First Responders.” The course has been developed to help first responders gain hands-on experience with personal protective equipment, monitoring and detection equipment, and the
basic control, containment, and confinement operations associated with fuel cell vehicles and stationary applications. It includes a hands-on training component and training scenarios to demonstrate the safe approach to a fuel cell vehicle, extinguishment of a compartment fire, extrication techniques, and hydrogen venting during a compartment fire. The Web-based “Introduction to Hydrogen Safety for First Responders” was registered on the Training Finder Realtime Affiliate Network (TRAIN) Web site, a central repository for health training courses, to reach out to the 30,000 emergency responder members of TRAIN.

The Education sub-program and the Safety, Codes and Standards sub-program expanded the code and permitting official e-learning package with indoor fueling information and developed permitting case studies, in support of increasing early market deployments. Like the introductory course for first responders, “Introduction to Hydrogen Safety for Code Officials” is a five-module, Web-based course that provides a general overview of hydrogen, its properties, and its applications; the course also includes information on the technology and equipment tailored to the needs of code and permitting officials. The case studies were based on actual forklift and backup power deployments supported by the Hydrogen Program, and were developed to assist code officials and project developers in the permitting and safety evaluation of similar installations. Additionally, the in-person code official workshop curriculum was updated to include modules on electric vehicles and infrastructure, to provide a more comprehensive perspective on future transportation technologies.

In FY 2010, an early market outreach education project conducted hydrogen education sessions accompanied by hands-on forklift demonstrations at material handling equipment dealerships, customer sites, community colleges, and regional green-business expos to educate facilities managers, operators, maintenance personnel, safety groups, first responders, authorities having jurisdiction, technical and community colleges, and the general public on the benefits of fuel cell forklifts. In parallel, month-long demonstrations of two hydrogen fuel cell–powered lift trucks at five major retailers in geographically diverse locations provided real-world experience and showcased the economic and environmental benefits of fuel cells. As evidence of the project’s success, one site has decided to acquire over 100 fuel cell forklifts as a result of their experience with the demonstration units.

The Education sub-program continued its efforts to reach out to and partner with state and local governments through seven outreach projects. These efforts focused on states with an active hydrogen and fuel cell presence, to develop case studies, best practices, and technical assistance resources to help decision-makers identify and assess opportunities for future deployment. In their second year, these projects finalized or are finalizing the resource development phase and have moved into the deployment phase. Many groups have been using the results of their research to work directly with state agencies to implement policies, programs, and best practices that can support the growth of hydrogen and fuel cell markets in local economies.

In FY 2010, the Education sub-program’s five university projects targeted a broad student audience through general education courses, specialized science and engineering courses, minor and concentration programs, curricula modules, internships, labs, lab kits, and textbook chapters. Also in their second year, these projects are finalizing development of curriculum and have moved into teaching, reviewing, and refining the course materials. Some projects are leveraging the newly formed core of hydrogen and fuel cell undergraduates by implementing student-taught middle school and high school workshops in addition to outreach targeted toward community college students. The next phase of deployment will involve publicly disseminating these teaching resources to other universities and colleges for adoption into their curricula.

“H2 Educate!," a set of lesson plans and activities for middle school teachers and students, continued to be disseminated through one-day teacher training workshops across the country. The companion effort for high schools, “HyTEC," is deploying a six-unit science curriculum and laboratory kit on hydrogen and fuel cells through professional development workshops and science teacher conferences across the country.
FY 2010 Accomplishments

- Deployed three sessions of the advanced-level prop-based course for first responders, in coordination with the Safety, Codes and Standards sub-program. After three sessions at the Hazardous Materials Management and Emergency Response training facility, DOE has trained 66 first responders from 14 states; an additional three courses are planned in California.

- In coordination with the Safety, Codes and Standards sub-program, increased accessibility of the “Introduction to Hydrogen Safety for First Responders” Web-based course by registering the course on the TRAIN Web site, a central repository for health training courses. Since its launch in January 2007, over 17,000 unique visitors have accessed the course, with an average of 300 to 500 users each month; user groups include the fire prevention/protection community, firefighters, fire department education coordinators, fire marshals, fire plan examiners/inspectors, code officials, law enforcement officials, and representatives from industry, universities, the military, and non-profit organizations.

- Expanded outreach to code officials through four in-person workshops, an updated “Introduction to Hydrogen Safety for Code Officials” Web-based training course, and case studies documenting the permitting process for two early market fuel cell installations in coordination with the Safety, Codes and Standards sub-program. The codes and standards workshops, held in collaboration with local fire department and government organizations, were expanded to include additional modules on electric vehicles and infrastructure in coordination with the DOE Vehicle Technologies Program. The e-learning package was updated with material on indoor hydrogen fueling to support the increasing number of fuel cell material handling equipment deployments. In support of the Fuel Cell Technologies Program, teams were asked to evaluate, assist with, and document the permitting of a backup fuel cell system and a fleet of fuel cell forklifts at two Department of Defense sites. The results were published as case studies to assist code officials and project developers in understanding the codes and standards and safety evaluations for similar early market installations.

- Outreach efforts continued for both first responder courses with the dissemination of hydrogen safety literature and course compact disks, promotion of the prop course, and demonstration of the small hydrogen flame prop at emergency responder conferences including Fire Department Instructor's Conference and Fire Rescue International.

- Conducted nearly 20 hydrogen education sessions with hands-on forklift demonstrations at material handling dealerships, customer sites, community colleges and regional green business expos to educate facilities management, operators, maintenance personnel, safety groups, first responders, authorities having jurisdiction, technical and community colleges, and the general public on the benefits of fuel cell forklifts. In parallel, month-long demonstrations of two hydrogen fuel cell-powered lift trucks at five high-profile geographically diverse locations provided real-world experience and showcased the economic and environmental benefits of fuel cells.

- Continued state and government outreach projects in states with an active hydrogen and fuel cell presence; these projects involved work with the Clean Energy State Alliance, Technology Transition Corporation, and state organizations in Connecticut, Texas, Ohio, South Carolina, and Virginia. These seven projects have conducted over 80 workshops, seminars, briefings, and Webinars across the country; they have also produced fact sheets, newsletters, best practice guides, Web sites, video segments, print articles, and an installation analysis tool to educate government officials and help decision-makers identify and assess opportunities for future deployments.

- Taught over 25 courses, labs, and curriculum modules at California State University, Los Angeles; Humboldt State University; University of California, Berkeley; Michigan Technological University; the University of Central Florida; and the University of North Dakota for general science and engineering programs and specialized hydrogen and fuel cell concentrations. These universities are developing senior design projects, building labs, and sponsoring teaching assistantships and internships to provide hands-on experience with the technologies. Lab kits, textbook modules, problem set workbooks, and course curricula will be integrated into existing science and engineering teaching materials and shared on the Internet to introduce hydrogen and fuel cell technologies to university students across the country.
Continued to disseminate the middle school teacher and student “H2 Educate!” curriculum through one-day teacher training workshops across the country. Since its inception, the sub-program has reached over 8,000 middle school teachers through workshops and conference sessions in 35 states.

Eleven high school science teachers in Connecticut, Georgia, New York, South Carolina, and southern California used the Hydrogen Technology and Energy Curriculum (HyTEC) to teach over 860 students about the science and engineering of hydrogen and fuel cells and their role in addressing energy needs. An additional 240 teachers were introduced to these course materials at science teacher conferences across the country.

Continued audience-targeted Fuel Cell Technologies Program exhibit outreach to early end-user conferences (e.g., U.S. Conference of Mayors, North American Material Handling Logistics Tradeshow, Next Generation Data Center), and hydrogen and fuel cell conferences (e.g., National Hydrogen Association Conference and Expo, Fuel Cell Seminar).

Published the final results from the 2008/2009 Hydrogen Knowledge and Opinions survey and analysis. This effort follows the baseline survey conducted in 2004 and includes a separate survey of code officials—an audience that had been previously incorporated into the state and local officials survey population but has since been prioritized as a separate key target audience essential to the early adoption of fuel cells.

**Budget**

In FY 2010 the Education sub-program returned from the Vehicle Technologies Program to be a part of the Fuel Cell Technologies Program, with an appropriation of $2.0 million. The FY 2009 appropriation allowed for full funding of many of the education portfolio projects. The work of these projects continued in FY 2010 and many of these projects were reviewed in the FY 2010 Annual Merit Review. The FY 2010 appropriation allowed for support of existing projects across the education portfolio, including outreach to state and local government officials, university hydrogen and fuel cell education programs, in addition to ongoing efforts to educate first responders, code officials, and teachers and students at the middle and high school levels.
**FY 2011 Plans**

In FY 2011, the Education sub-program will continue to focus on facilitating the introduction of hydrogen and fuel cell technologies into early markets. Future efforts will begin to examine workforce development needs and include nearer-term employment needs and projections with the Systems Analysis sub-program.

X.1 Hydrogen Safety Training for First Responders

Objectives

- Support the successful demonstration and deployment of hydrogen and fuel cell technologies by providing technically accurate hydrogen safety and emergency response information to first responders.

- Provide a one-day first responder training course, “Hydrogen Emergency Response Training for First Responders,” that integrates the use of DOE’s mobile hydrogen fuel cell vehicle (FCV) prop (initial offering in Fiscal Year [FY] 2009).

- Continue to support the Web-based awareness-level course, “Introduction to Hydrogen Safety for First Responders,” (initial offering in FY 2007).

- Disseminate first responder hydrogen safety educational materials at appropriate conferences to raise awareness.

Technical Barriers

This project addresses the following technical barriers from both the Education (ED) and Safety (SAF) sections of the Fuel Cell Technologies (FCT) Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Readily Available, Objective, and Technically Accurate Information (ED)

(C) Disconnect Between Hydrogen Information and Dissemination Networks (ED)

(D) Lack of Educated Trainers and Training Opportunities (ED)

(H) Lack of Hydrogen Knowledge by Authorities Having Jurisdiction (SAF)

(I) Lack of Hydrogen Training Facilities for Emergency Responders (SAF)

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education section (3.9) of the FCT Program Multi-Year Research, Development and Demonstration Plan:

In addition, the following milestones were met in previous years:

- Milestone 1: Develop “awareness-level” information package for first responders (4Q, 2006).
- Milestone 3: Develop “prop-course” using hands-on training devices for first responders (4Q, 2008).

Accomplishments

- **Prop-Based Course**: Three sessions were held at the Hazardous Materials Management and Emergency Response (HAMMER) facility in June 2009, August 2009, and April 2010 to train 66 students from 14 states. Extremely positive feedback reinforced the value of this course.

- **Awareness-Level Course**: Our Web site still averages 300-500 unique visits per month from almost every state and some foreign countries. We registered the course on the TrainingFinder Realtime Affiliate Network (TRAIN) Web site for broader dissemination to first responders. TRAIN is a central repository for public health training courses. Almost 30,000 TRAIN users identify themselves as emergency responders [1].
Outreach: Compact discs (CDs) of the awareness-level course, laminated posters, and Firehouse article reprints were distributed through the DOE Energy Efficiency and Renewable Energy Information Center [2]. PNNL and HAMMER hosted booths at two key first responder conferences.

Introduction

Safety in all aspects of a future hydrogen infrastructure is a top priority, and safety concerns influence all DOE hydrogen and fuel cell projects. Despite the most concerted effort, however, no energy system can be made 100% risk-free. Therefore, for any fuel and energy system, a suitably trained emergency response force is an essential component of a viable infrastructure. The FCT Program Office has identified training of emergency response personnel as a high priority, not only because these personnel need to understand how to respond to a hydrogen incident, but also because firefighters and other emergency responders are influential in their communities and can be a positive force in the introduction of hydrogen and fuel cells into local markets.

This project is employing the Occupational Safety and Health Administration (OSHA) and National Fire Protection Association (NFPA) frameworks for hazardous materials emergency response training to develop a tiered hydrogen safety education program for emergency responders. The overall first-responder education program will be developed over a number of years. The effort started with development and distribution of the awareness-level Web-based course in FY 2006-2007. A more advanced course and materials to facilitate education were developed in FY 2008-2009, complementing the design, construction, and operation of a fuel cell vehicle prop (developed under PNNL’s Hydrogen Safety project). In addition, PNNL has implemented outreach efforts to key stakeholder groups to facilitate delivery of the training to a broad audience.

Approach

PNNL works with subject matter experts in hydrogen safety and first responder training (e.g., the PNNL Hydrogen Safety Panel, other national laboratories, HAMMER, CaFCP), to develop hydrogen safety course materials. Draft materials are prepared and undergo considerable review and revision before being released. The PNNL team works with DOE to make stakeholder groups aware of training opportunities and to provide “live” training when appropriate. The prop-based course has been given at the HAMMER facility, but plans are in progress to deliver the course at three training centers in California during 2010 in order to reach larger audiences in areas where hydrogen and fuel cell technologies are being deployed.

Results

Prop-Based Course: The focus of the curriculum is on teaching first responders what is the same and what is different about hydrogen and FCVs as compared to conventional fuels and vehicles. Course evaluation forms are distributed and feedback obtained at each class to help us improve the course content and delivery. Based on feedback from the three class sessions held this year (June 2009, August 2009, and April 2010), we concluded that first responders are comfortable with hydrogen and prepared to operate in a safe and effective manner, if a hydrogen incident should occur in their jurisdiction.

The FCV prop (shown in Figure 1) demonstrates potential conditions that could be encountered during the control and suppression of a FCV fire. The prop has been integrated into the “Hydrogen Emergency Response Training for First Responders” course developed by PNNL, HAMMER, and the CaFCP for DOE. The figure shows a team of firefighters responding to a multi-vehicle accident involving a hydrogen FCV and two conventional vehicles.

Web-Based Course: Since the online course was launched in January 2007, there have been more than 17,000 unique visitors to the Web site. The site is still averaging 300-500 unique visitors each month from almost every state and many foreign countries. Typical users include the fire prevention/protection community, firefighters, fire department education coordinators, fire marshals, fire plan examiners/inspectors, code officials, law enforcement officials, and representatives from industry, universities, the military, and non-profit organizations. Feedback on the course has been positive.

FIGURE 1. FCV Prop Training Exercise
**Outreach:** To distribute information and raise awareness about hydrogen safety and the DOE-sponsored courses, PNNL and HAMMER staff participated in two major first-responder conferences in FY 2010:

- Fire Department Instructor’s Conference, April 2010, Indianapolis, IN.
- Fire Rescue International, August 2010, Chicago, IL.

Booths were set up to display and disseminate posters, announcements of course offerings, hydrogen safety literature, and awareness-level course CDs.

**Conclusions and Future Directions**

The introductory Web-based course has been quite successful, based on the usage recorded and feedback received. The course is fulfilling a need expressed by the first responder community to receive more information about hydrogen and fuel cells so they will be prepared in the rare event of a hydrogen incident. The in-depth prop-based course builds on that success and is very useful in giving first responders a hands-on experience with simulated FCV incidents that integrates well with classroom training. PNNL will continue to update both courses as needed to reflect current applications and markets for hydrogen and fuel cells.

There is an identified need for the prop course curriculum to achieve a better balance between the vehicles and stationary facilities modules, through the development of some type of prop for stationary applications of fuel cells. A virtual hydrogen fueling station model having dual capabilities to simulate both outdoor fueling of passenger FCVs and indoor fueling of hydrogen forklifts could address that need. We are planning to develop a virtual model with the following capabilities and attributes:

- Visualizations of outdoor and indoor hydrogen dispensing systems.
- Text pop-ups describing the key components of outdoor and indoor hydrogen fueling stations (e.g., compressor, cylinder storage, dispenser).
- Animations of 30-second emergency response scenarios that could occur at outdoor and indoor fueling stations (e.g., various hydrogen leaks and fires).
- Narration of scripts for outdoor and indoor fueling scenarios.

The prop course will be offered at three first responder training facilities in California in FY 2010 (Sunnyvale Public Safety Department in Sunnyvale, Rio Hondo Community College Fire Academy in Santa Fe Springs, and the Orange County Fire Authority in Irvine). The prop will be transported to California in its trailer and left at each site for about a week. Three classes will be given at each site, resulting in a total of ~300 first responders trained. In future years, the prop will be transported to other locations across the country for use in delivery of this course at training centers in areas that have emerging deployments of hydrogen and fuel cell technologies. PNNL will also work with DOE and other stakeholders to determine what, if any, additional types of educational courses and materials are warranted, and to develop and implement plans to provide education to specific groups.

**FY 2010 Publications/Presentations**

**References**

X.2 Education for Emerging Fuel Cell Technologies

Objectives

- Conduct research and development (R&D) needed to establish sound technical requirements for hydrogen and fuel cell codes and standards.
- Support code development for the safe use of hydrogen and fuel cell technologies.
- Advance safety, code development, and market transformation issues through collaborations with appropriate stakeholders.
- Facilitate the safe deployment of hydrogen and fuel cell fuel technologies.

Technical Barriers

This project addresses the following technical barriers from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Readily Available, Objective, and Technically Accurate Information
(B) Disconnect Between Hydrogen Information and Dissemination Networks

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

18. Develop end-user workshop materials for use at events. (4Q, 2009)
19. Develop short courses for end-users at technical colleges. (4Q, 2011)

Accomplishments

NREL has accomplished the following in support of section 3.9 of the DOE Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Codes and standards workshops: Expanded codes and standards workshops from Fiscal Year (FY) 2009 to cover more subject matter, including a new module on electric vehicles and infrastructure requirements for electric vehicles. Presented four workshops in FY 2010 partnering with local fire departments and government organizations.
- Web-based information compendium: Expanded compendium to include other vehicle fuels and to include updated code official training course that includes material on indoor hydrogen fueling.

Introduction

It is essential to develop and promulgate codes and standards in order to provide for the safe use of hydrogen and fuel cell technologies. With the help of key stakeholders, the DOE Fuel Cell Technologies Program and NREL are coordinating a collaborative national effort to prepare, review, and promulgate codes and standards for all hydrogen and fuel cell technologies.

Approach

The Fuel Cell Technologies Program recognizes that domestic and international codes and standards must
be established to enable the timely commercialization and safe use of hydrogen and fuel cell technologies. The lack of codes and standards applicable to hydrogen and fuel cell technologies is an institutional barrier to deploying these technologies. It is in the national interest to eliminate this potential barrier. As such, the Program works with domestic and international standards development organizations (SDOs) to facilitate the development of performance-based and prescriptive codes and standards. These standards are then referenced by building and other codes to expedite regulatory approval of hydrogen and fuel cell technologies. This approach ensures that U.S. consumers can purchase products that are safe and reliable, regardless of their country of origin, and that U.S. companies can compete internationally.

**Results**

The Safety Codes and Standards work is divided into three major areas:

- National Template Implementation
- Codes and Standards Research
- Codes and Standards Training and Outreach

This report will address codes and standards outreach.

**Codes and Standards Training and Outreach**

NREL has several active training and outreach projects in FY 2010 including the following:

- Codes and standards workshops.
- Update of code official on-line training course.
- Analysis of two emerging fuel cell technology projects (funded through Education).

NREL conducted four Codes and Standards Workshops in FY 2010. These workshops were held in Tampa, FL, New Orleans, LA, San Francisco, CA and Los Angeles, CA. All four were held in collaboration with local fire service departments or organizations. These workshops were targeted at code officials and project developers who would be working on fuel cell or hydrogen technology projects.

The proceedings from these workshops are posted at the Hydrogen Program Safety, Codes and Standards Web page. Generally, the workshops have been effective at getting information to individuals who will be directly involved in hydrogen and fuel cell projects. These individual include plans review officers for fire departments and project managers responsible for getting hydrogen and fuel cell projects built.

The code official training course that was placed on-line in FY 2009 was amended to include material on indoor fueling operations. Indoor fueling is a special concern because of the developing use of hydrogen-fueled forklifts that are typically fueled indoors.

Another key project is two case studies that address emerging fuel cell technologies. The first project is an evaluation of codes and standards and safety issues associated with a fuel cell system used to supply backup power at military base and the second is an evaluation of indoor fueling and forklift operations at a military storage facility. The analysis and findings from these projects will be published as an NREL technical report that would assist code officials and project developers in codes and standards and safety evaluations in similar projects.

Figure 1 shows how the work done in the outreach activities feeds into the research projects and codes and standards development work.

**Conclusions and Future Directions**

NREL will continue to support the development of codes and standards by:

- Working with DOE to implement a national template for vehicle codes and
- Continuing R&D support of the key technologies required to close the gaps identified in the codes and standards development process.
- Continuing R&D collaborations with national and international stakeholders on vehicle codes and standards activities.
- Performing outreach work to distribute information on hydrogen and fuel cell technologies to code officials, project
- Coordinating domestic codes and standards and International standards to ensure consistent requirements.

8. High pressure Hydrogen Storage; Validation Testing of SAE performance Based System Level Requirements, Burgess, R. published in the proceedings of the National Hydrogen Association 2010 Annual Conference.
X.3 Hydrogen and Fuel Cell Education at California State University, Los Angeles

Objectives

California State University, Los Angeles, has partnered with the Department of Energy in addressing the workforce preparation and public education needs of the fuel cell industry and the U.S. economy through a comprehensive set of curriculum development and training activities:

- Developing and offering several courses in fuel cell technologies, hydrogen and alternative fuels production, alternative and renewable energy technologies as means of zero emissions hydrogen economy, and sustainable environment.
- Establishing a zero emissions proton exchange membrane (PEM) fuel cell and hydrogen laboratory supporting curriculum and graduate students’ teaching and research experiences.
- Providing engaging capstone projects for multidisciplinary teams of senior undergraduate students.
- Fostering partnerships with automotive manufacturers and energy providers.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9.5) of the Fuel Cell Technologies (FCT) Program Multi-Year Research, Development and Demonstration Plan:

- Lack of Readily Available, Objective, and Technically Accurate Information
- Mixed Messages
- Lack of Educated Trainers and Training Opportunities

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education section of the FCT Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 11: Develop set of introductory materials suitable for a non-technical audience. (4Q, 2006)
- Milestone 21: Launch new university hydrogen education program. (4Q, 2009)
- Milestone 27: Launch high school teacher professional development. (4Q, 2008 through 3Q, 2011)

Accomplishments

In the 2009-2010 academic year, we continued to offer course modules and hydrogen fuel cell technology dedicated courses: ME 454-Renewable Energy and Sustainability (enrollment 26); ME 554-Fuel Cell Systems (graduate course; enrollment 10); TECH 478-Fuel Cell Applications (enrollment eight technology, seven mechanical); TECH 250-The Impact of Technology on the Individual and Society (detailed in the next section). M:21.

- TECH 250-The Impact of Technology on the Individual and Society course is a general education required course, which contains one week module on fuel cells and hydrogen economy. It is open to all majors in the university and is selected to deliver our message to the university-wide student body. Enrollment was as following: 2008-2009—186 students; 2009-2010—206 students. M:21.

- Work has continued within the Zero Emissions Fuel Cell and Hydrogen Laboratory (ZEFC). Major equipment purchased last year has been integrated into courses: Heliocentris -- Dr. Fuel Cell, Nexa Training System Complete, Nexa Integration Kit; and Proton-Hogen GC600 Electrolyzer. Two graduate and several undergraduate students
worked on educational and research projects in the laboratory. M:21, M:11.

- ECST assembled a multidisciplinary senior design team which is solving the problem of calibrating the amount of hydrogen dispensed at 5,000 psi by building a prototype for the 10,000 psi unit.
- The initial solar installation has grown from 2 kW to 10 kW. The system consists of 56 Sharp and 23 Solec modules. The ECST building is a 3-phase building which requires three inverters per each type of modules. However, SMA has come out with a Tripower inverter which is capable of dual maximum power point tracking and is 10 kW unit. This type is schedule for production in summer 2010 and CSULA is waiting for an available unit. The funds are being provided by Southern California Edison. M:21.
- ECST assembled a multidisciplinary senior design team to design and build a Hydrogen Safety demonstrator. The team consisted of two mechanical engineering and two electrical engineering students. The enabled experiments produced spectacular performance. For safety, the explosions are activated with a wireless remote. M:21.
- There has been an appreciable number of public outreach and educational activities through which fuel cell and hydrogen technologies and the new curriculum at CSULA were promoted. M:11.
- CSULA has raised funds and initiated the construction of a hydrogen station with 60 kg/day generation capacity. That will enable further development of educational program. M:21.
- Multidisciplinary team of CSULA faculty, including the principal investigator (PI), received National Science Foundation funding to establish the Center for Energy and Sustainability. One of the projects is to design and evaluate miniature direct-methanol fuel cell. This will contribute to the longevity of the research program. M:21.

Introduction

Our interest in developing hydrogen and fuel cell education stems from the recognition of the urgent need for workforce development and public education in the entire spectrum of alternative and renewable energy technologies (ARET). ECST is taking steps to graduate more students fluent in ARET as well as to raise campus and state-wide awareness of green technologies. This includes the ongoing construction of a Hydrogen fueling station on campus. The comprehensive nature of the university, its strategic location in the hydrogen and fuel cell abundant industrial region and a historically minority-serving charter make it an ideal candidate to carry out the tasks listed in the objectives.

Approach

Design of a comprehensive engineering and technology curriculum addressing fuel cells and hydrogen technologies is the foundation for our contribution toward green workforce training. This is accomplished through a mix of new courses or special modules in existing courses to introduce the concepts of fuel cell technologies, hydrogen and alternative fuels, alternative and renewable energy technologies as means of zero emissions hydrogen economy, and sustainable environment. ECST has established ZEFC to support curriculum, undergraduate and graduate students’ teaching and research experiences. Further, enrichment of student experiences is accomplished through projects and fostering partnerships with automotive manufacturers and industry.

Community education and public outreach goals are met through a series of on campus and off-campus public events and demonstrations.

Results

Four courses either with integrated modules or fully dedicated were continued to be offered within the interdisciplinary curriculum at ECST: ME 454-Renewable Energy and Sustainability, ME 554-Fuel Cell Systems, TECH 478-Fuel Cell Applications, TECH 250-The Impact of Technology on the Individual and Society. TECH 478 continued as flagship of the program. The class hosted the Honda Clarity fuel cell vehicle team that gave a lecture and a demonstration on Honda fuel cell vehicles as well as a visit by a renowned fuel cell researcher Dr. Subbarao Surampudi of the Jet Propulsion Laboratory. As part of the mid-term exam, students attended the 2010 National Hydrogen Association conference which was available locally.

Active work has continued within the ZEFC. The laboratory is designed to provide hands-on activities supporting fuel cell courses offered in the program. One graduate student developed: Lab1 a-b, Characteristic Curve and Efficiency of the Electrolyzer; Lab2 a-b, Characteristic Curve and Efficiency of the Fuel Cell; Lab3, Nexa Training System Complete: Fuel Cell Power Potential; abbreviated operating manuals for Nexa Training System Complete and Hogen Electrolyzer. He also assisted with teaching labs for undergraduate and graduate courses. The same student provided leadership for the “Hydrogen Community” design project sponsored by National Hydrogen Association. The project was called Soaring Eagle and five technology and two mechanical engineering students participated, see Figure 1.

The PI and the graduate student attended an intensive 3-day fuel cell course offered at Los Alamos National Laboratory. The training benefited student’s
graduate research and the PI’s course materials. Later, this student presentation “Root Cause Analysis of Low Fuel Cell Voltage Generation” was awarded the first place oral presentation in Engineering and Computer Science I at the CSULA 18th Annual Symposium on Research, Scholarship and Creative Activity. Among the winners from other disciplines, the student has been invited to the CSU statewide competition in San Jose.

CSULA has actively pursued public outreach and educational activities through which the DOE-sponsored fuel cell and hydrogen curriculum at CSULA is promoted. During the fall of 2009, ECST hosted a Boeing open house for middle and high-school students, about 150 of whom toured the ZEFC. ECST is executing its 2010 Research Experience for Undergraduate program in ZEFC through which two students are working on a photolysis shark project and five are building a fuel cell vehicle to demonstrate solar-hydrogen-to-wheel efficiencies. Multiple industry sponsored projects are supported by the PI and ZEFC facility. CSULA hosted 15 East Los Angeles College students for a week-long workshop where a LEGO Mindstorm robot powered by a Horizon 20 W fuel cell was built, see Figure 2.

CSULA has initiated the long awaited $4.5 M hydrogen station on campus, see Figure 3. It will deploy the latest technologies with the capacity of 60 kg/day, sufficient to fuel 15+ vehicles or a bus and five more vehicles. The station will be utilizing a Hydrogenics electrolyzer, first and second stage compressors capable of fast-filling at 5,000 psi and 10,000 psi, 60 kg of hydrogen storage. The station will be grid-tied and powered by 100% renewable power. The station construction has commenced and full operation is expected in January-March 2011.

The PI attended the 2010 Annual Merit Review in Washington DC; 2010 American Society for Engineering Education conference in Louisville, KY; and, 2010 National Hydrogen Assocation conference, Long Beach, CA.

**Conclusions and Future Directions**

CSULA has methodically pursued the stated objectives in executing the grant. The team has offered a comprehensive suite of courses addressing fuel cell and hydrogen technologies. In the second year significant improvements were made integrating experimental experience through ZEFC. The work in ZEFC is continued with the solar installation and student/industry projects far beyond those proposed initially.
Next year efforts will focus on further development of student research and projects to assure the long-term viability of the hydrogen and fuel cell program at CSULA. Significant activities will also be associated with the construction, operation and utilization of the hydrogen station for public outreach and education. Next level of the program development will take place in commissioning the station and raising support for hydrogen infrastructure related curriculum, data collection and research. The team plans to file for project extension beyond September 15, 2010.

**Special Recognitions & Awards/Patents Issued**

1. Best Paper Award (2nd place) in the Energy Conversion Division of American Society for Engineering Education, see below for full reference. The PI was the main co-author.

2. Education Award by Looking Green Magazine at Rose Bowl Green Expo, Pasadena, CA July 2010.

E-mail: Greg.Kleen@go.doe.gov

Contract Number: DE-FG36-08GO18107

Subcontractor:
University of California, Berkeley (UCB), Berkeley, CA

Project Start Date: September 15, 2008
Project End Date: September 15, 2011

Objectives
The Hydrogen Energy in Engineering Education ($H_2E^3$) project is designed to increase awareness of and hands-on experience with hydrogen and fuel cell technology among undergraduate engineering students in California's public universities. $H_2E^3$'s objectives are:

- to deliver effective, hands-on hydrogen energy and fuel cell learning experiences to a large number of undergraduate engineering students at multiple campuses in the California State University (CSU) and University of California (UC);
- to provide follow-on internship opportunities for students at hydrogen and fuel cell companies; and
- to develop commercializable hydrogen teaching tools including a basic fuel cell test station and a fuel cell/electrolyzer experiment kit suitable for use in university engineering laboratory classes.

Technical Barriers
This project addresses the following technical barriers from the Education section (3.9.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(D) Lack of Educated Trainers and Training Opportunities: Only a small number of universities in California offer hydrogen and fuel cell-specific learning opportunities for undergraduate engineering students. Even at these campuses, the number of engineering faculty with direct experience using fuel cells remains small, and fuel cell course content is underdeveloped.

(E) Regional Differences: California has the advantages of being home to many hydrogen and fuel cell developers and on the leading edge of hydrogen energy infrastructure development. These features call for a special hydrogen energy education effort in California universities that makes use of these existing resources available in close proximity to many campuses.

Contribution to Achievement of DOE Education Milestones
This project will contribute to achievement of the following DOE milestone from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- **Milestone 21: Launch new university hydrogen education program (4Q, 2009).** The project supports attainment of the above milestone by creating curriculum, teaching tools, and industry-based learning opportunities that can be replicated by other universities working with industry partners. By the same token, the project also supports completion of Task 5 in the Multi-Year Research, Development and Demonstration Plan: “Facilitate Development and Expansion of College and University Hydrogen Technology Education Offerings,” specifically the subtask described as “Work with university partners to develop and expand hydrogen technology course offerings and facilitate networking among schools with similar programs.”

Accomplishments
- Successfully introduced $H_2E^3$ curriculum in three engineering courses at HSU and two at UCB.
- Successfully incorporated $H_2E^3$ hardware in lab activities in a total of four engineering courses at the two campuses.
- Continued development of new curriculum materials.
- Performed monitoring and evaluation of the curriculum and lab hardware in use, using feedback.
Introduction

A recurring theme in the hydrogen energy field is the unmet need for a new generation of graduating engineers trained specifically in hydrogen and fuel cell energy technologies. The purpose of our project is to help meet this need, specifically in the context of the CSU and UC systems. Together these universities grant over 7,000 engineering degrees each year.

The three-year project, branded as “Hydrogen Energy in Engineering Education” (H₂E³) is being led by the Schatz Energy Research Center (SERC), a unit of the Humboldt State University Sponsored Programs Foundation. Our principal partner on the project is the UCB, represented by their Institute of Transportation Studies. The project also began with a number of fuel cell industry partners, but the participation of these manufacturers in the project as hosts for student interns is being reevaluated, as discussed in the following.

Approach

Adding hydrogen curriculum to existing undergraduate engineering programs is not a trivial task. Engineering departments and the organization that accredits them require students to meet numerous stringent requirements in order to graduate. There is little slack in a typical undergraduate engineering course plan to add new curriculum. In order to add hydrogen education to existing engineering programs, we need to find creative ways to fold it into courses and help instructors meet their existing course objectives.

We are working closely with engineering faculty to develop lesson plans that can be substituted for segments of existing courses, including introductory engineering, introductory and advanced thermodynamics, manufacturing engineering, upper-division engineering laboratory, and in courses on the general topic of energy and society. We are also developing laboratory hardware that the students will be able to use to perform hands-on experiments that reinforce key points covered in the lecture material. The partners on this effort bring years of relevant experience in teaching about hydrogen energy and developing fuel cell technology.

Results

Having completed development of hardware and begun curriculum development during the first year of the project, in year two we focused on introducing the curriculum and hardware into several engineering courses at UCB and HSU, and refining H₂E³ materials. We also worked on developing relationships that will allow us to reach out to additional campuses, incorporate studies of hydrogen fueling stations into H₂E³ (Figure 1), and establish student internships during year three.

Curriculum Development and Deployment. We introduced our curriculum, in the form of PowerPoint presentations, lab activities, and supporting documentation for lab instructors, into several engineering courses: introduction to environmental resources engineering, introductory thermodynamics, and advanced thermodynamics at HSU; and engineering design and analysis and energy and society at UCB.

Equipment Deployment. The two fuel cell test stations (Figures 2 and 3) and 24 fuel cell/electrolyzer kits (Figure 4) were used in each of the above courses for hands-on lab activities and/or instructor demonstrations. All of the equipment performed satisfactorily.

Monitoring and Evaluation. Project team members used a variety of assessment tools to analyze the effectiveness of the H₂E³ curriculum and lab activities. We had students complete pre- and post-lesson evaluations, we observed and made notes on lectures and lab activities, and we convened focus groups and one-on-one meetings with instructors and teaching assistants to solicit their feedback. Student and instructor feedback has been strongly positive but has also provided useful critique. We are using assessment outcomes to make iterative improvements to the curriculum and equipment.

FIGURE 1. HSU's hydrogen fueling station and fleet of hydrogen vehicles. The fueling station's performance will be analyzed by HSU engineering students as part of the H₂E³ curriculum.
Fuel Cell Industry Internships. Project plans originally called for student internships with a number of fuel cell manufacturer partners during the summers of 2010 and 2011. Due to the economic downturn in general and attrition in the fuel cell industry in particular, we have had difficulty in developing these internships. The only internships we were able to identify for 2010 were existing co-op arrangements, which require students to be available for six months out of the year for full-time work. This is not compatible with the academic schedules of students in the universities we have been working with. We are investigating alternatives, as discussed below.

Conclusions and Future Directions

The main outcome of year two of the project has been the successful introduction of the H₂E³ tools and curriculum into a variety of engineering courses at HSU and UCB. In year three we plan to expand the project by integrating the curriculum into still more engineering courses and reaching out to other California campuses. We have requested and been given tentative approval for an additional $15,000 in funding from DOE, which will permit us to build three additional sets of ten fuel cell/electrolyzer kits. We will distribute these sets to newly participating campuses, allowing current users of kits to keep using them at their campuses for longer periods.

In order to ensure the long-term success of H₂E³, we will follow up with faculty to determine to what extent the use of the H₂E³ materials persists among instructors who have been given access to the curriculum and equipment, and what the learning outcomes are in their courses. We will also continue to develop learning activities that incorporate analysis of operating fueling stations at HSU and elsewhere.

We hope to find or develop summer-season internships for 2011. In addition to making direct contacts with manufacturers, we plan to approach industry groups such as the U.S. Fuel Cell Council and the National Hydrogen Association to solicit their help with this. We are considering alternatives to manufacturer-funded internships, such as “distance internships,” perhaps supported by fixed stipends from a third party.
Special Recognitions & Awards/Patents Issued

1. “National Hydrogen and Fuel Cell Education Program Part I: Curriculum,” selected by Energy Conversion and Conservation Division of the American Society for Engineering Education as 2nd place winner of Best Paper Award at the 2010 ASEE Annual Conference & Exposition, Louisville, KY.

FY 2010 Publications/Presentations

6. Lab handout, blank wiring diagram, and safety guidelines for use in ENGR 115, introduction to environmental resources engineering (HSU).

7. Lab handout, blank wiring diagram, and safety guidelines for use in ENGR 331, introduction to thermodynamics (HSU).

8. PowerPoint presentation for E100, energy and society (UCB).

9. Monitoring and evaluation report on ENGR 331 (HSU) and E100 (UCB).

10. Lab handouts for use in ENGR 471, advanced thermodynamics (HSU):
   - Lab Experiment #1 – Operating the Fuel Cell Test Station
   - Lab Experiment #2 – Evaluating the Performance of a PEM Fuel Cell

11. Spanish translations of PowerPoint presentation originally developed for E100 and document on operation and maintenance of fuel cell/electrolyzer kits, for use at Universidad Don Bosco, El Salvador, by H₂E³ project team member Richard Engel.
Objectives

The objectives of this project are to educate university students on the advantages, disadvantages, challenges, and opportunities of hydrogen and hydrogen fuel cells within the United States energy economy. In particular, this project will:

- Develop and/or refine courses in hydrogen technology.
- Develop curriculum programs in hydrogen technology.
- Develop modules for core and elective engineering courses.
- Develop modules to supplement commonly used chemical engineering texts.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9) of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Readily Available, Objective, and Technically Accurate Information

(B) Mixed Messages

(C) Disconnect Between Information and Dissemination Networks

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education section (3.9) of the Hydrogen, Fuel Cells and Infrastructure Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 21: Launch new university hydrogen education program. (4Q, 2009)

Accomplishments

The major accomplishments of this project to date are listed below:

- We have developed and taught one lecture and one laboratory course in hydrogen energy and two courses in fuel cells.
- Effective April 2009, students can receive an “Interdisciplinary Minor in Hydrogen Technology.” The minor includes the elective courses mentioned above and project work in the alternative fuels group enterprise.
- The elective courses are also a component of the “Graduate Certificate in Hybrid and Electric Vehicles” approved May 2010.
- Nearly three dozen modules have been developed to introduce students in core chemical engineering courses to hydrogen and fuel cell technology; similar efforts are underway for mechanical and electrical engineering courses.
- Ninety example problems have been created as supplementary material to be used in the sophomore level introductory chemical engineering course.
- Over the entire project, eight oral presentations have been given and five conference proceedings have been published, with five oral presentations and four conference proceedings during the past year.

There is a strong need for a transformative curriculum to train the next generation of engineers who will help design, construct, and operate fuel cell vehicles and the associated hydrogen fueling infrastructure. In
this project, we build upon the project-based, hands-on learning that has been a cornerstone of engineering education at MTU. This teaching and learning style is supported by the engineering education literature which indicates that students learn by doing, particularly through team-based interactive projects with a real-world flavor.

This project has resulted in the formation of an “Interdisciplinary Minor in Hydrogen Technology” at MTU. We focus on student centered design projects, and add additional technical material through elective courses, modules for core courses, and textbook supplements. As a final note, aggressive dissemination of the project results will occur through presentations at the annual meetings of several professional societies.

Approach

The ultimate goal for the hydrogen education program should be to establish an educational infrastructure and database of hydrogen and fuel cell related educational materials, particularly projects and problem sets. The efforts of this project support this mission.

At MTU, we have embraced the concept of hands-on learning as the cornerstone of a newly approved “Interdisciplinary Minor in Hydrogen Technology.” Students that obtain this minor are also required to take newly developed elective courses in fuel cells and hydrogen technology. Focusing on a subset of graduates who choose these options is not enough. In order to reach a wider audience at MTU, modules are being developed for the core curricula in chemical engineering, mechanical engineering, and electrical engineering. Each module stands alone and can be assigned to students as an in-class problem, a homework assignment, or a project. The modules use the fundamental concepts taught within the core course and apply them to hydrogen generation, distribution, storage, or use within a fuel cell. Thus, students are able to see the applications of the fundamentals from their courses. Finally, we are creating supplements to two of the most popular chemical engineering textbooks as another way to introduce hydrogen technology and fuel cells to university students.

The core course modules are to be tested throughout the nation. The results of this curriculum project and testing results are to be disseminated through professional societies in chemical engineering, mechanical engineering, electrical engineering, and engineering education. Course materials, modules, and textbook supplements will be available for use by engineering educators worldwide.

Results

Results for Task 1.0, Develop and/or refine courses in hydrogen technology:

- To date, we have created two new courses, “Fundamentals of Hydrogen as an Energy Carrier” to be taught in fall semesters and “Hydrogen Measurements Laboratory” to be taught in spring semesters (Figure 1). The courses have been taught during the most recent academic year and were well received by students.

Results for Task 2.0, Develop curriculum programs in hydrogen technology:

- The “Interdisciplinary Minor in Hydrogen Technology” was approved by the university effective April 2009.
- The “Graduate Certificate in Hybrid and Electric Vehicles” was approved by the university effective May 2010.
- During the 2009-2010 academic year, there were several group projects in the “Alternative Fuels Group” Enterprise. This Enterprise consisted of undergraduate students in chemical, mechanical, and electrical engineering, as well as materials science and engineering. Students were in their sophomore, junior, or senior year of study. By participating in the group projects, students earned credit towards their degree and (if desired) towards the new minor mentioned above. Student projects included:
  - Hydrogen Student Design Contest (Figure 2)
  - Combined Heat and Power from a Fuel Cell
  - Carbon Dioxide Sequestration from a Large-Scale Hydrogen Production Plant

![FIGURE 1. 1.2 kW Hydrogen Fuel Cell used in Hydrogen Measurements Laboratory Course](image-url)
Results for Task 3.0, Develop modules for core and elective engineering courses:

- The third task of this project is to develop modules for core courses in chemical, mechanical, and electrical engineering courses. Up to this point, nearly three dozen chemical engineering modules and one dozen mechanical engineering modules have been developed. It is noted that the modules are available online at: http://www.chem.mtu.edu/~jmkeith/fuel_cell_curriculum/.

Results for Task 4.0, Develop modules to supplement commonly used chemical engineering texts:

- We have developed a set of 90 examples to supplement the textbook *Elementary Principles of Chemical Processes* authored by R. M. Felder and R. W. Rousseau and published by Wiley. The problems are organized in “workbook” format where there are blank spaces for students to insert numbers in order to carry out the solutions. It is noted that this textbook is used in the very first chemical engineering undergraduate course at most universities in the nation. The main emphasis of the course is on engineering problem solving for chemical engineers. Students learn best by solving a large number of problems. This supplement is intended to meet the student’s needs while teaching them about hydrogen technology and fuel cells.

**Conclusions and Future Directions**

The most significant result of this project to date is the approval of a new minor at MTU with title “Interdisciplinary Minor in Hydrogen Technology.” The groundwork is in place to teach new courses in hydrogen and fuel cell technology and to introduce these concepts in the core chemical engineering curriculum at MTU.

Future work will include the following:

- Future work for Task 1.0, Develop and/or refine courses in hydrogen technology: Continue to teach hydrogen and fuel cell courses, while improving curriculum material.
- Future work for Task 3.0, Develop modules for core and elective engineering courses: Continue to develop modules for core courses in mechanical engineering and electrical engineering curricula; test chemical engineering modules at MTU and other national universities.
- Future work for Task 4.0, Develop modules to supplement commonly used chemical engineering texts: Test supplementary material for Felder & Rousseau textbook; continue development of supplementary material for Geankoplis textbook (*Transport Processes and Separation Process Principles*, published by Prentice Hall, for junior chemical engineering courses).

**Special Recognitions & Awards/Patents Issued**

1. Jason Keith was named by MTU as the 2010 recipient of the Frederick D. Williams Instructional Innovation Award in recognition of using active learning in his courses and in leadership in the development of modules for hydrogen and fuel cell education.

Contract Number: DE-FG36-08GO18109
Subcontractor:
University of North Carolina at Charlotte, Charlotte, NC

Project Start Date: August 1, 2008
Project End Date: March 30, 2011

Objectives

- Develop and implement an accredited baccalaureate level hydrogen and fuel cell technologies (HFCT) university program.
- Prepare students to work as hydrogen and fuel cell technology professionals in government, industry, and academia.
- Prepare program graduates to demonstrate an appropriate mastery of the knowledge, techniques, skills and modern tools related to hydrogen and fuel cell technologies.
- Prepare program graduates to demonstrate an ability to apply current knowledge and adapt to emerging applications of hydrogen and fuel cell technologies.
- Disseminate program information and activities to community colleges, high schools, industrial partners, governmental agencies and universities.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Readily Available, Objective, and Technically Accurate Information
(B) Mixed Messages

Contribution to Achievement of DOE Education Milestones

- Milestone 21 – Launch new university hydrogen education program. (4Q, 2009)

Accomplishments

- Hydrogen and fuel cell courses have been developed and offered at University of Central Florida (UCF) and at University of North Carolina at Charlotte (UNCC).
- During 2009, program course development and offering was transferred to the UNCC because of academic program reductions at UCF. Administration of program remains at UCF.
- Courses that have been developed and offered are:
  - ETM 4220 Applied Energy Systems – offered in Spring 2009 at UCF.
  - ETGR 3000-002 and MEGR 3090-020 Combined Hydrogen and Production Storage – offered in Summer 2010 at UNCC.
  - Three laboratory experiments (Hydrogen Fuel Cells, Hydrogen as an Energy Carrier and Methanol Fuel Cells) were developed and offered as part of the Combined Hydrogen Production and Storage course.
  - Thermodynamics, Energy Management and Fluid Dynamics Lab courses have been offered at UNCC to complement the HFCT courses.
- Students from all engineering majors and from engineering technology can register for the above courses.
Introduction

The objective of the HFCT program is to develop and implement a baccalaureate level educational program that will supply the need for educating students that will comprise the next generation workforce needed for HFCT research, development, and demonstration activities within government, industry, and academia. The project includes the development and delivery of undergraduate courses at the Engineering Technology Department within an accredited Bachelor of Science in Engineering Technology (BSET). Courses will be offered at UNCC and the laboratory facilities that are developed will be located at UNCC.

Current public knowledge and awareness levels of hydrogen and fuel cells need improvements and have prevalent misunderstandings of hydrogen properties giving negative opinions about the safe use of hydrogen as an energy carrier. The Fuel Cell Technologies Education subprogram seeks to facilitate near-term market transformation and future commercialization by providing technically accurate and objective information to key target audiences, including: state and local government representatives, potential end users, safety and code officials, and local communities. Undergraduate and graduate students, university faculty, and middle and high school teachers and students comprise another important audience, as they are our nation’s future researchers, scientists, engineers, technicians, and technology users.

Approach

The approach for achieving the objectives of the project is to develop, offer, and sustain a BSET or BSE program that contains courses for an HFCT concentration. The course offerings were started in Spring 2009 and have continued through the present time. The original courses were offered at UCF and the courses and laboratories are now being offered at UNCC. Efforts to promote the program include advertisement, recruiting students and outreach plans, visits to community colleges and other institutions, publications and presentations in professional meetings.

Future efforts will include the evaluation of the HFCT program offerings using a wide range of qualitative and quantitative methods and triangulation procedures to assess and interpret a multiplicity of information. Data will be gathered during all phases of the program to provide timely formative feedback to/from project stakeholders on implementation, participants’ perspectives about the activities and what they may have learned, and how goals and objectives are being met. Formative evaluation will provide recommendations and allow for design modifications to improve course impact answering questions like: Is the program providing high-quality experiences? What impact is the program having on participating students’ attitude, interest, confidence and knowledge related to hydrogen and fuel cell technologies? Is faculty using project-developed content to replace some of their standard lessons?

Results

This project is comprised of completing three major tasks – developing courses, offering the developed courses, and promoting the program through advertisement, recruiting students and outreach plans. The results for these tasks follow.

Developing Courses

The courses that have been developed are:

- Hydrogen Production and Handling 3 Credit Hours
- System Analysis of Renewable Energy Systems 3 Credit Hours
- Analysis of Renewable Energy Systems 3 Credit Hours
- Combined Hydrogen Production and Storage 3 Credit Hours
- Fuel Cell Technologies I 3 Credit Hours

Other course development activities that will be offered in the Fall 2010 semester are:

- Hydrogen Laboratory Schedule
  - Introduction and Hydrogen Laboratory Safety
  - Gas Cylinder and Safety Handling
  - Instrumentation I
  - Instrumentation II
  - Material Balance
  - Characterization of Chemical Hydride Materials
  - Hydrogen Liquefaction Experiments
  - Student Project

- Fuel Cell Laboratory Schedule
  - Introduction and Laboratory Safety
  - Fuel Cell Chemistry and Efficiency
  - Electrochemistry
  - Fuel Cell Components and Assembly
  - Operating Conditions I
  - Operating Conditions II
  - Fuel Cell Diagnostics
  - Student Project

Work has also begun on development of two one credit hour courses called hydrogen lab and fuel cell lab. These will be offered at a time to be determined in the future. The course outlines for the two labs are:

- Hydrogen Laboratory Schedule
  - Introduction and Hydrogen Laboratory Safety
  - Gas Cylinder and Safety Handling
  - Instrumentation I
  - Instrumentation II
  - Material Balance
  - Characterization of Chemical Hydride Materials
  - Hydrogen Liquefaction Experiments
  - Student Project

- Fuel Cell Laboratory Schedule
  - Introduction and Laboratory Safety
  - Fuel Cell Chemistry and Efficiency
  - Electrochemistry
  - Fuel Cell Components and Assembly
  - Operating Conditions I
  - Operating Conditions II
  - Fuel Cell Diagnostics
  - Student Project

In addition, development has begun on a new senior design course.
Offering the Developed Courses

The course ETM 4220 Applied Energy Systems was offered in Spring 2009 at UCF. The course was taught by Dr. Sleiti as part of the HFCT program. Thirty-seven students took the course.

The course ETGR 3000-Analysis of Renewable Energy Systems was offered to UNCC students in the Spring Semester 2010. This course was taught by Dr. Sleiti. The course included lectures, field visits to energy related sites and power plants and a semester-long student project. Examples of the student projects are: Fuel Cell Applications in Transportation, Applying Geothermal to Recreation Facility, Solar Panels for UNCC Charlotte, and Wind Generation Plant Feasibility Study. The course was offered to all students in the College of Engineering with 22 students originally registered for the class – 20 are seniors and two are juniors. Two students withdrew from the course and 20 students successfully completed the course.

The syllabus and course analysis forms for Analysis of Renewable Energy Systems course are available, but not presented here. The syllabus includes the course title, name of the instructor, textbook used for the class, prerequisites and co-requisites, goals/objectives, course outcomes, term project description, course grading policy, course website, course policies, and a 16-week schedule of topics that are covered. The Course Analysis Form includes course assessment, program outcome assessment, recommendations and overall course observations and comments and student grades.

The course ETGR3000-002 and MEGR3090-020 — Combined Hydrogen Production and Storage was offered in the Summer Semester of 2010 to both Engineering Technology Students and Mechanical Engineering students. Five students completed the course. The syllabus and course analysis forms for the course are available. The experimental labs that were taken by the students as part of the courses are:

- Experiment 1 – Hydrogen Fuel Cells
- Experiment 2 – Hydrogen as an Energy Carrier
- Experiment 3 – Methanol Fuel Cells

Each experiment was designed to be completed within 2.5 hours and the students are required to submit a report including description, procedure, results, discussion and conclusion.

Other existing courses in the engineering technology program that complement the HFCT courses and that are being offered at UNCC are Thermodynamics, Energy Management and Fluid Dynamics Lab. Outlines for those three courses are available. Note is made that these courses are taught jointly by several instructors and they have more than one section. These courses and instructors are as follows:

<table>
<thead>

</tbody>
</table>

These courses will be repeated during subsequent semesters and will be available to students from all engineering and engineering technology majors.

Promoting the Program through Advertisement, Recruiting Students and Outreach Plans

During the past year, the following activities have been completed:

A. Visits to community colleges:

The team has been following up with and scheduling meetings with community colleges that currently have technology programs with potential to transfer students from those community colleges with associate of science degrees to the HFCT program. Visits to Central Piedmont Community College and participation in the Wake Tech Spring Fling have been done.

B. Visits to local industry:

The team established collaboration with Savannah River National Laboratory (SRNL) during a SRNL visit to UNCC on February 18, 2010 and have had collaborations with the following companies/organizations:

- North Carolina Hydrogen Economy and Advancement Team
- North Carolina Fuel Cell Alliance
- The Advanced Vehicle Research Center of North Carolina
- Duke Energy
- AREVA
- Electric Power Research Institute
- Shaw Group
- Siemens

C. Contacting Universities:

The team is continuing to contact universities around the country through e-mails to make the academic community aware of the HFCT program.
D. Other Activities:
The UNCC team is participating in high school competition and coordinating program information sessions each semester.

Project Management and Reporting

The major activity in the project management area was the termination, because of financial problems, of the Bachelor of Engineering Technology program at UCF and the changing of employment of the project Co-PI, Dr. Ahmad Sleiti, to the BET program at University of North Carolina at Charlotte. Following this change, the decision was made for UCF to retain project management and to subcontract project implementation to UNCC. A subcontract was issued to UNCC to be the provider for the HFCT courses beginning on January 4, 2010 and ending on March 30, 2011.

Conclusions and Future Directions

At the present time, course development and offering are 65% complete, and promotion is 80% complete. The overall project is estimated at 75% complete and there are no problems or issues that will delay completion.

The plans for finishing the program activities are:

- Continue offering the developed courses at UNCC for the HFCT concentration.
- Continue evaluation of courses offered.
- Continue development of HFCT courses and labs.
- Continue working on promoting the program and recruiting students.
- Attend seminars and meetings to disseminate program results.

FY 2010 Publications/Presentations

Special Recognitions & Awards/Patents Issued

It is noted that paper #1 was recognized by the American Society for Engineering Education Energy Conversion and Conservation Division as recipients of “Best Paper Award”.
Objectives

The objective of this project is to develop a comprehensive university-level education program that will:

- Provide exposure to the basics of hydrogen-based technologies to a large number of students. This exposure will provide a level of training that will allow students to converse and work with other scientists and engineers in this field. It will also serve to spark a level of interest in a subset of students who will then continue with more advanced coursework and/or research.

- Provide a “mid-level” training to a moderate level of students. More detailed and directed education will provide students with the ability to work to support industry and government development of hydrogen technologies. This level of training would be sufficient to work in the industry, but not be a leader in research and development.

- Provide detailed training to a smaller subset of students with a strong interest and propensity to make significant contributions to the technology development. These individuals will have extensive hands-on experience through internships that will allow them to play a major role in industry, government, and academia.

For the purposes of this grant, the terms hydrogen-based technologies, hydrogen energy and hydrogen education are used broadly to include the production, transport, storage, and utilization of hydrogen. This includes both electrolysis and fuel cell applications.

Technical Barriers

This project addresses the following technical barriers from the Education Section (3.9) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- (A) Lack of Readily Available, Objective, and Technically Accurate Information
- (B) Mixed Messages
- (C) Disconnect Between Hydrogen Information and Dissemination Networks
- (D) Lack of Educated Trainers and Training Opportunities

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 21: Launch new university hydrogen education program. (4Q, 2009)

Accomplishments

- Case studies targeting 1) freshman introductory engineering courses, 2) chemical engineering mass and energy balances, and 3) chemical engineering thermodynamics have been implemented into the undergraduate curriculum.

- The course content in EE 522-Renewable Energy Systems was modified to increase the content related to fuel cells and electrolysis. A new course, Hydrogen Production and Storage was developed and taught. Approximately 60 students per semester enroll in these two courses.

Two undergraduate students have been placed for internships as the Energy & Environmental Research Center’s (EERC’s) National Center for Hydrogen Technology. One intern from last year is now employed there. Two interns have been placed at Oak Ridge National Laboratory.
Three new experimental setups were designed and implemented into chemical and electrical engineering undergraduate laboratories.

Two senior design projects were completed focused on various aspects of hydrogen production.

The student organization, PowerOn developed experiments that will be incorporated into a mobile laboratory that are being presented to middle schools as a part of a program to stimulate interest in science, technology, engineering, and mathematics areas.

Introduction

The basic concept of the project is to introduce hydrogen education to a broad distribution of students through the use of structured case studies and experiments that are built into the students’ required coursework. This guarantees that all undergraduate students will be exposed to the technologies. This level of exposure should generate interest in a subset of these students who would then be interested in taking full semester courses related to hydrogen technologies. This will provide a significant cohort of students that will have a good understanding of the basics making them candidates for entry level jobs in hydrogen-related industries. A smaller subset of these students showing strong interest and aptitude will participate in directed research and internships to produce Bachelor of Science, Master of Science and Doctorate graduates that will play a major role in the future development of the hydrogen technology. UND’s distance education experience will be used to reach a large and widely dispersed group of students.

Approach

UND is taking advantage of existing infrastructure and programs to provide a comprehensive renewable hydrogen production and fuel cell education program. This program is comprehensive from the standpoint of the level and number of students that will be involved in the program. It is designed to provide multi-discipline formal training to both undergraduate and graduate level engineers and scientists. This will be accomplished by developing case studies that will be implemented into classes through all four years of the undergraduate curriculum. These case studies will be broadly disseminated though the National Center for Case Studies in Science Teaching Web site making them available to any school in the United States. Two new classes will be generated that will be offered as technical electives at the undergraduate and graduate level. In addition to our on-campus students, the undergraduate class will also be offered though our Distance Education Degree Program (DEDP) to provide access to hundreds of off-campus students across the country and other nations. UND’s DEDP program is the nation’s only ABET (formerly the Accreditation Board for Engineering and Technology) Engineering Accreditation Commission accredited undergraduate engineering program. Several new hydrogen-related student experiments will be added to our undergraduate laboratory sequence to provide hands-on experience for our students. Additional hands-on experience will be available to selected students through our on-going research at UND, and through summer intern programs to be established with the National Renewable Energy Laboratory (NREL) and Distributed Energy Systems (designer and manufacturer of proton exchange membrane [PEM] hydrogen production systems). UND will develop a hydrogen seminar, bringing in experts in the field from NREL and Distributed Energy Systems to present to UND students. Internships and research opportunities are also available for students at UND EERC.

This program is designed to provide an introduction of hydrogen energy to a large number of students, both on and off the UND campus through the case studies and student laboratories. It will provide more detailed training on the topic to a smaller, but still significant group of students through two new courses that will be added to our curriculum and offered through our distance program. In-depth training will be provided to a select group of undergraduate and graduate students through in-house research and internships with the EERC, NREL, and Distributed Energy Systems. We feel this approach will provide high quality students with the exposure of hydrogen energy required to support research, development, and demonstration activities in the government, industry and academia sectors.

Results

The first in a series of case studies developed for this program were implemented in the freshman Introduction to Chemical Engineering course this spring. The intent is to introduce students to the basics of a fuel cell and its importance and relative place in helping the U.S. meet its future energy needs. This case study will also be used to demonstrate the interactions between electrochemistry and chemical, electrical, and mechanical engineering required to fully develop and deploy fuel cell technology. Other case studies developed for courses such as Chemical Engineering Fundamentals, and Thermodynamics will focus on technical aspects of hydrogen production and use.

A course entitled Hydrogen Production and Storage was developed was taught during the fall semester. The course was being recorded and can be uploaded at a later date in the UND or DOE Web site.

Two new series of laboratory experiments have been developed and implemented into the undergraduate
curriculum using new experimental setups purchased from Heliocentris though the support of the DOE. The HP 600 includes a 600 watt water-cooled PEM fuel cell stack, a direct current (DC)/DC and DC/alternating current (AC) converter, metal hydride storage kit, electric load, and an integrated control system. The off-grid instructor includes a 40 watt fuel cell with integrated microprocessor, electronic load, metal hydride storage, and the constructor kit. A Masters student developed the set of laboratories that are being implemented into the undergraduate curriculum during the 2009-2010 academic year.

In addition to performing the basic experiments to generate current-voltage (IV) and power curves, an experiment was added to record individual cell responses to increases in load current. Ambient temperature (approximately 26°C versus stack temperature of approximately 40 degrees) impacts the performance of the outer cells, and therefore, the overall performance of the stack. However, it is assumed that the effect is minimal. Examining the performance of individual cells can help explain the overall behavior of the stack and is a good introduction for student investigation into the more complex reactions occurring in each cell (see Figure 1).

A second set of experiments was developed to demonstrate the effectiveness of the fuel cell as a power source under varying load conditions. Students begin by generating the typical IV curve and power curve to develop an understanding of efficiency as a function of load. Dynamic load tests show the students the lag time between a change in load and the response of the fuel cell. For electrical engineering labs, this can be further utilized to develop equivalent circuits and to study the time constants related to a dynamic system. Typical results are shown in Figure 2.

ABET requires institutions of higher education to demonstrate that their students achieve a number of program outcomes. Several of these outcomes and objectives address the need for engineers who can apply knowledge from the classroom to real-world problems. The use of hands-on experiments designed to encourage student exploration is one of the ways UND prepares students to be successful engineers. Hands-on experiential learning allows students to supplement their classroom background with actual results and to improve critical thinking skills by developing and solving research problems of their own design. Details of these student laboratories were presented at the 2010 summer meeting of the American Society of Engineering Education.

Two senior design projects were completed. One senior design group from chemical engineering chose to design a process that utilizes a waste gas stream from a biomass to fuel processing plant to produce hydrogen. The waste stream contained small amounts of hydrogen, methane, ethane, propane, with a larger amount of CO and the balance of nitrogen and CO₂. Using a steam reforming and high and low shift reactors followed by a Benfield separation plant, the group demonstrated that the process is technically and economically feasible. The group showed that this utilizing this waste stream as a source of hydrogen was technically feasible, and economically feasible (depending upon the assumptions made for the price of hydrogen). A senior design project in Electrical Engineering involved developing a lab-scale electrolyzer system that can be used as a teaching tool, or in applications requiring small hydrogen flows.

**Conclusions and Future Directions**

To date this project has impacted approximately 120 students, primarily through the classroom and laboratory experiences. When fully implemented, it is expected that approximately 200 students per year will be exposed to case studies and laboratories at UND. A group of approximately 10 students have been fully immersed in hydrogen technology through the capstone design experience.
During the next year work will continue on development of additional case studies. The case studies will be published to provide national access. Additional experiments and demonstrations will be developed for the new equipment. Recruitment and placement of additional internships will be undertaken. Efforts will be made to bring in an outside speaker for the hydrogen seminar.

**Special Recognitions & Awards**

**FY 2010 Publications/Presentations**

Objectives

Through both segments of the project: 1) education and 2) deployment, the objective has been focused on increasing hydrogen awareness through:

- Continued education of an ever-broadening group of stakeholders to the benefits of fuel cell and hydrogen technologies in material handling applications to include: facility management, operators, maintenance personnel, safety groups, first responders, authorities having jurisdiction, technical/community colleges.

- Demonstration of fuel cell and hydrogen technology through the continuing demonstration schedule of two hydrogen fuel cell-powered lift trucks in real-world applications at large prominent companies.

- Demonstration of these fuel cell-powered trucks at high profile public events.

- Assisting in the further commercialization of fuel cell and hydrogen technology by establishing a series of cost value propositions to interested companies.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.95) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(B) Mixed Messages

- Product Performance
- Limited Model Availability
- Infrastructure/Cost Justification

Contribution to Achievement of DOE Technology Validation Education Milestones

This project has and will continue to contribute to achievement of the following DOE milestones from the Education section of the Fuel Cell Technologies Multi-Year Research, Development and Demonstration Plan:

- **Milestone 1:** Developed “Awareness- Level” information for first responders (4Q, 2009). Accomplished by LiftOne’s on-site presentation to the Kannapolis, NC, Fire Department of the Hydrogen 101 seminar, with specific emphasis on hydrogen properties, safety items and general hydrogen awareness geared toward fuel cell applications for material handling applications. Included was a live demonstration of the fuel cell-powered lift truck (10/09). More are planned for September and October - 2010.

- **Milestone 14:** Hold community seminars to introduce local segments of the community to hydrogen (3Q, 2009, 4Q 2009, 1Q 2010). Accomplished through participation and “live” demonstrations at regional business events such as the “Green Is Good For Business Expo” (Columbia, SC - 9/2009); North Carolina Trucking Association Maintenance Council Chapter Meetings (Charlotte -10/09 and Asheville -1/10); BMW’s H2 Expo (Greer, SC 11/2009) (see Figure 1); “Upstate Green Business Summit”, (Spartanburg, SC - 4/10).

- **Milestone 18:** Develop end-user workshop materials for use at events. (3Q, 2009 through 4Q 2010). The LiftOne hydrogen fuel cell-powered lift trucks continue to be shown in conjunction with both the projects’ deployments and at the Hydrogen 101 Sessions conducted with end-users at the LiftOne branch locations in NC, SC and VA. Moreover, the education sessions were updated to include real-world performance data from the deployments and the evolving cost models for group discussions.
**Milestone 19**: Develop short courses for end-users at technical colleges (3Q, 2010 through 2Q, 2011). The LiftOne Hydrogen 101 Seminar has been condensed for presentations at local technical and community colleges, and includes the live demonstration of the fuel cell power pack. Two additional sessions are planned for the upcoming year.

**Milestone 29**: Evaluate knowledge and opinion of hydrogen technology of key target audiences and progress toward meeting objectives. (4Q, 2009 through 4Q, 2010). Each Hydrogen education session includes an introduction segment where the hydrogen awareness level of each attendee is assessed. Again, these sessions have primarily included attendees that manage material handling fleets at large companies.

**Accomplishments**

- Within the past 12 months, LiftOne has successfully executed and concluded five deployments of two CAT® electric sit-down rider lift trucks powered by the Hydrogenics Fuel Cell Power Packs. The data from these deployments were compiled and sent to the National Renewable Energy Laboratory for analysis.
- The final of the project’s six deployments commenced in early July and will continue through mid-August. Through these deployments, end-users are introduced to the benefits of fuel cell power with the hands-on experience of operation and refueling.
- LiftOne’s participation at one of the five sites (in conjunction with two other providers), led to an agreement for the eventual acquisition of over 100 fuel cells for a large corporation. The collective effort was a major triumph for the fuel cell industry.
- LiftOne’s continued participation at several regional city “Green Business” expos and forums, with live demonstrations of the working fuel cell-powered lift trucks, has provided a large cross-section of businesses with the opportunity to witness this alternative and clean source of fuel cell power. As a result, the general awareness level of hydrogen has been increased in regional areas including Charlotte, North Carolina, and the cities of Greenville, Columbia and Spartanburg in South Carolina.

**Introduction**

The materials handling industry, a $12 billion global market representing approximately 750,000 lift trucks sold each year, has proven to be a significant near-term market for fuel cell adoption in a mobility application. This is due to the lack of emissions and the increased productivity the technology provides vs. that of using lead-acid batteries or fossil fuels (propane, gasoline, diesel) for lift trucks and other material-handling units. As a leading dealership in the Carolinas and Virginia, LiftOne first demonstrated proton exchange membrane (PEM) fuel cells in 2007, and was able to gain early field trial experience, while recognizing the acute need for overall hydrogen education.

To assist in facilitating the integration of hydrogen fuel cells into real-world material handling application, LiftOne developed a Hydrogen education and awareness presentation for lift truck users. These sessions have been conducted at each of the LiftOne branches on a rotational basis. Additional sessions have been tailored for presentations at selected technical colleges, professional organization meetings, industrial shows and to large companies in a Web format. These Hydrogen awareness classes began in early 2009, and will continue through August of 2011. The Deployment Segment of the LiftOne project, where the two fuel cell-powered lift trucks are put into real-world applications at six strategically selected major companies’ facilities for one-month long trials, provide an excellent method for demonstrating the viability of fuel cell power. The deployments began in May of 2009 and will conclude in August of 2010.

**Approach**

Recognizing the need to help increase hydrogen awareness among material handling users, LiftOne’s approach for Hydrogen education has been focused on the identification of key target audiences. This strategy has been employed for both the education and deployment segments. For the education segment, the seminar content has been designed for the layman’s introduction to hydrogen and included in the 4-5 hour-long sessions are a thorough review of hydrogen uses, its properties, infrastructure review as well as

---

**FIGURE 1.** LiftOne’s Display Booth at the BMW H2 Expo, Greer, SC, November, 2009
acquisition cost models and a live demonstration. The target audience for the education segment includes representatives from companies operating medium to large electric material handling fleets, with a secondary audience being those operating fossil fuel-powered fleets. Smaller fleet operators also have participated.

For the LiftOne deployment segment, high profile companies with sizable fleets and multiple locations were selected for the trial sites, in order to gain the best opportunities with potential for effective regional exposure. For each site, presentations and proposals for the trials were made, detailing the equipment, fueler location/regulations, on-site monitoring arrangements and data gathering. At the conclusion of each deployment, comprehensive review meetings are held, in which all performance data presented, feedback from operators reviewed, and a cost justification evaluations presented with full proposals for fuel cell and infrastructure acquisition for more involved “pilot” type programs.

Results

Over the past year, LiftOne has seen positive results in both the education and deployment segments associated with the project. Close to 20 hydrogen education sessions have been conducted at the LiftOne branches, at customer locations, at community colleges and at the regional “Green” type business expos attended. At each session or event, LiftOne has included a live demonstration of the working fuel cell-powered lift truck, an essential element necessary to satisfy the interest present and maximize awareness. A positive development has been LiftOne’s tailoring of the hydrogen education session content to cater to the specific participating groups. In some cases, the session length has been shortened to encourage optimum participation. LiftOne also conducted a special session on hydrogen safety at the Kannapolis, NC, Fire Department that was transmitted simultaneously to multiple fire stations, and resulted from the fire department’s participation at the Deployment #1 Orientation.

For the deployment segment of the project there have generally been medium to excellent results. The deployments were conducted at: 1) Stanley Tools, 2) ABC Company (name withheld by request), 3) Bausch & Lomb, 4) BMW, 5) Electrolux and 6) AGI - In Store (underway presently). There were good results at all sites with regard to run time, truck performance, power, and ease of refueling. At site # 2, there was some component failure on the fuel cell power packs that were corrected with parts replacements. There was never any danger as the system detectors in the packs worked to detect and shut down, while the input gathered allowed the manufacturer to make corrections. All sites were able to experience fuel cell power, with well over 200 employees at each site made aware of the hydrogen power. Site # 4 had particularly good results, and the trial among three fuel cell companies resulted in a large-scale fuel cell adoption by that company (see Table 1). LiftOne was able to self-grade each of the five completed deployments (Table 2).

Conclusions and Future Directions

For the second year of the LiftOne hydrogen education project, the following conclusions have been determined:

- The intrigue concerning fuel cells was addressed, as a wide variety of users were able to learn and see the hydrogen fuel cells powering lift trucks in real-world applications.
- The fuel cell power option is a viable method of accomplishing the work in most lift truck applications – however not all applications are ideal, for a variety of reasons.
The cost justification is not there for every facility; larger fleets are still a requirement.

Infrastructure cost remains a major concern for companies considering eventual fuel cell adoption.

Future plans for year three of the project involve:

- The hydrogen education sessions will continue at the LiftOne branches, at company sites and in some cases in Web-based formats for larger companies with multiple locations.
- Continued participation at material handling events, seminars and area business expos.
- Continued follow up with completed deployment sites to encourage fuel cell acquisition.

**FY 2010 Publications/Presentations**

X.9 Hydrogen Education in Texas

Objectives

- Project Aim: Increase basic knowledge and awareness of Texas state and local government leaders about hydrogen and fuel cell technologies.
- Project Objectives:
  - Establish communications to reach the target audience.
  - Assemble needed materials for education and outreach.
  - Conduct workshops and webinars for the five major Texas cities/regions.

Technical Barriers

This project addresses the following technical barriers from the Education Section (3.9) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Readily Available, Objective, and Technically Accurate Information

(C) Disconnect Between Hydrogen Information and Dissemination Networks

(E) Regional Differences

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

Accomplishments

- Developed Texas e-mail hydrogen/fuel cell contact list to reach target audiences.
- Initiated discussions with regional contacts, including Clean Cities’ coordinators, to assist and participate in organizing and conducting metro area workshops.
- Conducted outreach and education activities including four Texas Hydrogen 101 education workshops in four target metro areas; eight outreach events featuring Hydrogen 101 education material and displays in the Dallas/Ft. Worth, Austin, San Antonio, and Houston metro areas and three briefings in Austin and Houston.
- Organized display and demonstration of hydrogen fuel cell transit bus at three outreach events; two in Austin and one in the Dallas/Ft. Worth area.
- Presented project at the DOE 2009 and 2010 Annual Merit Review events.
- Completed and deployed Web site design.
- Assembled basic educational materials, including information on Texas and hydrogen.
- Compiled baseline awareness information of workshop participants.
- Co-sponsored student participation in hydrogen fuel cell vehicle competition: University of Houston School of Technology; Shell Eco-Marathon.
- Organized tour of Houston food warehouse with new fuel cell fork trucks.

Introduction

Between 2000 and 2004, Texas demonstrated considerable interest and activity related to hydrogen and fuel cell technology. During that time, the HARC organized a fuel cell consortium and created a fuel cell testing lab. Interest and activities have declined in the State since 2004. In 2008, in cooperation with the Texas...
H2 Coalition and the State Energy Conservation Office, HARC developed the Texas Hydrogen Roadmap. It was apparent from analysis conducted for this report that Texas has significant advantages for hydrogen and fuel cell adoption, but there is relatively little activity within Texas compared with other key states. The provision of informational materials and activities through outreach and education was seen as an effective way of reaching decision makers in Texas. Previous hydrogen/fuel cell efforts by Texas and the Texas H2 Coalition had targeted the five major Texas urban areas, and this same targeting approach was adopted for this project.

**Approach**

The overall approach for this project takes advantage of HARC’s experience in energy and air quality programs to conduct outreach and education efforts to reach state and local government leaders. Many of these decision makers know of HARC and are located in the five largest metropolitan areas (Figure 1). In addition, the Texas H2 Coalition had worked in most of the target cities to explore hydrogen and fuel cell projects. The outreach and education activities identified for this project included establishing communications with key organizations in these areas (particularly Clean Cities), compiling contact information on the target audience, and conducting workshops and briefings to communicate hydrogen and fuel cell education information. These activities have been organized, whenever possible, in coordination with other metro area events and activities.

**Results**

The major results to date on this project have been (1) establishing key contacts in each of the target regions, (2) scheduling and implementing hydrogen education workshops, and (3) conducting outreach events in target metro areas. Based on discussions with other state hydrogen education programs, it was important to coordinate workshops with key organizations in the Texas metropolitan areas to best reach the target audience. The workshop format was revised to be shorter in duration with more opportunities for follow-up activities, such as briefings to identified individuals or groups, and participation at related conferences and workshops.

Educational materials developed by DOE and other organizations were reviewed by project staff to determine how they could be utilized. One-page flyers on each topical areas have been provided to participants, and incorporated in the project’s Web site. A limited number of links to key educational materials and sites was included in the Web site design to refer the target audience to the most relevant, accurate, and informative information sources (for example, DOE’s hydrogen code training Web site). HARC had previously published the Texas Hydrogen Roadmap working with the State Energy Conservation Office, and had compiled Texas-relevant information that could be used for outreach and education. Some of these were incorporated in presentation materials. In addition, HARC identified recent hydrogen fuel cell applications in Texas, including a fuel cell bus and fueling station at the University of Texas at Austin, over 130 new fuel cell fork trucks, and deployment of fuel cells for cell phone tower back-up power. These have been used in the project as real world examples for outreach and education. This included having the fuel cell bus at two workshops and speakers on the fuel cell fork truck deployments.

As an example of coordinative activities, HARC identified a joint opportunity with the National Renewable Energy Laboratory’s (NREL’s) hydrogen code training workshop in San Antonio. HARC worked with NREL staff and contractors to establish a date and meeting place for these two events. This enabled local government staff to publicize and recruit participants for these related events. HARC has been involved in a previous project with area government staff on alternative fuels for the regional airport. The
The San Antonio area has been considering hydrogen fuel cells as one of their options of interest for potential application at the airport and in related activities at or near the airport. The new fuel cell forklifts that are to be located in the San Antonio area will serve as a real world example for further outreach and education.

Following discussions with various organizations, workshop dates and venues were identified for the Houston, Austin, San Antonio, and Dallas/Ft. Worth areas. The Houston event occurred as part of two related events that reached the target audience, a conference on air quality and another on energy. In all target cities, HARC has worked with Clean Cities’ coordinators to communicate with the target audience.

The project has sought ways to assess progress on improving basic knowledge of hydrogen and fuel cells. Toward this end, questions have been posed as part ofbriefings and outreach to roughly assess the current level of knowledge of the target audience. Topic areas from the DOE’s hydrogen education surveys have been used for this purpose to help establish a baseline. Follow-up assessments will be used with workshop participants to gauge progress. This has not been intended as a test/post test survey process, but a rough guide to improving materials and messages in the workshops, as well as improving information on the website.

Finally, various incentives were used to help ensure active participation in Texas workshops and briefings. For example solar flashlights, fuel cell kits and a fuel cell remote control car were used as part of workshops and conference displays, and awarded to participants.

**Summary and Future Directions**

- The final Hydrogen 101 workshop will be held in the Austin area to follow up on contacts with key state and local leaders.
- Project staff will help inform target audiences in Texas of the Fuel Cell Seminar to be held in San Antonio, October 18-21, 2010.
- Additional opportunities for briefings to target audience will be identified.
- Target audience contacts will continue to be expanded.
- Follow-up assessments will be distributed to participants and the target email list.
- The major conclusions to date are: (1) the key role that Clean Cities programs can play as a conduit to target audiences, and (2) the importance of having real-world applications, such as fuel cell buses, fuel cell fork trucks, and associated hydrogen fueling, for gaining interest.

X.10 Development of Hydrogen Education Programs for Government Officials

Shannon Baxter-Clemmons (Primary Contact),
Chris Daetwyler
South Carolina Hydrogen and Fuel Cell Alliance (SCHFCA)
Post Office Box 12302
Columbia, SC 29211
Phone: (803) 727-2897
E-mail: baxterclemmons@schydrogen.org

DOE Technology Development Manager: Carole Read
Phone: (202) 586-3152
E-mail: Carole.Read@ee.doe.gov

DOE Project Officer: Gregory Kleen
Phone: (303) 275-4875
E-mail: Greg.Kleen@go.doe.gov

Contract Number: DE-FG36-08GO18113
Subcontractor: Greenway Energy, Aiken, SC

Project Start Date: October 1, 2008
Project End Date: September 30, 2011

Objectives:

- Synthesize objective and technically accurate information that will be made available to a wide audience through the internet, a national meeting, and training sessions.
- Design and develop educational programs that will clarify the benefits and challenges of moving to a hydrogen economy that avoid over-selling hydrogen technologies.
- Leverage relationships with project team organizations in South Carolina to deploy hydrogen education materials to government and code officials.
- Train a group of hydrogen educators at the project team institutions (The South Carolina Energy Office, The State Fire Marshal’s Office, the SCHFCA and Greenway Energy) who will be resources on hydrogen and fuel cells to the target audiences.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Readily Available, Objective, and Technically Accurate Information
(B) Mixed Messages
(C) Disconnect Between Hydrogen Information and Dissemination Networks
(D) Lack of Educated Trainers and Training Opportunities
(E) Regional Differences
(F) Difficulty of Measuring Success

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education (3.9) section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 11: Develop set of introductory materials suitable for a non-technical audience. (4Q, 2006)
- Milestone 13: Develop materials for community seminars. (4Q, 2008)
- Milestone 14: Hold community seminars to introduce local residents to hydrogen. (4Q, 2008 through 4Q, 2012)
- Milestone 29: Evaluate knowledge and opinion of hydrogen technology of key target audiences and progress toward meeting objectives. (4Q, 2009)

Accomplishments

- Conducted in-person presentations to over 20 groups of targeted South Carolina decision makers.
- Held eight Webinars to provide information to stakeholders throughout South Carolina.
- Reached 1,446 targeted additional state and local government officials and decision makers.
- Created a SlideShare channel through which webinar presentations can be viewed.
- Placed hydrogen education videos on the SCHFCA YouTube channel.
- Developed over 20 topic specific slides that included value proposition for telecommunications, permitting of fuel cells, etc.
- Produced a tri-fold handout that summarizes key messages with a fun quiz.
- Maintain a Web site that keeps a running log of industry news and allows access to fact sheets at www.schydrogen.org.
Introduction

Hydrogen and fuel cell technologies are moving out of the laboratory and into economically competitive niche markets such as cell phone tower back-up power and forklift operations. As hydrogen technologies become competitive in these early markets, communities will need to be educated about the opportunities afforded by hydrogen technologies and about safety concerns associated with them. The Hydrogen 101 program led by the SCHFCA seeks to raise awareness about hydrogen and fuel cells to community leaders within South Carolina and the Southeast.

South Carolina is among a small, but growing, number of states that have a hydrogen implementation strategy and is on the leading edge of fuel cell research and adoption. The state has been recognized as one of the top five fuel cell states by Fuel Cells 2000 in 2010 but a lack of information regarding the hydrogen and fuel cell industry still exists among state and local leaders. In order to maximize the resources existing in the state and surrounding region, it is imperative that an effective outreach and education program be conducted so that the decision to accept hydrogen technologies in the local community is informed and wise.

During the legislative process to pass the South Carolina Hydrogen and Fuel Cell Permitting Act into law, a need for additional educational efforts within the South Carolina legislature was identified. We learned that there was very little opposition to hydrogen and fuel cells in state government but quite a bit of ambivalence. The ambivalence grew from a lack of exposure and understanding to the potential for a hydrogen and fuel cell industry in South Carolina.

Approach

The project team is composed of South Carolina-based hydrogen experts with connections to technically accurate information; and, civic organizations and associations with the communications networks and events with our target audience already established. The entire team works together to identify specific messaging that local audiences are interested in. Based on the feedback we gather from the civic organizations and other community opinion leaders, education materials and demonstrations are developed.

The marketing of the program is conducted through the existing Web sites, e-mail distribution lists and communication networks. The distribution of the material is primarily conducted at events associated with each of the civic associations partnered on the project, however, several stand-alone events and Webinars were conducted.

Results

A major achievement of the SCHFCA was the creation of a support base among community leaders to champion hydrogen related initiatives at the state level. The support base was built through the DOE Hydrogen 101 program by delivering presentations and webinars to groups of leaders throughout the state. A good example of the progress achieve through the Hydrogen 101 program was the passage of the South Carolina Hydrogen and Fuel Cell Permitting Act that had support from project partners such as the South Carolina Municipal Association, the State Fire Marshal’s Office, local stakeholders and SCHFCA members.

After focusing mostly on maximizing the messaging to state leaders from the National Hydrogen Association meeting in Columbia in 2009, the Hydrogen 101 program in 2010 expanded its audience to include state and local government officials from a wide variety of groups impacting the adoption of hydrogen and fuel cells. The program performed outreach to these groups through group presentations, Webinars, and focused small group and individual meetings. Presentation materials and fact sheets were updated and expanded depending on the audience and tri-fold brochures were printed to summarize key messages.

The SCHFCA Hydrogen 101 program far exceeded the original goal of three Webinars and eight in-person presentations with eight Webinars and over 20 presentations. The direct number of targeted, high-quality stakeholders reached was 1,446 and the wider educational efforts that leveraged Hydrogen 101 materials reached over 1 million people. In addition to
education of leadership groups, the SCHFCA has started reaching out to candidates for political offices who will be filling vacated offices in 2010. This includes talking with candidates to replace the current term-limited governor and candidates running for three Congressional seats without an incumbent.

Groups have been overwhelmingly supportive of hydrogen and fuel cell technologies as a result of the presentations and view the technologies as having the potential to foster economic development within the state. There was significant interest in the value proposition for the fuel cell technologies and additional information regarding the economics of these technologies was of interest to the audiences.

Conclusions and Future Directions

The SCHFCA Hydrogen 101 program has met all of the yearly goals and our efforts are having an impact in creating wider support for hydrogen. A concrete goal that was assisted by Hydrogen 101 was the passage of the South Carolina Hydrogen and Fuel Cell Permitting Act. In 2011, our efforts will focus on:

- Finalizing the market value proposition case studies for cell tower backup power, material handling equipment and combined heat and power units.
- Using the case studies as an educational tool with government leaders and business decision-makers within industries that can utilize fuel cells (i.e. forklifts).
- Work with the South Carolina Department of Health and Environmental Control to investigate the streamlining of air permits for hydrogen and fuel cell technologies.

Contract Number: DE-FG36-08GO18115

Subcontractors:
- Catherine E. Grégoire Padró, P.E.
  Los Alamos National Laboratory, Los Alamos, NM
- Greg Jackson and Peter B. Sunderland
  University of Maryland, College Park, MD

Project Start Date: September 1, 2008
Project End Date: September 30, 2011

Objectives
The goal of the three-year project is to increase a targeted audience's understanding of hydrogen and fuel cells, including early market applications, and to provide specific examples of actions that the targeted audience - state and local government leaders - can take to support the development and use of hydrogen and fuel cell technology leading to better understanding of the community benefits that can result. The main objectives of the two-year project are to:

- Conduct a dozen workshops by technical experts and professional educators.
- Produce video resources for public television, seminar use, and DOE/general public.
- Use hardware demonstrations when possible and provide real-world examples of technology.
- Produce electronic “magazine” articles on hydrogen technology demonstrations and other instructional project deliverables.

Technical Barriers
This project addresses the following technical barriers from the Education section (3.9) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Readily Available, Objective, and Technically Accurate Information
(B) Mixed Messages
(C) Disconnect between Hydrogen Information and Dissemination Networks
(D) Lack of Educated Trainers and Training Opportunities
(F) Difficulty in Measuring Success

Contribution to Achievement of DOE Education Milestones
This project will contribute to achievement of the following DOE milestones from the Education Technical Plan (3.9) section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 17: Hold “Hydrogen 101” seminars.
  (4Q 2008 through 4Q, 2009)

Accomplishments
The following has been accomplished from July 2009 – June 2010 by Virginia Clean Cities and project partners:

- Developed key partnerships with over 30 different public and private organizations in Virginia/Washington D.C./Maryland to promote the Hydrogen Program and message.
- Conducted two “Hydrogen 101” seminars in Virginia and Washington D.C.
- Finished shooting for and wrapping up production of second year MotorWeek video.
- Completed four of four articles.
- Developed and updated Web site and social media tools (Facebook, YouTube, Twitter).
- Produced two versions of seminar curriculum.
- Held ride-n-drives of Equinox fuel cell electric vehicle and coordinated tour at Shell Hydrogen station in Washington D.C. for local decision makers.
- Published quarterly newsletters.
- Implemented surveys at each workshop.
- Developed draft for 3-part, 5-hour Web-based curriculum to be live Webcast and recorded for archiving.
Introduction

In order to change the way we use energy and to realize the vision of the hydrogen economy, not only will research and development need to persist by engineers and scientists, but decision makers will need to make informed public policy decisions and continue to support research and development as well as deployment activities. This project aims to raise awareness of hydrogen and fuel cell technologies, provide examples of what state and local government can do, and show how decision makers can support the development and use of hydrogen and fuel cell technologies.

The objectives of this project are to provide hydrogen and fuel cell technology learning opportunities through seminars, multi-media and video resources, technical support, and demonstrations to local and state government and decision makers in order to help state and local government leaders become familiar with hydrogen and how it fits in the portfolio of near-term and long-term energy choices, develop an accurate understanding of hydrogen safety, recognize opportunities, and understand their part in facilitating use of hydrogen and fuel cell technologies.

Approach

Our primary approach is to host in-person and Web-cast seminars for our target market, state and local governments. Messaging ties to the hydrogen knowledge survey, on which the subprogram objectives and targets are based. Under DOE guidance, existing Hydrogen Education subprogram resources and new contributions by team members are considered. Educational content focuses primarily on a basic understanding of hydrogen properties and the energy security and environmental benefits of hydrogen and fuel cell technologies, but also focuses on more technical subjects related to fuel cells and other modes of hydrogen energy conversion. Special consideration has been given to “following the technology” and resources also concentrate on areas where hydrogen and fuel cells are publicly visible through demonstration projects or early niche market commercialization efforts, such as the Defense Distribution Depot, Susquehanna, PA hydrogen fuel cell forklift project.

Key to state and local government representative education is a broad understanding of how hydrogen supports decision-making on current opportunities and laying the foundation for long-term change. Additionally, providing real-world examples and demonstrations has been a key component of each seminar when demonstrations have been available. Demonstrations and tours such as of the Shell Hydrogen station in the District of Columbia have been well received.

Results

The major achievements over the last year include designing curriculum for and hosting two successful, and highly received seminars to date, completing a shooting schedule and beginning production of a second seven-minute video for seminar use and broadcasting on the Public Broadcasting Service (PBS), developing Webinar curriculum and identifying ways to provide continuing education credit, and developing a university student senior thesis deployment project. Additionally, individuals were interviewed to gather information for four electronic technology demonstration articles, which are now completed and available online for download.

Seminar Results

The curriculum prepared and presented by Dr. Catherine E. Grégoire Padró of Los Alamos National Laboratory at the November 13, 2009 and December 3, 2009 seminars covered the following content:

- Our current energy system
- What is hydrogen and what is a fuel cell?
- Why hydrogen?
- Hydrogen production, storage, distribution, and use
- Environmental, energy and economic implications
- Safety
- The future of hydrogen and fuel cells

At both seminars, a pre- and post-workshop quiz was given by Dr. Padró. The survey consists of 11 questions that were taken directly from the original DOE survey, conducted in 2004 [1]. The idea for choosing these questions was to maintain the standard set of questions to gauge learning and to compare to the 2004 baseline.

MotorWeek “Hydrogen Update” Video

Virginia Clean Cities worked with MotorWeek to shoot footage for the second year video. In addition to footage of many of the manufacturer-prepared vehicles, and early market applications at the 2010 National Hydrogen Association conference, footage also included interviews with leaders of hydrogen and fuel cell focused organizations. The video will likely run around seven minutes, and cover the theme of hydrogen as part of a portfolio of options and discuss early market opportunities.

The video will be completed by September 2010 and is scheduled to air on MotorWeek in the fall of 2010. MotorWeek is available on PBS and the SPEED channel. The first year video is available for viewing on the Virginia Clean Cities YouTube Channel at http://www.youtube.com/virginiacleancities.
Conclusions and Future Directions

The seminars that have been held to date have been very well received and the participants’ knowledge of hydrogen and fuel cell technology has increased as indicated by the surveys. The next year of this project will focus on the following outputs described below, as well as continuous improvement and increasing attendance through creative dissemination means.

Future Project Outputs

Over the next year, Virginia Clean Cities and partners will:

• Host up to five in-person seminars and Webinars and work with National Education Energy Development to co-host teacher training seminars.
• Complete more “technology profiles”/articles.
• Finish production of a second MotorWeek video.
• Conduct follow-up surveys of participants from past seminars.
• Record and archive several of the seminars to be linked from the Website.
• Continue to update Twitter, Facebook and YouTube.
• Attend events to discuss and promote project and project outputs.

Planning and Improvements

After surveying several targeted individuals, it was confirmed that travel restrictions and time constraints have affected our ability to attract participants at in-person workshops. It is our hope that the Webinars will address this issue. A preliminary outline has been developed and is undergoing review by several experts. Scheduling is being worked on to accommodate main instructors’ schedules.

Virginia Clean Cities worked to facilitate the development of a student thesis project at James Madison University. Seniors will begin designing and building a hydrogen fuel cell motorcycle beginning fall semester of 2010. Additionally, the students will develop an education and outreach program to compliment their thesis project.

Key Issues

The main issue relates to extra demands falling on current project participants as well as target audiences over the last year.

**Objectives**
- Foster strong relationships among federal, state, and local government officials, industry, and appropriate stakeholders.
- Serve as a conduit between the DOE and state and local government decision makers.
- Provide technically accurate and objective information to government decision-makers and identified stakeholders to improve/enhance decision making.
- Increase the knowledge base and improve awareness regarding the use of hydrogen and fuel cells.
- Provide support for hydrogen and fuel cells in early market applications, consistent with DOE’s market transformation efforts.

**Technical Barriers**

This project addresses the following technical barriers from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Lack of Readily Available, Objective, and Technically Accurate Information
- Mixed Messages
- Disconnect Between Hydrogen Information and Dissemination Networks
- Lack of Educated Trainers and Training Opportunities
- Difficulty of Measuring Success

This project will contribute to achievement of the following DOE milestones from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 30: Evaluate knowledge and opinion of hydrogen technology of key target audit audiences and progress toward meeting objectives. (4Q, 2012)

**Accomplishments**

- Identified key stakeholders at the local and state level to expand and strengthen partnerships.
- Performed a preliminary survey of local stakeholders and decision makers.
- Developed resources to analyze potential sites for hydrogen and fuel cell development. Resources include a database of potential sites for technology deployment and a report to identify criteria for the deployment of technologies for transportation and stationary applications.
- Developed a Web-based virtual regional resource center that provides online information, models and other tools to assist local, state and regional planners quantify the costs and benefits of hydrogen and fuel cell technology at potential sites. Models address environmental value, energy management, renewable hydrogen generation, distributed technology comparisons, and cost/economics of stationary fuel cells.
- Presented at nine regional planning agencies/regional councils of government.
- Exhibited at the Connecticut Conference of Municipalities Conference.
- Presented on a Bi-Monthly State and Regional Initiatives Call.
- Developed and held a workshop for municipalities.
- Developed and held a legislative briefing/forum.
- Provided information to municipal decision makers including hydrogen and fuel cell benefits and project analysis.
- Monitored state energy studies/plans for accurate information regarding hydrogen and fuel cells.
- Developing a plan with the Connecticut Department of Transportation for hydrogen fueling infrastructure and vehicles.
- Identified financial and investment opportunities for local, state and federal stakeholders.
Planned a regional briefing for outreach and establishment of dialogue between New England hydrogen and fuel cell stakeholders and decision makers.

- CCAT developed two hydrogen and fuel cell educational videos available online for dissemination.

Introduction

This project assists with the building of partnerships between the DOE, states and municipalities. CCAT is implementing this process and structure that provides an opportunity for federal, regional, state, and local involvement to encourage and promote the use of hydrogen and fuel cell technology. The structure includes leadership by the DOE; the establishment of collaborative meetings, workshops, and briefings to provide information to municipal and state decision makers; the provision of assistance to municipalities for the development of local energy plans; support for state stakeholder groups to implement initiatives in support of state and federal policies; and implementation of strategies to facilitate the deployment of hydrogen and fuel cell systems in the state.

CCAT developed a virtual regional resource center (RRC) that provides online information, models, and other tools to assist decision makers and end users to quantify the costs and benefits of hydrogen and fuel cell technology at potential sites. The RRC will assist local and state planners and decision-makers in identifying potential opportunities. CCAT developed models that assess environmental value, energy management, renewable energy, cost and economics, and comparisons of competing technologies.

Approach

CCAT’s approach has been to develop resources for hydrogen and fuel cell deployment to aid in the education of state and local decision makers. These resources include online information, models, and tools for potential users to analyze the costs and benefits of hydrogen and fuel cell technology. Coordination and cooperation is sought by both local and state decision-makers in order to introduce hydrogen and fuel cell technology in early market applications. The project uses local “bottoms up” decisions guided by state/regional “tops down” assistance to help reduce conflict, improve state/regional and municipal relations, and provide better solutions to community-based energy problems. Because of the high risk and high capital cost of implementing new technologies, CCAT also coordinates with local, state, and regional decision makers to identify innovative funding and procurement mechanisms, such as group purchases and corporate tax credits, to encourage market growth, reduce costs, and increase public acceptance.

Results

- CCAT has developed models that assess environmental value, energy management, renewable energy, cost and economics, and comparisons of competing technologies. These models make available information for non-technical and technical audiences, including state and local decision makers and potential end users and will be an integral component of education and outreach efforts. The models are described in the following.

Environmental Model

The Environmental Model assesses the environmental benefits of hydrogen and fuel cell applications compared with other conventional technologies. The model can be used to assess potential emissions reductions, including greenhouse gases, using hydrogen and fuel cell technology.

Economic/Cost Model

The Economic/Cost Model assesses potential yearly heating and electricity cost savings when using a commercially available fuel cell for baseload power. The model allows users to assess the economic viability of a fuel cell system.

Energy Management Model

The Energy Management Model assesses the efficiency benefits of stationary fuel cell applications. The model can be used to assess the potential energy savings using a fuel cell to replace conventional electricity generating technologies.

Distributed Technology Comparison

The Distributed Technology Comparison allows a user to compare fuel cells with other distributed energy technologies including microturbines, combustion turbines, reciprocating engines, photovoltaic systems, and wind turbines, based on certain criteria such as installation cost, efficiency, emissions, heat rate, etc.

Hydrogen Generation from Renewable Technology Model

The Renewables to Hydrogen Model assesses wind, photovoltaic and hydroelectric power generation technologies to identify hydrogen production capacities and average cost per kilogram of generated hydrogen from these renewable technologies.
CCAT has also completed a preliminary assessment of the level of knowledge and opinions of hydrogen and fuel cell technologies of local and state stakeholders to determine the effectiveness of the project implementation. In addition, other resources have been developed including criteria for target locations (i.e. supermarkets, institutions, industrial facilities) for the deployment of hydrogen and fuel cell technologies and educational videos that serve to increase the awareness levels of local and state stakeholders.

Through the development of models and associated outreach activities, CCAT has provided analytical services and project development assistance. Table 1 below depicts notable results from outreach efforts. In addition, CCAT has provided assistance to over 24 additional end-users including municipalities, state government, and commercial and industrial facilities.

**Conclusions and Future Directions**

This partnership effort has successfully created criteria, models and tools that allow for effective deployment of hydrogen and fuel cell technologies in early market applications. Models and tools have been created to facilitate the education of decision makers and end users as well as the ability to analyze potential sites for hydrogen and fuel cell technology.

Next steps include the execution of a regional briefing to be held on July 22, 2010 which will discuss federal, regional and state efforts, partnership opportunities, planning efforts and tools to facilitate project identification and development. CCAT will also undertake a concluding project survey to assess the effectiveness of the current outreach program.

Finally, CCAT seeks to leverage additional DOE funding to continue education and outreach efforts on the regional scale to encourage and support the development of state roadmaps. Through past project success, CCAT can effectively encourage and support the successful development and deployment of hydrogen and fuel cell projects in the New England region.

X.13 Raising $H_2$ and Fuel Cell Awareness in Ohio*

Patrick Valente  
Ohio Fuel Cell Coalition  
737 Bolivar Road, Suite 1000  
Cleveland, OH 44115  
Phone: (216) 363-6890  
E-mail: Pat.valente@fuelcellcorridor.com

DOE Technology Development Manager: Carole Read  
Phone: (202) 586-3152  
E-mail: Carole.Read@ee.doe.gov

DOE Project Officer: Gregory Kleen  
Phone: (303) 275-4875  
E-mail: Greg.Kleen@go.doe.gov

Contract Number: DE-FC36-08GO18117

Subcontractor:  
Edison Material Technology Center (EMTEC),  
Dayton, OH

Project Start Date: March 2009  
Project End Date: June 30, 2011  
*Congressionally directed project

**Objectives:**

- Increase understanding of hydrogen and fuel cell technologies among state and local governments by 10% compared to 2004 baseline.
- Increase knowledge of hydrogen and fuel cell technologies among key target populations (state and local governments) by 20 percent compared to 2004 baseline.

**Technical Barriers**

This project addresses the following technical barriers from the Education section of the Fuel Cell Technology Program Multiyear Research Development and Demonstration Plan:

(A) Lack of Readily Available, Objective and Technical Accurate Information

(B) Mixed Messages

(C) Disconnect Between Hydrogen Information and Dissemination Networks

(D) Lack of Educated Trainers and Training Opportunities

(E) Regional Differences

(F) Difficulty of Measuring Success

**Contribution to Achievement of DOE Education Milestones**

This project will contribute to the following milestones from the Education section of the Fuel Cell Technologies Program Multiyear Research Development and Demonstration Plan.

- **Milestone 11**: Develop set of introductory materials suitable for a non-technical audience (3Q, 2009)
- **Milestone 13**: Develop material for community seminars (ongoing)
- **Milestone 16**: Develop database of state activities (ongoing)
- **Milestone 17**: Hold “Hydrogen 101” seminars (3Q, 2009 through 2Q, 2011)

**Accomplishments**

- August 21, 2009 – ADA – Ohio Northern University – 50 people
- September 2, 2009 – Youngstown University – 50 people
- September 14, 2009 – Dayton, Ohio – 25 people
- October 19, 2009 – AFRL
- October 20, 2009 - Akron Sierra Club
- November 12, 2009 - Wayne County Sustainability Forum
- November 16, 2009 - US Fuel Cell Council Seminar
- December 12, 2009 - State House of Representatives Hearing
- January 13, 2010 – Ohio Board of Regents – Green Pathways Inaugural Meeting, Columbus, Ohio - 25 people
- February 4, 2010 – Presentation at Great Lakes Educational Partnership at Stark State College - 20 people
- February 23, 2010 – Ohio Economic Education Summit III - 50 people
- March 2, 2010 – STEM Education Panel at COSI in Columbus, Ohio - 40 people.
- April 9, 2010 – Dublin, Ohio - 75 people – Fuel Cells Opportunity for Growth in Central Ohio
- April 16, 2010 – Aurora, Ohio – 20 people – Industrial Advisory Board for the College of Technology of Kent State University
- May 4, 2010 – Columbus, Ohio – 40 people – 2010 Ohio State University Sustainability Conference
- May 6 and 7, 2010 – Cleveland, Ohio – 180 people – 2010 Symposium
The Ohio Fuel Cell Coalition was tasked with raising the awareness and understanding of fuel cells and the hydrogen economy. In 2009 through 2010 the Ohio Fuel Cell Coalition held 19 community leaders forums. A community leaders forum was held in conjunction with the 2010 Ohio Fuel Cell Symposium. On May 6 and 7 over 200 people gathered at the Great Lakes Science Center for the 2010 Ohio Fuel Cell Symposium. The Symposium presented by the Ohio Fuel Cell Coalition began with two community leaders forums where participants had an opportunity to learn about fuel cells and the hydrogen economy. Day 2 of the symposium opened with the focus in the morning on the theme of “Ten Years of Success and Beyond” and in the afternoon “Fuel Cells in the Commercial Market.” In the morning of the first day we honored Governor Bob Taft and Chairman Emeritus of the Ohio Fuel Cell Coalition, Trevor Jones for their lifetime achievements in advancing the fuel cell initiative in the State of Ohio. A panel discussion followed were Rodger McKain of Rolls-Royce, Lionel Batty of GrafTech, Bill Dawson of NexTech and Frank Svet of EMTEC discussed their successes over the last 10 years. In the afternoon, we started out with a panel discussion on the proposed Great Lakes Science Center Electrolysis Project. On that panel were Valerie Lyons of the National Aeronautics and Space Administration (NASA), Pete Buca of Parker Hannifin and George Shaw of NASA. They were followed by Bill Whittenberger of Catacel, Bob Rose of the US Fuel Cell Council and Mike McKay of the Ohio Department of Development. This event allowed the Coalition to educate over 200 individuals on fuel cells and the hydrogen economy which exceeded our expectations.

Approach

The approach we used and will be using for all the community leaders forums will be presentations by the Ohio Fuel Cell Coalition in conjunction with regional leaders. The presentations will be followed by question and answers periods followed up by informal discussions on fuel cells and the hydrogen economy.

Results

In summary, as you see the community leaders forums have been very successful in the last year with over 800 people being drawn to them. As always we followed up the forums with a survey and the survey results were very positive in that the participants had a significant increase in knowledge and awareness of fuel cells and the hydrogen economy.

Conclusions and Future Directions

We have received additional input on the community leaders forums and we continued to add input to future events. The following community leader forums will be held in the next three months:
- Cincinnati, Ohio
- Toledo, Ohio
- Athens, Ohio
- Dayton, Ohio
- Akron, Ohio
- Canton, Ohio
Objectives

- Create presentation materials tailored to effectively communicate with state and local government leaders...relate hydrogen to their interests and spheres of responsibility.
- Establish pathways for working with national associations of state and local officials as a route for disseminating information about hydrogen...set pattern for on-going information flow.
- Launch learning sessions by conducting initial workshops for local and state officials at national gatherings...achieve nationwide reach.
- Create the following report: Infrastructure for Fuel Cells Market Analysis. This report will establish improved understanding of the current state of production, distribution, storage, and the use of hydrogen, which is a critical fuel for the fuel cell industry and the backbone of fuel cell infrastructure. The data gathering and analysis will focus on the following main topics related to infrastructure for fuel cells.

Technical Barriers

This project addresses the following technical barriers from the Education section of the Fuel Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Lack of Readily Available, Objective, and Technically Accurate Information
- Mixed Messages
- Disconnect Between Hydrogen Information and Dissemination Networks
- Lack of Educated Trainers and Training Opportunities

Contribution to Achievement of DOE Education Milestones

The H2L3 project will directly address the following milestones of the Education sub-program:

- 17: Hold “Hydrogen 101” seminars. (4Q, 2008 through 4Q, 2012)
- 18: Develop end-user workshop materials for use at events. (4Q, 2009)
- 30: Evaluate knowledge and opinion of hydrogen technology of key target audiences and progress toward meeting objectives. (4Q, 2012)

The H2L3 project directly contributes to achieving these milestones by conducting education workshops with hundreds of local and state officials from across the country and, further, by training motivated local officials to replicate the workshops in their own communities. By fostering and using the H2L3 team’s existing dissemination network of national associations of local and state government officials, the reach and the credibility of the outreach will be substantially and uniquely strengthened. This dissemination network will continue to pay dividends to DOE beyond the three-year life of this project by establishing institutional relationships that will enable on-going and expanding opportunities for hydrogen outreach through the national associations representing local and state officials.

Accomplishments

- Core Curriculum
  - Comprehensive, basic presentation developed to communicate with audiences of state and local officials.
  - Curriculum trimmed or modified to tailor further for specific audiences as needed.
- Advisory Committee of Local and State Officials
  - Established an advisory committee comprised of Public Technology Institute members (local),
Introduction

Increasing education about hydrogen and fuel cells is a key need to enable widespread commercialization and in many cases the introduction of the related technologies. This project began with a focus on educating local leaders and has developed to include other ways to reach new audiences with educational and information tools that increase knowledge about hydrogen and fuel cells.

Approach

Activities include Hydrogen 101 in-person presentations, Webinars, the creation of a market report that features industry data not published before, the creation of a business solution forum for existing and potential hydrogen customers and a student contest to engage university students to design a hydrogen community in southern California.

Results

For brevity’s sake here is a summary of select results:

For the Hydrogen 101 presentations, through several different venues connected with the Public Technology Institute and the National Association of State Energy Officials, local leaders have been engaged from the following areas:

- Cincinnati Health Department
- City of Boston Environment Dept.
- City of Carlsbad, CA
- City of Cincinnati, OH
- City of Culver, CA
- City of Dayton, OH
- City of Des Moines, IA
- City of Fort Wayne IN
- City of Fort Worth, TX
- City of North Kingstown, RI
- City of Orlando, FL
- City of Phoenix, AZ
- City of San Diego, CA
- City of Santa Monica, CA
- City of South Sioux City, NE
- City of Wilmington, NC
- City of Winston-Salem, NC
- District of Washington, D.C.
- Fairfax County Dept. of Vehicle Services, VA
- Los Angeles County, CA
- Regional Governmental Services of CA
- San Diego County, CA
Feedback from attendees Hydrogen 101:

- “Very understandable”
- “For the first time, I understood what hydrogen is.”
- “Personally, I’m not that interested in this [topic] but my boss needed me to learn about it and now I won’t be totally lost.”
- “This was really good.”
- “Really informative.”
- “Showing the number of fueling stations made it real. I thought hydrogen was more of an impossibility before.”

Regarding the U.S. Market Report: Hydrogen and Fuel Cells, the report includes dozens of pages of results covering 57 different research areas. The full report and 8-point brief (see Figure 1) can be viewed and downloaded from: http://hydrogenassociation.org/marketreport. As of July 2010, the report has become the most popular download on the NHA Web site (see Table 1).

- “It’s outstanding and will be a very useful resource for the community. NHA should be proud to put our logo on your work..... Thanks for the chance to review this impressive document.” – Ken Schultz, Operations Director, Energy Group, General Atomics.
- “Lot of great data. I had no idea that there are so many renewable projects.” – Sandy Thomas, former President, H2Gen Innovations.
- “A really good report. I think the front sections will make a great reference tool on the hydrogen industry generally and I already learned a few things!” – Lisa Calaghan Jerram, Fuel Cell Today.
- “This is an excellent report. I think it is very useful.” – Dr. Finis H. Southworth, Chief Technology Officer, AREVA NP Inc.
- “I am working on a hydrogen study for the University of Colorado and the Reliability and Sustainability Energy Institute (RASEI). Your US Market report on Hydrogen is great.”
- “Excellent reports - some of the most salient data & information out there, and very well presented.” – Randy Cole, CEO at Renewable Opportunities, Inc, via LinkedIn.
- “Love the 8-point brief. Succinct and direct. Thanks for drawing our attention to it.” – Tom Sperrey, CEO, UPS Systems plc, via LinkedIn.
- “The brief version is my kind of report! The full version looks very useful; many thanks for sharing the link.” – Graham Cooley, CEO at ITM Power Plc, via LinkedIn.
- “Very well done and very much needed!” – Bay Elliott, EVP, Partner, Executive Recruiter, The Farwell Group, via LinkedIn.

**TOTAL DOWNLOADS (15July10)** 45,686
“Is it possible to obtain a copy of your report in a non-pdf format? I would like to utilize some of the graphs and figures regarding H2 Energy in an internal slide presentation. If not the whole study, specifically pages 26-37” – from an industrial gas supplier (obviously a significant compliment if they’re happy using this information internally).

“These are very nice reports. I circulated them within Proton.” – Mark Schiller, VP Business Development, Proton Energy Systems.

“You and your team did an excellent job. Congratulations!” – Patricia Irving, Ph.D., President & CEO, InnovaTek, Inc.

“This looks really, really nice. Thank you. I’ve stared teaching the graduate course at Wayne State University in alternative energy, and I plan to share this report with my class, as well as working it into my thinking about price and market position. Thank you again, and good luck with your work.” – Robert Buxbaum, President, REB Research & Consulting.

The 2010 Hydrogen Student Design Contest challenged teams of university students from around the world to plan and design the basic elements of a hydrogen community in Santa Monica, CA. They were asked to design one scalable hydrogen fueling station; identify renewable hydrogen sources in the community; and identify customers for early market hydrogen applications.

University teams from the United States, Canada, Bangladesh and Ukraine submitted contest entries. These entries were evaluated across ten different categories by a team of judges from government and industry.

The team from Missouri University of Science and Technology was declared the Grand Prize winner (see team photo, Figure 2). Teams from the University of Waterloo and the National University of Kyiv received Honorable Mention awards.

Conclusions and Future Directions
The feedback we have received through this project has been overwhelmingly positive. Where improvements have been suggested, adjustments have been made to improve the experience for any audience being education. Going forward, we recommend continuation of the Hydrogen 101 presentations, an expansion of the Market Report to include the next year’s data to show trends and future Hydrogen Student Design Contests.

FY 2010 Publications/Presentations

FIGURE 2. The Hydrogen Student Design Contest’s 2009-10 grand-prize winning team: Missouri University of Science and Technology, http://www.hydrogencontest.org/
Objectives

- To build greater familiarity and understanding of stationary fuel cell technologies and applications among state policymakers.
- To disseminate and encourage the adoption of best practice policies which accelerate the adoption and reduce barriers to fuel cell installations.

Technical Barriers

This project addresses the following technical barriers from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Readily Available, Objective, and Technically Accurate Informationn
(B) Mixed Messages
(C) Disconnect Between Hydrogen Information and Dissemination Networks

Contribution to Achievement of DOE Hydrogen Education and Outreach Milestones

This project will contribute to achievement of the following DOE milestones from the Hydrogen Education and Outreach section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

16. Develop database of state activities. (2Q, 2007)

Accomplishments

- Completed survey of state hydrogen and fuel cell programs and policies.
- Developed case studies of exemplary state programs.
- Developed series of four briefing guides for state policymakers on fuel cell technologies, policies and programs, critical power applications and hydrogen production, transport and storage.
- Established and maintained fuel cell listserv and Web pages providing current news on state policies and programs.
- Co-organized series of Webinars on fuel-cell related topics.
- Established sub-contractor relationship with National Council of State Legislators to assist in outreach to their members.

Introduction

While stationary fuel cell installations have been growing at a rapid rate in the United States, this growth has been concentrated in just a few states that have provided strong financial incentives to encourage their use. This project addresses the need for more supportive state policies and programs to further accelerate the adoption of stationary fuel cells. In this project, Clean Energy States Alliance (CESA) will track, identify, evaluate, communicate, and facilitate state adoption of effective financial, policy, and technology activities and best practices that accelerate fuel cell and hydrogen technologies. CESA is using its membership network of state clean energy funds to educate state clean energy policy makers and program managers about fuel cell and hydrogen technology developments and the efforts by states to advance these technologies. With the outreach assistance provided by NCSL, CESA will have increased access to state legislators from all 50 states to provide information on hydrogen/fuel cell issues and policies.

This project is emphasizing efforts to develop stationary fuel cell industries and markets without directly advancing transportation technologies (with the
understanding that advancing stationary and portable fuel cell applications could facilitate the development and deployment of transportation fuel cells).

**Approach**

The basic approach to the project involves three stages:

First, CESA gathered baseline information on state programs and policies to advance fuel cell industries and deployment including the development of case studies to identify exemplary programs (Connecticut, Ohio, California, New York, Hawaii). This research was conducted to identify policies that appear to be most effective as well as the barriers which states have erected or failed to remove that impede the deployment of hydrogen infrastructure and stationary fuel cell deployment.

Second, CESA developed a series of briefing reports providing background on fuel cell technologies and best state programs and policies. These are targeted at both state policymakers and state renewable energy program fund managers. CESA also continues to enhance its hydrogen and fuel cell Web pages by posting current information on new program and policy development at both the state and federal levels.

CESA is currently in the third stage of this project which focuses on direct outreach to state legislators, policy managers, and renewable energy program managers. CESA is organizing a workshop on stationary fuel cell deployment for its fall CESA member national meeting in Washington, DC. Working with our partner, the NCSL, CESA will also be organizing a Webinar for state legislators and a presentation at NCSSL’s fall legislative summit. CESA will also be seeking selective opportunities to present at both the state and regional level to targeted audiences such as building code officials, and state and higher education facilities managers (emphasizing the value proposition of fuel cells for critical power).

**Results**

CESA has now developed a comprehensive set of best practice programs and policies supporting hydrogen and fuel cell industrial development and project deployment. We have produced educational materials which should prove effective in engaging state policymakers and others on the value of supporting fuel cell technologies. We are beginning to reach out directly to policymakers to further explain the technologies and how they fit within the overall framework of clean energy development within their states. It is difficult, however, to measure the results of these educational and outreach efforts against either the project’s or DOE’s objectives. State-level policy changes can take several years to occur. In addition, while we can track state renewable energy program spending on fuel cells, near-term spending increases are most likely to occur in those states with existing fuel cell programs.

**Conclusions and Future Directions**

- There is little state-level engagement on fuel cell deployment beyond the handful of states with active programs and funding (CA, CT, HI, MA, NY).
- Other states (OH, SC) have active fuel cell industry development programs but little in the way of project deployment support.
- More effort is needed to build policymaker knowledge of and engagement in hydrogen and fuel cell technologies and policies (beyond vehicles). In particular, states which have been supportive of distributed, non-dispatchable renewable energy technologies (solar and wind) need to recognize the benefits of a clean (though not necessarily renewable) distributed energy technology which can provide baseload power while also meeting thermal energy loads.
- The future direction of this project will be focused on communicating this “value proposition” to the states.

Carole Read  
Phone: (202) 586-3152  
E-mail: Carole.Read@ee.doe.gov

DOE Project Officer: Gregory Kleen  
Phone: (303) 275-4875  
E-mail: Greg.Kleen@go.doe.gov

Contract Number: DE-FG36-04-GO14277

Subcontractor:  
Schatz Energy Research Center (SERC),  
Humboldt State University, Arcata, CA

Project Start Date: September 1, 2004  
Project End Date: February 28, 2012

Objectives

- Develop, field test, revise, publish, and disseminate three curriculum modules and integrate hydrogen and fuel cells into existing Lawrence Hall of Science (LHS) high school materials.
- Develop and implement a professional development plan for teachers who will use the materials.
- Develop a model for collaboration among school districts, informal science centers, university scientists, local transportation agencies, and other leaders in the field.
- Disseminate the materials to a broad national audience.
- Evaluate the quality and effectiveness of the curriculum materials and professional development strategies.

Technical Barriers

This project addresses the following technical barriers from the Education section (3.9.5) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

(A) Lack of Readily Available, Objective, and Technically Accurate Information

(C) Disconnect between Hydrogen Information and Dissemination Networks

(D) Lack of Educated Trainers and Training Opportunities

(E) Regional Differences

Contribution to Achievement of DOE Education Milestones

This project will contribute to achievement of the following DOE milestones from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:

- Milestone 26: Develop modules for high schools. (4Q, 2007)
- Milestone 27: Launch high school teacher professional development. (4Q, 2008 through 3Q, 2011)

Accomplishments

- Eleven new teachers piloted the module in their classrooms and provided feedback.
- The curriculum module manuscript was submitted to the publisher, LAB-AIDS, Inc. and professional editing is in progress.
- LAB-AIDS produced prototype electrolyzers for the student curriculum kit. These have been tested by LHS and SERC, and are undergoing further modification for the commercial kit.
- The materials were disseminated via 10 presentations to secondary science educators and hydrogen and fuel cell professionals.

Introduction

This project is producing a curriculum module about hydrogen and fuel cells for high school students. A group of experienced science curriculum developers, teacher professional developers, leaders in the field of hydrogen and fuel cell technology and its application to transportation, and the publishers of instructional materials are collaborating to develop commercial educational modules that will fit into high school courses such as physical science, chemistry, environmental science, and physics. In order to ensure that it will fit into typical high school classrooms, the module addresses topics teachers usually teach and correlates to the National Science Education Standards and/or state and local standards. This project is also developing
professional development workshops to prepare teachers to teach the curriculum and develop teacher leaders. Project evaluation focuses on investigating students’ progress toward the intended learning goals and evaluating the professional development workshops.

The past year focused on expanding implementation of the curriculum into new sites and preparing the curriculum and materials kit for commercial distribution.

Approach

The curriculum materials are developed and revised through a close collaboration between curriculum developers at LHS, scientists and engineers at SERC, experienced teacher associates, local and national field test teachers, and LAB-AIDS, Inc., an established publisher of kit-based science curriculum materials. The materials are developed by LHS with input from SERC, and classroom-tested by the developers, then by expert teachers, and finally by a broader group of teachers from local and national sites. The module uses an issue-oriented approach to teaching concepts related to chemistry and energy topics. This approach teaches about hydrogen and fuel cells in the context of energy issues and demonstrates to students both the relevance of their science education to their lives and the role of scientists and engineers in solving practical problems.

Teachers who field-test the curriculum receive two to three days of professional development before they use the materials, and additional support as needed during use. This prepares the teachers to give thorough feedback on the curriculum and also informs future professional development activities. In addition, these early professional development workshops for field-test teachers help to identify teachers who assist with dissemination and implementation of the published curriculum.

Dissemination is conducted by presentations at science teacher education conferences and through the extensive networks of both LHS and LAB-AIDS, Inc.

Results

The curriculum module addresses Education Technical Barrier A (Lack of Readily Available, Objective, and Technically Accurate Information) by providing information about hydrogen and fuel cells in a curriculum format that is usable by teachers and students in typical classrooms. The curriculum is developed by the Science Education for Public Understanding Program (SEPUP), a curriculum development group that produces issue-oriented science materials that avoid advocacy. The module is extensively reviewed for technical accuracy by scientists and engineers at SERC.

The professional development work addresses Education Technical Barriers C (Disconnect between Hydrogen Information and Dissemination Networks) and D (Lack of Educated Trainers and Training Opportunities) by building on the dissemination networks of the LHS and partners and preparing teachers who will be able to provide professional development in their regions. Teachers receive professional development in the unit content, teaching approaches, science of hydrogen and fuel cells, and fuel cell applications.

The expanded implementation during the past year addressed Barrier E (Regional Differences), by testing the curriculum in new locations and Barrier D (Lack of Educated Trainers) by providing professional development and implementation experience to teachers from school districts in these new locations. New teacher participants taught the curriculum to over 860 students in new sites in Connecticut, Georgia, New York, South Carolina, and Southern California. The classrooms using the materials in the past year included chemistry, physical science, physics, and environmental chemistry classrooms in public comprehensive, magnet, and alternative high schools in urban and suburban settings. In this final year of testing, most participating teachers had not previously worked with the SEPUP curriculum development group or SEPUP products, to ensure usability of the materials by a variety of teachers. Figure 1 shows two of the new teachers, from Georgia and Connecticut, who implemented the curriculum during the 2009–2010 school year.

An online survey was used to collect feedback on the curriculum and kit from the new participating teachers. Eleven teachers completed the survey, which includes questions about the curriculum module as a whole and about each of the six curriculum activities.

FIGURE 1. Teachers Trained in June 2009 Implemented the Module during the 2009–2010 School Year
Feedback was generally positive about the module, with many constructive suggestions for improving specific activities. Figure 2 summarizes feedback on teachers' interest in using the module again. All teachers indicated that they would teach the core activities of the module again either as is or with minor changes. One teacher responded: “Using this kit is an excellent way to bring in the concepts of science and social responsibility. The concepts were challenging and thought provoking, but obtainable and relevant.” Another wrote, “I really enjoyed the approach that was used to teach this unit.” Several included in their written comments their hopes that their school will purchase the curriculum when commercially available.

Presentations at science teacher conferences reached over 240 teachers during the past year. In these one to two-hour presentations, teachers were introduced to the module, given background on fuel cells, and conducted an activity on the fuel cell reaction (Activity 4 from the module) that they were then given to take back to their classrooms and try out.

Commercialization of the module and accompanying kit is expected to take place this fall. The curriculum kit includes a student electrolyzer produced specifically for this project. LAB-AIDS has produced and modified prototype electrolyzers for the kit based on original prototypes developed by SERC, and LHS and SERC have tested these prototypes. Final modifications are currently being made to produce the commercial student electrolyzers. The manuscript for the module has been submitted to LAB-AIDS and professional editing is in progress.

![Figure 2. Teacher Survey Responses: “Would you use this unit again?”](image)

**FIGURE 2.** Teacher Survey Responses: “Would you use this unit again?”

**Conclusions and Future Directions**

**Conclusions:**

- The instructional materials and kit can be used by high school teachers working in a variety of science subject areas (chemistry, physics, physical science, integrated science, and advanced placement environmental science), in diverse settings, and with diverse student populations. Students and teachers continue to react positively to these materials. Over 860 students participated in the module in the past year.
- Presentations at nine national, state, and regional teacher workshops reached over 240 teachers. Reactions to these workshops were positive.

**Future work will focus on:**

- Publishing and distributing the HyTEC module print and kit materials.
- Expanding work with new school districts, and strengthening collaborations with current districts.
- Reaching greater numbers of teachers by presenting the project at science teacher conventions and working with the publisher to disseminate the module. So far, sessions have been accepted or submitted for Fall 2010 teacher conferences in California, Connecticut, North Carolina, South Carolina, Texas, and the National Science Teachers Association Northeastern Regional Conference in Baltimore. The project will also be presented at the Spring 2011 National Science Teachers Association National Convention in San Francisco.
- Expanding professional development for teachers and implementation of the curriculum at existing and new sites. A conference to prepare a new group of teachers is planned for early 2011.
- Preparing additional student materials and teacher support materials for the project website.

**FY 2010 Publications/Presentations**

X.17 $H_2$ Educate – Middle School Hydrogen Education Program

Mary E. Spruill  
The National Energy Education Development (NEED) Project  
8408 Kao Circle  
Manassas, VA 20110

Phone: (503) 275-4929  
E-mail: Reginald.Tyler@go.doe.gov  

Contract Number: DE-FG36-04GO14278  

Subcontractors:  
- Senterch, Inc., Bethesda, MD  
- Los Alamos National Laboratory, Los Alamos, NM  

Start Date: August 1, 2004  
Projected End Date: July 30, 2010, extension to July 30, 2011  

Objectives

- Collaborate to develop, design, and deliver a first-class, comprehensive middle school hydrogen education program that includes: training, classroom materials, technical and best-practices exchange, and evaluation.  
- Design a program to link hydrogen science and technology and the concept of a hydrogen economy to the classroom.  
- Educate the K-12 audience about hydrogen and fuel cell technologies to facilitate market acceptance.

Technical Barriers

This project addresses the following barriers from the Education section of the Fuel Cell Technologies Multi-Year Program Plan:

A. Lack of Readily Available, Objective, and Technically Accurate Information

As awareness of hydrogen increases with increased media activity and inclusion in many state and local energy plans, there continues to be a lack of information that is readily available, accurate, and objective. Many hydrogen advocacy groups have produced educational information that in some areas would be considered more public relations information than education. This project addresses the need for educational materials that are available, objective, and accurate. Harnessing NEED’s primary objective of objective information across its curriculum portfolio, the $H_2$ Educate materials are reviewed by subject matter experts, are made readily available via Web and partner Web sites as well as workshops, and are compared and contrasted with other hydrogen materials on a regular basis. This project's materials will continue to adapt as the need for additional and more robust materials becomes apparent.

B. Mixed Messages

This project was created and continues with the intent to provide cornerstone materials that address misconceptions, provide clarity of information, and link to accurate and available information when necessary and possible. The hydrogen community continues to have disparate views on certain subjects and the key messaging to use. NEED, with review from DOE, national labs, and subject matter experts, works to provide this project with common, clear language and messaging that students, teachers, and their families find useful and appropriate for age and knowledge level. NEED works to remove the misinformation from the diverse messages and provide a concise message for the intended audience.

C. Disconnect between Hydrogen Information and Dissemination Networks

NEED has capitalized on this disconnect and continues to work with information networks to become a stronger dissemination network – using local energy information networks to deliver training and information about hydrogen to the project's intended audience. Working with the information networks, NEED – acting as a dissemination network – provides a conduit for valuable and accurate hydrogen information for the 4-12 community. In addition, NEED has created its own information and dissemination network of 4-12 educators and the education community to deliver quality hydrogen education materials and training.

D. Lack of Educated Trainers and Training Opportunities

This project addresses the lack of educated trainers by providing professional development opportunities for teachers and energy professionals. These training
opportunities provide participants with general background, foundation knowledge, and expansion information for more technically advanced audiences. NEED trains a network of trainers to deliver the information in local communities as well.

E. Regional Differences

This project is adapted – in training methods and messaging – for local and regional differences – including proximity to hydrogen use and production. NEED’s programming is locally based, with local needs – both economic and educational – considered as programs are created. Regional differences in attitudes are addressed and discussed in training programs. In addition, regional access to hydrogen infrastructure is part of the program. Should hydrogen fueling stations, vehicles or fuel cells be nearby, the infrastructure is included in the programming.

F. Difficulty in Measuring Success

The project is measuring knowledge gain among its target audience and finding good results. Educational programs often have longer term impacts that are not easily measurable in the course of a month or year. True attitude change takes a longer period of time than information gain. In all cases, educators report a minimum of a 40% knowledge increase in hydrogen knowledge upon completion of the H2 Educate workshop.

Contribution to Achievement of DOE Education Milestones

This project contributes to achievement of the following DOE education milestones from the Education section of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan – Task Six: Facilitate Development and Expansion Hydrogen Technology Education for Middle and High Schools

- Milestone 6.22: Develop curriculum for middle schools (2Q, 2006)
- Milestone 6.26 and 27: Materials developed are in use in high schools and training provided to high school educators.

G. Accomplishments

- In 50% of the time estimated, the team created the middle school H2 Educate learning module. In spite of resource constraints, the project is 100% complete with its revised scope and now is in replication and outreach to more communities. The project is scalable and can be deployed incrementally with additional resources.
  - The effort has garnered additional support from a variety of partners – state energy offices, Clean Cities organizations, utilities, energy companies and others.
  - Over 8,000 teachers trained.
  - Training programs completed in 35 states with additional training in 2011 due to extension of DOE funding.
  - Pre-survey scores were 5 out of 15 correct on the survey of hydrogen knowledge and 13 out of 15 correct on post-surveys.

Approach

The NEED Project brings its 30-year history in energy education, curriculum development, teacher training, and networking efforts to H2 Educate for middle school curriculum development, teacher training, and the expansion of hydrogen understanding and knowledge in classrooms throughout the country. NEED, with Sentech, Inc. of Bethesda, Maryland as a key partner, launched a bold effort to exceed the DOE’s expectations for a hydrogen education program in 2004 and have exceeded development calendar and outreach targets.

H2 Educate and the activities undertaken as part of this project are the result of a collaborative effort among teachers, students, advisors, technical specialists, federal employees and professional educators. This effort brings together resources from NEED and its national partners and the DOE, to capitalize on success, resources, networking opportunities, and curriculum development and delivery capabilities. Key elements of this project are NEED’s national network, a strong relationship with the National Association of State Energy Officials, and an annual budget capable of doubling the resources provided by this cooperative agreement. Making up this network are a conservatively estimated 65,000 classrooms touched by NEED materials and training each year.

Results

Results of the project continue to show success with pre-training survey results showing a 5 out of 15 correct successful response and a post-training survey result showing a 15 out of 15 correct successful response.

Workshop outreach expanded from six training programs and several hundred teachers trained in the
first year of the project with over 8,000 teachers trained by 2010. NEED works to deliver the H₂ Educate curriculum throughout the network of NEED schools and the schools they reach with educational outreach.

Curriculum materials are live on the NEED and DOE Web sites and Web stats indicated substantial download activity.

Addition of hydrogen information and activities to the Energy Information Administration Kid’s Page www.eia.doe.gov/kids (350,000 users per month).

Students and teachers show knowledge gain and deeper understanding of hydrogen knowledge.

On post-workshop surveys, teachers indicate feeling prepared to teach the materials in their classrooms.

Conclusions and Future Directions

H₂ Educate programs this year continued to expand the reach of the project to middle schools throughout the country. Additional outreach via state energy offices has allowed additional programs to be delivered outside of the programs within the DOE funding for this project. NEED has included the project in its partnership with the BP A+ for Energy Program and the Pacific Gas and Electric Solar Schools Program thus allowing several thousand teachers to benefit from the project training and curriculum materials. NEED continues to provide hydrogen materials through the National Energy Conference for Educators, the National Science Teachers Association annual conference and a number of state science conferences throughout the country.

The Virginia Department of Mines, Minerals and Energy and the Virginia General Assembly appropriated funding to provide teacher workshops and curriculum kits and materials to schools in Virginia in execution of the Virginia Hydrogen Roundtable recommendations.

Future Directions

- H₂ Educate sessions will be hosted at NEED’s two National Energy Conferences for Educators in July and August 2010.
- H₂ Educate materials presented at 650 local teacher workshops.
- Work with other hydrogen partners to maximize reach of programs and materials – i.e. working with infrastructure grantees to provide educational resources.
- Continue incorporation of materials and programming into NEED’s existing training initiatives.
- Annually update materials with new data and provide major changes to educational community. Hydrogen curriculum will be redesigned as part of the redesign of NEED curriculum for the 2010 – 2011 school year.
- Addition of H₂ Educate Web site for materials, links and additional information.
- Deliver maximum number of hands-on resources to classrooms leveraging resources to do so. Expand partnerships with infrastructure grant recipients to provide outreach and education programming to additional communities.
XI. AMERICAN RECOVERY AND REINVESTMENT ACT ACTIVITIES
XI.0 American Recovery and Reinvestment Act Activities

Introduction

In April 2009, the DOE announced the investment of $41.9 million in American Recovery and Reinvestment Act (ARRA) funding for fuel cell technologies to accelerate the commercialization and deployment of fuel cells and to build a robust fuel cell manufacturing industry in the United States, with accompanying jobs in fuel cell manufacturing, installation, maintenance, and support services. Twelve grants were awarded to develop and deploy a variety of fuel cell technologies including polymer electrolyte membrane, solid oxide, and direct-methanol fuel cells in auxiliary power, backup power, combined heat and power (CHP), lift truck, and portable applications. The cost share provided by the project teams is about $54 million, over 56% of the total cost of the projects.

These projects are addressing the objectives stated above as well as the overall ARRA goals to create new jobs and save existing ones; spur economic activity; and invest in long-term economic growth. Deployment of nearly 1,000 fuel cells is planned in these applications. These efforts have required the DOE and ARRA project teams to identify and address key challenges in technology innovation and deployment, and also in reporting requirements, performance measurement and tracking, and safety and environmental management.

Reports addressing technology and deployment status and jobs and costing data are submitted quarterly by the project teams and are available to the public through the Recovery.gov Web site. Collection and analysis of operational and performance data from the fuel cell deployments are being performed by the National Renewable Energy Laboratory (NREL) Hydrogen Secure Data Center (HSDC) to assess the performance and commercial readiness of the fuel cell technologies. Data are aggregated across multiple systems, sites and teams, and are made available quarterly through composite data products (CDPs) available on the NREL Web site. In addition, detailed data products (DDPs), shared only with the project partner, are produced twice annually for each fuel cell system and site. Safety plans are being developed by all project teams and will be reviewed by the Hydrogen Safety Panel.

The Safety, Codes and Standards sub-program is facilitating market entry for fuel cell-powered lift trucks, through tank testing and analysis, which it initiated at Sandia National Laboratories in Fiscal Year (FY) 2010. This effort addresses fatigue crack initiation and growth in steel tanks used in high-cycle applications. The test tanks were obtained from two ARRA project fuel cell partner companies and from tank manufacturers. Hydrogen pressure-cycle testing and engineering analysis of commercial Type-1 hydrogen pressure vessels are being performed under conditions similar to in-service environments for lift truck storage tanks. Results will be used to help inform design methodologies and code development processes for high-frequency refueling applications, and to provide the technical basis for Canadian Standards Association HPIT1.

ARRA Project Summaries

Auxiliary Power

Delphi Automotive (Troy, Michigan and Rochester, New York): Delphi will develop a 3- to 5-kW solid oxide fuel cell (SOFC) auxiliary power unit (APU) for heavy-duty commercial Class 8 trucks at their laboratory in Rochester, New York. Delphi will test and demonstrate the diesel APU in a high visibility fleet vehicle that will provide power for vehicle hotel loads and other vehicle needs under real-world operating conditions. There will also be a series of in-house tests, including on-vehicle testing, to validate the “road worthiness” of the diesel APU, prior to installation on the demonstration truck. Delphi will provide a comprehensive system specification and—with heavy-duty truck manufacturer partner PACCAR—will define commercial requirements. System development efforts will improve Delphi’s current generation SOFC technology by increasing net output power and fuel processing efficiency, decreasing heat loss and parasitic power loss, and establishing diesel fuel compatibility. The primary focus will be accelerating the development and acceptance of the APU by the Class-8 heavy-duty truck market. Partners include Electricore Inc., PACCAR Inc., and TDA Research Inc.

1“Hydrogen Safety, Codes and Standards R&D—Materials and Components Compatibility,” Daniel Dedrick et al., this volume.
Backup Power

**ReliOn, Inc. (Spokane, Washington):** ReliOn is deploying over 150 fuel cell systems into the telecommunications and utility networks at AT&T and PG&E for backup power, across nine states, combined with the deployment of a refillable stationary hydrogen storage module unit and accompanying refueling logistics platform for AT&T sites. This effort will add reliability to communications networks where no backup power was previously available. ReliOn will provide DOE with installation, fueling logistics, and operating data for fuel cells in voice and data communications networks in mountain, desert, and urban locations. Partners include Air Products & Chemicals, Inc., AT&T, and PG&E.

**Sprint Nextel Corp. (Reston, Virginia):** Sprint Nextel is planning to demonstrate the technical and economic viability of deploying 1-kW to 10-kW polymer electrolyte membrane (PEM) hydrogen fuel cells with 72 hours of on-site fuel storage (using a new Medium Pressure Hydrogen Storage Solution [MPHSS] with on-site refueling) to provide backup power for critical code division multiple access cell sites on the Sprint Wireless network. Over 200 new hydrogen fuel cell systems will be deployed to sites in California, Connecticut, New Jersey, and New York. In addition, 70 already in-service fuel cell systems at cell sites in Louisiana and/or Texas will be converted from a low-pressure storage solution (bottle swap) to the new MPHSS. Partners include Air Products & Chemicals, Inc., Altergy Systems, Black & Veatch Corporation, Burns & McDonnell Engineering Co. Inc., Ericsson Services Inc., and ReliOn, Inc.

**Plug Power Inc. (Latham, New York):** This project will demonstrate the market viability of low-temperature, 6-kW PEM GenCore® fuel cells fueled by liquid petroleum gas (LPG) to provide clean and reliable primary power and emergency backup power (72 hours or more). Plug Power will install and operate 20 fuel cell systems at Fort Irwin in Barstow, California, and Warner Robins Air Force Base in Warner Robins, Georgia. These units will run continuously on LPG, providing power to the grid and will switch to emergency backup power during a grid failure. A small battery pack will be used for spikes in power demand. Partners include the Army Corp of Engineers' Construction Engineering Research Laboratory (CERL), Warner Robins Air Force Base, and Fort Irwin.

Combined Heat and Power

**Plug Power Inc. (Latham, New York):** Plug Power is evaluating the performance of 12 high temperature, natural gas-fueled, 5-kW micro-CHP fuel cell units (GenSys Blue®). The objective of the project is to validate the durability of the fuel cell system and verify its commercial readiness. Six units will undergo an internal Plug Power test regime to estimate failure rates, and six units will be installed and tested in real-world residential and light commercial end-user locations in California. Partners include Sempra Energy and the National Fuel Cell Research Center at the University of California, Irvine.

Fuel-Cell Powered Lift Trucks

**FedEx Freight East (Harrison, Arkansas):** FedEx is deploying 35 fuel cell systems as battery replacements for a complete fleet of electric lift trucks at FedEx's service center in Springfield, Missouri. Success at this service center may lead to further fleet conversions at some or all of FedEx's other 470 service centers. Partners include Air Products & Chemicals, Inc. and Plug Power Inc.

**GENCO (Pittsburgh, Pennsylvania):** Over 350 fuel cell systems are being deployed as battery replacements for fleets of electric lift trucks at five existing distribution centers (Coca-Cola in Charlotte, North Carolina; Kimberly Clark in Graniteville, South Carolina; Sysco Foods in Philadelphia, Pennsylvania; Wegmans in Pottsville, Pennsylvania; and Whole Foods in Landover, Maryland). Success at these distribution centers may lead to further fleet conversions at some or all of GENCO’s other 109 distribution centers. Partners include Air Products & Chemicals, Inc., Linde North America, and Plug Power Inc.

**Nuvera Fuel Cells (Billerica, Massachusetts):** Nuvera is deploying 14 fuel cell forklifts in H-E-B Grocery Company's distribution facility in San Antonio, Texas. Fuel will be supplied by Nuvera's natural gas reformer and its storage and dispensing system. Partners include H-E-B Grocery Co.
Sysco of Houston (West Houston, Texas): Sysco is deploying 98 fuel cell systems as battery replacements for a fleet of lift trucks at Sysco’s new distribution center in Houston, Texas, opened in March 2010. This installation is the first-ever greenfield installation without battery infrastructure for a pallet truck fleet. Success at this distribution center may lead to further fleet conversions at some or all of Sysco’s other 169 distribution centers. Partners include Air Products & Chemicals, Inc. and Plug Power Inc.

Portable Power

Jadoo Power (Folsom, California): Jadoo Power is developing portable, propane-fueled SOFC generators and an electro-mechanical propane fuel interface, as a potential replacement for traditional gas/diesel generators and lead-acid battery power sources. Two portable fuel cell generators will be deployed in this project. One of them will be used in a demonstration with police and fire first-responders in the City of Folsom, California, to power equipment in emergency and off-grid situations; both units will then be used to power media production equipment at automobile racing events at multiple locations throughout the United States. Partners include Delphi Inc., NASCAR Media Group, and the City of Folsom, California.

MTI MicroFuel Cells (Albany, New York): MTI is demonstrating a 1-watt consumer electronics power pack. The project is focused on improving reliability to meet the standards required by the electronics market and includes testing of individual components, subsystems, and complete direct methanol fuel cell (DMFC) systems. MTI is also developing manufacturing processes to improve product yields and reduce overall costs.

University of North Florida (Jacksonville, Florida): The University of North Florida is further integrating and miniaturizing the components of a portable power system for use in mobile computing, and analyzing failure modes to increase durability. The power system would be a DMFC that meets the requirements for power density, energy density, and operating lifetime. The university will also conduct a design for manufacturability and assembly review to ensure that the systems meet the cost targets for commercialization. Partners include the University of Florida, Gainesville.

FY 2010 Status and Accomplishments

As of the end of September 2010, 276 fuel cell lift trucks and 24 fuel cell backup systems for communication cell towers had been deployed and 51% of the ARRA project funds had been spent by the projects. A total of 36 direct jobs have been created or retained as a result of the Fuel Cell Technologies ARRA projects (excluding supply chain and other indirect jobs). NREL’s HSDC has set up data reporting protocols with each of the project teams. CDPs and DDPs showing progress to-date have been prepared. The CDPs are available on the NREL HSDC Web site, www.nrel.gov/hydrogen/news/2010/807.html.

Auxiliary Power

Delphi Automotive Systems has completed initial system specifications and system design and layout for their SOFC APU, and they have identified its commercial requirements. Initial system and subsystem vibration testing and analysis have been completed, as has initial on-vehicle testing and demonstration; component fabrication is underway. Over the next year, Delphi will complete and test the APU system/subsystem build. Delphi will also complete the integration and characterization of the system and begin their full-scale demonstration.

Backup Power

Plug Power is working with CERL to identify deployment sites at Warner Robins Air Force Base in Warner Robins, Georgia, and Fort Irwin in Barstow, California, for 20 GenCore® fuel cells. It was determined that a system that starts quickly with hydrogen and runs for extended periods with LPG or natural gas is more favorable, economically, than a pure hydrogen system. The first fleet is currently being built and module testing and qualification are being performed.
ReliOn, Inc. has completed the site qualification stage for over 150 communications sites. They have fabricated, integrated, and delivered fuel cell equipment to AT&T for 132 sites, and hydrogen storage modules for 69 sites. Fuel cell equipment has been fabricated and integrated for all nine PG&E sites. ReliOn had installed fuel cells at 24 sites as of the end of September 2010. Technology and methodology for remote monitoring and collection of operational data have been developed.

Sprint Nextel is addressing siting and permitting requirements necessary for the deployment of hydrogen fuel cell systems at their communications sites. Design of the MPHSS is being completed. The project team plans to benchmark the life-cycle costs, performance, and operational characteristics of the hydrogen fuel cell systems against incumbent technologies (batteries and diesel generators).

**Combined Heat and Power**

Plug Power has built and commissioned an internal GenSys Blue® micro-CHP test fleet and is conducting durability tests. Control and efficiency of the units have been improved, resulting in faster start-ups and thermal response time, improved heat modulation, and increased total efficiency. Manufacturability improvements have reduced build time by over 55%, and material costs for low-volume production of the fuel cell units have been reduced. Site selection has been initiated for external customer testing in California.

**Fuel Cell-Powered Lift Trucks**

FedEx Freight East deployed 35 fuel cell-powered lift trucks in June 2010 at their distribution center in Springfield, Missouri. These fuel cell systems will serve as battery replacements for the complete fleet of Class-I electric lift trucks in their 53,000-square-foot facility. A permanent hydrogen fueling infrastructure has been built and installed by Air Products & Chemicals, Inc., including liquid hydrogen handling and gaseous compression, storage, and dispensing (for two indoor dispenser stations) equipment. Success in this project may lead to additional fleet conversions at some or all of FedEx's other 470 centers.

Sysco of Houston has deployed 98 hydrogen fuel cell-powered pallet trucks and forklifts at Sysco Corporation's new 585,000-square-foot food distribution facility in Houston, Texas, and a permanent hydrogen fueling infrastructure has been built and installed by Air Products & Chemicals Inc. In the first quarter of 2010, 2,664 fills were logged. On June 17, 2010, business leaders and government representatives attended an official ribbon cutting and media event at this facility.

GENCO has deployed 59 GenDrive® fuel cell lift trucks at a Wegman’s distribution facility in Pottsville, Pennsylvania. The units logged over 24,000 operating hours during the first quarter of 2010. The Wegman’s fueling station completed almost 2,000 hydrogen fills during the first quarter of 2010. By the end of September 2010, 61 GenDrive® fuel cell lift trucks were delivered to Whole Foods in Landover, Maryland, and nine fuel cell lift trucks were delivered to Kimberly Clark in Graniteville, South Carolina. Deployment of an additional 228 fuel cell lift trucks is planned for four different distribution facilities.

Nuvera has installed 14 PowerEdge™ fuel cells in lift trucks and completed installation of their PowerTap™ hydrogen infrastructure technology at the H-E-B Grocery Co. distribution center in San Antonio, Texas. At this site, fuel cell forklifts and battery forklifts are operating in parallel to allow direct comparison. An initial productivity gain of 10% from the use of fuel cells instead of lead-acid batteries has been reported.

**Portable Power**

Jadoo has developed preliminary requirements for the portable generator and fuel interface. Desulfurizer hardware has been delivered from Delphi and reformer testing has been initiated. Existing technologies and methodologies applicable to a portable SOFC propane fueling system have been compared and evaluated. Site specific baseline load data on media equipment power requirements have been collected.
MTI MicroFuel Cells has demonstrated reduced cost, manufacturability, and assembly for a redesigned one-watt DMFC charger for consumer electronics. System level testing has verified that the charger is capable of operating well during transients such as start-up and shut-down and at all specified temperatures, humidity, and orientations. High power density, high fuel efficiency, and low stack degradation rates exceeding product requirements have also been demonstrated. Seventy-five fuel cell charger systems are being deployed to organizations and individuals for evaluation and feedback.

The University of North Florida has completed component design requirements for the DMFC portable power system and started analysis of design failure modes. The university will continue component development and testing and will demonstrate that component performance meets system requirements. Subsequently, they will integrate components and subsystems into a packaged unit and conduct extensive system tests to evaluate performance, robustness, and durability.

FY 2011 Plans

Completion of all project safety plans and National Environmental Policy Act compliance reviews are priorities for early FY 2011. The Fuel Cell Technologies Safety Panel will review the project safety plans and submit formal written assessments to DOE and the project teams. In addition, safety panel members will visit at least four project sites to discuss project-specific safety issues, as well as findings that may have broader impact on the fuel cell community.

In FY 2011, deployment of over 500 additional fuel cell systems for backup power, CHP, and lift truck applications is planned. It is anticipated that the NREL HSDC will be able to report performance and productivity data in FY 2011, beginning with the first-quarter FY 2011 CDP.
Finally, in FY 2011, DOE will begin documentation of lessons-learned associated with the ARRA projects, including the strategies developed for risk management with respect to safety, environmental and siting requirements, and market entry. Planning for business case analysis and case studies will be initiated.

Project Start Date: January 8, 2009  
Project End Date: December 31, 2010

Objectives

Demonstrate and field test a commercially viable 1 Watt direct methanol fuel cell (DMFC) charger for consumer electronic devices:

- Design for low-cost, high-volume manufacturing processes and ease of assembly.
- Demonstrate performance across temperature and humidity range of consumer electronic devices.
- Deploy 75 units into the field to obtain real world usage feedback.

Relevance to the American Recovery and Reinvestment Act (ARRA) goals of saving and creating jobs:

- Project funding created/retained 14 full-time equivalent jobs in Albany, NY.
- The leverage DOE funds offered enabled MTI to obtain private investment.

Relevance to the U.S. DOE Fuel Cell Technologies (FCT) ARRA goals of accelerating the commercialization and deployment of fuel cells:

- Fuel cell charger will be ready for commercialization at the end of this project.
- Components have been redesigned for low-cost, high-volume manufacturing.
- Seventy-five fuel cell systems will be deployed in 2010 during the field test.

Technical Barriers

Progress against the barriers listed below is discussed in the following sections:

- Cost and manufacturability
- Performance and degradation
- Market acceptance

Accomplishments

- Reduced cost and improved manufacturability and assembly:
  - Previously machined components are now being produced using injection molding for plastic parts and metal stamping for metallic parts.
  - Over 50% reduction in labor content achieved in system assembly.

- Achieved over 6,000 hours of stack operation with less than 5% decay per 1,000 hours.
- Demonstrated high performance, high fuel efficiency, and low degradation.
- Demonstrated system temperature and humidity latitude (0-40°C, 0-90% relative humidity, RH).
- Achieved all technical metrics and passed the Go/No-Go phase gate on-schedule.

Introduction

The objective of this project is to demonstrate and field test a commercially viable 1 Watt DMFC charger for consumer electronic devices. The fuel cell system and replaceable methanol cartridge will meet all requirements for commercialization. The system will achieve targets of cost, performance, and design reliability at a level compatible to the standards and requirements of the consumer electronics market.

Approach

The project’s environmental and safety plans had been developed and submitted during 2009. The project has been organized into three phases. Phase 1 demonstrates alpha level of capability and readiness for a consumer product, Phase 2 demonstrates beta level of capability and readiness for a consumer product,
and Phase 3 demonstrates usability in the hands of the customer by conducting a field test with 75 units.

The tasks in Phase 1 include component cost reduction, redesign for manufacturability, performance and reliability testing, and system integration. Phase 2 tasks include tool fabrication, debugging, and tooling component prove-out in working systems. Phase 3 tasks include demonstrating the DMFC charger’s functionality in the hands of real users while also providing feedback for potential design improvements. This field test will be the first time a significant number of MTI units will be put into the field to test usability and functionality. This field test will generate user feedback on product viability as well as identify potential improvements. The fuel cell charger will be ready for commercialization at the completion of this project.

Results

A major focus of this project was to reduce the cost of MTI’s DMFC-powered charger to attain a competitively priced product when in production. To achieve a low-cost system many of the components had to be redesigned so that they could be produced using low-cost, high-volume, manufacturing processes. The system also had to be redesigned for ease of assembly to increase build yield and reduce the amount of labor content needed. In addition, the assembly process had to be simplified so that technicians and assemblers could perform the assembly rather than engineers and scientists.

During Phase 1 of this project many parts and process steps were completely eliminated or were significantly simplified. In one instance a complete subassembly, with all associated cost and reliability issues, was eliminated. Phase 1 of the project was completed during the fall of 2009 and there was a successful Go/No-Go review meeting that occurred on November 5, 2009 at MTI’s facility in Albany, NY. At the completion of Phase 1 almost all components were redesigned for reduced cost and high-volume manufacturing. The following are examples of component redesigns implemented to reduce cost and make the components capable of being manufactured using common, low-cost, high-volume manufacturing processes:

- Plastic components previously machined were designed to be injection moldable.
- Sheet metal components previously machined were redesigned to be stamped and coined.
- Laser cut free-standing gaskets were redesigned to be profiled gaskets, either over-molded onto components they seal or otherwise easily placed.
- Many adhesives and small bridge plates were completely eliminated by integrating their function in other interfacing components.

There were several performance improvements achieved at the engine/stack subsystem level. Figure 1 demonstrates an engine/stack completing over 6,000 hours of operation with a decay rate of only 5% per 1,000 hours. This decay rate was achieved on multiple engine/stack subsystems.

The engine stack subsystem also demonstrated increased performance for membrane electrode assembly (MEA) power density. Figure 2 shows the power density of 85 mw/cm² and 100 mw/cm² corresponding to two different fuel feed rates. Part of this achievement was due to engine/stack design changes that enable the engine to efficiently consume methanol at higher fuel feed rates. In past engine/stack designs there was a substantial efficiency fall off at higher fuel feed rates. Figure 3 shows the stack/engine life test obtaining both high power density and relatively high fuel efficiency at increased fuel feed rates.

During Phase 2 of the project, tools were fabricated and parts were produced for evaluation of the design intent. This required several iterations of part, tool and process changes until the parts produced off of the tooling met the design requirements. Comprehensive
subsystem level testing was carried out to quantify the impact the redesigned subsystems had on durability and performance. There was also a significant amount of system integration work done to bring the new lower cost subsystems together. Testing at the system level was used to verify that the system is capable of operating well during transients such as start-up and shut-down and at all specified temperatures, humidity, and orientations.

At the system level there were several configuration changes that required system integration activities followed by complete system characterization testing. Testing at the system level included:

- Algorithm development
- Performance and qualification testing:
  - Sound testing
  - Cold and hot ambient start-up
  - Surface temperature measurement
  - Drop testing
  - Temperature and humidity latitude (0-40°C, 0-90% RH)
- Life testing
  - Steady-state decay rate
  - Start-stop decay rate

**Conclusions and Future Directions**

- High power density and high fuel efficiency has been achieved simultaneously.
- Low stack degradation rate exceeding product requirements has been demonstrated.
- Performance of system at temperature and humidity latitude (C-40°C, 0-90% RH) has been demonstrated.
- Phase 3 field test underway:
  - First units shipped in June.
  - Participants identified for the field trail.
  - Field trial feedback forms designed.

The main area of future work for this project is to complete the field test successfully. Support for the fuel cell units in the field with additional cartridges and quickly addressing any issues that arise is important to obtaining the maximum amount of useful information from the field test. Areas of particular interest in the evaluation are the user interface, field reliability and performance, and determining new user preferences.

XI.2 Solid Oxide Fuel Cell Diesel Auxiliary Power Unit Demonstration

Steven Shaffer (Primary Contact), Gary Blake
Delphi Automotive Systems, LLC
Troy, MI
Phone: (585) 359-6615
E-mail: steven.shaffer@delphi.com

DOE Technology Development Manager: Dimitrios Papageorgopoulos
Phone: (202) 586-5463
E-mail: Dimitrios.Papageorgopoulos@ee.doe.gov

DOE Project Officer: David Peterson
Phone: (303) 275-4956
Email: David.Peterson@go.doe.gov

Contract Number: DE-EE0000478

Subcontractors:
• PACCAR, Inc., Bellevue, WA
• TDA Research, Inc., Wheat Ridge, CO
• Electricore, Inc., Suite 105, Valencia, CA

Project Start Date: August 1, 2009
Project End Date: January 31, 2012

Objectives

• Design, develop and demonstrate a 3-5 kW solid oxide fuel cell (SOFC) auxiliary power unit (APU) for heavy-duty commercial Class 8 trucks.
• Utilize Delphi’s next generation SOFC system as the core power plant and prove the viability of the market opportunity for a 3-5 kW diesel SOFC system.

• Test and demonstrate the diesel APU system in a high visibility fleet customer vehicle application that will support hotel loads and other real-world operating conditions.

Technical Barriers

This project addresses the following technical barriers from the Fuel Cells section (3.4) of the Fuel Cell Technologies Program Multi-Year Research, Development and Demonstration Plan:
(A) Durability
(B) Cost
(C) Performance
(G) Start-up and Shut-down Time and Energy/Transient Operation

This project also is key to the development of the SOFC technology specific to the transportation industry which will have the opportunity to create new high tech jobs while maintaining and growing existing technical and non-technical jobs. The long-term economic impact can be very significant and will enable America’s dominance in this area.

This project in conjunction with other efforts is assisting in enabling the acceleration of Delphi’s commercialization goals for SOFCs which are in line with the DOE Fuel Cell Team’s ARRA project goals of accelerating the commercialization and deployment of fuel cells and fuel cell manufacturing, installation, maintenance, and support services.

1 Operating on Standard Ultra-Low Sulfur Diesel
2 Initial targets for program as defined in 2003 SOPO
3 Regulated DC Net/Lower heating value of fuel
4 Heavy duty truck market is highly price sensitive.
5 < 50 System Cycles but >200 stack Cycles
Accomplishments

- Completion and submission of Delphi’s Hydrogen Safety Plan and National Environmental Policy Act documentation.
- Completed initial system specifications and commercial requirements.
- Completed system design and layout.
- Initiated component fabrication.
- Completed initial on-vehicle testing/demonstration.
- Completed initial system (Level A) and subsystem vibration testing and analysis.
- Onsite project review with DOE.

Introduction

Based on previous APU work with DOE Topic 2 contract DE-FC56-04GO14319, Delphi has teamed with heavy-duty truck manufacturer PACCAR Incorporated (PACCAR), and catalysts and advanced materials firm TDA Research, Inc. to develop, test and demonstrate a diesel APU that will meet or exceed the 2010 development targets for APUs.

In addition, Delphi has identified the following barriers that must be addressed:
- System Vibration Robustness
- Packaging/Size (Form factor)
- System Weight
- System Cost
- System Manufacturability
- System Durability/Reliability

The project will test and demonstrate the diesel APU in a high visibility fleet vehicle that will provide power for vehicle hotel loads and other needs under “real world” operating conditions. There will also be a series of in-house tests, including on-vehicle testing, to validate the “road worthiness” of the diesel APU prior to installation on the demonstration truck. The primary focus will be the acceleration of the development and acceptance of the diesel APU by the Class 8 heavy-duty truck market. The project will also focus on meeting the 2015 technical targets specified within this project. Delphi will demonstrate an integrated SOFC APU system on an in-service long-haul Class 8 commercial truck. The project will include:
- Operating data from at least one field unit at a customer site.
- Degradation analysis including failure mode analysis.
- Projection of system lifetime.

Approach

Based on manufacturer, market and DOE requirements, Delphi will develop, test and demonstrate a next generation diesel APU (Gen5 APU) that will meet or exceed current development targets. Working with PACCAR, Delphi will create a detailed application and commercial requirements list for the diesel Gen5 APU for on-board auxiliary power. These along with DOE requirements will become part of a comprehensive system specification. The specifications include:
- Application requirements and metrics formalization;
- Defining of real-world, on-road operating conditions for the APU;
- Defining electrical load duty cycles for testing the APU; and
- Obtaining load cycles from PACCAR for system electrical testing.

Delphi will focus on several key enabling developments in order to implement the new APU. The new Gen5 APU that will be developed as part of this project will then be deployed as the demonstration unit. Data from this unit will be collected, analyzed, and reported in the final report.

Results

Delphi has updated the customer requirements using Peterbilt as the primary point of contact. The document was updated for size; mass; forecast thermal cycles; and reliability. With that information, Delphi modified the existing APU to the Gen5 APU configuration (see Figure 1 for the basic outline).

FIGURE 1. DPS3000D Design Level A Layout
Conclusions and Future Directions

The project is on target and will meet the budget and timing requirements. During this next year Delphi will complete the following:

- System/Subsystem Build and Test
- System Integration
- System Characterization
- Demonstration Initiation

FY 2010 Publications/Presentations:

XI.3 Highly Efficient, 5 kW CHP Fuel Cells Demonstrating Durability and Economic Value in Residential and Light Commercial Applications

Introduction

The high-temperature proton exchange membrane (PEM) fuel cell system is the culmination of a nine-year technology development effort that has produced numerous technical innovations. Plug Power began exploring the application and feasibility of high-temperature PEM technology in 1999 with the creation of an “Alpha” system to demonstrate technical feasibility. It was quickly evident that the high-quality heat produced and the resulting system simplification would make this a preferred technology for micro-CHP applications—one that held the promise of a commercial, grid-connected, stationary fuel cell product that provided a cost benefit to the end user. Indeed, high-temperature PEM technology offers a unique value proposition over low-temperature PEM systems in applications where heat utilization is required. In a low-temperature system, the quality of the heat supplied is insufficient to meet consumer needs and comfort requirements, so peak heaters or supplemental boilers are required. Low temperature systems operate between 55 and 75°C and after capturing the heat and delivering it to an end use the resultant temperature is a maximum of around 50°C preventing it from being used as a stand-alone heating device. By contrast, the higher operating temperature of the polybenzimidazole (PBI) membrane technology allows the fuel cell to operate at temperatures that can produce heat sufficient to meet the comfort demand without the additional equipment.

GenSys Blue is a pre-commercial, 5 kW, natural gas-fueled product technically ready to be demonstrated in real-world residential and light commercial installations. There are no major technical risk areas to be described. Further refinements in the areas of PBI technology, stacks, advanced controls, and fuel reforming will be made from the standpoint of design hardening or design for manufacturing criteria, as Plug Power begins to separate technology development from product development with this fuel cell system.

Objectives

- Demonstrate the durability and economic value of GenSys Blue.
- Verify its technology and commercial readiness for the marketplace.

Relevance to ARRA and DOE-FCT Goals

- Deploy 12 GenSys Blue, natural gas-fueled, micro-combined heat and power (CHP) fuel cell units that provide economic savings and environmental benefits for residential and light commercial users.
- Maintain five U.S., high-tech jobs in New York State and provides work for U.S. suppliers and field service contractors.

Accomplishments

- Controls and efficiency improvements resulting in faster start-ups, thermal response time, heat modulation and increased total efficiency from 89 to 94%.
- Manufacturability improvements to enclosure, piping, insulation and wiring which has reduced build time from over 120 hours to below 50.
- Reduction in material cost from $90k to $58k in volumes less than 20 units.
- Steady-state system model was developed and much progress made on the dynamic model.
- Long-term reliability testing established in Plug Power labs with over 3,500 run hours demonstrating, increasing reliability and decreasing failure rates.

Introduction

The high-temperature proton exchange membrane (PEM) fuel cell system is the culmination of a nine-year technology development effort that has produced numerous technical innovations. Plug Power began exploring the application and feasibility of high-temperature PEM technology in 1999 with the creation of an “Alpha” system to demonstrate technical feasibility. It was quickly evident that the high-quality heat produced and the resulting system simplification would make this a preferred technology for micro-CHP applications—one that held the promise of a commercial, grid-connected, stationary fuel cell product that provided a cost benefit to the end user. Indeed, high-temperature PEM technology offers a unique value proposition over low-temperature PEM systems in applications where heat utilization is required. In a low-temperature system, the quality of the heat supplied is insufficient to meet consumer needs and comfort requirements, so peak heaters or supplemental boilers are required. Low temperature systems operate between 55 and 75°C and after capturing the heat and delivering it to an end use the resultant temperature is a maximum of around 50°C preventing it from being used as a stand-alone heating device. By contrast, the higher operating temperature of the polybenzimidazole (PBI) membrane technology allows the fuel cell to operate at temperatures that can produce heat sufficient to meet the comfort demand without the additional equipment.

GenSys Blue is a pre-commercial, 5 kW, natural gas-fueled product technically ready to be demonstrated in real-world residential and light commercial installations. There are no major technical risk areas to be described. Further refinements in the areas of PBI technology, stacks, advanced controls, and fuel reforming will be made from the standpoint of design hardening or design for manufacturing criteria, as Plug Power begins to separate technology development from product development with this fuel cell system.
**Approach**

Plug Power is executing a demonstration project that will test multiple units of its high-temperature, PEM fuel cell system in residential and light commercial micro-CHP applications in California. The specific objective of the proposed demonstration project is to substantiate the durability of GenSys Blue, and, thereby, verify its technology and commercial readiness for the marketplace. In the proposed demonstration project, Plug Power, in partnership with the National Fuel Cell Research Center (NFCRC) at the University of California, Irvine (UCI), and Sempra, will execute two major tasks:

- **Task 1**: Internal durability/reliability fleet testing. Six GenSys Blue units will be built and will undergo an internal test regimen consisting of typical residential load profiles to estimate failure rates.

- **Task 2**: External customer testing. Six GenSys Blue units will be installed and tested in real-world residential and light commercial end user locations in California.

**Results**

Five percent of Plug Power’s employees are supporting this effort maintaining an internal and external reliability fleet of 12 GenSys Blue natural gas power systems. Automotive suppliers are delivering stack, reformer and balance of plant components.

The NFCRC at UCI began its dynamic modeling efforts of the GenSys Blue system this year. The team began with the modification of an older SU-1 based model to a high-temperature PBI model. SU-1 was Plug's attempt to penetrate the residential market with low-temperature PEM technology. After achieving reasonable correlation with a simplified system model, the team’s focus became the integration of the system components, including autothermal reformer, anode tail-gas oxidizer, cathode recirculation and the burner model.

Sempra Energy and members of the Plug Power team have begun to finalize the list of sites for the California fleet and have begun preliminary planning and design. In evaluating homes as installation candidates, the criteria for selection consists of the owner being a Sempra Energy employee with an understanding of the technology, a home with a persistent need for the generated heat (presence of a heated pool or equivalent), a home with close proximity to UCI and with upper-half California population electrical requirements. Sempra received a robust response to their polling for volunteers and three leading candidates have been down selected. The final selection process should be complete by the end of July.

With the “go ahead” from DOE to begin work on this project after its award but prior to contract signing, the team ordered the parts and began building the systems to the upgraded design. To date, Plug Power has received in roughly $740,000 in materials. This material has enabled the assembly of the first six systems which have been installed and are currently in test within our labs. Additionally, 70% of all critical components and long lead items have been received for the next three systems.

The team commenced long-term reliability testing on the internal fleet installed in Plug Power labs (Figure 1). Each system is being tested according to a predetermined test plan with the goal of generating preliminary fleet reliability statistics which we can use to make engineering improvements and programmatic decisions. It is this information that will allow us to gauge our readiness for the commercial market.

The project is experiencing a high number of facility, test equipment and program issues causing uncharged downtime. While we do not count facility related shutdowns against reliability statistics, there is a strong likelihood that these failures, which would rarely be seen in the field, cause damage to systems. We have attempted to add hardware and software provisions against these accidents (such as loss of natural gas supply) but their impact (fuel starvation, for example) must be evaluated in reviewing long term test results. Raw reliability numbers and system degradation rates should be considered conservative when viewed against these disturbances (Table 1).

A noted noise factor in our test plan is our inability to closely control the ambient temperatures in which the systems operate. This makes cabinet temperature and heat loss vary from system to system as they are commissioned between January and May. Three systems began operation in January with an ambient temperature...
of ~10°C. The remaining systems are seeing ambient temperature ranges of 20-30°C for their first 1,000 hrs.

Another noise factor is the introduction of control upgrades as the team learns about the long-term operation of the system. These will allow newer systems to operate more robustly as control upgrades are implemented. This process is inevitable but must be considered when evaluating overall fleet reliability trends.

The statistical significance of the current data is moderate with relatively high confidence intervals since collected run hours per system average below 1,000 hrs. The team's confidence in the data set will improve dramatically over the next quarter when average run times per system should be well over 2,000 hours with a fleet total of over 10,000 hours. At this point the team will feel more comfortable using conclusions from the fleet to guide program decision making and investment.

The failure and maintenance call rate has a decreasing trend. March 2010 data is mostly an accumulation of three systems worth of data for three months of operation. April 2010 data is the cumulative reliability statistics of four months of operation with four systems (Fox Trot3 is commissioned in March).

Controls, thermal management and air delivery module problems dominate as the cause of unscheduled shutdown events. Failure modes unique to 2010 hardware improvements have been discovered and highlighted. Controller lockups due to software bugs and stepper motor position losses were the major contributors to downtime. Coolant leaks did not cause a downtime but counted as failures. All failures were contained and controls provisions are added to resolve the issues.

The fleet has experienced one stack failure in system EpsilonPlus9 after just less than 1,600 hours of operation (~1,000 hours debug and 580 hours reliability test). This stack was suspect upon commissioning and was useful in debugging the system and collecting runtime hours until a replacement could be built. The team believes the stack failed due to an internal coolant leak and it is scheduled for autopsy and analysis (Figure 2).

In the past year the team participated in community events designed to increase the public’s awareness and education level regarding renewable energy in general and micro-CHP technology in particular. The first event was showcasing a GenSys Blue system at Union College in Schenectady, New York for their alumni day. Members of the team explained the system and its economic benefits to over 50 Union College alumni, members of the faculty and their families. The second event was also a showcase at Ballston Spa High School in Ballston Spa, NY for the annual New York State Science, Technology, Engineering and Mathematics Educational Collaborative where team members introduced the system and its benefits to New York State educators from all over the state.

### Conclusions and Future Directions

The internal test fleet is built and commissioned. A reliability activity complete with metrics has been established. Sites have begun to be selected for the external customer testing in California. Future milestones include:

- First Go/No-Go decision.
- Completion of the system model by NFCRC.
- Ship six systems to California.
- Maintain the reliability fleet, capturing requirements from the California market.

XI.4 Advanced Direct Methanol Fuel Cell for Mobile Computing

Objectives

- The project objective is to develop a direct methanol fuel cell (DMFC) power supply for mobile computing using the novel passive water recycling technology acquired by UNF from PolyFuel, Inc., which enables significant simplification of DMFC systems.

- The objective of the 2010 effort to date is to define the system concept and develop the required design requirements (system, sub-system, and component) in order to achieve the 2010 technical targets. Initial component development effort, based on the component design requirements (CDRs), is nearly completed.

Technical Barriers

- Storage Degradation - The prototype stack technology developed previously by PolyFuel displays a moderate level of degradation during storage, which needs to be understood and possibly mitigated before such technology can progress into commercialization. Extensive testing continues to refine hypotheses and zero in on root causes for such degradation. Recent testing has identified at least one factor and has also shown some degree of reduction is such degradation with extended time. As there are no qualified accelerated tests for this important barrier, such testing will continue in parallel with other activities for the duration of the project.

- Integration of Component Subsystems - Engineering efforts to create integrated subsystems which meet functional and power density targets and are also on the design path toward volume production is the near term technical barrier to be overcome. New components are being designed and evaluated to meet aggressive technical targets and brassboard testing is planned in the coming quarter.

This project will contribute to the relevance of DOE’s objectives for ARRA projects in general and the DMFC projects in particular.

- Create direct and supporting jobs nationwide as the UNF fuel cell technology becomes commercially available.

- Reduce the necessity and use of the power grid as fuel cells power increasing numbers of portable electronic devices, thereby creating more “green” jobs.

- Create more business activity in the fuel cell supply industry.
• Expand the user base of new alternative power technologies.
• Increase the level of competition among producers of alternative energy technologies.

While this project is recently funded (January 1, 2010), significant milestones to date are:
• CDRs – 90% complete
• Design failure mode effects and analysis (FMEA) – 25% complete
• Key subsystems prototypes – 25% complete
• Fuel cartridge prototype – 25% complete
• Numerous other tasks at least 20% complete

Approach

The approach of the project is to develop a revised set of CDRs based on concept design that integrates revised component packaging and integration of key sub-systems. The focus of the approach is to both miniaturize balance-of-plant components and integrate them into sub-systems such as the fuel recirculation pump, the carbon dioxide separator and the retained liquid reservoir. These components will be rigorously tested individually, as sub-systems, and ultimately at the system level. Initially, existing components will be evaluated for durability and failure modes, and the results will be used to help further define component requirements. Once available, the new design prototype components will be evaluated for durability and robustness. As functional performance data from component and integrated sub-system testing become available, the system model will be refined to reflect the optimized performance characteristics. Sub-systems will be integrated for testing, first onto a brassboard enabling detailed instrumentation of the system and verification of sub-system design, and then into an integrated package with auxiliary instrumentation. Control system development will optimize the key operational protocols for start-up, rest/rejuvenation, and shut-down to optimize operating lifetime and minimize both operational and storage degradation rates. A test plan driven by the consumer electronics performance requirements for operational and storage degradation rates and nominal and extreme operating conditions will establish a benchmark for a statistically significant sample of systems for a thorough evaluation of durability and robustness of the system.

Accomplishments

The project was initiated in January 2010. Major accomplishments are:
• Submitted a hydrogen safety plan.
• CDRs completed.
• System design review with project members.
• Membrane electrode assembly prototype production facility online.

Future Directions

• Complete FMEA.
• Complete component development and rigorous testing.
• Assemble brassboard system for system testing.
• Key Milestone: Demonstrate component performance meets requirements.
• Complete development of advanced control strategies.
• Integrate components and sub-systems into packaged unit.
• Test the system extensively to evaluate performance, robustness, and durability.
XI.5 Jadoo Power Fuel Cell Demonstration

E-mail: Ned.Stetson@ee.doe.gov

DOE Project Officer: Gregory Kleen
Phone: (503) 275-4875
E-mail: Greg.Kleen@go.doe.gov

Contract Number: DE-36-09GO0000479
Subcontractor:
Delphi Corporation, Troy, MI

Project Start Date: January 1, 2010
Project End Date: January 31, 2012

Objectives

- The development of two portable electrical generators in the 1,000 watt range utilizing solid oxide fuel cells (SOFCs) as the power element and propane as the fuel.
- The development and demonstration of a proof-of-concept electro-mechanical propane fuel interface that provides a user-friendly capability for managing propane fuel in a manner that supports the widespread adoption of fuel cells.
- The deployment and use of the fuel cell portable generators to power media production equipment over the course of several months at multiple high profile automobile racing events staged in multiple locations throughout the United States.
- The deployment and use of the fuel cell portable generators at scheduled events by first responders (police, fire) of the City of Folsom, California to power equipment in emergency and/or off-grid situations.
- Capturing data with regard to the systems’ ability to meet DOE technical targets and evaluating the ease of use and potential barriers to further adoption of the systems.

Technical Barriers

- Reducing stack and balance of system to size allowing portability.
- Reliability of SOFC system under rough field conditions.
- User factors related to start-up times and refueling.
- Effectiveness/complexity of processing propane to remove sulfur.
- Potential constraints on type or source of propane.

This project addresses the following technical barriers from the Fuel Cells section of the Fuel Cell Technologies (FCT) Program Multi-Year Research, Development and Demonstration Plan:

(A) Durability
(C) Performance
(E) System Thermal and Water Management
(G) Start-up and Shut-down Time and Energy/Transient Operation

Relevance to ARRA

The Jadoo project will result in the saving of five to six jobs at Jadoo Power and Delphi Automotive. Longer term, the project will provide data in a high-profile environment to potential users of fuel cell generators, and hence will ultimately spur economic activity by promoting the procurement of more fuel cell generators for similar applications.

The project also is relevant to the DOE-FCT’s ARRA project goals by accelerating the commercialization and deployment of fuel cells and fuel cell manufacturing, installation, maintenance and support services for these fuel cells.

Technical Targets

- Propane desulfurizer to reduce the level of sulfur in propane to less than 10 ppb for eight continuous hours.
• Propane fuel interface that can indicate the amount of propane within ± 10% of the actual amount for the entire range from full to empty.

Approach

This project will develop and install two SOFC systems in "real world" portable generator applications in order to ascertain that applicability of fuel cell solutions with respect to operational requirements and constraints, portability, and ease of use. Data capture will be done with regard to the systems’ ability to meet DOE technical targets and potential barriers to further adoption of the systems.

Two portable generators will be developed by leveraging parallel work by Delphi related to the use of SOFCs in truck auxiliary power unit applications. Delphi SOFC technology will be modified and packaged for portable application with alternating current power capability. Delphi will develop a desulfurizer to allow use of commonly available propane as the fuel source. Delphi will also develop a reformer for commonly available propane fuel. Jadoo Power will develop an electromechanical fuel interface by leveraging prior learning from development of an interface between proton exchange membrane fuel cells and metal hydride canisters, used in both government and commercial applications. Both SOFC systems will have final validation at the Jadoo facility prior to initial deployment at the City of Folsom. The systems will then be deployed and transported between multiple National Association of Stock Car Racing events to evaluate ruggedness, portability and suitability for “real world” applications.

This project’s environmental and safety plans for both hydrogen and propane for both the Delphi site and the Jadoo site, in addition to the test sites, are presently under development and will be based on prior environmental and safety plans of both Delphi and Jadoo.

Accomplishments

• Analyzed drawbacks for police and fire agencies of utilization of gasoline-powered generators.
• Conducted site survey of National Association of Stock Car Racing event and gathered site-specific baseline load data on media equipment power requirements.
• Researched propane industry standards and practices for storage, transport, safety and measurement of propane fuel, including methods of propane fuel level measurement, tank designs and sizes.
• Compared various current industry technologies and methodologies for measurement of propane levels.
• Evaluated potential of applying existing technologies and methodologies to a portable SOFC propane fueling system.
• Determined potential factors that may relate to application requirements for portable fuel cell propane tank fuel level determination, operation and safety.
• Surveyed current fueling and fill status monitoring techniques, evaluated capabilities and drawbacks, and developed set of potential solutions for this application.
• Developed preliminary requirements for fuel interface.
• Developed generic requirements for a portable generator.
• Facility support of propane complete.
• Reformer testing has begun.
• Blue Rhino propane characterization test complete. Data currently being analyzed.
• Desulfurizer hardware for performance testing has been delivered and on schedule for test start.
• System start-up requirements have been evaluated.
• Fuel delivery system design 75% complete.
• An environmental and safety plan has been developed in its basic form, and will be expanded to provide coverage to all manufacturing and test sites.

Future Directions

• Requirements definition complete
• Applications specifications design review
• System design – generator
• System design – desulfurizer
• Demonstrate sulfur removal – less than 10 ppb for eight hours
• System design – propane fuel canister interface
• Build and test generators
• Build and test propane fuel canister interface
• Demonstrate state-of-fill performance at ± 10%
• Demonstrate generation of 1 kW for eight hours
• Deployment, demonstrations and field tests
• Follow up tests, analysis and report generation

Contract Number: DE-EE0000487

Subcontractors:
• Fortune Wireless, Indianapolis, IN
• Betacom, Inc., Pompano Beach, FL
• United Commercial Real Estate Services, Inc., Lake Mary, FL
• Peek Site-Com, Inc., Auburn, CA
• Jeffrey Rome and Associates, Newport Beach, CA
• Vertical Horizons Contracting, Lincoln, NE
• Telecom, Tower and Power, LLC, Romulus, MI
• Front Range Wireless, Centennial, CO
• Air Products and Chemicals, Inc. (APCI), Allentown, PA

Project Start Date: August 1, 2009
Project End Date: July 31, 2011

Objectives

• Install 189 fuel cell systems with 72-hour capacity as back-up power equipment for communications sites in use by Pacific Gas and Electric (PG&E), a California utility, and as critical emergency reserve power for cell sites operated by AT&T.
• Demonstrate that fuel cells are a reliable source of clean back-up power for key communications facilities.
• Transform the market within PG&E and AT&T by moving beyond limited demonstration sites to wider deployments.

Market Transformation Barriers

This project addresses the barriers to market transformation for stationary fuel cell equipment:

• Site Selection: myriad considerations in site selection factor into the adoption of fuel cells for backup equipment.
• Permitting: multiple stakeholders, including authorities having jurisdiction, fire officials, building officials, and landlords, all have varying perspectives and reference a variety of non-harmonized standards for permitting.
• Fueling infrastructure: this program deploys a new model for stationary hydrogen fuel cells, relying on a refillable storage module, in place of the historically used cylinder exchange model. This requires the development of a fueling infrastructure that can deliver bulk compressed hydrogen to small, geographically diverse, remote sites.

Relevance to the goals of the American Recovery and Reinvestment Act (ARRA) of 2009, and to the goals of U.S. DOE Fuel Cell Technologies’ (FCT) ARRA project for accelerating the commercialization and deployment of fuel cells and fuel cell manufacturing, installation, maintenance, and support services.

This project will contribute to achievement of the DOE’s objectives for ARRA projects in general, and the FCT projects in particular:
• Create direct and indirect jobs in seven regions across the continental U.S., throughout the supply chain.
• Train and deploy installers of fuel cell systems.
• Increase the number of commercially available fuel cell systems.
• Generate volume for fuel cell supply chain.
• Create and deploy new refillable hydrogen storage for stationary hydrogen fuel cells.
• Create and deploy new hydrogen delivery model for stationary hydrogen fuel cells.
• Expand practical user operating experiences.
• Validate performance.

This project includes milestones to measure progress:
• Survey candidate sites to identify 189 sites for installation.
• Secure all permitting, site acquisition, lease amendments, etc. to proceed with installations.
• Manufacture, ship, install, and commission 189 stationary fuel cell sites.
• Collect data on operation, fuel service, and maintenance.
Accomplishments

- Submitted required documentation for National Environmental Policy Act (NEPA) clearance, and received a categorical exclusion.
- Submitted a hydrogen safety plan.
- Reviewed database records of 654 candidate AT&T sites to down-select sites based on the feasibility of fuel cell installation and on-site refueling accessibility.
- Performed physical site surveys at 460 candidate AT&T sites to further down-select sites based on the feasibility of fuel cell installation and refueling accessibility.
- Generated and delivered 380 unique quotes for the 180 AT&T sites to be constructed.
- Processed 509 unique purchase orders from AT&T Procurement for equipment, site acquisition (SAC) services, fuel cell installation services, and supplemental shelter direct air cooling equipment and installation services.
- Initiated the SAC process (leasing, zoning/planning, permits, etc.) on 188 AT&T sites.
- Completed the SAC process for 16 AT&T sites.
- Fabricated, integrated, and delivered fuel cell equipment for 132 sites, and hydrogen storage modules (HSMs) for 69 sites.
- Constructed and commissioned eight sites and provided hand-off to the customer.
- Performed physical site surveys at 36 PG&E candidate sites to evaluate the feasibility of fuel cell installation.
- Generated 25 unique scopes of work for PG&E sites to be constructed (customer subsequently selected nine of these viable sites).
- Completed all contract negotiations with PG&E and processed the final purchase order for the installation of fuel cells at nine sites in the PG&E network.
- Fabricated and integrated nine sets of fuel cell equipment for all nine PG&E sites.
- Developed the methodology, and validated the equipment and network architecture required to remotely obtain operational data from the sites in order to satisfy the National Renewable Energy Laboratory (NREL) data gathering obligation.

Introduction

Market transformation is best achieved by reaching a critical mass in the market that significantly raises awareness and direct experience of the value proposition. With the assistance of this project, ReliOn is installing 189 fuel cell systems into the telecommunications and utility networks at AT&T and PG&E for back-up power, across nine states, combined with the deployment of a refillable stationary HSM unit and the accompanying refueling logistics platform for 180 AT&T sites. These are real-world, tangible changes to the market resulting in the use of hydrogen-based systems to harden critical communications networks.

Approach

ReliOn’s approach begins with the basic research needed to identify viable candidate sites and then narrow down the list in order to focus efforts on the most viable and critical sites that can be installed and refueled successfully, ensuring that these assets will remain viable for decades. This work is primarily performed by ReliOn personnel. The next task is to secure rights to perform the construction through the use of SAC vendors who structure the leasing and permitting packages to prepare the sites for construction. ReliOn utilizes third parties who are skilled in this profession and will remain part of the project until all SAC activities have been completed.

As a site clears the SAC process, it is then constructed (typically within 15 business days) and brought on-line as a fully functional back-up power system. Installation construction is performed only after the SAC vendor has secured the installation and operating rights for each site. ReliOn utilizes third parties to perform installation construction, yet retains the roles of project management and supervision. ReliOn partnered with an established hydrogen provider, APCI, an industry expert in hydrogen storage and delivery for the development and production of the HSM. Once the sites are installed, fueled and operational, they are monitored remotely for data collection. ReliOn personnel collect and report fuel cell operational data to NREL. The use of both ReliOn and third party resources maximizes the effectiveness of the project, creates or retains jobs across a breadth of companies and regions, and delivers the maximum amount of infrastructure for the given financial investment.

Results

To date, ReliOn has completed the site qualification stage for the entire project. This has allowed for the successful initiation of SAC activities on all target sites, plus a few reserve sites as contingencies for sites that may fail to complete the SAC process due to unforeseen circumstances. SAC has been completed on the first 16 AT&T sites. ReliOn has installed fuel cells at eight sites to date with eight more sites pending construction. Of the eight sites installed, three systems are installed in Colorado and five systems installed in Utah. This ongoing process of SAC approval and site construction
has resulted in the continuous need for labor and has secured multiple jobs. PG&E performed the SAC of their nine sites using their internal real estate and legal department resources, and PG&E construction will commence in August of 2010.

Figure 1 shows the first site completed within the project. This is an AT&T site located in Arvada, CO. This fuel cell system is on-line and fully operational. The leftmost cabinet is the fuel cell equipment enclosure with an adjacent 6-cylinder hydrogen storage cabinet. The larger cabinet to the right is the HSM. The HSM is connected to the system in parallel with the 6-cylinder hydrogen storage cabinet, and contains the majority of the fuel capacity.

Figure 2 shows the second site completed within the project. This is an AT&T site located in Byers, CO. The photograph shows the HSM cabinet receiving its initial fueling from the bulk hydrogen refueling vehicle.

This project deploys fuel cell systems into eight states as shown in Figure 3, though it promotes jobs and supports business in other states which are the home bases of various subcontractors. AT&T will have systems operating in all eight states. As a California utility, all of PG&E’s systems are located within California. As discussed earlier, the SAC activity is a primary task which must be completed before fuel cell system installation construction can commence. Figure 4 shows the original schedule for the AT&T SAC activity, and progress made towards this goal. Delays in ‘SAC Initiation’ during the months of February and March were the result of end-user corporate approval processes which were completed at the beginning of the second quarter of 2010. Once ReliOn received approval to proceed, sites were released to begin the SAC process, and the schedule was recovered.

Conclusions and Future Directions

During the past year of effort, ReliOn has learned that the initial site identification process is much more
involved than originally anticipated. Many sites that the ReliOn field survey engineer qualified as serviceable based on an acceptance rubric provided by APCI for refueling vehicle access were subsequently rejected during secondary surveys by APCI drivers who provide the refueling service. This required the refueling vendor to be much more involved in the site selection and qualification process from the beginning. It was also discovered that the SAC process takes longer on average than original estimated by subcontractors. Where originally two months was considered an adequate gestation period for the process, in reality it was discovered that three to four months is more typical.

Tasks planned for the next year include:

- Complete the SAC process for all remaining sites within the project.
  - This activity includes working with the local authorities having jurisdiction to educate them on hydrogen safety, fuel cells, and codes and standards to resolve any questions/issues that arise during SAC.
- Construct all remaining sites and commission the equipment for hand-off to the customer/end-user.
- Obtain and report operational data to fulfill the DOE/NREL data reporting requirement.

DOE Project Officer: Reg Tyler
Phone: (303) 275-4929
E-mail: Reginald.Tyler@go.doe.gov

Contract Number: DE-EE0000448
Project Start Date: June 1, 2009
Project End Date: December 31, 2011

Objectives
- Increase distributed power generation.
- Improve reliability and efficiency of mission critical backup power.
- Decrease fossil fuel dependencies for power generation.

Relevance to ARRA and DOE-Fuel Cell Technologies
Goals
- Demonstrates market viability and increase pull of hydrogen and fuel cell systems within our government customers/partners.
- Deploys 20 GenSys hybrid, hydrogen start/liquefied petroleum gas (LPG) or natural gas run units that provide economically viable backup power in excess of 72 hours.
- Maintains seven U.S., high-tech jobs in New York State and provides work for U.S. suppliers and field service contractors.

Accomplishments
- Warner Robins Air Force Base in Georgia and Fort Irwin in California have expressed interest in being site hosts for extended backup GenSys and Plug Power conducted a site review at Warner Robins in March 2010.
- An economically viable path to 72 hours worth of backup power with a pure hydrogen solution was not determined and the focus of the project has shifted to a successful hydrogen start with an LPG/natural gas run.

Introduction
Since 2001, Plug Power has installed more than 800 fuel cell systems worldwide. Plug Power’s prime power systems have produced approximately 6.5 million kilowatt hours of electricity and have accumulated more than 2.5 million operating hours. Intermittent or backup power products have been deployed with telecommunications carriers, government and utility customers in North and South America, Europe, the United Kingdom, Japan and South Africa. Some of the largest material handling operations in North America are currently using the company’s motive power units in fuel cell-powered forklifts for their warehouses, distribution centers and manufacturing facilities. The low-temperature GenSys fuel cell system provides remote, off-grid and primary power where grid power is unreliable or nonexistent. Built reliable and designed rugged, low-temperature GenSys delivers continuous or backup power through even the most extreme conditions. Coupled with high-efficiency ratings, low-temperature GenSys reduces operating costs making it an economical solution for prime power requirements. Currently, field trials at telecommunication and industrial sites across the globe are proving the advantages of fuel cells—lower maintenance, fuel costs and emissions, as well as longer life—compared with traditional internal combustion engines.

Plug Power has determined that extended backup power requirements of 72 hours and beyond can be best met with a hybrid GenSys solution. This system can both meet the demands of Department of Defense customers, and a broad global commercial market. At this time Plug Power was unable to determine an economically viable path to 72 hours worth of backup power with a pure hydrogen solution and has therefore stopped development of a pure hydrogen solution. The hybrid hydrogen/LPG or natural gas solution provides the economics needed for a flexible backup power solution.

Approach
This project will leverage technology from Plug Power’s two existing product lines to create a reliable power source that starts fast and runs as long as fuel is available. The project tasks and status are shown in Table 1:

For the past year Plug Power has collaborated with partners the Army Construction Engineering Research Laboratory and Warner Robins Air Force Base to demonstrate market viability and increase market pull of hydrogen fuel cell systems. To date, 38 percent of the project has been completed and barriers are actively being addressed, including: cost, system reliability and market volume.

Results

Fifteen percent of Plug Power’s employees are supporting this effort to deploy 20 GenSys hybrid hydrogen start/LPG or natural gas run units. Automotive suppliers are delivering stack, reformer and balance-of-plant components.

Eighty-five percent of the cost analysis and commercialization study has been completed. The GenSys offers economic and environmental benefits over the incumbent diesel generator technology. It has a nearly threefold advantage in system life with only 20-25 percent higher maintenance cost and offers the customer a 20-30 percent decrease in power generation expense (Table 2).

An economically viable path to 72 hours worth of backup power with a pure hydrogen solution was not determined, shifting focus to the success of a hydrogen start with LPG/natural gas run. This solution provides for a more flexible backup power solution.

In March 2010 Plug Power visited Warner Robins Air Force Base in Warner Robins, Georgia to discuss its viability as a site. Warner Robins Air Force Base requires extended backup power to enable base service operations, including a server room and heating, ventilation and air conditioning. Although hydrogen is available on site its proximity to potential unit placement and logistics may be difficult and costly.
XI.8 H-E-B Grocery Total Power Solution for Fuel Cell-Powered Material Handling Equipment

Objectives

- Validate DOE market transformation activities by demonstrating fuel cell forklifts operating in highly transient environments and demonstrating a distributed natural gas-based hydrogen refilling system as a precursor to future automotive fuel cell refilling stations.
- Install one PowerTap™ hydrogen generation system and 14 PowerEdge™ fuel cell power pack units for use in the dry goods and produce sections of the H-E-B Grocery, Inc. (H-E-B), San Antonio, Texas distribution center.

Expected Outcomes

- One PowerTap™ and 14 PowerEdge™ fuel cell systems delivered, installed in forklifts and operated at the H-E-B distribution center.
- Periodic performance reports documenting results from operating systems including any safety or performance data and issues identified during the operation of the units.
- Widespread adoption of hydrogen and fuel cell technology by employing this as a best practice across the H-E-B fleet of 1,000 forklifts upon verification of the value proposition.

Relevance to ARRA and U.S. DOE Fuel Cell Technologies Goals

The project, per the methodology in quarterly reporting via grants.gov, has preserved 2.05 full-time equivalent jobs annualized. In addition, this project facilitates the fuel cell market transformation initiative by deploying 14 fuel cell power pack units and one on-site hydrogen generation system into a strategic early market application for this industry.

Other Accomplishments

- Conducted site planning and secured all required permits and insurance coverage.
- Created a site-specific service plan for both the PowerEdge™ and PowerTap™ products.
- Completed the installation of PowerTap™ hydrogen infrastructure.
- Completed the installation of 14 PowerEdge™ fuel cells in forklift trucks.
- Verified an initial productivity gain of 10% versus operation on standard lead acid batteries.

Introduction

H-E-B is a privately-held, San Antonio, Texas-based supermarket chain with 310 stores throughout Texas and northern Mexico. H-E-B management believes that fuel cell forklifts can help alleviate several issues in their distribution centers including truck operator downtime associated with battery changing (labor savings), truck and battery maintenance costs (expense savings), and reduction of grid electricity usage (environmental savings).

Currently, the H-E-B distribution center operates a total of approximately 300 Class II reach trucks and 700 Class III pallet jacks over two work shifts, for a total of 20 hours per day. There are three temperature zones in the facility, ranging from dry goods at ambient temperature, to refrigerated goods at 34°F (1°C), to freezer goods at -13°F (-25°C). The PowerEdge™ units provided will fit into Class II fork lift trucks designed for use with 1,000 Ah lead acid batteries, and are capable of operation in both the ambient and refrigerated goods temperature zones of the San Antonio facility.
Approach

The approach taken for this installation was to develop a site-specific installation plan that detailed where all hydrogen generation, compression, storage, and dispensing equipment would be placed. As the site plan was being developed, the PowerTap™ and PowerEdge™ equipment was manufactured and delivered to the H-E-B facility, where it was installed in accordance with all required codes and standards. Upon final sign-off from both the local authorities having jurisdiction and the insurance carrier, the forklift fleet was deployed for operation in the grocery and perishable sections of the distribution center alongside forklifts operating with standard lead-acid batteries. The fuel cell forklifts and the battery forklifts will operate in parallel to allow direct comparison between the two, allowing H-E-B and DOE to validate the value proposition associated with the PowerEdge™ and PowerTap™ products.

Market Transformation Barriers

As presented at the Annual Merit Review meeting on June 10th, 2010, the market transformation barriers and risks included “fuel cell operation and maintenance” and “hydrogen station operation and maintenance.”

Fuel Cell Operation and Maintenance

Nuvera conducted an engineering trial at H-E-B in early December 2009 to tune the RL25 (PowerEdge™, motive power unit) field configurable parameters for optimal performance in H-E-B’s produce warehouse. Discovered that the RL25 was not able to consistently satisfy all of the requirements of the customer's forklift duty cycle, which was considerably more intensive than any duty cycles previously measured. During the peak season demands of November-December, the duty cycle began to approach and exceed the 5 kW sustained maximum power rating of the RL25. As a high productivity warehouse, H-E-B has continually sought to move more pallets, of heavier weight, and be able to store them on higher racks. While the RL25 could effectively keep up with most of the needs of H-E-B’s produce warehouse, it could not do so over multiple shifts without requiring a change in H-E-B’s fleet operation. After extensive testing of performance and sustainable capability, as of January, 2010, 12 of the 14 trucks were transferred to the grocery warehouse for continuing operation.

Hydrogen Station Operation and Maintenance

For the infrastructure, several challenges specific to project location have been identified:

- **Environment**: High ambient temperatures required design modifications for improved cooling of both the PowerTap™ generation and compression modules. San Antonio averages 111 days per year >90°F. The hydrogen infrastructure also needed to be upgraded to withstand 120 mph winds as tropical storms are prone to come in from the Gulf Coast.

- **Electrical Power Quality**: The San Antonio grid is susceptible to frequent brown-outs and instability of the local 480 V 3-phase power. This required design modifications to reduce sensitivity to momentary disruptions or fluctuations in power.

- **Natural Gas Quality**: The San Antonio region has unusually high levels of mercaptan in the natural gas composition. This has required tailoring of the PowerTap™ desulfurizing media and the replacement schedule in order ensure high fuel processor lifetime and hydrogen purity for the fuel cell vehicles.

- **City Water Quality**: The San Antonio region also suffers from very high water hardness levels. This has required more frequent replacement of membranes in the reverse osmosis water treatment system in order to prevent scaling in the steam generation subsystem.

Results

As presented in Table 1, the build of all 14 PowerEdge™ systems and the PowerTap™ hydrogen refueling equipment was complete as of October 30, 2009. In parallel, Nuvera application engineers, working with H-E-B facility engineers, created site-specific service and installation plans. As part of the process, Nuvera conducted a survey of H-E-B’s site to identify potential locations for the on-site hydrogen generation and refueling infrastructure, and applied our knowledge of H-E-B’s fleet operation in order to minimize the travel time to the dispensing locations.

Based on the agreed site plan, Nuvera identified and provided basic training to H-E-B service personnel. The role of these service personnel is to keep the PowerEdge™ systems operational by providing a fast response to diagnosing and repairing system faults. This type of service includes scheduled preventive maintenance, basic troubleshooting, and the repair or replacement of non-safety critical items. Nuvera’s Customer Care group provided spare parts, training, data analysis, and more complex field support, including troubleshooting and repairs of safety-critical items (high pressure, high voltage).

During this process, all relevant codes and standards were identified, and working with the local authorities having jurisdiction and the H-E-B insurance carrier, all permits were obtained for site construction, installation, and operation.
The deployment process began upon establishing the final site plan, shown pictorially in Figure 1, and was completed on February 28, 2010. During this process the following tasks were performed:

**Hazards and Operability Analysis**: Ensure safe design, installation, and operation of the equipment by rigorously identifying all potential hazards, and quantifying the resulting risks.

**Site Layout**: Apply knowledge of the applicable national and local codes to ensure proper offset distances between the hydrogen generation and refueling equipment, structures, and potential hazards.

**Permitting and Approvals**: Submit the site plan to qualified professional engineer for approval.

Review the approved site plan with local authorities having jurisdiction with regard to applicable permits and approvals. Obtain applicable permits to allow commencement of site construction activities.

**Site Construction**: Prepare final site drawings for use by mechanical, electrical, and civil contractors. Source and select appropriate contractors and construct site.

**Wireless Data Collection Infrastructure**: Deploy a wireless infrastructure that collects operational and fault data from the fuel cell fleet and hydrogen generation and refueling equipment.

**Installation, Commissioning, and Training**: Deploy the fuel cell fleet and hydrogen generation and refueling equipment and complete the site acceptance test for each. Provide training to the forklift operators regarding safety, operation, refueling procedures, and appropriate responses to system faults.

The resulting deployment of PowerEdge™ fuel cell forklifts and PowerTap™ hydrogen generation, compression, storage, and dispensing products are shown in Figures 2 and 3, respectively.

Since the commencement of full fuel cell fleet operations in March 2010, H-E-B has operated the equipment in normal daily service, and continues to compare the productivity and life cycle costs of operation on a side-by-side basis with standard lead acid battery powered forklifts. Over the first three months of operation, H-E-B reported an increase in productivity of 10% for the PowerEdge™ systems compared to forklifts running on batteries, as shown in Figure 4.

As part of the ongoing project, Nuvera provides data to the National Renewable Energy Laboratory (NREL) using jointly agreed data templates. Information collected during the course of daily operations includes the following:

- Power pack fault code indication
- Service notifications

* FAT - factory acceptance test. For the PowerEdges, this consisted of a two-week trial with two trucks versus electric stockpickers to verify productivity. For PowerTap, the FAT verified 50 kg daily production and purity.

**FIGURE 1. Location of Hydrogen Infrastructure at H-E-B Grocery Site**
XI. ARRA

Mitchell – Nuvera Fuel Cells, Inc.

Currently, the PowerTap™ hydrogen generation, compression, storage, and dispensing system, as well as all 14 PowerEdge™ hybrid fuel cell power systems, are fully operational and are being used in normal daily operations. Over the next 12 months, H-E-B will:

- Continue to operate fleet in normal operations to gain durability and life cycle cost information on the fuel cell systems.
- Monitor and record the long-term operation cost of on-site hydrogen generation.
- Compile performance data of PowerEdge™ and PowerTap™ systems and send to NREL for analysis.
- Continue to assess the increase in productivity associated with the fuel cell solution in comparison with the lead acid battery forklift.
- Assess whether to increase the size of the fleet as expansion opportunities arise.
- Nuvera completed revisions to safety plan and submitted final version on July 3, 2010.

Conclusions and Future Directions

FY 2010 Publications/Presentations

Objective

- Safe and reliable operations of hydrogen material handling equipment (MHE).
- Convert an entire MHE fleet at FedEx Springfield, MO facility with fuel cell-powered forklifts (class-1).
- Demonstrate economic benefits of conversion.
- Provide cost effective and reliable hydrogen.
- Spur further lift truck fleet conversions.
- Establish proving ground for hydrogen MHE.

Technical Barriers

- Interim forklifts at new facility until fuel cells come online.
  - Because it was not possible to have the fuel cells operational at the time the new center opened, propane forklifts were used until the fuel cells could come online. The forklifts were pulled from other centers that at the time were not being used. However freight levels are beginning to rise and there is a need for the forklifts to be moved back to their original center. That is why it was imperative to get the fuel cell up and running.

- Permits for indoor dispensing.
  - There was an issue with the permitting of the dispensers because the city of Springfield went by a different set of codes for putting in hydrogen than what Air Products was used to and these codes did not match up in all areas. An example of this was that it was required from the city that the indoor dispensers required labeling that it was rated for dispensing indoors. This was new to Air Products so they had to go back to the dispensers' manufacturers and have the dispensers tested by a 3rd party and labeled that they were rated for indoor dispensing.

- Introducing hydrogen into the everyday world of FedEx Freight.
  - Working with hydrogen is very new to FedEx Freight. This created some challenges on how to address uninformed and inaccurate perceptions regarding hydrogen safety risks, to having to know how to work with new equipment, to how to do accounting for the project. Despite these challenges FedEx Freight has work to learn more about fuel cells and how they work to overcome these challenges.

American Recovery and Reinvestment Act

The purchase or these fuel cells from Plug Power resulted in approximately five jobs created at Plug Power to build the fuel cells. In addition, the success of this project could contribute to accelerating commercialization and deployment of fuel cells and hydrogen technologies, with an accompanying increase in jobs for fuel cell manufacturers, hydrogen providers, and associated maintenance and support services.

Accomplishments

- Plug Power built and delivered 35 GenDrive class-1 power units two months ahead of schedule.
- Air Products installed the liquid hydrogen handling and gaseous compression, storage and dispensing equipment.
- This includes all interconnecting piping, civil, electrical and mechanical connections, and safety systems:
  - Two indoor dispensers
  - 6,000 US gallon liquid hydrogen horizontal tank
  - Refuel time 3-6 minutes
  - ~91 kg/day usage
Introduction

This project addresses the DOE’s priorities related to acquiring data from real-world fuel cell operation, eliminating non-technical barriers, and increasing opportunities for market expansion of hydrogen fuel cell technologies.

Approach

The project involves replacing the batteries in a complete fleet of class-1 electric lift trucks at FedEx Freight’s Springfield, MO service center with 35 Plug Power GenDrive fuel cell power units. Fuel for the power units involves on-site hydrogen handling and dispensing equipment and liquid hydrogen delivery by Air Products.

The project builds on FedEx Freight’s previous field trial experience with a handful of Plug Power’s GenDrive power units. Those trials demonstrated productivity gains and improved performance compared to battery-powered lift trucks. Full lift truck conversion at our Springfield location allows improved competitiveness of operations and helps the environment by reducing greenhouse gas emissions and toxic battery material use. Success at this service center may lead to further fleet conversions at some of the other larger FedEx Freight service centers and possible conversion of other fleets in the Less-than-Truckload market.

Conclusions and Future Directions

FedEx Freight’s project is well under way. The GenDrive units have been delivered, hydrogen infrastructure is completed and approved and is in use. Now that the units and infrastructure are in use the remainder of the project will require regular monitoring and evaluation. This includes:

- Data collection from the power units and evaluation of performance, operability and safety.
- Data collection from the liquid and gaseous hydrogen fueling equipment and evaluation of performance, operability and safety.

FY 2010 Publications/Presentations

XI.10 Fuel Cell-Powered Lift Truck Sysco Houston Fleet Deployment

Accomplishments

- Converted the entire class-2 and class-3 lift truck fleet to fuel cell use.
- Built permanent hydrogen fueling infrastructure.
- Trained over 100 employees on operation and safety of hydrogen use.
- Improved operator productivity due to elimination of battery degradation and charging time.
- Through life of project 5.5 jobs have been created.
- Completed 2,664 fills in first quarter 2010.

Introduction

This project addresses the DOE’s priorities related to acquiring data from real-world fuel cell operation, eliminating non-technical barriers, and increasing opportunities for market expansion of hydrogen fuel cell technologies.

Sysco Houston’s objectives are to support the American Recovery and Reinvestment Act goals of long-term economic growth by successfully demonstrating this new technology. Establishing a proving ground for expanded use of hydrogen fueling technology at Sysco promotes future adoption of fuel cells in other applications thereby driving their use in the U.S. Sysco also hopes to promote the economic and environmental benefits of hydrogen fuel cell technology.

To see these objectives to fruition, Sysco Houston has and is:

- Converted the entire class-2 and class-3 lift truck fleet to fuel cell use.
- Demonstrating the economic benefits of large fleet conversions of lift trucks from lead-acid batteries to fuel cell power units by measuring, analyzing and reporting on the performance, operability and safety of the systems.
- Demonstrating freezer operability.
- Spurring further fuel cell lift truck fleet conversions.
- Establishing a proving ground for hydrogen fueling technology that will promote the future adoption of fuel cells in other applications and help drive the use of fuel cell technology in the United States.

Technical Barriers and Goals

This project addresses the following technical barriers:

- Safe hydrogen use in high throughput distribution center.
- Full fleet conversion to Greenfield center.
- Operator productivity improvements.
- Fuel cell use in freezer setting.
- GenDrive fuel cell lifetime and reliability.

Approach

The project involves replacing the batteries in a complete fleet of class-3 electric lift trucks at Sysco’s new Houston, TX distribution center with 72 Plug Power GenDrive fuel cell power units (plus the rental of seven additional class-3 power units for 6-month use in rented lift trucks). Fuel for the power units involves on-

Objectives

- Convert the entire class-3 lift truck fleet at a Greenfield distribution center in Houston, Texas to fuel cell use.
- Demonstrate the economic benefits of large fleet conversions of lift trucks from lead-acid batteries to fuel cell power units by measuring, analyzing and reporting on the performance, operability and safety of the systems.
- Demonstrate freezer operability.
- Provide affordable and reliable hydrogen.
- Spur further fuel cell lift truck fleet conversions.
- Establish a proving ground for hydrogen fueling technology that will promote the future adoption of fuel cells in other applications and help drive the use of fuel cell technology in the United States.
site hydrogen handling and dispensing equipment and liquid hydrogen delivery by Air Products.

The project builds on Sysco’s previous field trial experience with more than 40 of Plug Power’s GenDrive power units. Those trials demonstrated productivity gains and improved performance compared to battery-powered lift trucks. Full lift truck conversion at the Houston location allows improved competitiveness of operations and helps the environment by reducing greenhouse gas emissions and toxic battery material use. Success at this distribution center may lead to further fleet conversions at some or all of Sysco’s 170 distribution centers.

Sysco Houston’s hydrogen safety plan has been fully implemented and all National Environmental Policy Act forms have been submitted for review and approval.

The liquid tank operates with a maximum allowable working pressure of 150 psig and the bulk high-pressure storage tanks operate at 6,000 psig. The indoor dispensers are 250 bar and capable of over 700kg/day. A pin code and badge scan is required for dispenser operation. Hydrogen gas detectors alarm at 25 percent of the lower explosive level and will shut down the system automatically.

Sysco Houston is successfully using hydrogen fuel cell technology for the first time in a fleet environment and the facility has proper safety, backup and operational procedures in place. Close monitoring and return on investment calculations have increased Sysco’s involvement in fuel cell-powered lift truck operations.

### Conclusions and Future Directions

Sysco Houston is successfully using hydrogen fuel cell technology for the first time in a fleet environment. The facility has proper safety, backup and operational procedures in place and a fully implemented hydrogen safety plan. Close monitoring and return on investment calculations have increased Sysco’s involvement in fuel cell-powered lift truck operations. One hundred and five of Plug Power’s GenDrive units are currently in use and hydrogen fueling is occurring regularly, Air Products providing the hydrogen support.

The majority of the project tasks have been completed at the front end of the project. The balance of the demonstration period will include:

- Monitoring GenDrive power units project performance, operability and safety.
- Monitoring liquid and gaseous hydrogen fueling equipment project performance, operability and safety.
- Monitoring and providing project performance, operability and safety reports to the DOE, including any safety and performance data and issues identified during operation of the power units. This encompasses maintenance and operation of the GenDrive units.
- Supporting DOE communication efforts.

DOE Project Officer:  Jim Alkire  
Phone: (303) 275-4795  
E-mail: James.Alkire@go.doe.gov

Contract Number:  DE-EE0000483

Subcontractors:
• Plug Power Inc., Latham, NY
• Air Products and Chemicals, Inc., Allentown, PA
• Linde North America, Murray Hill, NJ

Project Start Date:  October 1, 2009  
Project End Date:  September 30, 2013

Objectives

• Convert electric-drive fork lift truck fleets to fuel cell use in a variety of large distribution centers and manufacturing facilities.
• Demonstrate the economic benefits of large fleet conversions of lift trucks from batteries to fuel cell power units by measuring, analyzing and reporting on the performance, operability and safety of the systems.
• Provide affordable and reliable hydrogen.
• Spur further fuel cell lift truck fleet conversions.
• Establish a proving ground for hydrogen fueling technology that will promote the future adoption of fuel cells in other applications, such as cars, and help drive the use of fuel cell technology in the United States.

Accomplishments

General

• Nine jobs were maintained through the third quarter of 2010 in New York.

Wegmans

• National Environmental Policy Act (NEPA) environmental forms have been approved and the fueling station is operational, logging almost 2,000 hydrogen fills during first quarter 2010.
• Fifty-nine GenDrive power units are running and have logged 24,375 operating hours during the first quarter of 2010.
• Nine of the GenDrive power units were delivered two months ahead of schedule.
• Wegmans has achieved all project milestones and is pleased with performance of GenDrive power units.

Sysco Philadelphia

• Sysco contractors have completed concrete pad for the hydrogen fueling station.
• The remainder of the fueling station will be completed concurrent with building construction.
• NEPA environmental forms are nearing completion.

Coca-Cola

• NEPA environmental forms have been approved.
• Linde fueling station contracts are under final negotiation.

Kimberly-Clark

• Lease arrangement has been completed.
• Air Products fueling station contracts are under final negotiation.
• Nine GenDrive power units have been delivered to date.
• NEPA environmental forms have been approved.
• Permits have been secured.
• Site contractor has poured pad.
• Air Products to set equipment for the fuel station the week of October 19.

Whole Foods

• Linde fueling station contracts are under final negotiation.
• Permit application is ready for submission.
• All sixty-one GenDrive power units have been delivered.
• NEPA environmental forms have been approved.
Introduction

This project addresses the DOE’s priorities related to acquiring data from real-world fuel cell operation, eliminating non-technical barriers, and increasing opportunities for market expansion of hydrogen fuel cell technologies.

Approach

The project involves replacing the batteries in 357 electric lift trucks with 110 class-1, 61 class-2, 14 stock picker (modified class-2) and 172 class-3 Plug Power GenDrive fuel cell power units at five distribution centers. These distribution centers handle goods for Wegmans (Pottsville, PA), Coca-Cola (Charlotte, NC), Sysco Foods (Philadelphia, PA), Whole Foods (Landover, MD) and Kimberly-Clark (Graniteville, SC). Fuel for the power units involves on-site hydrogen handling and dispensing equipment and liquid hydrogen delivery by Air Products or Linde, depending on location.

The project builds on GENCO’s previous field trial experience with a handful of Plug Power’s GenDrive power units. Those trials demonstrated productivity gains and improved performance compared to battery-powered lift trucks. Full lift truck conversion at the five distribution center locations allows improved competitiveness of operations and helps the environment by reducing greenhouse gas emissions and toxic battery material use. Success at these distribution centers may lead to further fleet conversions at some or all of GENCO’s 110 distribution centers.

Conclusions and Future Directions

GENCO has made great strides facilitating hydrogen fuel cell usage at the Wegmans site and progress is being made to bring the four remaining sites online. Successful integration of Plug Power’s GenDrive power units into each facilities material handling operations will continue. Working with hydrogen providers Air Products and Linde, each of the five sites will incorporate hydrogen fueling into their daily activities. Table 2 provides detailed information on when the remaining sites will be fully operational.

FY 2010 Publications/Presentations

Introduction

The relevance of this project to the goals of the American Recovery and Reinvestment Act (ARRA) of 2009 is threefold. First, Sprint seeks to support the creation of new jobs, as well as maintain existing jobs, to successfully complete this deployment effort. Second, Sprint intends to spur economic activity through the positive impact to various industries and service providers at all levels of the supply chain. And finally, Sprint is confident that this investment in proton exchange membrane (PEM) hydrogen fuel cells (HFCs), to provide emergency power to our critical wireless network facilities, will truly benefit our nation’s long-term economic growth.

Objectives

- Eliminate Barriers to Siting and Permitting
- 72-Hours of Hydrogen Fuel Storage
- Eliminate Barriers to Re-Fueling Sites at the Required Level of Performance
- Collect and Analyze Data Sample to Evaluate Economic and Operational Metrics

Technical Barriers

The overarching goal of this project, as stated in our application originally, is to support the DOE Fuel Cell Technologies ARRA project goal of accelerating the commercialization and deployment of fuel cells. In order to accomplish this goal, specific barriers that were encountered during our initial HFC deployment need to be overcome.

One major barrier involves the difficulty associated with the siting and permitting required for the installation of an HFC. With the vast number of local municipalities that need to be engaged, and the fact that they may recognize various code authorities, as well as different issues of the same code, a fact-based presentation, citing specific code interpretations, must be crafted to educate the authorities having jurisdiction (AHJ).

Another barrier we must overcome deals with the difficulties associated with refueling the HFC. In our earlier deployment, low-pressure hydrogen storage tanks were utilized. Based upon the site loads, we were able to provide backup power for a period of 14–20 hours before refueling was required. This refueling methodology requires the replacement (bottle swap) of the low-pressure bottles - a slow, cumbersome process that is impractical, as well as unmanageable during a widespread power outage event (i.e. hurricane). In addition, the runtime provided by this low-pressure solution comes nowhere close to the 72-hour runtime available from the incumbent technology, the diesel generator.

Finally, the success of this effort cannot be determined until the HFC, with the medium-pressure hydrogen storage solution, is installed and placed in service. The unit’s performance in real world situations, based on financial and operational performance data collected, analyzed and reported, shall be the confirmation or denial of its ability to provide a cost-
effective, operationally accepted option for providing backup power at critical sites.

Technical Targets

This project is demonstrating the economic and operational viability of using PEM fuel cells to provide emergency power at critical code division multiple access sites on the Sprint Nextel Network. We plan to more than double the number of PEMs deployed in our network. In addition, we plan to retrofit approximately 25% of our current installed base with a new hydrogen storage solution to extend PEM runtime by a factor of three. The data collected from these newly deployed and/or modified units will, it is hopes, provide supporting documentation to create a “market pull” within the telecom space, as well as across various industries, for additional PEM fuel cell deployments. Project targets as follows (Figure 1):

- PEM sites currently in-service: 237
- Additional PEMs to be deployed: 260
- Low-pressure hydrogen storage runtime: 14–20 hours
- Medium-pressure hydrogen storage runtime: ~72 hours
- Deployment will expose three additional states, and impacted local municipalities, to the use of hydrogen fuel for backup power purposes:
  - Connecticut
  - New Jersey
  - New York
- Existing PEMs to convert to refillable on-site medium-pressure hydrogen storage: 70

These targets dovetail very well with the objectives stated under the ARRA. By doubling our installed base of HFCs, numerous jobs shall be created and maintained. From jobs within the equipment manufacturing facilities, to personnel engineering, constructing, maintaining, and refueling these devices, the ripple effect is enormous. Our expansion into three additional states, and our increased footprint in another, shall permit Sprint to interface with the AHJ personnel which will help acquaint them with the use of hydrogen as a fuel, and the associated codes to which we must adhere.

Approach

After reviewing the code division multiple access Network Site Inventory, a master candidate site list was created based upon the restoration priority of the facility, and whether or not the site was equipped with a fixed generator. Sprint focused on specific markets to exploit the site’s proximity to the hydrogen distribution facility (within 200 miles), as well as to concentrate on market clusters to minimize site acquisition, siting/permitting, installation, commissioning, and training expenditures. In addition, this cluster approach helps to minimize costs associated with the maintenance of a PEM spare parts inventory. Finally, this concentration permits a consistent presentation to the local building officials,
which in turn helps to clarify applicable code (Uniform Building Code, National Fire Protection Association, etc.) interpretations. In theory, all of these efforts should help to facilitate a rapid, safe, and successful deployment in the market.

**Accomplishments**

Following the execution of the contract with the Department of Energy on March 18, 2010 purchase orders (260 orders with a total value of $335,510) were generated to our architectural and engineering (A&E) project partners for Phase 1 (lease review and site assessment) work. Phase 1 progress, by state, is as follows:

- **New York** – 65 sites targeted; 155 in pool; 66 site surveys completed; as of this report, Phase 2 (site acquisition, permitting, pre-notice to proceed) orders are being prepared for 20 sites.
- **Connecticut** – 30 sites targeted for deployment; candidate pool consists of 131 sites; sites surveyed - 65 sites. Site surveys are being reviewed for determination of next steps.
- **California** - 100 targeted; pool of 331; sites surveyed - 81 sites. Uploaded site surveys are being reviewed.
- **New Jersey** – 65 targeted; 137 in pool. Site surveys began on Monday, July 12, 2010.

Design of the medium-pressure hydrogen storage solution is well underway with final drawings scheduled for completion by July 30, 2010.

Sprint is working internally to create purchase orders for equipment (fuel cells, as well as hydrogen storage modules). Our intent is to have orders in the pipeline so that material delivery can coincide with the start of Phase 3 (installation/commissioning).

Working with our project partners, on July 13, 2010, the Sprint Hydrogen Safety Plan was provided to our DOE Project Officer.

We are continuing to assemble the required information/documentation to request a National Environmental Policy Act Categorical Exclusion for this project – targeting a mid-August, 2010 submission.

Per our calculations, 6.5 jobs have been created/maintained during this portion of the Phase 1 activities completed to date.

**Future Directions**

Complete Phase 1 (Site Survey) work to identify the final site list for deployments. Once a site is selected for the final list, a purchase order is generated to our A&E project partner for Phase 2 work. In Phase 2, the A&E will perform all required site acquisition work, as well as secure all permits required by the AHJ. Also during Phase 2, purchase orders are generated to procure all required material (PEM, hydrogen storage, etc.). Phase 2 is considered complete when Sprint issues a notice to proceed to the A&E.

When the notice to proceed is issued, Phase 3 (installation and commissioning) purchase orders are generated to the A&E. The release of Phase 3 purchase orders shall coincide with the delivery date of all required material to the site.

After the PEM is commissioned on-site, two things happen. First, project closure activity is initiated to permit the shutdown of the project within the various impacted Sprint systems. Second, the newly commissioned PEM is added to our remote data collection/performance monitoring system to ensure contractually mandated operational reporting requirements are captured and delivered to the National Renewable Energy Laboratory.

**FY 2010 Publications/Presentations**

1. Presentation deck from the Department of Energy Project Kickoff Meeting conducted at the Sprint Executive Briefing Center in Reston, VA, on May 20, 2010.
XII. SMALL BUSINESS INNOVATION RESEARCH (SBIR) HYDROGEN PROGRAM NEW PROJECTS AWARDED IN FY 2010
The Small Business Innovation Research (SBIR) program provides small businesses with opportunities to participate in DOE research activities by exploring new and innovative approaches to achieve research and development (R&D) objectives. The funds set aside for SBIR projects are used to support an annual competition for Phase I awards of up to $100,000 each for about nine months to explore the feasibility of innovative concepts. Phase II is the principal research or R&D effort, and these awards are up to $750,000 over a two-year period. Small Business Technology Transfer (STTR) projects include substantial (at least 50%) cooperative research collaboration between the small business and a non-profit research institution.

Table 1 lists the SBIR projects awarded in FY 2010 related to the Hydrogen Program. On the following pages are brief descriptions of each.

### TABLE 1. FY 2010 SBIR Projects Related to the Hydrogen Program

PHASE I PROJECTS

XII.1 Low-Cost, Durable Water Vapor Transport Exchanger

Creare Incorporated
16 Great Hollow Road
P.O. Box 71
Hanover, NH 03755-3116

This project will develop critical technology that will enable vehicle propulsion and stationary power generation using low-cost, durable fuel cell power systems. This water management technology will enable reliable fuel cell operation by preventing dryout of the fuel cell and providing water needed for fuel processing.

XII.2 Hydrogen Fueling Station Cost Reduction; Study of a Cryogenic Liquid Phase Pump as an Alternative to Gas Compression

Engineering, Procurement & Construction, LLC
12211 W Alameda Parkway
Suite #105
Lakewood, CO 80228-2825

This project will develop a database of hydrogen refueling costs, and create a methodology to evaluate technology lifecycle cost reduction. Hydrogen compression costs which currently account for a substantial portion for the total costs of hydrogen fueling infrastructure must be reduced for low cost dispensing to become commercially viable.

XII.3 Low Cost Metal Hydride Hydrogen Storage System for Forklift Applications

Hawaii Hydrogen Carriers, LLC
531 Cooke Street
Honolulu, HI 96813-5235

This project will develop a low cost metal hydride hydrogen storage solution for fork lift trucks thus to enable widespread consumer uptake of hydrogen fuel cell-powered fork lift trucks due to the increased overall value proposition and inherent safety of these low pressure systems.
XII.4 Low Cost Large Scale PEM Electrolysis for Renewable Energy Storage

Proton Energy Systems  
10 Technology Drive  
Wallingford, CT 06492-1955

This company manufactures hydrogen generation systems which can be integrated with renewable energy sources to generate hydrogen fuel while producing minimal carbon footprint. This project aims to reduce the cost of this technology through development of improved membrane technology designed to reduce raw material cost and improve electrical efficiency. (See II.E.4 for complete report.)

XII.5 Thermochemically Integrated Solid State Hydrogen Separator and Compressor

FuelCell Energy, Inc.  
3 Great Pasture Rd.  
Danbury, CT 06813-1305

This project focuses on the development of a thermally integrated solid-state hydrogen separator and compressor to produce high pressure, high purity hydrogen to meet future hydrogen refueling infrastructure needs. (See III.16 for complete report.)

XII.6 A Novel Process for Improved Hydrogen Separation and Recovery

Reaction Systems, LLC  
19039 E. Plaza Dr., Suite 290  
Parker, CO 80134-8704

This project will develop a technology that will allow hydrogen to be produced more economically facilitating the increased use of fuel cells, which will reduce our energy consumption.

XII.7 Poison-Tolerant WGS Catalyst for Biomass-Coal Co-Gasification Systems

TDA Research, Inc.  
12345 W. 52nd Ave.  
Wheat Ridge, CO 80033-1916

This project will develop an enabling technology for Coal-Biomass-to-Liquids (CBTL) processes. The CBTL system uses domestic feedstock and will have a greenhouse gas footprint better than conventional coal or petroleum fuels allowing a highly efficient and environmentally responsible utilization of coal.
XII. Small Business Innovation Research

STTR PROJECT

XII.8 Novel Ceramic Membranes for Efficient Hydrogen Recovery

Technology Assessment and Transfer, Inc.
133 Defense Hwy., Suite 212
Annapolis, MD 21401-8907

This project will develop an all-ceramic separation membrane module to cleanly recover hydrogen gas from coal. This module will increase the efficiency of the process and eliminate U.S. dependence on precious metals used for hydrogen separation.

PHASE II PROJECTS

XII.9 Unitized Design for Home Refueling Appliance for Hydrogen Generation to 5000 psi

Giner Electrochemical Systems, LLC
89 Rumford Avenue
Newton, MA 02466-1311

This project will develop a “unitized” electrolyzer design that can be used as a home refueling appliance and will result in a safe, high efficiency, low capital cost system that will provide competitively-priced hydrogen for fuel-cell vehicles. (See II.1.5 for complete report.)

XII.10 Process Intensification of Hydrogen Unit Operations Using an Electrochemical Device

H2 Pump, LLC
11 Northway Lane
North Albany, NY 12110

This project will develop a technology that is a simplified, multi-functional device which pumps, purifies, and pressurized hydrogen in a single, low cost, efficient, non-mechanical process.

XII.11 Hydrogen by Wire Home Fueling System

Proton Energy Systems
10 Technology Drive
Wallingford, CT 06492-1955

This project will develop a high pressure hydrogen system that eliminates major noise pollution and frequent maintenance requirements. It is also an attractive option for backup power when integrated with a proton exchange membrane fuel cell and has advantages over batteries in factors such as available life and safety. (See II.1.7 for complete report.)

XV. Hydrogen Program Contacts

Sunita Satyapal, Program Manager
DOE Hydrogen Program
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-2336
E-mail: Sunita.Satyapal@ee.doe.gov

Rick Farmer, Deputy Program Manager
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-1623
E-mail: Richard.Farmer@ee.doe.gov

John Vetrano
Materials Sciences and Engineering Division
Office of Basic Energy Sciences
DOE Office of Science
Phone: (301) 903-5976
E-mail: John.Vetrano@science.doe.gov

Guido B. Dehoratiis
Division of Advanced Energy Systems
DOE Office of Fossil Energy
Phone: (202) 586-2795
E-mail: Guido.B.Dehoratiis@hq.doe.gov

Carl Sink
Office of Gas Cooled Reactor Technologies
DOE Office of Nuclear Energy
Phone: (301) 903-5131
E-Mail: Carl.Sink@nuclear.energy.gov

Hydrogen Production and Delivery

Sara Dillich, Acting Hydrogen Production and Delivery Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-7925
E-mail: Sara.Dillich@ee.doe.gov
Hydrogen Storage

Ned Stetson, Acting Hydrogen Storage Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-9995
E-mail: Ned.Stetson@ee.doe.gov

Fuel Cells

Dimitrios Papageorgopoulos, Fuel Cells Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-5463
E-mail: Dimitrios.Papageorgopoulos@ee.doe.gov

Manufacturing R&D

Nancy Garland, Acting Manufacturing R&D Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-5673
E-mail: Nancy.Garland@ee.doe.gov

Technology Validation

John Garbak, Technology Validation Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-1723
E-mail: John.Garbak@ee.doe.gov

Safety, Codes & Standards

Antonio Ruiz, Safety, Codes and Standards Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-0729
E-mail: Antonio.Ruiz@ee.doe.gov

Education

Carole Read, Acting Education Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-3152
E-mail: Carole.Read@ee.doe.gov
Market Transformation and Intergovernmental Coordination

Pete Devlin, Market Transformation and Intergovernmental Coordination Manager
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-4905
E-mail: Peter.Devlin@ee.doe.gov

Systems Analysis

Fred Joseck, Systems Analysis Team Leader
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-7932
E-mail: Fred.Joseck@ee.doe.gov

American Recovery and Reinvestment Act (ARRA) Activities

Sara Dillich, Lead for Fuel Cell Technologies ARRA Activities
Fuel Cell Technologies Program
DOE Office of Energy Efficiency and Renewable Energy
Phone: (202) 586-7925
E-mail: Sara.Dillich@ee.doe.gov
XVI. Project Listings by State

Alabama

V.B.2 CFD Research Corp.: Water Transport in PEM Fuel Cells: Advanced Modeling, Material Selection, Testing, and Design Optimization .......................................................... 711

Alaska

VIII.9 Tanadgusix Foundation: TDX Foundation Hydrogen Project/PEV Project .......................................................... 1288
VIII.9 TDX Power: TDX Foundation Hydrogen Project/PEV Project .......................................................... 1288
VIII.9 Alaska Center for Energy and Power: TDX Foundation Hydrogen Project/PEV Project .......................................................... 1288

Arizona

II.C.3 Arizona State University: Zeolite Membrane Reactor for Water-Gas Shift Reaction for Hydrogen Production .......................................................... 67
V.D.10 University of Arizona: Protic Salt Polymer Membranes: High-Temperature Water-Free Proton-Conducting Membranes .......................................................... 786
V.D.10 Arizona State University: Protic Salt Polymer Membranes: High-Temperature Water-Free Proton-Conducting Membranes .......................................................... 786
VI.5 Arizona State University: Adaptive Process Controls and Ultrasomics for High Temperature PEM MEA Manufacture .......................................................... 1144

Arkansas

II.G.11 University of Arkansas, Little Rock: Photoelectrochemical Generation of Hydrogen .......................................................... 182
II.G.13 University of Arkansas, Little Rock: Photoelectrochemical Generation of Hydrogen from Water Using Visible Light Sensitive Ferro-Electric BiFeO3 and Semiconductor Nanotubes .......................................................... 191
IV.H.4 University of Arkansas, Little Rock: An Integrated Approach of Hydrogen Storage in Complex Hydrides of Transitional Elements .......................................................... 639
XI.9 FedEx Freight: Fuel Cell-Powered Lift Truck FedEx Freight Fleet Deployment .......................................................... 1466

California

II.C.2 University of Southern California, Los Angeles: Development of Hydrogen Selective Membranes/Modules as Reactors/Separators for Distributed Hydrogen Production .......................................................... 62
II.F.2 Science Applications International Corporation: Solar High-Temperature Water-Splitting Cycle with Quantum Boost .......................................................... 120
II.G.3 University of California, Santa Barbara: Photoelectrochemical Hydrogen Production Using New Combinatorial Chemistry Derived Materials .......................................................... 145
II.G.4 Stanford University: Semiconductor Materials for Photoelectrolysis .......................................................... 150
II.G.12 Lawrence Livermore National Laboratory: Characterization and Optimization of Photoelectrode Surfaces for Solar-to-Chemical Fuel Conversion .......................................................... 187
II.H.1 University of California, Berkeley: Maximizing Light Utilization Efficiency and Hydrogen Production in Microalgal Cultures .......................................................... 195
II.I.1 Physical Optics Corporation: Photochemical System for Hydrogen Generation .......................................................... 212
II.I.3 Sierra Marine Technologies: Aqueous Phase Base-Facilitated Reforming (BFR) of Renewable Fuels .......................................................... 220
III.4 HyGen Industries: Development of a Centrifugal Hydrogen Pipeline Gas Compressor .......................................................... 267
III.7 Lawrence Livermore National Laboratory: Inexpensive Delivery of Cold Hydrogen in High Performance Glass Fiber Pressure Vessels .......................................................... 282
California (Continued)

III.7 Spencer Composites: Inexpensive Delivery of Cold Hydrogen in High Performance Glass Fiber Pressure Vessels .................................................. 282

III.12 Sandia National Laboratories: Hydrogen Embrittlement of Structural Steels .................. 306

III.20 Lawrence Livermore National Laboratory: Rapid Low-Loss Cryogenic Hydrogen Refueling ..... 341

IV.A.1a Sandia National Laboratories: Five-Year Review of Metal Hydride Center of Excellence .... 361

IV.A.1d Sandia National Laboratories: Development of Metal Hydrides at Sandia National Laboratories .......................................................... 377

IV.A.1j Jet Propulsion Laboratory: Development and Evaluation of Advanced Hydride Systems for Reversible Hydrogen Storage .................................. 408

IV.A.1j California Institute of Technology: Development and Evaluation of Advanced Hydride Systems for Reversible Hydrogen Storage .................. 408

IV.A.3 University of California, Los Angeles: Efficient Discovery of Novel Multicomponent Mixtures for Hydrogen Storage: A Combined Computational/Experimental Approach .................. 428

IV.C.1e Karl Gross: NREL Research as Part of the Hydrogen Sorption Center of Excellence .......... 486

IV.C.1h Lawrence Livermore National Laboratory: Carbon Aerogels for Hydrogen Storage ....... 502

IV.D.1a Jet Propulsion Laboratory: Hydrogen Storage Engineering Center of Excellence .......... 514

IV.D.1a California Institute of Technology: Hydrogen Storage Engineering Center of Excellence .......... 514

IV.D.1i Jet Propulsion Laboratory: Key Technologies, Thermal Management, and Prototype Testing for Advanced Solid-State Hydrogen Storage Systems .............. 556

IV.D.1i California Institute of Technology: Key Technologies, Thermal Management, and Prototype Testing for Advanced Solid-State Hydrogen Storage Systems .............. 556

IV.F.1 University of California, Los Angeles: A Joint Theory and Experimental Project in the Synthesis and Testing of Porous COFs for On-Board Vehicular Hydrogen Storage ....... 591

IV.G.1 Lawrence Livermore National Laboratory: Extended Dormancy, Vacuum Stability, and Para-Ortho Hydrogen Conversion in Cryogenic Pressure Vessels .............. 615

IV.H.1 Trulite Inc.: NaSi and Na-SG Powder Hydrogen Fuel Cells ........................................ 628

V.B.1 Lawrence Berkeley National Laboratory: Water Transport Exploratory Studies .................. 706

V.D.1 Lawrence Livermore National Laboratory: New Polyelectrolyte Materials for High Temperature Fuel Cells .................................................. 741

V.E.1 Jet Propulsion Laboratory: Advanced Cathode Catalysts and Supports for PEM Fuel Cells .... 790

V.E.4 California Institute of Technology: Non-Platinum Bimetallic Cathode Electrocatalysts .......... 811

V.E.5 University of California, Riverside: Advanced Cathode Catalysts ...................................... 816

V.E.7 University of California, Riverside: Extended, Continuous Pt Nanostructures in Thick, Dispersed Electrodes .................................................. 830

V.E.7 Stanford University: Extended, Continuous Pt Nanostructures in Thick, Dispersed Electrodes .... 830

V.E.8 Jet Propulsion Laboratory: Nanosegregated Cathode Alloy Catalysts with Ultra-Low Platinum Loading .................................................. 835

V.E.11 Lawrence Livermore National Laboratory: Molecular-Scale, Three-Dimensional Non-Platinum Group Metal Electrodes for Catalysis of Fuel Cell Reactions .............. 850

V.G.1 Intelligent Energy: Development and Demonstration of a New Generation High Efficiency 10-kW Stationary PEM Fuel Cell System ........................................... 861
California (Continued)

V.G.4 University of California, Davis: Research and Development for Off-Road Fuel Cell Applications ................................................................. 873

V.H.2 Lawrence Berkeley National Laboratory: Durability Improvements through Degradation Mechanism Studies ........................................ 881

V.H.5 Lawrence Berkeley National Laboratory: Accelerated Testing Validation ................................................................. 895

V.I.2 Electricore, Inc.: Solid Oxide Fuel Cell Development for Auxiliary Power in Heavy Duty Vehicle Applications ......................................................... 907

V.J.1 Jet Propulsion Laboratory: Novel Approach to Advanced Direct Methanol Fuel Cell (DMFC) Anode Catalysts ........................................ 911

V.J.2 QuantumSphere Inc.: Novel Materials for High Efficiency Direct Methanol Fuel Cells ................................................................. 915

V.K.1 Honeywell Aerospace: Development of Thermal and Water Management System for PEM Fuel Cell ................................................................. 919

V.M.2 Lawrence Livermore National Laboratory: Fuel Cell Fundamentals at Low and Subzero Temperatures ................................................................. 948

V.M.3 Sandia National Laboratories: Development and Validation of a Two-Phase, Three-dimensional Model for PEM Fuel Cells ................................................................. 952

V.M.3 Lawrence Berkeley National Laboratory: Development and Validation of a Two-Phase, Three-dimensional Model for PEM Fuel Cells ................................................................. 952

V.N.2 Jet Propulsion Laboratory: Resonance-Stabilized Anion Exchange Polymer Electrolytes ................................................................. 967

V.N.2 University of Southern California, Los Angeles: Resonance-Stabilized Anion Exchange Polymer Electrolytes ................................................................. 967

V.P.24 Stanford University: Development and Mechanistic Characterization of Alloy Fuel Cell Catalysts ................................................................. 1095

V.P.28 Lawrence Livermore National Laboratory: The Development of Nano-Composite Electrodes for Solid Oxide Electrolyzers ................................................................. 1109

V.P.30 Lawrence Berkeley National Laboratory: Proton Conduction in Rare-Earth Phosphates ................................................................. 1115

VI.3 UltraCell Corporation: Modular, High-Volume Fuel Cell Leak-Test Suite and Process ................................................................. 1135

VI.10 Quantum Fuel Systems Technologies Worldwide, Inc.: Development of Advanced Manufacturing Technologies for Low Cost Hydrogen Storage Vessels ................................................................. 1165

VII.2 Sandia National Laboratories: Analysis of Energy Infrastructures and Potential Impacts from an Emergent Hydrogen Fueling Infrastructure ................................................................. 1181

VII.7 Lawrence Livermore National Laboratory: Hydrogen and Water: Engineering, Economics and Environment ................................................................. 1200

VIII.2 Hyundai-KIA America Technical Center Inc.: Controlled Hydrogen Fleet and Infrastructure Demonstration and Validation Project ................................................................. 1261

VIII.2 Alameda-Contra Costa Transit: Controlled Hydrogen Fleet and Infrastructure Demonstration and Validation Project ................................................................. 1261

VIII.2 Southern California Edison: Controlled Hydrogen Fleet and Infrastructure Demonstration and Validation Project ................................................................. 1261

VIII.3 Mercedes-Benz Research & Development North America, Inc.: Hydrogen to the Highways ................................................................. 1264

VIII.6 University of California, Irvine: California Hydrogen Infrastructure Project ................................................................. 1277

IX.1 Steele Consulting: National Codes and Standards Template ................................................................. 1307

IX.3 Steele Consulting: Codes and Standards Training and Outreach and Education for Emerging Fuel Cell Technologies ................................................................. 1315

IX.3 Smart Chemistry: Codes and Standards Training and Outreach and Education for Emerging Fuel Cell Technologies ................................................................. 1315
