(a) The R<sup>2</sup><sub>P</sub> and R<sup>2</sup><sub>V</sub> statistics for the full 25-component linear mixture model are less than zero because of the sensitivity of non-significant models terms to data. This is a result of the modeling datasets having minimal support for some components in the 25-component LM models.

- (a) Model results and summary statistics were generated using PCT-B normalized releases calculated to many decimal places. Rounded versions of these PCT-B values are given in Table 5.3. Conducting modeling with the rounded versions of the PCT-B normalized releases may result in slightly different model results and summary statistics.
- (b) The model evaluation statistics are defined in Section C.3 of Appendix C. Model validation statistics are defined in Section C.5 of Appendix C.
- (c) NA denotes that it is not applicable to perform a statistical t-test on linear terms in a mixture model (see Section C.5.1).
- (d) The 566 separate HLW glass compositions with PCT-B data for validation (mostly extrapolative) of PCT-B models are discussed in Section 5.1.4.
- (e) For the 18-term partial quadratic mixture model, the “Others” component includes Ag<sub>2</sub>O, As<sub>2</sub>O<sub>5</sub>, BaO, BeO, Bi<sub>2</sub>O<sub>3</sub>, Ce<sub>2</sub>O<sub>3</sub>, Cl, CoO, Cs<sub>2</sub>O, CuO, Dy<sub>2</sub>O, Eu<sub>2</sub>O, F, Gd<sub>2</sub>O<sub>3</sub>, HfO<sub>2</sub>, HgO, MoO<sub>3</sub>, Nd<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>, PdO, Pr<sub>2</sub>O<sub>3</sub>, Rb<sub>2</sub>O, Re<sub>2</sub>O<sub>7</sub>, Rh<sub>2</sub>O<sub>3</sub>, RuO<sub>2</sub>, SO<sub>3</sub>, Sm<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>, Tc<sub>2</sub>O<sub>7</sub>, TeO<sub>2</sub>, V<sub>2</sub>O<sub>5</sub>, WO<sub>3</sub>, Y<sub>2</sub>O<sub>3</sub>, CaO, CdO, Cr<sub>2</sub>O<sub>3</sub>, K<sub>2</sub>O, La<sub>2</sub>O<sub>3</sub>, MgO, NiO, PbO, Sb<sub>2</sub>O<sub>3</sub>, SeO<sub>2</sub>, TiO<sub>2</sub>, and Tl<sub>2</sub>O.
- (f) The bias correction is a constant adjustment applied to glasses with predicted PCT-B releases > 0.5 ln(g/L). See Equation (5.9) in Section 5.7.

- (a) Model results and summary statistics were generated using PCT-Li normalized releases calculated to many decimal places. Rounded versions of these PCT-Li values are given in Table 5.3. Conducting modeling with the rounded versions of the PCT-Li normalized releases may result in slightly different model results and summary statistics.
- (b) The model evaluation statistics are defined in Section C.3 of Appendix C. Model validation statistics are defined in Section C.5 of Appendix C.
- (c) NA denotes that it is not applicable to perform a statistical t-test on linear terms in a mixture model (see Section C.5.1).
- (d) The 480 separate HLW glass compositions with PCT-Li data for validation (mostly extrapolative) of PCT-Li models are discussed in Section 5.1.4.
- (e) For the 18-term partial quadratic mixture model, the “Others” component includes Ag<sub>2</sub>O, As<sub>2</sub>O<sub>5</sub>, BaO, BeO, Bi<sub>2</sub>O<sub>3</sub>, Ce<sub>2</sub>O<sub>3</sub>, Cl, CoO, Cs<sub>2</sub>O, CuO, Dy<sub>2</sub>O, Eu<sub>2</sub>O, F, Gd<sub>2</sub>O<sub>3</sub>, HfO<sub>2</sub>, HgO, MoO<sub>3</sub>, Nd<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>, PdO, Pr<sub>2</sub>O<sub>3</sub>, Rb<sub>2</sub>O, Re<sub>2</sub>O<sub>7</sub>, Rh<sub>2</sub>O<sub>3</sub>, RuO<sub>2</sub>, SO<sub>3</sub>, Sm<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>, Tc<sub>2</sub>O<sub>7</sub>, TeO<sub>2</sub>, V<sub>2</sub>O<sub>5</sub>, WO<sub>3</sub>, Y<sub>2</sub>O<sub>3</sub>, CaO, CdO, Cr<sub>2</sub>O<sub>3</sub>, K<sub>2</sub>O, La<sub>2</sub>O<sub>3</sub>, MgO, NiO, PbO, Sb<sub>2</sub>O<sub>3</sub>, SeO<sub>2</sub>, TiO<sub>2</sub>, and Tl<sub>2</sub>O.
- (f) The bias correction is a constant adjustment applied to glasses with predicted PCT-Li releases > 0.5 ln(g/L). See Equation (5.9) in Section 5.7.

- (a) Model results and summary statistics were generated using PCT-Li normalized releases calculated to many decimal places. Rounded versions of these PCT-Li values are given in Table 5.3. Conducting modeling with the rounded versions of the PCT-Li normalized releases may result in slightly different model results and summary statistics.
- (b) The model evaluation statistics are defined in Section C.3 of Appendix C. Model validation statistics are defined in Section C.5 of Appendix C.
- (c) NA denotes that it is not applicable to perform a statistical t-test on linear terms in a mixture model (see Section C.5.1).
- (d) The 480 separate HLW glass compositions with PCT-Li data for validation (mostly extrapolative) of PCT-Li models are discussed in Section 5.1.4.
- (e) For the 15-term partial quadratic mixture model, the “Others” component includes Ag<sub>2</sub>O, As<sub>2</sub>O<sub>5</sub>, BaO, BeO, Bi<sub>2</sub>O<sub>3</sub>, Ce<sub>2</sub>O<sub>3</sub>, Cl, CoO, Cs<sub>2</sub>O, CuO, Dy<sub>2</sub>O, Eu<sub>2</sub>O, F, Gd<sub>2</sub>O<sub>3</sub>, HfO<sub>2</sub>, HgO, MoO<sub>3</sub>, Nd<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>, PdO, Pr<sub>2</sub>O<sub>3</sub>, Rb<sub>2</sub>O, Re<sub>2</sub>O<sub>7</sub>, Rh<sub>2</sub>O<sub>3</sub>, RuO<sub>2</sub>, SO<sub>3</sub>, Sm<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>, Tc<sub>2</sub>O<sub>7</sub>, TeO<sub>2</sub>, V<sub>2</sub>O<sub>5</sub>, WO<sub>3</sub>, Y<sub>2</sub>O<sub>3</sub>, CaO, CdO, Cr<sub>2</sub>O<sub>3</sub>, K<sub>2</sub>O, La<sub>2</sub>O<sub>3</sub>, MgO, NiO, PbO, Sb<sub>2</sub>O<sub>3</sub>, SeO<sub>2</sub>, TiO<sub>2</sub>, and Tl<sub>2</sub>O.
- (f) The bias correction is a constant adjustment applied to glasses with predicted PCT-Li releases > 0.5 ln(g/L). See Equation (5.9) in Section 5.7.

- (a) Model results and summary statistics were generated using PCT-Na normalized releases calculated to many decimal places. Rounded versions of these PCT-Na values are given in Table 5.3. Conducting modeling with the rounded versions of the PCT-Na normalized releases may result in slightly different model results and summary statistics.
- (b) The model evaluation statistics are defined in Section C.3 of Appendix C. Model validation statistics are defined in Section C.5 of Appendix C.
- (c) NA denotes that it is not applicable to perform a statistical t-test on linear terms in a mixture model (see Section C.5.1).
- (d) The 554 separate HLW glass compositions with PCT-Na data for validation (mostly extrapolative) of PCT-Na models are discussed in Section 5.1.4.
- (e) For the 18-term partial quadratic mixture model, the “Others” component includes Ag<sub>2</sub>O, As<sub>2</sub>O<sub>5</sub>, BaO, BeO, Bi<sub>2</sub>O<sub>3</sub>, Ce<sub>2</sub>O<sub>3</sub>, Cl, CoO, Cs<sub>2</sub>O, CuO, Dy<sub>2</sub>O, Eu<sub>2</sub>O, F, Gd<sub>2</sub>O<sub>3</sub>, HfO<sub>2</sub>, HgO, MoO<sub>3</sub>, Nd<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>, PdO, Pr<sub>2</sub>O<sub>3</sub>, Rb<sub>2</sub>O, Re<sub>2</sub>O<sub>7</sub>, Rh<sub>2</sub>O<sub>3</sub>, RuO<sub>2</sub>, SO<sub>3</sub>, Sm<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>, Tc<sub>2</sub>O<sub>7</sub>, TeO<sub>2</sub>, V<sub>2</sub>O<sub>5</sub>, WO<sub>3</sub>, Y<sub>2</sub>O<sub>3</sub>, CaO, CdO, Cr<sub>2</sub>O<sub>3</sub>, K<sub>2</sub>O, La<sub>2</sub>O<sub>3</sub>, MgO, NiO, PbO, Sb<sub>2</sub>O<sub>3</sub>, SeO<sub>2</sub>, TiO<sub>2</sub>, and Tl<sub>2</sub>O.
- (f) The bias correction is a constant adjustment applied to glasses with predicted PCT-Na releases > 1.0 ln(g/L). See Equation (5.9) in Section 5.7.

- (a) Model results and summary statistics were generated using PCT-Na normalized releases calculated to many decimal places. Rounded versions of these PCT-Na values are given in Table 5.3. Conducting modeling with the rounded versions of the PCT-Na normalized releases may result in slightly different model results and summary statistics.
- (b) The model evaluation statistics are defined in Section C.3 of Appendix C. Model validation statistics are defined in Section C.5 of Appendix C.
- (c) NA denotes that it is not applicable to perform a statistical t-test on linear terms in a mixture model (see Section C.5.1).
- (d) The 554 separate HLW glass compositions with PCT-Na data for validation (mostly extrapolative) of PCT-Na models are discussed in Section 5.1.4.
- (e) For the 15-term partial quadratic mixture model, the “Others” component includes Ag<sub>2</sub>O, As<sub>2</sub>O<sub>5</sub>, BaO, BeO, Bi<sub>2</sub>O<sub>3</sub>, Ce<sub>2</sub>O<sub>3</sub>, Cl, CoO, Cs<sub>2</sub>O, CuO, Dy<sub>2</sub>O, Eu<sub>2</sub>O, F, Gd<sub>2</sub>O<sub>3</sub>, HfO<sub>2</sub>, HgO, MoO<sub>3</sub>, Nd<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>, PdO, Pr<sub>2</sub>O<sub>3</sub>, Rb<sub>2</sub>O, Re<sub>2</sub>O<sub>7</sub>, Rh<sub>2</sub>O<sub>3</sub>, RuO<sub>2</sub>, SO<sub>3</sub>, Sm<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>, Tc<sub>2</sub>O<sub>7</sub>, TeO<sub>2</sub>, V<sub>2</sub>O<sub>5</sub>, WO<sub>3</sub>, Y<sub>2</sub>O<sub>3</sub>, CaO, CdO, Cr<sub>2</sub>O<sub>3</sub>, K<sub>2</sub>O, La<sub>2</sub>O<sub>3</sub>, MgO, NiO, PbO, Sb<sub>2</sub>O<sub>3</sub>, SeO<sub>2</sub>, TiO<sub>2</sub>, and Tl<sub>2</sub>O.
- (f) The bias correction is a constant adjustment applied to glasses with predicted PCT-Na releases > 1.0 ln(g/L). See Equation (5.9) in Section 5.7.

- (a) The composition in mass fractions is from Table 5.2.
- (b) NA indicates that a term is not included in a specific PCT model.
- (c) Bias-correction.
- (d) The bias-correction term does not depend on glass composition.

**Table 5.27. HLW06-15 Composition in Formats Needed to Illustrate the Use of PCT Models for HLW Glasses.**

- (a) The composition in mass fractions is from Table 5.2.
- (b) NA indicates that a term is not included in a specific PCT model.
- (c) Bias-correction.
- (d) The bias-correction term does not depend on glass composition.

- (a) The three PCT-B models are given in Tables 5.6, 5.19, and 5.20. The three PCT-Li models are given in Tables 5.10, 5.21, and 5.22. The three PCT-Na models are given in Tables 5.14, 5.23, and 5.24. Note that LM = linear mixture and PQM = partial quadratic mixture. The bias-correction terms are not needed for HLW03-06.
- (b) For comparison purposes, the measured releases (in g/L) for HLW03-06 are 0.301 for PCT-B, 0.378 for PCT-Li, and 0.164 for PCT-Na.
- (c) The standard deviation is for the ln(PCT) prediction considered to be the mean of such values for the HLW03-06 glass.
- (d) All calculations were performed using the HLW03-06 glass composition, model coefficients, and variance-covariance matrix values given in tables of this report. The calculated ln(g/L) values were rounded to four decimal places in this table. The g/L values were calculated by exponentiating the ln(g/L) values before rounding, then rounding the resulting values to three decimal places in this table.

**Table 5.29. Predicted PCT Releases and Corresponding 95% UCIs and 95% SUCIs for the HLW06-15 Composition Used in PCT Models for HLW Glasses.**

| PCT Release | Model <sup>(a)</sup>                     | Predicted ln(PCT) [ln(g/L)] | Predicted PCT <sup>(b)</sup> [g/L] | SD of Predicted ln(PCT) <sup>(c)</sup> [ln(g/L)] | 90% UCI on Mean ln(PCT) [ln(g/L)] | 90% UCI on Median PCT [g/L] | 90% SUCI on Mean ln(PCT) [ln(g/L)] | 90% SUCI on Median PCT [g/L] |

(a) The Group IDs are described in Sections 2.1.1 to 2.1.9.

(b) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for property-composition modeling.

**Table 6.1. Normalized 25-Component Compositions (mass fractions) of 168 HLW Glasses with Spinel as the Primary Crystalline Phase and Used in Spinel T<sub>1%</sub> Modeling (continued).**

| Glass ID | Group ID <sup>(a)</sup> | Al <sub>2</sub> O <sub>3</sub> | B <sub>2</sub> O <sub>3</sub> | CaO    | CdO    | Cr <sub>2</sub> O <sub>3</sub> | Fe <sub>2</sub> O <sub>3</sub> | K <sub>2</sub> O | La <sub>2</sub> O <sub>3</sub> | Li <sub>2</sub> O | MgO    | MnO    | Na <sub>2</sub> O | NiO    | PbO    | Sb <sub>2</sub> O <sub>3</sub> |

(a) The Group IDs are described in Sections 2.1.1 to 2.1.9.

(b) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for property-composition modeling.

**Table 6.1. Normalized 25-Component Compositions (mass fractions) of 168 HLW Glasses with Spinel as the Primary Crystalline Phase and Used in Spinel T<sub>1%</sub> Modeling (continued).**

| Glass ID | Group ID <sup>(a)</sup> | Al <sub>2</sub> O <sub>3</sub> | B <sub>2</sub> O <sub>3</sub> | CaO    | CdO    | Cr <sub>2</sub> O <sub>3</sub> | Fe <sub>2</sub> O <sub>3</sub> | K <sub>2</sub> O | La <sub>2</sub> O <sub>3</sub> | Li <sub>2</sub> O | MgO    | MnO    | Na <sub>2</sub> O | NiO    | PbO    | Sb <sub>2</sub> O <sub>3</sub> |

(a) The Group IDs are described in Sections 2.1.1 to 2.1.9.

(b) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for property-composition modeling.

(a) The Group IDs are described in Sections 2.1.1 to 2.1.9.

(b) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.

(a) The Group IDs are described in Sections 2.1.1 to 2.1.9.

(b) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for property-composition modeling.

**Table 6.2. Temperature and Volume %-Crystallinity Data for 168 HLW Glasses with Spinel as the Primary Crystalline Phase and Used in Spinel T<sub>1%</sub> Modeling.**

| Glass ID | Group ID | Temperature in °C |     |      |      |             |             |     |             |             |             |             |             |              |              |      |      |      |      |

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) A dash (—) indicates that no data were collected for the specified temperatures.
- (c) Table entries that were excluded from calculations to determine the T<sub>1%</sub> value for a glass are shaded gray.

**Table 6.2. Temperature and Volume %-Crystallinity Data for 168 HLW Glasses with Spinel as the Primary Crystalline Phase and Used in Spinel T<sub>1%</sub> Modeling (continued).**

| Glass ID | Group ID | Temperature in °C |     |      |     |             |             |     |             |             |             |             |             |              |              |      |      |      |                    |
|----------|----------|-------------------|-----|------|-----|-------------|-------------|-----|-------------|-------------|-------------|-------------|-------------|--------------|--------------|------|------|------|--------------------|

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) A dash (—) indicates that no data were collected for the specified temperatures.
- (c) Table entries that were excluded from calculations to determine the T<sub>1%</sub> value for a glass are shaded gray.
- (d) This value was originally reported as < 0.1 vol%, but was assigned the value of 0.1 vol% for purposes of calculating T<sub>1%</sub> values.

**Table 6.2. Temperature and Volume %-Crystallinity Data for 168 HLW Glasses with Spinel as the Primary Crystalline Phase and Used in Spinel T<sub>1%</sub> Modeling (continued).**

| Glass ID | Group ID | Temperature in °C |     |      |     |             |             |     |             |             |             |             |             |              |              |      |      |      |      |

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) A dash (—) indicates that no data were collected for the specified temperatures.
- (c) Table entries that were excluded from calculations to determine the T<sub>1%</sub> value for a glass are shaded gray.

**Table 6.2. Temperature and Volume %-Crystallinity Data for 168 HLW Glasses with Spinel as the Primary Crystalline Phase and Used in Spinel T<sub>1%</sub> Modeling (continued).**

| Glass ID | Group ID | Temperature in °C |      |      |      |             |             |     |             |             |             |             |             |              |              |      |      |      |      |
|----------|----------|-------------------|------|------|------|-------------|-------------|-----|-------------|-------------|-------------|-------------|-------------|--------------|--------------|------|------|------|------|

- (a) The intercept and slope are from fitting the inverse regression equation in Equation (E.1) of Appendix E to the temperature versus spinel percent crystallinity data for each glass given in Table 6.2.
- (b) Estimated T<sub>1%</sub> values in this table have been rounded to one decimal place; intercepts, slopes, and standard deviations have been rounded to two decimal places.
- (c) NA = not applicable for glasses not included in data splitting validation sets because they were replicates. These glasses were included in the modeling splits rather than the validation splits.
- (d) NA = The standard deviation of the estimated spinel T<sub>1%</sub> value could not be calculated because only 2 data points were available.

**Table 6.3. Number of Temperature vs. Vol%-Crystallinity Points, Intercepts, Slopes, Estimated T<sub>1%</sub> Values, and Standard Deviations of T<sub>1%</sub> Values for 168 HLW Glasses Having Spinel as the Primary Crystalline Phase and Used for Spinel T<sub>1%</sub> Modeling (continued).**

| Glass ID | Primary & Secondary Crystalline Phases      | Inverse Regression Used to Calculate T <sub>1%</sub> |                          |                        | Estimated Spinel T <sub>1%</sub> (°C) | SD(T <sub>1%</sub> ) (°C) | Spinel T <sub>1%</sub> Data Splitting Validation Set |

- (a) The intercept and slope are from fitting the inverse regression equation in Equation (E.1) of Appendix E to the temperature versus spinel percent crystallinity data for each glass given in Table 6.2.
- (b) Estimated T<sub>1%</sub> values in this table have been rounded to one decimal place; intercepts, slopes, and standard deviations have been rounded to two decimal places.
- (c) NA = not applicable for glasses not included in data splitting validation sets because they were replicates. These glasses were included in the modeling splits rather than the validation splits.
- (d) NA = The standard deviation of the estimated spinel T<sub>1%</sub> value could not be calculated because only 2 data points were available.

**Table 6.3. Number of Temperature vs. Vol%-Crystallinity Points, Intercepts, Slopes, Estimated T<sub>1%</sub> Values, and Standard Deviations of T<sub>1%</sub> Values for 168 HLW Glasses Having Spinel as the Primary Crystalline Phase and Used for Spinel T<sub>1%</sub> Modeling (continued).**

- (a) The intercept and slope are from fitting the inverse regression equation in Equation (E.1) of Appendix E to the temperature versus spinel percent crystallinity data for each glass given in Table 6.2.
- (b) Estimated T<sub>1%</sub> values in this table have been rounded to one decimal place; intercepts, slopes, and standard deviations have been rounded to two decimal places.
- (c) NA = not applicable for glasses not included in data splitting validation sets because they were replicates. These glasses were included in the modeling splits rather than the validation splits.
- (d) NA = The standard deviation of the estimated spinel T<sub>1%</sub> value could not be calculated because only 2 data points were available.

**Table 6.3. Number of Temperature vs. Vol%-Crystallinity Points, Intercepts, Slopes, Estimated T<sub>1%</sub> Values, and Standard Deviations of T<sub>1%</sub> Values for 168 HLW Glasses Having Spinel as the Primary Crystalline Phase and Used for Spinel T<sub>1%</sub> Modeling (continued).**

- (a) The intercept and slope are from fitting the inverse regression equation in Equation (E.1) of Appendix E to the temperature versus spinel percent crystallinity data for each glass given in Table 6.2.
- (b) Estimated T<sub>1%</sub> values in this table have been rounded to one decimal place; intercepts, slopes, and standard deviations have been rounded to two decimal places.
- (c) NA = not applicable for glasses not included in data splitting validation sets because they were replicates. These glasses were included in the modeling splits rather than the validation splits.
- (d) NA = The standard deviation of the estimated spinel T<sub>1%</sub> value could not be calculated because only 2 data points were available.

**Table 6.3. Number of Temperature vs. Vol%-Crystallinity Points, Intercepts, Slopes, Estimated T<sub>1%</sub> Values, and Standard Deviations of T<sub>1%</sub> Values for 168 HLW Glasses Having Spinel as the Primary Crystalline Phase and Used for Spinel T<sub>1%</sub> Modeling (continued).**

- (a) The intercept and slope are from fitting the inverse regression equation in Equation (E.1) of Appendix E to the temperature versus spinel percent crystallinity data for each glass given in Table 6.2.
- (b) Estimated T<sub>1%</sub> values in this table have been rounded to one decimal place; intercepts, slopes, and standard deviations have been rounded to two decimal places.
- (c) NA = not applicable for glasses not included in data splitting validation sets because they were replicates. These glasses were included in the modeling splits rather than the validation splits.
- (d) NA = The standard deviation of the estimated spinel T<sub>1%</sub> value could not be calculated because only 2 data points were available.

**Table 6.3. Number of Temperature vs. Vol%-Crystallinity Points, Intercepts, Slopes, Estimated T<sub>1%</sub> Values, and Standard Deviations of T<sub>1%</sub> Values for 168 HLW Glasses Having Spinel as the Primary Crystalline Phase and Used for Spinel T<sub>1%</sub> Modeling (continued).**

| Glass ID   | Primary & Secondary Crystalline Phases | Inverse Regression Used to Calculate T <sub>1%</sub> |                          |                      | Estimated Spinel T <sub>1%</sub> (°C) | SD(T <sub>1%</sub> ) (°C) | Spinel T <sub>1%</sub> Data Splitting Validation Set |

- (a) The intercept and slope are from fitting the inverse regression equation in Equation (E.1) of Appendix E to the temperature versus spinel percent crystallinity data for each glass given in Table 6.2.
- (b) Estimated T<sub>1%</sub> values in this table have been rounded to one decimal place; intercepts, slopes, and standard deviations have been rounded to two decimal places.
- (c) NA = not applicable for glasses not included in data splitting validation sets because they were replicates. These glasses were included in the modeling splits rather than the validation splits.
- (d) NA = The standard deviation of the estimated spinel T<sub>1%</sub> value could not be calculated because only 2 data points were available.

**Table 6.4. Spinel T<sub>1%</sub> Data and Standard Deviations for Replicates of HLW Glasses Used for Modeling.**

| Glass IDs of Replicate Sets                                                          | Estimated Spinel T <sub>1%</sub> Values and SDs (°C) | SDs from Replicate Spinel T <sub>1%</sub> Values (°C) |

- (a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for property-composition modeling.
- (b) This glass has nearly 0.09 (9 wt%) of its composition involved in 9 components not varied as part of statistically designed test matrices, and was also found to be a significant outlier in initial model development and validation work. Hence, it was excluded from the spinel  $T_{1\%}$  validation dataset.

**Table 6.5. Compositions of 39 HLW Glasses (Mass Fractions of 25 Normalized Components) for Validating Spinel T<sub>1%</sub> Models (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for property-composition modeling.

**Table 6.6. Temperature and Volume %-Crystallinity Data for 39 HLW Glasses with Spinel as the Primary Crystalline Phase and Used in Validating Spinel  $T_{1\%}$  Models.**

| Glass ID | Vol% | Temp | Glass ID | Vol% | Temp | Glass ID              | Vol% | Temp |

- (a) Personal communication from Jarrod Crum at PNNL based on reviewing data records for these glasses.
- (b) The number of points are the number of (temperature, vol% crystallinity) data points for each glass used to fit Equation (E.1) in Appendix E. The intercept and slope are from fitting Equation (E.1) to the data in Table 6.6.
- (b) Estimated  $T_{1\%}$  values in this table have been rounded to one decimal place. Intercepts, slopes, and standard deviations have been rounded to two decimal places.

**Table 6.8. Coefficients and Performance Summary for the 25-Component Full Linear Mixture Model on Spinel T<sub>1%</sub> for HLW Glasses.<sup>(a)</sup>**

- (a) Model results and summary statistics were generated using estimated spinel T<sub>1%</sub> values calculated to many decimal places. Rounded versions of these spinel T<sub>1%</sub> values are given in Table 6.3. Conducting modeling with the rounded versions of the estimated spinel T<sub>1%</sub> values may result in slightly different model results and summary statistics.
- (b) The model evaluation statistics are defined in Section C.3 of Appendix C. Model validation statistics are defined in Section C.5 of Appendix C. A negative value for R<sup>2</sup><sub>v</sub> means that the sum of squares of model prediction errors is larger than if the mean response value over the validation data set were used as the predicted value for each glass. In other words, the model predicts worse for the validation data than the mean response value does.
- (c) NA denotes that it is not applicable to perform a statistical t-test on linear terms in a mixture model (see Section C.5.1).
- (d) The 38 separate HLW glass compositions with spinel T<sub>1%</sub> data for validation (mostly extrapolative) of spinel T<sub>1%</sub> models are discussed in Section 6.1.4.
- (e) The partition of the spinel T<sub>1%</sub> modeling dataset into modeling and validation subsets is described in Section 6.1.3.
- (f) The evaluation and validation statistics calculated for data-splits are defined the same as for separate modeling and validation sets. Section 6.1.2 describes how the data-splitting was accomplished.
- (g) For the 25-component full linear mixture model, the “Others” component includes Ag<sub>2</sub>O, As<sub>2</sub>O<sub>5</sub>, BaO, BeO, Bi<sub>2</sub>O<sub>3</sub>, Ce<sub>2</sub>O<sub>3</sub>, Cl, CoO, Cs<sub>2</sub>O, CuO, Dy<sub>2</sub>O, Eu<sub>2</sub>O, F, Gd<sub>2</sub>O<sub>3</sub>, HfO<sub>2</sub>, HgO, MoO<sub>3</sub>, Nd<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>, PdO, Pr<sub>2</sub>O<sub>3</sub>, Rb<sub>2</sub>O, Re<sub>2</sub>O<sub>7</sub>, Rh<sub>2</sub>O<sub>3</sub>, RuO<sub>2</sub>, SO<sub>3</sub>, Sm<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>, Tc<sub>2</sub>O<sub>7</sub>, TeO<sub>2</sub>, V<sub>2</sub>O<sub>5</sub>, WO<sub>3</sub>, and Y<sub>2</sub>O<sub>3</sub>.

- (a) Model results and summary statistics were generated using estimated spinel T<sub>1%</sub> values calculated to many decimal places. Rounded versions of these spinel T<sub>1%</sub> values are given in Table 6.3. Conducting modeling with the rounded versions of the estimated spinel T<sub>1%</sub> values may result in slightly different model results and summary statistics.
- (b) The model evaluation statistics are defined in Section C.3 of Appendix C. Model validation statistics are defined in Section C.5 of Appendix C. A negative value for R<sup>2</sup><sub>v</sub> means that the sum of squares of model prediction errors is larger than if the mean response value over the validation data set were used as the predicted value for each glass. In other words, the model predicts worse for the validation data than the mean response value does.
- (c) NA denotes that it is not applicable to perform a statistical t-test on linear terms in a mixture model (see Section C.5.1).
- (d) The 38 separate HLW glass compositions with spinel T<sub>1%</sub> data for validation (mostly extrapolative) of spinel T<sub>1%</sub> models are discussed in Section 6.1.4.
- (e) The partition of the spinel T<sub>1%</sub> modeling dataset into modeling and validation subsets is described in Section 6.1.3.
- (f) The evaluation and validation statistics calculated for data-splits are defined the same as for separate modeling and validation sets. Section 6.1.2 describes how the data-splitting was accomplished.
- (g) For the 15-component reduced linear mixture model, the “Others” component includes Ag<sub>2</sub>O, As<sub>2</sub>O<sub>5</sub>, BaO, BeO, Bi<sub>2</sub>O<sub>3</sub>, CaO, CdO, Ce<sub>2</sub>O<sub>3</sub>, Cl, CoO, Cs<sub>2</sub>O, CuO, Dy<sub>2</sub>O, Eu<sub>2</sub>O, F, Gd<sub>2</sub>O<sub>3</sub>, HfO<sub>2</sub>, HgO, K<sub>2</sub>O, La<sub>2</sub>O<sub>3</sub>, MgO, MoO<sub>3</sub>, Nd<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>, PbO, PdO, Pr<sub>2</sub>O<sub>3</sub>, Rb<sub>2</sub>O, Re<sub>2</sub>O<sub>7</sub>, Rh<sub>2</sub>O<sub>3</sub>, RuO<sub>2</sub>, SO<sub>3</sub>, Sb<sub>2</sub>O<sub>3</sub>, SeO<sub>2</sub>, Sm<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>, Tc<sub>2</sub>O<sub>7</sub>, TeO<sub>2</sub>, TiO<sub>2</sub>, Tl<sub>2</sub>O, V<sub>2</sub>O<sub>5</sub>, WO<sub>3</sub>, and Y<sub>2</sub>O<sub>3</sub>.

- (a) Model results and summary statistics were generated using estimated spinel T<sub>1%</sub> values calculated to many decimal places. Rounded versions of these spinel T<sub>1%</sub> values are given in Table 6.3. Conducting modeling with the rounded versions of the estimated spinel T<sub>1%</sub> values may result in slightly different model results and summary statistics.
- (b) The model evaluation statistics are defined in Section C.3 of Appendix C. Model validation statistics are defined in Section C.5 of Appendix C. A negative value for R<sup>2</sup><sub>v</sub> means that the sum of squares of model prediction errors is larger than if the mean response value over the validation data set were used as the predicted value for each glass. In other words, the model predicts worse for the validation data than the mean response value does.
- (c) NA denotes that it is not applicable to perform a statistical t-test on linear terms in a mixture model (see Section C.5.1).
- (d) The 38 separate HLW glass compositions with spinel T<sub>1%</sub> data for validation (mostly extrapolative) of spinel T<sub>1%</sub> models are discussed in Section 6.1.4.
- (e) The partition of the spinel T<sub>1%</sub> modeling dataset into modeling and validation subsets is described in Section 6.1.3.
- (f) The evaluation and validation statistics calculated for data-splits are defined the same as for separate modeling and validation sets. Section 6.1.2 describes how the data-splitting was accomplished.
- (g) For this 20-term partial quadratic mixture model, the “Others” component includes Ag<sub>2</sub>O, As<sub>2</sub>O<sub>5</sub>, BaO, BeO, Bi<sub>2</sub>O<sub>3</sub>, CaO, CdO, Ce<sub>2</sub>O<sub>3</sub>, Cl, CoO, Cs<sub>2</sub>O, CuO, Dy<sub>2</sub>O, Eu<sub>2</sub>O, F, Gd<sub>2</sub>O<sub>3</sub>, HfO<sub>2</sub>, HgO, K<sub>2</sub>O, La<sub>2</sub>O<sub>3</sub>, MgO, MoO<sub>3</sub>, Nd<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>, PbO, PdO, Pr<sub>2</sub>O<sub>3</sub>, Rb<sub>2</sub>O, Re<sub>2</sub>O<sub>7</sub>, Rh<sub>2</sub>O<sub>3</sub>, RuO<sub>2</sub>, SO<sub>3</sub>, Sb<sub>2</sub>O<sub>3</sub>, SeO<sub>2</sub>, Sm<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>, Tc<sub>2</sub>O<sub>7</sub>, TeO<sub>2</sub>, TiO<sub>2</sub>, Tl<sub>2</sub>O, V<sub>2</sub>O<sub>5</sub>, WO<sub>3</sub>, and Y<sub>2</sub>O<sub>3</sub>.

- (a) Summary statistics were generated using estimated T<sub>1%</sub> values as the response. Rounded versions of these T<sub>1%</sub> values are given in Table 6.3. Fitting the models with the rounded versions of the estimated T<sub>1%</sub> values may result in slightly different summary statistic values.
- (b) The ‘X’ represents some other crystal form identified in the 24 ‘spinel plus other crystal’ glasses discussed in Section 6.1.1.
- (c) R<sup>2</sup> statistics can take negative values for validation data, indicating that model predictions are worse than just using the mean of the validation response values (spinel T<sub>1%</sub>) as the predicted value for all validation glasses.

**Table 6.13. Fit and Validation Statistics for Selected Spinel T<sub>1%</sub> Models Based on 168 HLW Glasses in the Modeling Dataset<sup>(a)</sup>.**

- (a) The three spinel T<sub>1%</sub> models are given in Tables 6.9, 6.10, and 6.11. Note that LM = linear mixture and PQM = partial quadratic mixture.
- (b) The estimated spinel T<sub>1%</sub> value for HLW03-06 is 950°C (see Table 6.3). The recommended 20-term PQM1a model has predicted value closest to this estimated value.
- (c) All calculations were performed using the HLW03-06 glass composition, model coefficients, and variance-covariance matrix values given in tables of this report. The calculated spinel T<sub>1%</sub> values were rounded to one decimal place in this table.

- (a) SnO<sub>2</sub> is not expected to significantly affect glass properties and hence these glasses will be retained for initial modeling work.
- (b) Specific archived HLW06 glasses were selected for viscosity and electrical conductivity measurement to support model development. Therefore, they were to be retained in the modeling datasets unless they had extreme outliers in viscosity or electrical conductivity response.

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 7.2. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 208 HLW Glasses Used for Electrical Conductivity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 7.2. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 208 HLW Glasses Used for Electrical Conductivity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 7.2. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 208 HLW Glasses Used for Electrical Conductivity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 7.2. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 208 HLW Glasses Used for Electrical Conductivity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 7.2. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 208 HLW Glasses Used for Electrical Conductivity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 7.2. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 208 HLW Glasses Used for Electrical Conductivity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 7.3. Temperature and Electrical Conductivity Observations and Data-Splitting Validation Sets for Each of the 208 HLW Glasses Used for Electrical Conductivity Model Development.**

| Glass ID | Group ID <sup>(a)</sup> | Temp1 (°C) | EC1 (S/cm) | Temp2 (°C) | EC2 (S/cm) | Temp3 (°C) | EC3 (S/cm) | Temp4 (°C) | EC4 (S/cm) | EC Data Splitting Validation Set <sup>(b)</sup> |

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) Numbers from 1 to 5 denote the five split validation subsets. NA denotes “not applicable”, because these replicate glasses were forced into the modeling subsets, and thus were not parts of the validation subsets.
- (c) NA-Rep indicates glasses that were not included in any of the validation splits because they were replicates.

**Table 7.3. Temperature and Electrical Conductivity Observations and Data-Splitting Validation Sets for Each of the 208 HLW Glasses Used for Electrical Conductivity Model Development (continued).**

| Glass ID | Group ID <sup>(a)</sup> | Temp1 (°C) | EC1 (S/cm) | Temp2 (°C) | EC2 (S/cm) | Temp3 (°C) | EC3 (S/cm) | Temp4 (°C) | EC4 (S/cm) | EC Data Splitting Validation Set <sup>(b)</sup> |
|----------|-------------------------|------------|------------|------------|------------|------------|------------|------------|------------|-------------------------------------------------|

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) Numbers from 1 to 5 denote the five split validation subsets. NA denotes “not applicable”, because these replicate glasses were forced into the modeling subsets, and thus were not parts of the validation subsets.
- (c) NA-Rep indicates glasses that were not included in any of the validation splits because they were replicates.

**Table 7.3. Temperature and Electrical Conductivity Observations and Data-Splitting Validation Sets for Each of the 208 HLW Glasses Used for Electrical Conductivity Model Development (continued).**

| Glass ID | Group ID <sup>(a)</sup> | Temp1 (°C) | EC1 (S/cm) | Temp2 (°C) | EC2 (S/cm) | Temp3 (°C) | EC3 (S/cm) | Temp4 (°C) | EC4 (S/cm) | EC Data Splitting Validation Set <sup>(b)</sup> |

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) Numbers from 1 to 5 denote the five split validation subsets. NA denotes “not applicable”, because these replicate glasses were forced into the modeling subsets, and thus were not parts of the validation subsets.
- (c) NA-Rep indicates glasses that were not included in any of the validation splits because they were replicates.

**Table 7.3. Temperature and Electrical Conductivity Observations and Data-Splitting Validation Sets for Each of the 208 HLW Glasses Used for Electrical Conductivity Model Development (continued).**

| Glass ID   | Group ID <sup>(a)</sup> | Temp1 (°C) | EC1 (S/cm) | Temp2 (°C) | EC2 (S/cm) | Temp3 (°C) | EC3 (S/cm) | Temp4 (°C) | EC4 (S/cm) | EC Data Splitting Validation Set <sup>(b)</sup> |

(a) The Group IDs are described in Sections 2.1.1 to 2.1.9.

(b) Numbers from 1 to 5 denote the five split validation subsets. NA denotes “not applicable”, because these replicate glasses were forced into the modeling subsets, and thus were not parts of the validation subsets.

**Table 7.3. Temperature and Electrical Conductivity Observations and Data-Splitting Validation Sets for Each of the 208 HLW Glasses Used for Electrical Conductivity Model Development (continued).**

| Glass ID   | Group ID <sup>(a)</sup> | Temp1 (°C) | EC1 (S/cm) | Temp2 (°C) | EC2 (S/cm) | Temp3 (°C) | EC3 (S/cm) | Temp4 (°C) | EC4 (S/cm) | EC Data Splitting Validation Set <sup>(b)</sup> |
|------------|-------------------------|------------|------------|------------|------------|------------|------------|------------|------------|-------------------------------------------------|

(a) The Group IDs are described in Sections 2.1.1 to 2.1.9.

(b) Numbers from 1 to 5 denote the five split validation subsets. NA denotes “not applicable”, because these replicate glasses were forced into the modeling subsets, and thus were not parts of the validation subsets.

**Table 7.3. Temperature and Electrical Conductivity Observations and Data-Splitting Validation Sets for Each of the 208 HLW Glasses Used for Electrical Conductivity Model Development (continued).**

- (a) All replicates appear in pairs of HLW glasses except for HLW02-46, HLW03-42, and HLW07-02.
- (b) Electrical conductivity values are listed at the exact temperatures near the nominal temperature values.
- (c) %RSD = 100\*(Standard Deviation / Mean), calculated using the S/cm values.
- (d) Calculated using ln(S/cm) values.
- (e) The individual and pooled SDs estimate  $\sqrt{\sigma_G^2 + \sigma_T^2}$  in ln(S/cm) units (see Section C.2.2 of Appendix C).
- (f) The %RSD and SD values are uncertainties of EC values, not temperature values. Because EC values at actual temperatures were used, temperature and EC columns are listed. The %RSD and SD values are merely listed under these columns.

**Table 7.5. Variation in Electrical Conductivity Values for Replicate Glasses Interpolated at Nominal Temperatures.**

- (a) All replicates appear in pairs of HLW glasses except for HLW02-46, HLW03-42, and HLW07-02.
- (b) Electrical conductivity values were interpolated at the nominal temperature values using a T2-equation (see Section C.2.1) fit for each glass.
- (c) %RSD = 100\*(Standard Deviation / Mean), calculated using the S/cm values.
- (d) Calculated using ln(S/cm) values.
- (e) The individual and pooled SDs estimate  $\sqrt{\sigma_G^2 + \sigma_T^2}$  in ln(S/cm) units (see Section C.2.2 of Appendix C).

**Table 7.6. Coefficients and Performance Summary for the 44-Term Truncated T2-Linear Mixture Model on the Natural Logarithm of Electrical Conductivity for HLW Glasses.**

(a) The model evaluation statistics are defined in Section C.3 of Appendix C. Model validation statistics are defined in Section C.5 of Appendix C.

(b) The “Others” component includes Ag<sub>2</sub>O, As<sub>2</sub>O<sub>5</sub>, BaO, BeO, Bi<sub>2</sub>O<sub>3</sub>, Ce<sub>2</sub>O<sub>3</sub>, Cl, CoO, Cs<sub>2</sub>O, CuO, Dy<sub>2</sub>O<sub>3</sub>, Eu<sub>2</sub>O<sub>3</sub>, F, Gd<sub>2</sub>O<sub>3</sub>, HfO<sub>2</sub>, HgO, K<sub>2</sub>O, La<sub>2</sub>O<sub>3</sub>, MoO<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>, PdO, Pr<sub>2</sub>O<sub>3</sub>, Rb<sub>2</sub>O, Re<sub>2</sub>O<sub>7</sub>, Rh<sub>2</sub>O<sub>3</sub>, RuO<sub>2</sub>, SO<sub>3</sub>, Sm<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>, Te<sub>2</sub>O<sub>7</sub>, TeO<sub>2</sub>, TiO<sub>2</sub>, V<sub>2</sub>O<sub>5</sub>, WO<sub>3</sub> and Y<sub>2</sub>O<sub>3</sub>.

(c) A dash (–) indicates the term was not included in the model.

(d) The evaluation and validation statistics calculated for data-splits are defined the same as for separate modeling and validation sets. Section 7.1.2 describes how the data-splitting was accomplished..

- (a) The electrical conductivity models contain  $x_i/(T/1000)^2$  terms in addition to the  $x_i$  and  $x_i x_j$  terms shown in this column. The purpose of this table is to show the compositional forms needed for model predictions, so the temperature-containing terms are not shown.
- (b) The composition in mass fractions is from Table 7.2.
- (c) See Table 7.7.
- (d) See Table 7.9.
- (e) NA = not applicable, because the model does not contain this term.

- (a) The two models in this column are given in Tables 7.9 and 7.7, respectively.
- (b) The temperature of 1140°C was chosen because it was one of the temperatures at which the EC of HLW03-06 was measured. This facilitates comparison of the predicted and measured values.
- (c) Of the two models, the one with the predicted EC value at 1140°C closest to the measured value of 0.302 S/cm is the 22-term EC model.
- (d) The standard deviation is for the ln(EC) prediction at 1140°C considered to be the mean of such values for the HLW03-06 glass.
- (e) UCI = upper confidence interval, LCI = lower confidence interval, and CI = two-sided confidence interval (see Section C.7 of Appendix C).
- (f) All calculations were performed using the HLW03-06 glass composition, model coefficients, and variance-covariance matrix values given in tables of this report. The calculated ln(S/cm) values were rounded to four decimal places in this table. The S/cm values were calculated by exponentiating the ln(S/cm) values before rounding, then rounding the resulting values to three decimal places in this table.

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 8.1. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 197 HLW Glasses Used for Viscosity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 8.1. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 197 HLW Glasses Used for Viscosity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 8.1. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 197 HLW Glasses Used for Viscosity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 8.1. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 197 HLW Glasses Used for Viscosity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 8.1. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 197 HLW Glasses Used for Viscosity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 8.1. Normalized<sup>(a)</sup> 22-Component Compositions (mass fractions) of 197 HLW Glasses Used for Viscosity Model Development (continued).**

- (a) Normalized to sum to 1.00000 over the 22 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.00000 were used for property-composition modeling.
- (b) The Group IDs are described in Sections 2.1.1 to 2.1.9.

**Table 8.2. Temperature and Viscosity Observations and Data-Splitting Validation Sets for Each of the 197 HLW Glasses Used for Viscosity Model Development.**

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) Numbers from 1 to 5 denote the five split validation subsets. NA denotes “not applicable”, because these replicate glasses were forced into the modeling subsets, and thus were not parts of the validation subsets.
- (c) NA-Rep indicates glasses that were not included in any of the validation splits because they were replicates.

**Table 8.2. Temperature and Viscosity Observations and Data-Splitting Validation Sets for Each of the 197 HLW Glasses Used for Viscosity Model Development (continued).**

| Glass ID | Group ID <sup>(a)</sup> | Temp1 (°C) | Vis1 (P) | Temp2 (°C) | Vis3 (P) | Temp3 (°C) | Vis3 (P) | Temp4 (°C) | Vis4 (P) | Visc. Data Splitting Validation Set <sup>(b)</sup> |

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) Numbers from 1 to 5 denote the five split validation subsets. NA denotes “not applicable”, because these replicate glasses were forced into the modeling subsets, and thus were not parts of the validation subsets.
- (c) NA-Rep indicates glasses that were not included in any of the validation splits because they were replicates.

**Table 8.2. Temperature and Viscosity Observations and Data-Splitting Validation Sets for Each of the 197 HLW Glasses Used for Viscosity Model Development (continued).**

| Glass ID | Group ID <sup>(a)</sup> | Temp1 (°C) | Vis1 (P) | Temp2 (°C) | Vis2 (P) | Temp3 (°C) | Vis3 (P) | Temp4 (°C) | Vis4 (P) | Visc. Data Splitting Validation Set <sup>(b)</sup> |

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) Numbers from 1 to 5 denote the five split validation subsets. NA denotes “not applicable”, because these replicate glasses were forced into the modeling subsets, and thus were not parts of the validation subsets.
- (c) NA-Rep indicates glasses that were not included in any of the validation splits because they were replicates.

**Table 8.2. Temperature and Viscosity Observations and Data-Splitting Validation Sets for Each of the 197 HLW Glasses Used for Viscosity Model Development (continued).**

| Glass ID   | Group ID <sup>(a)</sup> | Temp1 (°C) | Vis1 (P) | Temp2 (°C) | Vis2 (P) | Temp3 (°C) | Vis3 (P) | Temp4 (°C) | Vis4 (P) | Visc. Data Splitting Validation Set <sup>(b)</sup> |
|------------|-------------------------|------------|----------|------------|----------|------------|----------|------------|----------|----------------------------------------------------|

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) Numbers from 1 to 5 denote the five split validation subsets. NA denotes “not applicable”, because these replicate glasses were forced into the modeling subsets, and thus were not parts of the validation subsets.
- (c) NA-Rep indicates glasses that were not included in any of the validation splits because they were replicates.

**Table 8.2. Temperature and Viscosity Observations and Data-Splitting Validation Sets for Each of the 197 HLW Glasses Used for Viscosity Model Development (continued).**

| Glass ID   | Group ID <sup>(a)</sup> | Temp1 (°C) | Vis1 (P) | Temp2 (°C) | Vis2 (P) | Temp3 (°C) | Vis3 (P) | Temp4 (°C) | Vis4 (P) | Visc. Data Splitting Validation Set <sup>(b)</sup> |
|------------|-------------------------|------------|----------|------------|----------|------------|----------|------------|----------|----------------------------------------------------|

- (a) The Group IDs are described in Sections 2.1.1 to 2.1.9.
- (b) Numbers from 1 to 5 denote the five split validation subsets. NA denotes “not applicable”, because these replicate glasses were forced into the modeling subsets, and thus were not parts of the validation subsets.
- (c) NA-Rep indicates glasses that were not included in any of the validation splits because they were replicates.

**Table 8.3. Variation in Viscosity Values for Replicate Glasses at Actual Temperature Measurements.**

| Glass IDs of Replicate Glasses <sup>(a)</sup> | Viscosity Values For Exact Temperatures Near Each Nominal Temperature <sup>(b)</sup> |              |              |              |              |              |              |              | Pooled Over Temp. |              |

(a) All replicates appear in pairs of HLW glasses except for HLW02-46, HLW03-42, and HLW07-02.

(b) Viscosity values are listed at the exact temperatures near the nominal temperature values.

(c) %RSD = 100\*(Standard Deviation / Mean), calculated using the Poise values.

(d) Calculated using ln(Poise) values.

(e) The individual and pooled SDs estimate  $\sqrt{\sigma_G^2 + \sigma_T^2}$  in ln(Poise) units (see Section C.2.2 of Appendix C).

(f) The %RSD and SD values are uncertainties of viscosity values, not temperature values. Because viscosity values at actual temperatures were used, temperature and viscosity columns are listed. The %RSD and SD values are merely listed under these columns.

**Table 8.4. Variation in Viscosity Values for Replicate Glasses Interpolated at Nominal Temperatures.**

| Glass IDs of Replicate Glasses <sup>(a)</sup> | Viscosity Values Interpolated at Nominal Temperatures <sup>(b)</sup> |              |               |              |               |              |               |              | Pooled Over Temp. |              |

(a) All replicates appear in pairs of HLW glasses except for HLW02-46, HLW03-42, and HLW07-02.

(b) Viscosity values were interpolated at the nominal temperature values using a T<sub>2</sub>-equation (see Section C.2.1) fit for each glass.

(c) %RSD = 100\*(Standard Deviation / Mean), calculated using the Poise values.

(d) Calculated using ln(Poise) values.

(e) The individual and pooled SDs estimate  $\sqrt{\sigma_G^2 + \sigma_T^2}$  in ln(Poise) units (see Section C.2.2 of Appendix C).

**Table 8.5. Coefficients and Performance Summary for the 44-Term Truncated T2-Linear Mixture Model on the Natural Logarithm of Viscosity Fitted to Data on 197 HLW Glasses.**

(a) The model evaluation statistics are defined in Section C.3 of Appendix C. Model validation statistics are defined in Section C.5 of Appendix C.

(b) The “Others” component includes Ag<sub>2</sub>O, As<sub>2</sub>O<sub>5</sub>, BaO, BeO, Bi<sub>2</sub>O<sub>3</sub>, CdO, Cr<sub>2</sub>O<sub>3</sub>, Ce<sub>2</sub>O<sub>3</sub>, Cl, CoO, Cs<sub>2</sub>O, CuO, Dy<sub>2</sub>O<sub>3</sub>, Eu<sub>2</sub>O<sub>3</sub>, F, Gd<sub>2</sub>O<sub>3</sub>, HfO<sub>2</sub>, HgO, K<sub>2</sub>O, La<sub>2</sub>O<sub>3</sub>, MoO<sub>3</sub>, NiO, P<sub>2</sub>O<sub>5</sub>, PbO, PdO, Pr<sub>2</sub>O<sub>3</sub>, Rb<sub>2</sub>O, Re<sub>2</sub>O<sub>7</sub>, Rh<sub>2</sub>O<sub>3</sub>, RuO<sub>2</sub>, Sb<sub>2</sub>O<sub>3</sub>, SeO<sub>2</sub>, SO<sub>3</sub>, Sm<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>, Tc<sub>2</sub>O<sub>7</sub>, TeO<sub>2</sub>, TiO<sub>2</sub>, Tl<sub>2</sub>O, V<sub>2</sub>O<sub>5</sub>, WO<sub>3</sub> and Y<sub>2</sub>O<sub>3</sub>.

(c) A dash (–) indicates the term was not included in the model.

(d) The evaluation and validation statistics calculated for data-splits are defined the same as for separate modeling and validation sets. Section 8.1.2 describes how the data-splitting was accomplished.

**Table 8.7. Coefficients and Performance Summary for the 24-Term Truncated T2-Linear Mixture Model on the Natural Logarithm of Viscosity Fitted to Data on 197 HLW Glasses.**

| Mixture Term ( $x_i$ )                                   | Coefficient Estimate | Coefficient Standard Deviation | Mixture-Temp. Term [ $x_i/(T/1000)^2$ ]               | Coefficient Estimate | Coefficient Standard Deviation | t-value = Coeff/SD | p-value        | Modeling Data Statistic, 197 Glasses <sup>(a)</sup> | Value  |

(a) The model evaluation statistics are defined in Section C.3 of Appendix C. Model validation statistics are defined in Section C.5 of Appendix C.

(b) The “Others” component includes Ag<sub>2</sub>O, As<sub>2</sub>O<sub>5</sub>, BaO, BeO, Bi<sub>2</sub>O<sub>3</sub>, CdO, Cr<sub>2</sub>O<sub>3</sub>, Ce<sub>2</sub>O<sub>3</sub>, Cl, CoO, Cs<sub>2</sub>O, CuO, Dy<sub>2</sub>O<sub>3</sub>, Eu<sub>2</sub>O<sub>3</sub>, F, Gd<sub>2</sub>O<sub>3</sub>, HfO<sub>2</sub>, HgO, K<sub>2</sub>O, La<sub>2</sub>O<sub>3</sub>, MoO<sub>3</sub>, NiO, P<sub>2</sub>O<sub>5</sub>, PbO, PdO, Pr<sub>2</sub>O<sub>3</sub>, Rb<sub>2</sub>O, Re<sub>2</sub>O<sub>7</sub>, Rh<sub>2</sub>O<sub>3</sub>, RuO<sub>2</sub>, Sb<sub>2</sub>O<sub>3</sub>, SeO<sub>2</sub>, SO<sub>3</sub>, Sm<sub>2</sub>O<sub>3</sub>, SnO<sub>2</sub>, Tc<sub>2</sub>O<sub>7</sub>, TeO<sub>2</sub>, TiO<sub>2</sub>, Tl<sub>2</sub>O, V<sub>2</sub>O<sub>5</sub>, WO<sub>3</sub> and Y<sub>2</sub>O<sub>3</sub>.

(c) A dash (–) indicates the term was not included in the model. The evaluation and validation statistics calculated for data-splits are defined the same as for separate modeling and validation sets. Section 8.1.2 describes how the data-splitting was accomplished.

- (a) The viscosity models contain  $x_i/(T/1000)^2$  terms in addition to the  $x_i$  and  $x_i x_j$  terms shown in this column. The purpose of this table is to show the compositional forms needed for model predictions, so the temperature-containing terms are not shown.
- (b) The composition in mass fractions is from Table 8.1.
- (c) See Table 8.8.
- (d) See Table 8.7.
- (e) NA = not applicable, because the model does not contain this term.

- (a) The two models in this column are given in Tables 8.7 (24-term model) and 8.8 (29-term model).
- (b) The temperature of 1146°C was chosen because it was one of the temperatures at which the viscosity of HLW03-06 was measured. This facilitates comparison of the predicted and measured values.
- (c) Of the two models, the one with the predicted viscosity value at 1146°C closest to the measured value of 93.53 Poise is the recommended 29-term viscosity model.
- (d) The standard deviation is for the ln( $\eta$ ) prediction at 1146°C considered to be the mean of such values for the HLW03-06 glass.
- (e) UCI = upper confidence interval, LCI = lower confidence interval, and CI = two-sided confidence interval (see Section C.7 of Appendix C).
- (f) All calculations were performed using the HLW03-06 glass composition, model coefficients, and variance-covariance matrix values given in tables of this report. The calculated ln(P) values were rounded to three decimal places in this table. The Poise values were calculated by exponentiating the ln(P) values before rounding, then rounding the resulting values to three decimal places in this table.

- (a) The results are given for the 266 glasses in the PCT-Na modeling dataset. Differences resulting from there being only 264 glasses in the PCT-B modeling dataset and 250 glasses in the PCT-Li dataset are noted via footnotes.
- (b) Only 100 of the 102 HLW02 and HLW03 glasses (excluding HLW03-01 and HLW03-08) were used to develop TCLP-Cd models. Note that the summary statistics are based on the mass fractions before the normalization to the number of components in the TCLP-Cd models. See Kot et al. (2004).
- (c) The minimum Li<sub>2</sub>O is 0 for the PCT-B and PCT-Na datasets. The minimum for the PCT-Li dataset is 0.0025.
- (d) The maximum MnO is 0.08000 for the PCT-B and PCT-Na datasets. The minimum for the PCT-Li dataset is 0.07012.
- (e) The mass fraction of the Others component was calculated as one minus the sum of the mass fractions of the 24 listed components.

**Table 9.2. Minimums and Maximums of HLW Glass Components (in Mass Fractions) Included in the Others Group in Table 9.1 for Compositions in the Modeling Datasets for Each HLW Glass Property.**

- (a) The results are the same for the 264, 250, and 266 glasses in the PCT-B, PCT-Li, and PCT-Na modeling datasets, respectively.
- (b) Only 100 of the 102 HLW02 and HLW03 glasses (excluding HLW03-01 and HLW03-08) were used to develop TCLP-Cd models. Note that the summary statistics are based on the mass fractions before the normalization to the number of components in the TCLP-Cd models. See Kot et al. (2004).

**Table 9.3. Lower and Upper Bounds on HLW Glass Components (in Mass Fractions) that Partially Define the Composition Validity Regions for IHLW Property Models.<sup>(a)</sup>**

| Others <sup>(g)</sup>             | 0 <sup>(f)</sup>   | 0.052                | 0 <sup>(f)</sup>       | 0.038    | 0 <sup>(f)</sup> | 0.038    | 0 <sup>(f)</sup>        | 0.038    | 0.012              | 0.022    |

- (a) The lower and upper bounds for these components are the minimum and maximum values from Table 9.1, with the lower bounds rounded down and the upper bounds rounded up, each to the third decimal place.
- (b) The results are given for the 266 glasses in the PCT-Na modeling dataset. Differences resulting from there being only 264 glasses in the PCT-B modeling dataset and 250 glasses in the PCT-Li dataset are noted via footnotes.
- (c) Only 100 of the 102 HLW02 and HLW03 glasses (excluding HLW03-01 and HLW03-08) were used to develop TCLP-Cd models. Note that the lower and upper bounds are based on the mass fractions before the normalization to the number of components in the TCLP-Cd models. See Kot et al. (2004).
- (d) The Li<sub>2</sub>O lower bound is 0 for the PCT-B and PCT-Na datasets and is 0.002 for the PCT-Li dataset.
- (e) The MnO upper bound is 0.081 for the PCT-B and PCT-Na datasets and is 0.071 for the PCT-Li dataset.
- (f) The lower bound was set to zero even though the rounded value to three decimals was slightly larger than zero.
- (g) The components in Others are listed in the second half of the table on the following page.

**Table 9.3. Lower and Upper Bounds on HLW Glass Components (in Mass Fractions) that Partially Define the Composition Validity Regions for IHLW Property Models (continued).<sup>(a)</sup>**

| HLW Glass Property                | PCT                |          | Spinel T <sub>1%</sub> |          | Viscosity |          | Electrical Conductivity |          | TCLP-Cd            |          |

- (a) The lower and upper bounds for these components are the minimum and maximum values from Table 9.2, with the lower bounds rounded down and the upper bounds rounded up, each to the third decimal place.
- (b) The results are the same for the 264, 250, and 266 glasses in the PCT-B, PCT-Li, and PCT-Na modeling datasets, respectively.
- (c) Only 100 of the 102 HLW02 and HLW03 glasses (excluding HLW03-01 and HLW03-08) were used to develop TCLP-Cd models. Note that the summary statistics are based on the mass fractions before the normalization to the number of components in the TCLP-Cd models. See Kot et al. (2004).

**Table 9.4. Minimum and Maximum Temperatures at Which Electrical Conductivity and Viscosity were Measured for HLW Glass Compositions in the Modeling Datasets Along with the Lower and Upper Bounds on Temperature that Partially Define the Validity Regions for IHLW Electrical Conductivity and Viscosity Models.**

| Temperature for Glass Property     | Minimum     | Maximum     |
|------------------------------------|-------------|-------------|
| T (°C) for Electrical Conductivity | 908         | 1277        |
| T (°C) for Viscosity               | 931         | 1281        |
|                                    |             |             |
| Temperature for Glass Property     | Lower Bound | Upper Bound |
| T (°C) for EC & Viscosity          | 900         | 1290        |

**Table 9.5. Minimums and Maximums of Measured Property Values for HLW Glass Compositions in the Modeling Dataset for Each HLW Glass Property.**

| HLW Glass Property             | Minimum                                   | Maximum |
|--------------------------------|-------------------------------------------|---------|
| PCT-B (g/L)                    | 0.104                                     | 21.903  |
| PCT-Li (g/L)                   | 0.141                                     | 10.675  |
| PCT-Na (g/L)                   | 0.050                                     | 11.819  |
| Spinel T <sub>1%</sub> (°C)    | 635.7                                     | 1230.7  |
| Electrical Conductivity (S/cm) | Functions of temperature, see Figure 9.1. |         |
| Viscosity (poise)              | Functions of temperature, see Figure 9.2. |         |
| TCLP-Cd <sup>(a)</sup> (mg/L)  | 0.007                                     | 1.240   |

(a) Based on the 100 of 102 HLW02 and HLW03 glasses used in the modeling dataset and the model summarized in Table 6.16 of Kot et al. (2004).

**Table 9.6. Multiple-Component and Multiple-Variable Constraints that Partially Define the Composition Validity Regions for IHLW Property Models.**

| HLW Glass Property <sup>(a)</sup>        | Lower Bound                              | Upper Bound                              |

- (a) These constraints (lower and upper bounds) on HLW glass property values are implemented using the HLW glass property models recommended in Sections 5 to 8 for all of the properties except TCLP-Cd release. The recommended model for TCLP-Cd release is discussed in Section 6.5.2 of Kot et al. (2004). Thus, these property constraints are actually indirect constraints on HLW glass composition.
- (b) See the discussion in Section 9.2.1 for how these upper bounds were determined.
- (c) The spinel T<sub>1%</sub> lower and upper bounds are rounded versions of the minimum and maximum estimated values from Table 9.5
- (d) See the discussion in Section 9.2.1 for how this upper bound was determined.

**Table 9.7. Minimum and Maximum Values of Multi-Component Constraint Expressions Calculated for 302 HLW Glasses<sup>(a)</sup>**

- (a) The 302 HLW glasses are the ones having values for at least one of the four main properties (PCT, crystallinity, electrical conductivity, and viscosity) addressed in this report.
- (b) In calculating the constraint expressions, revised oxides were substituted for original oxides (e.g.,  $UO_3$  in place of  $UO_2$ ) in cases where the constraint expression involved original oxides.
- (c) TCLP B = normalized boron release from the TCLP (g/L).  $T_{LS}$  = liquidus temperature of Cr-bearing spinel (°C). Values were calculated using the model coefficients derived from constraint coefficients in Table 7 of Cooley et al. (2003).
- (d)  $T_{LZ}$  = liquidus temperature of zircon (°C). Coefficients for the  $T_{LZ}$  model are from the “TRU + CVS” column of Table 4 in Rao et al. (1997). The Others coefficient in that model was used as the coefficient for all components in the combined WTP HLW glass database without coefficients.
- (e)  $T_{LZO}$  = liquidus temperature of zirconia (°C). Coefficients for the  $T_{LZO}$  model are from the baddeleyite (Z) column of Table II in Plaisted et al. (2000). The Others coefficient in that model was used as the coefficient for all components in the combined WTP HLW glass database without coefficients. Note that this model was only 7 coefficients fitted to 14 data points, with an  $R^2$  of only 0.548. Hence, predictions with this model can be expected to have large uncertainties.
- (f) AlFeZr =  $Al_2O_3+Fe_2O_3+ZrO_2$  (wt%), AlFeZrTh =  $Al_2O_3+Fe_2O_3+ZrO_2+3ThO_2$  (wt%), LiNaTh =  $2Li_2O+Na_2O-3.75ThO_2$  (wt%) to limit thorium crystallization, LiNa =  $Na_2O+2Li_2O$  (wt%). Values shown are mass fractions calculated using glass compositions expressed in the revised (new) oxide forms (see Table 2.10).
- (g) The overall maximum TCLP B value exceeds the upper limit of 0.3 mg/L imposed for HLW02, HLW03, and HLW05, as shown in Table 2.6.
- (h) The overall maximum  $T_{LS}$  value exceeds the upper limit of 1150°C imposed for HLW03, as shown in Table 2.6.
- (i) The overall maximum  $T_{LZ}$  value exceeds the upper limits of 1150°C imposed for HLW03, as shown in Table 2.6.
- (j) The overall maximum  $T_{LZO}$  value exceeds the upper limit of 1420°C imposed for HLW06, as shown in Table 2.6.
- (k) AlFeZr has values significantly below the lower limit of 18 wt% imposed for HLW02, HLW05, and HLW07, as shown in Table 2.6. AlFeZr also has values noticeably above the upper limit of 27 wt% imposed for HLW05.
- (l) AlFeZrTh has values significantly outside the limits of 19 to 34 wt% imposed for HLW03, as shown in Table 2.6.
- (m) LiNaTh has values below the lower limit of 0 wt% imposed for HLW03, as shown in Table 2.6.
- (n) LiNa has values that exceed the upper limit of 24 wt% imposed for HLW05, as shown in Table 2.6.

**Table 9.8. Summary of Constraints Specifying the Model Validity Region for each HLW Glass Property.**

| Aspect of Model Validity Region         | PCT-B                                    | PCT-Li     | PCT-Na     | Spinel T <sub>1%</sub> | Electrical Conductivity | Viscosity     | TCLP-Cd   |
|-----------------------------------------|------------------------------------------|------------|------------|------------------------|-------------------------|---------------|-----------|
| Single-component lower and upper bounds | As listed for each property in Table 9.3 |            |            |                        |                         |               |           |
| Temperature bounds <sup>(b)</sup>       | N/A <sup>(a)</sup>                       | N/A        | N/A        | N/A                    | 900 – 1290°C            | 900 – 1290°C  | N/A       |
| Property bounds <sup>(c)</sup>          | ≤ 6.61 g/L                               | ≤ 4.27 g/L | ≤ 5.53 g/L | 630 – 1260°C           | See Table 9.6           | See Table 9.6 | 0.80 mg/L |

(a) N/A = not applicable.

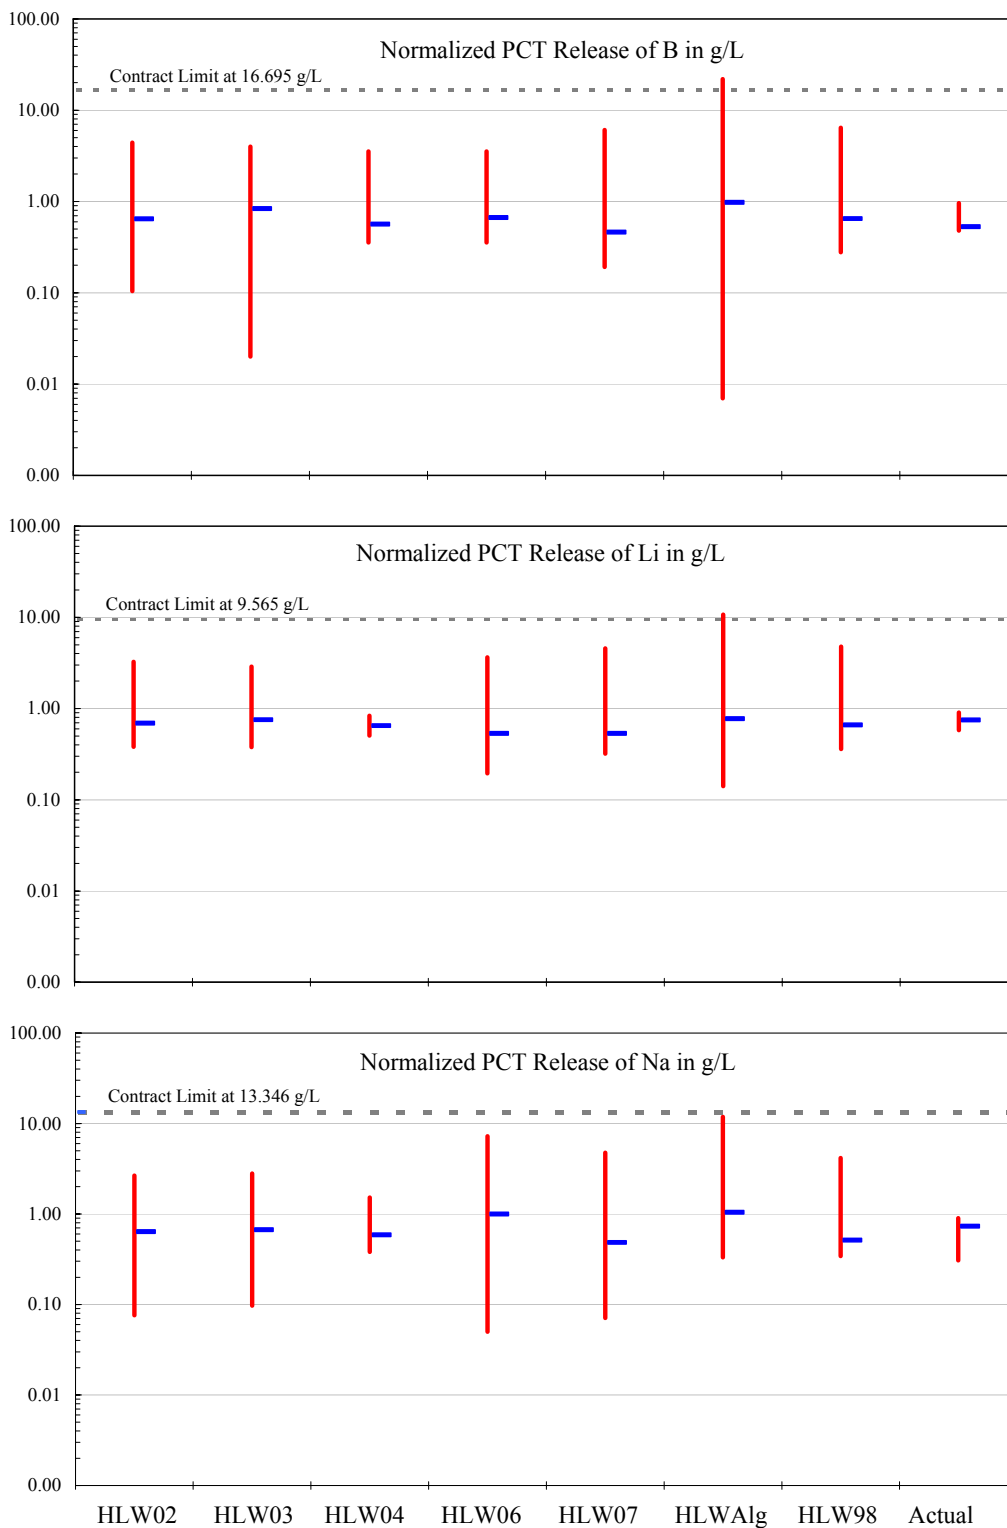

(b) From Table 9.4.

(c) From Table 9.6. The property bounds for PCT-B, PCT-Li, PCT-Na, and spinel T<sub>1%</sub> are indirect multiple-component constraints on HLW glass composition. The property bounds for electrical conductivity and viscosity are indirect multiple-variable constraints on combinations of HLW glass composition and melt temperature. The property bounds are implemented using the recommended model for each property.

**Figure 9.1. Illustration of How the PCT-B Model Validity Upper Bound was Determined for the Recommended 18-Term PQM Model with Bias Correction. The model validity upper bound is indicated by the dashed line and value. It was determined by the glass HLW-ALG-03, the only glass in the PCT-B modeling dataset with measured PCT-B release greater than the corresponding DWPF-EA glass limit.**

**Figure 9.2. Model Validity Constraints on HLW Glass Electrical Conductivity as Functions of Temperature. The constraints were determined to include all measured and predicted electrical conductivity values for glass-temperature combinations in the electrical conductivity modeling dataset.**

**Figure 9.3. Model Validity Constraints on HLW Glass Viscosity as Functions of Temperature. The constraints were determined to include all measured and predicted viscosity values for glass-temperature combinations in the viscosity modeling dataset.**

## **APPENDIX A**

### **Selection of Test Matrices to Support Development of Phase 2 Property-Composition Models for WTP HLW Glasses**

## **Appendix A**

### **Selection of Test Matrices to Support Development of Phase 2 Property-Composition Models for WTP HLW Glasses**

This appendix summarizes the selection of two test matrices to provide additional data for Phase 2 of the work to develop property-composition models for Waste Treatment and Immobilization Plant (WTP) high-level waste (HLW) glasses. The appendix was written in early 2006 to document the test matrix development work performed in 2005 and 2006. The text refers to the testing and data generation in the future tense because it had not been performed at the time the appendix was originally written. Some revisions have been made to the original version of this appendix for clarity and consistency as part of this report. References to Battelle-Pacific Northwest Division (PNWD) rather than Pacific Northwest National Laboratory (PNNL) and to Duratek rather than Energy Solutions are used because those were the names of the entities who performed the work at the time.

Section A.1 presents relevant background and introduces the test matrix development work. Section A.2 discusses the optimal experimental design approach used to select the test matrices. Section A.3 describes the work to develop the first test matrix, which is a subset of 10 glasses from the HLW05 and HLW06 matrices for which viscosity and electrical conductivity will be measured. Section A.4 discusses the generation of the second test matrix (referred to as the HLW07 matrix), which consists of 40 HLW glasses selected to cover a newly defined experimental glass composition region (EGCR). Section A.5 discusses the Quality Assurance (QA) aspects of the work.

#### **A.1. Introduction**

This appendix is responsive to the Test Plans (Gan and Pegg 2002, Piepel and Cooley 2003), Test Specifications (Swanberg 2001, 2002), and Test Exceptions (Kelly 2002, Westsik 2003a, 2003b) to develop HLW glass property-composition models for the WTP project. The purpose of the work described in those documents is to develop data, mathematical models, and corresponding statistical uncertainty expressions that relate waste form performance and glass processing properties to the chemical composition of Immobilized High-Level Waste (IHLW) glasses. These property-composition models and uncertainty expressions will provide the basis for (1) qualifying waste forms, (2) defining viable operating envelopes, and (3) selecting target glass compositions for the range of possible HLW waste types to be treated in the WTP. During operation of the WTP HLW vitrification facility, the models and uncertainty expressions will also be used to make various operating decisions and to demonstrate that the resultant IHLW meets compliance requirements.

In order to develop IHLW property-composition models, adequate property-composition data covering the EGCR of interest are required. This appendix addresses the generation of two test matrices to support the collection of the necessary data on four HLW glass properties:

1. Normalized releases (g/L) of B, Li, and Na from the Product Consistency Test (PCT)
2. The temperature ( $^{\circ}\text{C}$ ) at which 1% (by volume) of a glass melt is comprised of spinel crystals, denoted by spinel  $T_{1\%}$
3. Viscosity as a function of temperature (poise)
4. Electrical conductivity as a function of temperature (S/cm)

Previous work developed the property-composition data and models for release of cadmium from HLW glass subjected to the Toxicity Characteristic Leaching Procedure (TCLP) (Piepel et al. 2002a, Cooley et al. 2003, Kot et al. 2004).

Property-composition data to develop models for WTP HLW glasses were developed in several test matrices prior to those discussed in this appendix (see Section 2.1). These test matrices are referred to by the prefixes used in the Glass IDs for glasses in the test matrices, namely HLW02, HLW03, HLW04, HLW05, HLW06, and HLWAlg<sup>1</sup>. The HLW02 and HLW03 matrices were constructed in Phase 1 of the work to develop property-composition models for WTP HLW glasses.

Because HLW glasses are mixtures of oxide and halogen components, their mass fractions must sum to 1 (equivalently, their wt% values must sum to 100). Such problems are referred to as *mixture experiments*. Statistical experimental design, modeling, and data analysis methods for mixture experiments (Cornell 2002) are applicable for selecting the two test matrices and developing property-composition models.

## A.2 Optimal Experimental Design Approach

An optimal experimental design approach was used to select the two test matrices described in Sections A.3 and A.4. This section describes in general terms the optimal experimental design approach used. The specifics for each of the two test matrices are described in Sections A.3 and A.4.

An optimal experimental design approach provides for selecting the points of an experimental design to optimize a specified mathematical criterion (referred to as an *optimal design criterion*). Many optimal design criteria are available in the statistical experimental design literature, but in general they quantify in a single number the goodness of an experimental design. Optimal design criteria often depend on the form of a mathematical model assumed to adequately represent the true form of the relationship between the response to be modeled (e.g., glass properties) and the predictor variables (e.g., mass fractions of glass components). Because

---

<sup>1</sup> “HLWAlg” stands for HLW algorithm support glasses, which were developed by the WTP project to assess performance of the glass formulation algorithm being developed by the project.

many mathematical functions can be adequately approximated by first- or second-order Taylor series expansions, often first-order (linear) or quadratic (second-order) polynomial models are used to construct optimal experimental designs. Finally, the optimal experimental design approach can be used to optimally augment existing data, or it can be used to build a design from scratch if there are no appropriate existing data.

The optimal experimental design approach used in Sections A.3 and A.4 consists of the following steps. The terminology of HLW glass test matrices is used.

1. Select the existing HLW glass compositions to be augmented.
2. Specify the property-composition model form assumed to provide an adequate approximation of the true property-composition relationships for the HLW glass properties of interest.
3. Specify the optimal design criterion to be used.
4. Select or generate the candidate set of glass compositions from which new design (test matrix) compositions are to be selected by the optimal experimental design software.
5. Use the optimal design software to select the glass compositions for the design (test matrix) from the candidate set to optimally (according to the assumed model form and optimality criterion selected) augment the existing glasses.

Three optimal design criteria commonly used to construct experimental designs are as follows, where  $\mathbf{X}$  denotes the “model matrix” and  $\mathbf{x}$  denotes a point from the EGCR. The model matrix is the design matrix (existing points plus new design points) expanded in the assumed model form.

- D-optimal: Minimize  $|(X'X)^{-1}|$ , where the vertical bars denote a matrix determinant. The D-optimal criterion seeks to minimize the uncertainty in coefficients of models developed from the resulting data.
- G-optimal: Minimize  $\max_{\mathbf{x}} \mathbf{x}'(X'X)^{-1}\mathbf{x}$ . The G-optimal criterion seeks to minimize the maximum uncertainty (imprecision) in predictions made with the model developed from the resulting data.
- V-optimal: Minimize  $\text{avg}_{\mathbf{x}} \mathbf{x}'(X'X)^{-1}\mathbf{x}$ . The V-optimal criterion seeks to minimize the average uncertainty (imprecision) in predictions made with the model developed from the resulting data.

In the G- and V-optimal criteria, the maximum and average are ideally with respect to all glasses  $\mathbf{x}$  in the constrained glass composition region to be covered by the design. However, in practice the maximum and average are often taken with respect to the set of candidate points as well as existing points if they exist, which is what was done for the designs presented in Sections A.3 and A.4. In general, the D-, G-, V-optimal criteria are appropriate for selecting the test matrices

so that property-composition models developed from the resulting data have low prediction uncertainties.

The D-optimal criterion was used to select the test matrix in Section A.3, while all three optimal-design criteria were considered in selecting the test matrix in Section A.4. See those sections for the specifics of the optimal experimental design approach used in each case. See Atkinson and Donev (1992) and Cornell (2002) for more general discussion of optimal experimental design and its application to mixture experiments.

### A.3 Selecting a Subset of HLW05 and HLW06 Glasses for Viscosity and Electrical Conductivity Measurements

As shown in Tables 2.1 to 2.4 of Section 2, the ranges of some components investigated in the HLW05 and HLW06 studies were expanded compared to the previous HLW02 and HLW03 studies. However, viscosity and electrical conductivity (EC) were not measured for HLW05 and HLW06 glasses. These two facts indicate that the composition region over which models could be developed and considered valid would be smaller for viscosity and EC than for PCT and spinel  $T_{1\%}$ . Thus, the WTP project decided that a subset of the HLW05 and HLW06 glasses should be selected for viscosity and EC measurement. The goal was to select the subset to expand the IHLW component ranges covered for viscosity and electrical conductivity to be similar to the component ranges covered for PCT and spinel  $T_{1\%}$ . Those component ranges are defined by the least restrictive of the component ranges for HLW02, HLW03, HLW05, and HLW06. As seen from Table 2.1, the component ranges for HLW06 are the least restrictive with one exception. For HLW06 the range of  $\text{ThO}_2$  is 0 to 5.94 wt%, whereas the least-restrictive range is 0 to 6 wt%. For convenience, the least-restrictive component ranges over the HLW02, HLW03, HLW05, and HLW06 studies are listed in Table 2.5.<sup>2</sup>

The Vitreous State Laboratory (VSL) checked archive materials of the 65 HLW05 and HLW06 glasses and confirmed there was sufficient material remaining to measure both viscosity and EC on any of the 65 glasses. However, VSL was concerned that glasses with high spinel  $T_{1\%}$  values may show crystallization to various extents, which could compromise the viscosity and EC measurements. Therefore, VSL recommended conservatively excluding all glasses with spinel  $T_{1\%} > 950^\circ\text{C}$ , which left 25 of the 65 HLW05 and HLW06 glasses. These glasses were HLW05-1, 2, 3, 4, 5, 7, 9, 10, 11, 13, 14, 15, 20, 21, 22, 27, and 30, and HLW06-2, 4, 5, 15, 22, 32, 34, 35.

The number of glasses to select from the candidate set of 25 HLW05 and HLW06 glasses was not specified by the WTP project. It was decided to select subsets of 5, 10, and 15 glasses and to assess the relationship between the number of glasses selected and the extent to which the component ranges of interest were covered. Subsets of these sizes were selected from the 25 candidate HLW05 and HLW06 glasses using optimal experimental design software. The subsets

<sup>2</sup> Table 2.5 actually lists the least restrictive component limits for HLW02, HLW03, HLW05, HLW06, and HLW07. However, except for minor exceptions noted in footnotes of that table, all component ranges were achieved prior to HLW07.

were selected to augment 143 “existing” glasses that had (or would have after scheduled testing) data for viscosity and EC. A linear mixture experiment model (see Section C.1.1 of Appendix C) was assumed for purposes of this optimal design augmentation. Most optimal experimental design software will select replicate points if that is what yields an optimal design. However, in this situation we did not want to select replicate glasses out of the 25 candidate HLW05 and HLW06 glasses. The ACED optimal design software (Welch 1987) that has been used for previous WTP work was too complicated to revise so that replicates would not be selected. Instead, modifications were made by the vendor to the D-optimal<sup>3</sup> design routine DMAX in the MIXSOFT software (Piepel 2006a) to allow optimally selecting each candidate point only once.

The selected subsets of 5, 10, and 15 glasses were compared graphically to the set of 143 existing glasses as well as to the set of 25 candidate glasses. The goal was to cover the expanded component ranges in Table 2.5 with as few glasses as possible, and also obtain a good distribution of predicted viscosity and EC values. The subset of 10 glasses clearly did better covering the desired component ranges than did selecting 5 glasses, whereas selecting 15 didn’t improve (compared to 10) the coverage of the desired component ranges. Based on (1) a telephone conference discussion of this topic with the WTP project, Duratek, and VSL, and (2) subsequent direction by the WTP project, the subset of 10 of the 25 HLW05 and HLW06 glasses was chosen. This decision was made based on the consideration that investigating subsets of between 5 and 10 glasses would be more time-consuming and costly than the little savings in less viscosity and EC testing work it would provide.

Table A.1 lists the Glass IDs of the 143 existing glasses that have data for viscosity and EC and meet applicable QA requirements. Also listed in Table A.1 are the Glass IDs of the 25 HLW05 and HLW06 candidate glasses. The IDs of the 10 glasses selected from the 25 candidates using the DMAX routine in MIXSOFT (Piepel 2006) are also identified in Table A.1. Tables A.2, A.3, and A.4 list the compositions of the 143 existing glasses having viscosity and EC data. Tables A.5, A.6, and A.7 list the compositions of the 10 of 25 HLW05 and HLW06 glasses selected to have viscosity and electrical conductivity measured. The HLW glass compositions in Table A.2 (143 existing) and Table A.5 (10 HLW05 and HLW06 glasses) are listed in terms of 14 individual components and 4 grouped components as defined for the HLW07 test matrix development (see Section A.4). Table A.3 (143 existing glasses) and Table A.6 (10 HLW05 and HLW06 glasses) list the expansions of the Others1, Others2, and Constant grouped components. Table A.4 (143 existing glasses) and Table A.7 (10 HLW05 and HLW06 glasses) list the expansions of the Remaining grouped component.

Figure A.1 displays component distributions (unnormalized mass fractions) for the 14 main components selected for study in Phase 2 property-composition modeling for HLW glasses (see Section A.4.2). This figure shows the 10 glasses selected from the HLW05 and HLW06 matrices as red triangles, and the 143 existing glasses as black circles. Because the HLW05 and HLW06 test matrices were constructed as layered designs (Piepel et al. 1993, Piepel et al. 2002b), they each contain glass compositions on outer and inner layers of their respective EGCRs. For comparison purposes in Figure A.1, the inner-layer single-component constraints from the HLW06 study are marked with blue dashed lines; the outer-layer single-component

<sup>3</sup> The D-optimal design criterion and other optimal design criteria are discussed in Section A.2.

constraints from the HLW06 study are marked with red solid lines. The component mass fraction values are displayed along the x-axes, whereas the “index number” of each glass is displayed along the y-axis. Indices 1 to 143 correspond to the existing glasses, while indices 144 to 153 correspond to the 10 selected HLW05 and HLW06 glasses.

Figure A.2 shows predicted property distributions for the 143 existing glasses and the 10 newly selected glasses (plotting symbols as before). The red solid lines represent the property constraint limits or values of interest: 1000°C for spinel  $T_{1\%}$  (constraint limit); 4 g/L for PCT-B release (value of interest); 10 and 100 poise for viscosity at 1150°C (constraint limits); and 0.2 and 0.7 S/cm for EC at 1150°C (constraint limits).

Figure A.3 shows component distributions (unnormalized mass fractions for the 14 main components) for the selected 10 of 25 candidate HLW05 and HLW06 glasses. The 10 glasses selected from the HLW05 and HLW06 datasets are marked with red triangles, and the 15 not selected are marked with black circles. Figure A.3 better shows the choice of the 10 HLW05 and HLW06 glasses from the 25 candidate glasses. The plots in Figure A.3 show that there were no HLW05 and HLW06 candidate glasses with the lower limits of  $\text{Na}_2\text{O}$  or the upper limits of  $\text{NiO}$ ,  $\text{SiO}_2$ , and  $\text{ZnO}$ . Also, there was only one candidate glass with the upper limit of  $\text{ZrO}_2$ .

Figure A.4 shows the predicted property distributions for the selected 10 of 25 candidate HLW05 and HLW06 glasses (same plotting symbols as before). The properties include PCT-B release (g/L), spinel  $T_{1\%}$  (°C), viscosity at 1150°C (poise); and EC at 1150°C (S/cm).

#### A.4 Construction of the HLW07 Test Matrix

This section discusses how the HLW07 test matrix was constructed. Based on input from the WTP project, the principal objective for the HLW07 test matrix was to augment the existing HLW glass property-composition data to reflect the current understanding of the waste feed compositions to the WTP HLW vitrification facility. A secondary objective included filling in any composition subregions having limited data with respect to both composition coverage and property coverage. The purpose of these objectives was to ensure that the composite data set (existing data plus the HLW07 test matrix) provides an adequate region of validity for the final property-composition models for HLW glasses.

Section A.4.1 describes the experimental design approach used to construct the HLW07 test matrix. Section A.4.2 discusses the inputs considered by VSL (with input from the WTP project) in developing the HLW glass components and constraints that define the EGCR to be covered by the HLW07 test matrix. Section A.4.3 presents the glass components and single-component constraints used to define the EGCR for the HLW07 study. Section A.4.4 discusses the waste-loading constraint chosen to help define the HLW Phase 2 EGCR. Section A.4.5 presents the glass property constraints and the property-composition models used to help define the EGCR for the HLW07 study. Section A.4.6 discusses how the outer and inner layers of the HLW07 EGCR were defined using the single-component and multi-component (waste loading and property-based) constraints. Section A.4.7 describes steps of the process and software used by PNWD to construct the HLW07 test matrix. Section A.4.8 describes the model form for glass

property-composition relationships used in constructing the test matrix using optimality criteria described in Section A.2. Section A.4.9 presents graphical views of the 125 existing glasses and 40 HLW glasses in the HLW07 test matrix to assess how well the HLW07 EGCR of interest is covered.

#### **A.4.1 Experimental Design Approach for Generating the HLW07 Test Matrix**

The experimental design approach used to generate the HLW07 test matrix was to augment existing glasses (from the previous HLW studies: HLW02, HLW03, HLW05, and HLW06) with additional glass formulations within the HLW07 EGCR (described subsequently in Section A.4.6). A *layered design* approach (Piepel et al. 1993, Piepel et al. 2002b) was chosen to generate the HLW07 test matrix, with HLW glass compositions on one outer layer, one inner layer, and a center point. The layered design approach provides for collecting data on a larger glass composition region (the outer layer), a smaller glass composition region (the inner layer), and at the center of the EGCR. Each of the previous HLW glass test matrices (which provide the existing data to be augmented by the HLW07 test matrix) were constructed using a layered design approach.

A layered design approach is well-suited for constructing the HLW07 test matrix, because the objectives involve (1) augmenting existing data, (2) covering the glass composition region likely to be associated with the current understanding of the waste feed compositions to the WTP HLW vitrification facility, and (3) filling in any areas of limited data with respect to both composition coverage and property coverage. The HLW07 test matrix includes a center glass, glasses from the outer and inner layers of the HLW07 EGCR, and several replicate glass formulations. The outer- and inner-layer glasses were selected to optimally augment the existing glasses having values of the four properties discussed in Section A.1.

#### **A.4.2 Bases for the Components and Constraints Defining the HLW07 EGCR**

In order to select the HLW glass components and constraints to define the EGCR for the HLW07 test matrix, the following starting points were used:

1. Previous statistically-designed HLW glass test matrices (HLW02, HLW03, HLW05 and HLW06) that provide the existing data for developing property-composition models.
2. Property constraints employed in the previous test matrices and property-composition models developed during Phase 1.
3. Tank waste compositions and flow-sheet projections of glass composition ranges.
4. Glass component ranges spanned by existing data.
5. Contract waste loading requirements.

The components, component constraints, and property constraints used to develop the previous statistically-designed HLW glass test matrices (HLW02, HLW03, HLW05, and HLW06) are summarized in Section 2.1. Data from these previous test matrices were graphically evaluated using

- Histograms of the distributions of major glass components and key properties.
- Selected pair-wise scatter plots of component vs. component or property vs. components.

The following paragraphs discuss the histogram results. The scatter plots were examined to identify subregions of composition or property space with little or no data. However, such areas are primarily determined by component and property constraints. The constraints were reviewed and determined to be what was desired, and so the scatter plot results are not presented in this appendix or discussed further.

Histograms for 14 glass components ( $Al_2O_3$ ,  $B_2O_3$ ,  $Cr_2O_3$ ,  $Fe_2O_3$ ,  $Li_2O$ ,  $MnO$ ,  $Na_2O$ ,  $NiO$ ,  $SiO_2$ ,  $SrO$ ,  $ThO_2$ ,  $UO_3$ ,  $ZnO$ , and  $ZrO_2$ ) over all 167 HLW02, HLW03, HLW05, and HLW06 glasses are shown in Figures A.5 to A.18. As can be seen in the figures, the values of some components are reasonably well distributed over their ranges of interest ( $Al_2O_3$ ,  $B_2O_3$ ,  $Li_2O$ ,  $Na_2O$ ,  $NiO$ ,  $SiO_2$ ,  $ZnO$ ), while other components have at least one gap in their distribution of values ( $Cr_2O_3$ ,  $SrO$ ) or have noticeably skewed distributions ( $MnO$ ,  $SrO$ ,  $ThO_2$ ,  $UO_3$ ). Even for some components listed as having reasonably well-distributed data, there are sub-ranges having limited data.

The histograms for key properties [spinel  $T_{1\%}$  ( $^{\circ}C$ ), viscosity at  $1150^{\circ}C$  (poise), EC at  $1150^{\circ}C$  (S/cm), and PCT-B release (g/L)] are shown in Figures A.19 to A.22. Table A.8 summarizes some observations based on the histograms. These histograms and observations were subsequently used to select property constraints, which are discussed in Section A.4.5.

#### **A.4.3. HLW Glass Components and Single-Component Constraints**

This section discusses the HLW glass components included (individually or in grouped components) or excluded from defining the outer and inner layers of the EGCR for the HLW07 test matrix. It also presents the component lower and upper limits used to define the outer and inner layers of the HLW07 EGCR as a step toward constructing a layered design.

The HLW glass components used to define the HLW07 EGCR are given in Table A.9. The first 14 components listed in Table A.9 ( $Al_2O_3$ ,  $B_2O_3$ , ... ,  $ZrO_2$ ) are the main HLW glass components with the potential to affect at least one HLW glass property. The next two components, Others1 and Others2, are each mixtures of minor HLW glass components (as defined in Table A.10 and Table A.11, respectively). Finally, Table A.9 lists the Constant component, which is a mixture of minor HLW glass components defined in Table A.12. Note in Table A.9 that the Constant component is constant only separately for the HLW07 outer layer and the HLW07 inner layer. The Constant component takes different values for each of the outer

and inner layers, and hence is a component that varies across the HLW07 EGCR. Thus, Constant was treated as a varied component in developing the HLW07 test matrix. In summary, Table A.9 lists 17 HLW glass components that were to be varied in the HLW07 test matrix.

The component distributions for the existing HLW test matrix glasses (HLW02, HLW03, HLW05, and HLW06) are shown in Figures A.5 to A.18. These distributions of component values for the existing glasses were reviewed and used to select the lower and upper limits on the components for both outer and inner layers of the HLW07 EGCR. The limits were selected such that they tend to fall in the locations of gaps in the previous data. The single-component lower and upper limits for the outer and inner layers of the HLW07 EGCR are listed in Table A.9. These lower and upper limits are compared to the lower and upper limits for the outer and inner layers of previous WTP HLW glass studies in Table 2.1 of the main body of the report.

Because the grouped components (Others1, Others2, and Constant) vary, the individual components comprising each group also vary. Tables A.10, A.11, and A.12 respectively list, for Others1, Others2, and Constant, the maximum values (wt%) of the individual components that can occur. The bases for the maximum values of each component are listed in the final columns of Tables A.10, A.11, and A.12. In some cases the maximum desired value of a minor component was achieved in a previous HLW test matrix, and it was decided to consider smaller, more realistic upper limits in the HLW07 test matrix. In the remaining cases the desired maximum values of minor components are achieved in the HLW07 test matrix. These maximum values either correspond to (1) limits in Specification 8.1 of the WTP contract (U. S. DOE-ORP 2003), or (2) calculations made with the WTP dynamic simulation flowsheet (Deng 2004, Vora 2004) for actual waste compositions.

Table A.13 lists the minor components that were excluded from the HLW07 study. These components were excluded because they had occurred in previous test matrix HLW glasses up to or approaching the maximum values of interest. Hence, the WTP project directed that these minor components should be omitted from the HLW07 study.

#### A.4.4 Waste Loading Constraint

Only a single waste-loading constraint

$$X_{Al_2O_3} + X_{Fe_2O_3} + X_{ZrO_2} \geq 18 \text{ wt\%} \tag{A.1}$$

was selected to help define both the outer and inner layers of the EGCR for the HLW07 study. In (A.1), the  $X_i$  are weight percents of the components included in the constraint. Note that the single-component constraints in Table A.9 allow  $X_{Al_2O_3} + X_{Fe_2O_3} + X_{ZrO_2}$  to go as low as 8 wt% on the outer layer and as low as 13.5 wt% on the inner layer. Hence, setting a lower limit of 18 wt% does not allow all three of the components to take their lower limits at the same time.

No upper-limit constraint was employed because waste loading was implicitly limited by other EGCR constraints such as single-component limits and the spinel T<sub>1%</sub> constraint. The

Phase 1 spinel  $T_{1\%}$  model was not available for the design of previous HLW studies, which instead made necessary the use of multiple waste-loading constraints.

#### A.4.5 Glass Property Constraints

Glass property constraints for the HLW07 EGCR were selected based on the histograms of property values for studies that had been completed at the time of the test matrix development work (HLW02, HLW03, HLW05, and HLW06). The property constraints and the models for implementing the constraints are listed in Table A.14 and Table A.15, respectively. Explanations of the property constraints are given in the following bullets.

- The spinel  $T_{1\%}$  data are relatively well-distributed (see Figure A.19), so it was decided to focus the HLW07 study on glasses with spinel  $T_{1\%}$  values around the limit of 950°C. Consequently, an upper constraint of 1000°C was specified.
- No constraints on  $T_{1\%}$  for Th- and Zr-containing phases were specified for two reasons. First, reliable property-composition models for  $T_{1\%}$  of Th and Zr phases are not available to implement the constraints. Second, the relatively low limits of ThO<sub>2</sub> and ZrO<sub>2</sub> recommended in the composition constraints (see Table A.9) suggests that the number of glasses with Th- or Zr-containing primary phases should be small.
- Existing data for viscosity at 1150° ( $\eta_{1150}$ ) are heavily skewed to the right (see Figure A.20), with the majority of data below about 40 poise. Data from 40 poise to about 110 poise are relatively evenly scattered. Although additional data in the 50 to 70 poise range would be desirable, it was decided not to impose such tight constraints for the HLW07 study. Hence, lower and upper limits for  $\eta_{1150}$  were maintained at the processing limits of 10 to 100 poise, the full range that has been used in previous WTP HLW glass studies.
- Existing data for EC at 1150° ( $\epsilon_{1150}$ ) are relatively well distributed (see Figure A.21), although the data beyond about 0.55 S/cm is limited. It was decided to maintain the lower and upper limits for  $\epsilon_{1150}$  at the processing limits of 0.2 to 0.7 S/cm, the full range that has been used in previous WTP HLW glass studies.
- None of the HLW02, HLW03, HLW05, and HLW06 glasses have exhibited PCT responses that exceed the Defense Waste Processing Facility Environmental Assessment (DWPF-EA) glass limits (Jantzen et al. 1993). This is illustrated in Figure A.22 for PCT-B release [ln(g/L)]. Hence, it appears that the combination of other constraints is sufficient to avoid exceeding the PCT limits. Conceptually it would be good to have more data on HLW glasses with PCT responses up to and somewhat past the limits for the DWPF-EA glass. With such data, the resulting PCT response models would be able to better predict higher PCT responses. However, it would be artificial to specify an EGCR subregion of HLW glasses with higher PCT responses in an attempt to fill the gap between the bulk of the data and the PCT

values for the DWPF-EA glass. Also, it is relatively easy to make HLW glasses with PCT-B (and other) releases in the range for the bulk of the data in Figure A.22. Thus, it was decided that no PCT constraint would be imposed to define the EGCR for the HLW07 study.

It was decided to use the same property constraints for the outer and inner layers. This was because the lower- and upper-limits for both layers were previously selected to fill in the gaps in the existing data base. Hence, there were no obvious advantages to employ different constraints for the two layers in the HLW07 study.

Note that the property constraints in Table A.14 do not achieve all of the possible property-related objectives listed in the last column of Table A.8. Those objectives were considered secondary, and were not always jointly possible. Also, there was concern that too tightly restricting the HLW07 EGCR to obtain certain ranges of property values as well as composition values might result in too artificial of a data set.

#### **A.4.6 Outer and Inner Layers of the HLW07 EGCR**

The outer and inner layers of the EGCR for the HLW07 study are defined by the single-component constraints in Table A.9 and the multi-component constraints in Table A.16. The multi-component constraints consist of the waste-loading constraint from Equation (A.1), and three constraints on glass properties (spinel  $T_{1\%}$ ,  $\eta_{1150}$ , and  $\varepsilon_{1150}$ ) constructed from the information in Table A.14 and Table A.15. The single- and multi-component constraints were expressed in terms of mass fractions of the 17 HLW glass components used to construct the HLW07 test matrix (see Section A.4.7). Because the mass fractions of these 17 HLW glass components must sum to one and the nature of the single- and multi-component constraints, the outer and inner layers of the EGCR are 16-dimensional irregularly-shaped polyhedrons.

We now describe how the three property-based constraints in Table A.16 were developed from the information in Table A.14 and Table A.15. To help define the outer and inner layers of the EGCR for the HLW07 study, the glass property constraints had to be rewritten in terms of the 17 HLW glass components to be varied in the HLW07 test matrix. Because the property constraints were the same for the outer and inner layers, they only had to be rewritten once. The steps of rewriting the three constraints (spinel  $T_{1\%}$ , viscosity at 1150°C, and EC at 1150°C) in terms of the mass fractions of the 17 components to be varied in HLW07 test matrix are described in the following paragraphs.

Spinel T<sub>1%</sub>

The spinel T<sub>1%</sub> constraint in Table A.14 implemented using the reduced linear mixture model in Table A.15 is given by

$$\text{Spinel } T_{1\%} = \sum_{i=1}^{13} b_i x_i^* \leq 1000 \tag{A.2}$$

where the  $b_i$  ( $i = 1, 2, \dots, 13$ ) are the Phase 1 spinel T<sub>1%</sub> model coefficients in Table A.15 (from Table 6.8 of Kot et al. 2005a) and the

$$x_i^* = \frac{x_i}{\sum_{j=1}^{13} x_j}, \quad i = 1, 2, \dots, 13 \tag{A.3}$$

are normalized mass fractions of the 13 components in the spinel T<sub>1%</sub> model. Substituting Equation (A.3) into Equation (A.2) and collecting terms yields

$$\sum_{i=1}^{13} b_i \left( \frac{x_i}{\sum_{j=1}^{13} x_j} \right) \leq 1000$$

$$\sum_{i=1}^{13} b_i x_i \leq 1000 \left( \sum_{j=1}^{13} x_j \right)$$

$$0 \leq \sum_{i=1}^{13} (1000 - b_i) x_i . \tag{A.4}$$

The constraint is now expressed in terms of unnormalized mass fractions  $x_i$  of 13 of the 17 HLW glass components for the HLW07 study. The missing four components are UO<sub>3</sub>, Others1, Others2, and Constant, which can be thought of as having zero coefficients in Equations (A.2) to (A.4).

Viscosity at 1150°C

The lower and upper limit constraints on viscosity at 1150°C ( $\eta_{1150}$ ) in Table A.14 were implemented using the model in Table A.15. That model was denoted Model 16 in Table 8 from Gan et al. (2004). The lower and upper constraints on  $\eta_{1150}$  are given by

$$\ln(10) \leq \ln(\eta_{1150}) \leq \ln(100)$$

$$\ln(10) \leq a_0 + \sum_{i=1}^{11} a_i \frac{X_i}{T^2} + a_{CdO} \frac{X_{CdO}}{T^2} + a_{Sb_2O_3} \frac{X_{Sb_2O_3}}{T^2} + a_{SeO_2} \frac{X_{SeO_2}}{T^2} + a_{Ti_2O} \frac{X_{Ti_2O}}{T^2} \leq \ln(100)$$

$$\ln(10) \leq a_0 + \sum_{i=1}^{11} a_i \frac{X_i}{(1423.15)^2} + a_{CdO} \frac{X_{CdO}}{(1423.15)^2} + a_{Sb_2O_3} \frac{X_{Sb_2O_3}}{(1423.15)^2} + a_{SeO_2} \frac{X_{SeO_2}}{(1423.15)^2} + a_{Ti_2O} \frac{X_{Ti_2O}}{(1423.15)^2} \leq \ln(100)$$

$$\ln(10) \leq a_0 + \sum_{i=1}^{11} a_i \frac{100x_i}{(1423.15)^2} + a_{CdO} \frac{100x_{CdO}}{(1423.15)^2} + a_{Sb_2O_3} \frac{100x_{Sb_2O_3}}{(1423.15)^2} + a_{SeO_2} \frac{100x_{SeO_2}}{(1423.15)^2} + a_{Ti_2O} \frac{100x_{Ti_2O}}{(1423.15)^2} \leq \ln(100) \quad (A.5)$$

where the  $a_0$  and  $a_i$  are the coefficients for the  $\ln(\eta_{1150})$  model in Table A.15, the  $X_i$  are weight percents of components included in the model, the  $x_i$  are mass fractions of the components included in the model, and  $T$  is temperature in Kelvin (so that  $1150^\circ\text{C} = 1423.15\text{K}$ ). Rewriting the constraints to simplify yields

$$\frac{(1423.15)^2[\ln(10) - a_0]}{100} \leq \sum_{i=1}^{11} a_i x_i + a_{CdO} x_{CdO} + a_{Sb_2O_3} x_{Sb_2O_3} + a_{SeO_2} x_{SeO_2} + a_{Ti_2O} x_{Ti_2O} \leq \frac{(1423.15)^2[\ln(100) - a_0]}{100}$$

Note that the mass fractions of components  $\text{SeO}_2$ , and  $\text{Ti}_2\text{O}$  are zero (i.e.,  $x_{SeO_2} = x_{Ti_2O} = 0$ ) in the HLW07 study per Table A.13. Rewriting the viscosity constraints to account for these substitutions yields

$$\frac{(1423.15)^2[\ln(10) - a_0]}{100} \leq \sum_{i=1}^{11} a_i x_i + a_{CdO} x_{CdO} + a_{Sb_2O_3} x_{Sb_2O_3} \leq \frac{(1423.15)^2[\ln(100) - a_0]}{100}$$

Two more substitutions are possible. First, per Table A.12,  $x_{Sb_2O_3} = 0.1149 x_{Constant}$ . However, in rewriting the viscosity constraints,  $x_{Sb_2O_3} = 0$  was inadvertently used (which had been the case for the constraints before the final revisions). Second, note that  $x_{CdO} = 0.4032 x_{Others2}$  per Table A.11. However, because  $0 \leq x_{CdO} \leq 0.01$  for the outer layer of the EGCR,  $x_{CdO} = 0.005$  was inadvertently used as a substitution. Making these two modified substitutions yields the following lower and upper limit constraints on viscosity

$$\frac{(1423.15)^2[\ln(10) - a_0]}{100} \leq \sum_{i=1}^{11} a_i x_i + a_{CdO} (0.005) \leq \frac{(1423.15)^2[\ln(100) - a_0]}{100}$$

$$\frac{(1423.15)^2[\ln(10) - a_0]}{100} - a_{CdO} (0.005) \leq \sum_{i=1}^{11} a_i x_i \leq \frac{(1423.15)^2[\ln(100) - a_0]}{100} - a_{CdO} (0.005) \quad (A.6)$$

Making the unmodified substitutions yields the following lower and upper limits constraints on viscosity

$$\frac{(1423.15)^2[\ln(10) - a_0]}{100} \leq \sum_{i=1}^{11} a_i x_i + a_{CdO} (0.4032 x_{Others2}) + a_{Sb_2O_3} (0.1149 x_{Constant}) \leq \frac{(1423.15)^2[\ln(100) - a_0]}{100} \quad (A.7)$$

The consequence of having used the viscosity modified constraints in Equation (A.6) instead of the unmodified constraints in Equation (A.7) was investigated. This was done by predicting for the 40 HLW07 test matrix glasses (discussed subsequently in Section A.4.7) the viscosity at 1150°C, using the model in the center of the inequality in Equation (A.5) with

- Case 1:  $x_{Sb_2O_3} = 0$  and  $x_{CdO} = 0.005$
- Case 2:  $x_{Sb_2O_3} = 0.1149 x_{Constant}$  and  $x_{CdO} = 0.4032 x_{Others2}$

substitutions. For Case 1, which was used to develop the HLW07 test matrix,  $\eta_{1150}$  predictions varied between 10 and 100 poise per the lower and upper limit constraints in Table A.14. For Case 2,  $\eta_{1150}$  predictions varied between 9.84 and 103.5 poise. A plot of the Case 1 versus Case 2 predictions were tightly scattered about a 45° line. Hence, there was negligible impact of having used Equation (A.6) rather than Equation (A.7) for implementing the viscosity constraints.

### Electrical Conductivity at 1150°C

The lower and upper limit constraints on EC at 1150°C ( $\epsilon_{1150}$ ) in Table A.14 were implemented using the model in Table A.15. That model was denoted Model 10 in Table 10 from Gan et al. (2004). The lower and upper constraints on EC are given by

$$\ln(0.2) \leq \ln(\epsilon_{1150}) \leq \ln(0.7)$$

$$\ln(0.2) \leq \sum_{i=1}^9 a_i X_i + c_{ZrO_2} \frac{X_{ZrO_2}}{T} + d_{B_2O_3} \frac{X_{B_2O_3}}{T^2} + d_{MnO} \frac{X_{MnO}}{T^2} + d_{SiO_2} \frac{X_{SiO_2}}{T^2} + d_{SrO} \frac{X_{SrO}}{T^2} \leq \ln(0.7)$$

$$\ln(0.2) \leq \sum_{i=1}^8 a_i X_i + a_{ZrO_2} X_{ZrO_2} + c_{ZrO_2} \frac{X_{ZrO_2}}{T} + d_{B_2O_3} \frac{X_{B_2O_3}}{T^2} + d_{MnO} \frac{X_{MnO}}{T^2} + d_{SiO_2} \frac{X_{SiO_2}}{T^2} + d_{SrO} \frac{X_{SrO}}{T^2} \leq \ln(0.7)$$

$$\begin{aligned} \ln(0.2) \leq & \sum_{i=1}^8 a_i X_i + a_{ZrO_2} X_{ZrO_2} + c_{ZrO_2} \frac{X_{ZrO_2}}{1423.15} + d_{B_2O_3} \frac{X_{B_2O_3}}{(1423.15)^2} + d_{MnO} \frac{X_{MnO}}{(1423.15)^2} \\ & + d_{SiO_2} \frac{X_{SiO_2}}{(1423.15)^2} + d_{SrO} \frac{X_{SrO}}{(1423.15)^2} \leq \ln(0.7), \end{aligned}$$

where  $X_i$  denotes the wt% of the  $i^{th}$  HLW glass component,  $T$  denotes temperature in Kelvin (so that 1150°C = 1423.15K), and the  $a_i$ ,  $c_i$ , and  $d_i$  are the coefficients for the  $\ln(\epsilon_{1150})$  model in Table A.15. Collecting terms yields

$$\begin{aligned} \ln(0.2) \leq & a_{Al_2O_3} X_{Al_2O_3} + a_{Fe_2O_3} X_{Fe_2O_3} + a_{Li_2O} X_{Li_2O} + a_{Na_2O} X_{Na_2O} \\ & + (a_{ZrO_2} + \frac{c_{ZrO_2}}{1423.15}) X_{ZrO_2} + [a_{B_2O_3} + \frac{d_{B_2O_3}}{(1423.15)^2}] X_{B_2O_3} + [a_{MnO} + \frac{d_{MnO}}{(1423.15)^2}] X_{MnO} \\ & + [a_{SiO_2} + \frac{d_{SiO_2}}{(1423.15)^2}] X_{SiO_2} + [a_{SrO} + \frac{d_{SrO}}{(1423.15)^2}] X_{SrO} \leq \ln(0.7) \end{aligned}$$

Converting from components expressed in wt% ( $X_i$ ) to components expressed in mass fractions ( $x_i$ ) yields

$$\begin{aligned} \ln(0.2) \leq & 100a_{Al_2O_3}x_{Al_2O_3} + 100a_{Fe_2O_3}x_{Fe_2O_3} + 100a_{Li_2O}x_{Li_2O} + 100a_{Na_2O}x_{Na_2O} \\ & + 100\left(a_{ZrO_2} + \frac{c_{ZrO_2}}{1423.15}\right)x_{ZrO_2} + 100\left[a_{B_2O_3} + \frac{d_{B_2O_3}}{(1423.15)^2}\right]x_{B_2O_3} + 100\left[a_{MnO} + \frac{d_{MnO}}{(1423.15)^2}\right]x_{MnO} \\ & + 100\left[a_{SiO_2} + \frac{d_{SiO_2}}{(1423.15)^2}\right]x_{SiO_2} + 100\left[a_{SrO} + \frac{d_{SrO}}{(1423.15)^2}\right]x_{SrO} \leq \ln(0.7) \end{aligned}$$

Finally, dividing all sides by 100 yields

$$\begin{aligned} \frac{\ln(0.2)}{100} \leq & a_{Al_2O_3}x_{Al_2O_3} + a_{Fe_2O_3}x_{Fe_2O_3} + a_{Li_2O}x_{Li_2O} + a_{Na_2O}x_{Na_2O} \\ & + \left(a_{ZrO_2} + \frac{c_{ZrO_2}}{1423.15}\right)x_{ZrO_2} + \left[a_{B_2O_3} + \frac{d_{B_2O_3}}{(1423.15)^2}\right]x_{B_2O_3} + \left[a_{MnO} + \frac{d_{MnO}}{(1423.15)^2}\right]x_{MnO} \quad (A.7) \\ & + \left[a_{SiO_2} + \frac{d_{SiO_2}}{(1423.15)^2}\right]x_{SiO_2} + \left[a_{SrO} + \frac{d_{SrO}}{(1423.15)^2}\right]x_{SrO} \leq \frac{\ln(0.7)}{100}. \end{aligned}$$

This expression then gives the constraints for EC at 1150°C expressed in the mass fractions of components to be varied in the HLW07 test matrix.

### Standardization of Constraint Coefficients

Finally, the coefficients of the re-expressed property constraints for spinel T<sub>1%</sub> [in Equation (A.4)],  $\ln(\eta_{1150})$  [in Equation (A.6)], and  $\ln(\varepsilon_{1150})$  [in Equation (A.7)] were standardized so that, in absolute value, the largest coefficient would equal 1. This was accomplished by dividing both sides of a property inequality constraint by the absolute value of the largest (in absolute value) coefficient. This process results in the largest (in absolute value) coefficient being either +1 or -1 depending on its original sign. Dividing both sides of an inequality by a positive value yields a mathematically equivalent constraint. Hence, the standardization process yielded mathematically equivalent constraints for the three HLW glass properties. Note that the waste-loading constraint already had its largest coefficient equal to 1, and thus did not need to be standardized. Standardizing the coefficients of the property constraints was required so that the same criterion could be used to apply and check constraints in the software used to generate candidate design points for the outer and inner layers of the HLW07 EGCR.

#### **A.4.7 HLW Phase 2 Test Matrix**

A 40-glass HLW07 layered design (test matrix) was constructed based on the HLW glass component lower and upper limits for outer and inner layers (as discussed in previous subsections). The 40-glass test matrix contains

- the center glass of the HLW07 inner layer (formed by averaging all of the vertices of the inner-layer constrained region)
- replicates of four glasses studied in previous phases (HLW02-22, HLW02-46, HLW03-07, and HLW03-41)
- 20 outer-layer glasses
- 15 inner-layer glasses

The outer- and inner-layer glasses were selected to optimally augment 125 existing HLW glasses (from previous testing performed by the WTP project) having data for all four of the properties of interest (PCT, spinel  $T_{1\%}$ , viscosity, and EC). The approach of only augmenting glasses having data for every property was chosen as providing an optimized common set of data to develop models for all four properties of interest. Of course, previously tested glasses that have data for fewer than all four properties will still be used for modeling.

The detailed steps of the process used to generate the HLW07 test matrix are now described.

- Step 1. The 125 existing HLW glasses having data for all four properties of interest were identified. The Glass IDs and 18-component compositions of these 125 glasses are listed in Table A.17. Tables A.18 and A.19 list the compositions of the grouped components (Others1, Others2, Constant, and Remaining) for the 125 existing glasses. Note that the “Constant” component was not constant for these existing glasses. The “Remaining” group of components was required to account for components included in previous WTP HLW glass studies that were not included in any component of the HLW07 study. Note that only five of the ten HLW05 and HLW06 glasses selected as discussed in Section A.3 appear in the list of 125 glasses. Specifically, only the five HLW06 glasses (HLW06-2, HLW06-4, HLW06-22, HLW06-32, and HLW06-34) appear because the PCT was not performed for HLW05 glasses.
- Step 2. The MCCVRT routine of MIXSOFT (Piepel 2003) was used to generate a set of 218,514 vertices for the constrained outer-layer region involving 17 HLW07 glass components ( $\text{Al}_2\text{O}_3$ ,  $\text{B}_2\text{O}_3$ ,  $\text{Cr}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$ ,  $\text{Li}_2\text{O}$ ,  $\text{MnO}$ ,  $\text{Na}_2\text{O}$ ,  $\text{NiO}$ ,  $\text{SiO}_2$ ,  $\text{SrO}$ ,  $\text{ThO}_2$ ,  $\text{UO}_3$ ,  $\text{ZnO}$ ,  $\text{ZrO}_2$ , Others1, Others2, and Constant). The mass fractions of these 17 components sum to 1 for each of the outer-layer vertices. To match the 18-component format of the 125 existing glasses, a “Remaining” component with value equal to 0 was appended to the end of every 17-component outer-layer vertex. All of the single- and multi-component constraints were necessary, meaning they all were active in defining the outer-layer boundary and calculating its vertices.

- Step 3. The MCCVRT routine of MIXSOFT (Piepel 2003) was used to generate a set of 178,438 vertices for the constrained inner-layer region involving the 17 HLW07 glass components. The mass fractions of these 17 components sum to 1 for each of the inner-layer vertices. To match the 18-component format of the 125 existing glasses, a “Remaining” component with value equal to 0 was appended to the end of every 17-component inner-layer vertex. All of the single- and multi-component constraints were necessary (meaning they all were active in defining the inner-layer boundary and calculating its vertices) except for two. The lower limit constraint on viscosity (10 poise) and the upper limit constraint on EC (0.7 S/cm) were not necessary. Over the inner-layer vertices, the smallest predicted viscosity was 13.34 poise, while the largest predicted EC was 0.463 S/cm.
- Step 4. Center points of the constrained regions defined by the outer layer and the inner layer were calculated by averaging the vertices in each set. The glass compositions of the outer-layer and inner-layer center points were graphically compared to each other and to the center points of previous WTP HLW studies. The inner-layer center point was the most different from previous center points, and was thus selected for inclusion in the HLW07 test matrix. This center point glass is listed as HLW07-01 in Tables A.20, A.21, and A.22.
- Step 5. Replicates of four glasses tested in previous WTP HLW glass studies were included in the HLW07 test matrix. Including replicates of glasses tested in previous studies provides for assessing the longer-term sources of variation and uncertainty affecting property-composition data (including batching and melting of glasses, as well as property measurements). Most of the replicates included in previous test matrices of WTP HLW glasses were same-study replicates, and thus only provided for assessing short-term sources of uncertainty. The four replicate glasses were selected to be as spread apart as possible, both in terms of compositions and property values (PCT-B release, spinel  $T_{1\%}$ , viscosity at 1150°C, and EC at 1150°C). The glasses selected for replication were HLW02-46 (HLW02 inner layer), HLW03-41 (HLW03 center point), HLW02-22 (HLW02 outer layer), and HLW03-07 (HLW03 outer layer). These glasses are respectively listed as HLW07-02 to HLW07-05 in Tables A.20, A.21, and A.22.
- Step 6. ACED (Welch 1987) was used to select 60 candidate subsets of 20 outer-layer glass compositions: 20 subsets each corresponding to the D-, G-, and V-optimal criteria<sup>4</sup>, to optimally augment 130 glasses (the 125 existing glass compositions from Step 1, the center point from Step 4, and the four replicates from Step 5). An 86-term partial quadratic mixture (PQM) model form was assumed to implement the optimality criteria. The model form consisted of linear terms for the 18 mixture components ( $\text{Al}_2\text{O}_3$ ,  $\text{B}_2\text{O}_3$ ,  $\text{Cr}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$ ,  $\text{Li}_2\text{O}$ ,  $\text{MnO}$ ,  $\text{Na}_2\text{O}$ ,  $\text{NiO}$ ,  $\text{SiO}_2$ ,  $\text{SrO}$ ,  $\text{ThO}_2$ ,  $\text{UO}_3$ ,  $\text{ZnO}$ ,  $\text{ZrO}_2$ , Others1, Others2, Constant, and Remaining), 12 squared terms, and 56

<sup>4</sup> Optimal design software does not guarantee an optimal solution on any given try, so multiple tries must be made to increase the chances of finding the best design. Twenty tries were made with each of the D-, G-, and V-optimal design criteria. These design criteria are discussed in Section A.2. Typically, most or all of a set of 20 tries achieves very close to the same optimality properties.

crossproduct terms for a total of 86 model terms. This model form is further described in Section A.4.8. The 86-term model form is not necessarily the one that will be fit to the resulting property-composition data. Rather, developing optimal designs based on such a model produces a test matrix that supports modeling nonlinear blending effects of important glass components if needed. Design summary statistics (i.e., D-, G-, and V-optimal measures) output by ACED were compared and used, together with plots of predicted property values produced by R (as described in Step 7), to select one of the best options among the available 60 subsets of 20 outer-layer glass compositions.

- Step 7. R (Ihaka and Gentleman 1996) was used to plot predicted property values and visually inspect the predicted property distributions for each of the 60 candidate subsets of 20 outer-layer glass compositions. Of particular interest were the predicted T<sub>1%</sub> and viscosity distributions, which differed dramatically among the 60 subsets of candidate outer-layer glasses, even though summary statistics for the optimality criteria used by ACED were very similar.<sup>5</sup> Property constraints were included in the MIXSOFT MCCVRT runs used to calculate vertices for each layer. Thus, all candidate glass compositions satisfy property constraints, meaning that the predicted property values associated with each outer-layer vertex must fall within the limiting range for each property of interest. However, an even coverage of the predicted property space is desirable. Therefore, the 20 outer-layer design points that were ultimately selected in this step were chosen because they performed well in terms of the D-, G-, and V-optimal measures from ACED and had predicted property distributions that provided ‘good’ coverage of the specified property ranges. R was used to select a ‘best’ set of 20 outer-layer glass compositions to be used in the augmentation test matrix. The selected outer-layer glass compositions are listed as HLW07-06 to HLW07-25 in Tables A.20, A.21, and A.22.
- Step 8. ACED was used to select 60 candidate subsets of 15 inner-layer glass compositions: 20 subsets, each corresponding to the D-, G-, and V-optimal criteria. These sets of 15 inner-layer glass compositions were chosen to optimally augment 150 glasses (the 125 existing glass compositions from Step 1, the center glass from Step 4, the four replicates from Step 5, and the 20 outer-layer glasses from Step 7). The same 86-term model (see Step 6 and Section A.4.8) was used to implement the optimality criteria for the inner-layer ACED run as was used for the outer-layer ACED run. Design summary statistics (i.e., D-, G-, and V-optimal measures) output by ACED were compared and used, together with plots of predicted property values produced by R (as described in Step 9), to select one of the best options among the available 60 subsets of 15 inner-layer glass compositions.
- Step 9. R (Ihaka and Gentleman 1996) was used to plot predicted property values and visually inspect the predicted property distributions for each of the 60 candidate subsets of 15 inner-layer glass compositions. As with the outer-layer glass compositions, the

---

<sup>5</sup> Optimal experimental design software packages such as ACED only consider the distribution of design points in design variable space (i.e., glass compositions in this application), not property variable space. Hence, it was necessary to separately consider distributions of predicted property values as well as optimized distributions of compositions provided by ACED.

predicted  $T_{1\%}$  and viscosity distributions showed considerable differences among the 60 subsets of candidate inner-layer glass compositions. The 15 inner-layer glass compositions that were ultimately selected were chosen because they performed well in terms of the D-, G-, and V-optimal measures from ACED and had predicted property distributions that provided ‘good’ coverage of the property ranges. R was used to select a ‘best’ set of 15 inner-layer glass compositions to complete the HLW07 test matrix. The selected inner-layer glass compositions are listed as HLW07-26 to HLW07-40 in Tables A.20, A.21, and A.22.

In summary, the 40-glass HLW07 test matrix consists of a center point (HLW07-01), four replicates (HLW07-02 to HLW07-05), 20 outer-layer glasses (HLW07-06 to HLW07-25), and 15 inner-layer glasses (HLW07-26 to HLW07-40). The 18-component compositions of the glasses in the test matrix are given in Table A.20. Expansions of the Others1, Others2, and Constant components are given in Table A.21, while expansions of the Remaining component are given in Table A.22.

In preparing the list of expanded compositions of HLW07-01 and HLW07-06 to HLW07-40,  $Ta_2O_5$  in the “Constant” grouped component was inadvertently omitted from the expansion.  $Ta_2O_5$  was intended to have occurred at 0.01 wt% in outer-layer glasses and 0.005 wt% in inner-layer glasses. The omission of  $Ta_2O_5$  (plus minor round-off differences in the calculation of outer- and inner-layer vertices) led to renormalizing these glass compositions so their mass fractions would sum to exactly 1 (wt% values would sum to 100). This renormalization led to minor impacts on the values of all glass components (not just those included in the “Constant” component). This issue was brought to the attention of the WTP project technical contacts for the test matrix development work at PNWD. It was concluded that the omission of  $Ta_2O_5$  and the minor impacts of renormalization were not of practical technical impact. Hence, 18-component compositions of the HLW07 glasses in Table A.20 and the expansions of the grouped components in Tables A.21 and A.22 correspond to the actual compositions. The compositions of the 125 existing glasses listed in Tables A.17 to A.19 were not affected by this issue. Similarly, the compositions of the four replicate glasses in the HLW07 test matrix (HLW07-02, HLW07-03, HLW07-04, and HLW07-05) were not affected by this issue because they are replicates of existing glasses which did not contain  $Ta_2O_5$ .

#### **A.4.8 Model Form Used in Optimal Experimental Design Approach**

The 20 outer-layer and 15 inner-layer glasses of the HLW07 test matrix were selected using optimal experimental design methods as described in the previous subsection. The optimal experimental design approach requires specifying a model form that is assumed to be adequate to represent the linear as well as any nonlinear blending effects of the HLW07 glass components. The sets of 20 outer-layer glasses and 15 inner-layer glasses were optimally selected for a PQM model form consisting of 18 linear terms ( $Al_2O_3$ ,  $B_2O_3$ ,  $Cr_2O_3$ ,  $Fe_2O_3$ ,  $Li_2O$ ,  $MnO$ ,  $Na_2O$ ,  $NiO$ ,  $SiO_2$ ,  $SrO$ ,  $ThO_2$ ,  $UO_3$ ,  $ZnO$ ,  $ZrO_2$ , Others1, Others2, Constant, and Remaining) along with:

- a) all pairwise crossproduct and squared terms of the five components included in the PQM model optimization of the HLW Phase 1b augmentation test matrix ( $\text{Al}_2\text{O}_3$ ,  $\text{B}_2\text{O}_3$ ,  $\text{Li}_2\text{O}$ ,  $\text{Na}_2\text{O}$ ,  $\text{SiO}_2$ ) and the five components affecting spinel  $T_{1\%}$  ( $\text{Cr}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$ ,  $\text{MnO}$ ,  $\text{NiO}$ ,  $\text{ZnO}$ )
- b) all pairwise crossproduct and squared terms of the five components included in the PQM model optimization of the augmentation matrix ( $\text{Al}_2\text{O}_3$ ,  $\text{B}_2\text{O}_3$ ,  $\text{Li}_2\text{O}$ ,  $\text{Na}_2\text{O}$ ,  $\text{SiO}_2$ ) as well as  $\text{ThO}_2$  and  $\text{ZrO}_2$ . These last two components were previously found to have statistically significant effects on HLW glass properties. Also, although generating additional glasses with primary Th and Zr crystalline phases was not a goal of this study, including crossproducts and squared terms of  $\text{ThO}_2$  and  $\text{ZrO}_2$  may generate some glasses with these primary crystalline phases. Such data would be useful in any future efforts to model  $T_{1\%}$  for Th- or Zr-containing crystalline phases.

There are 10 squared and 45 crossproduct terms in a), plus 2 more squared terms and 11 more crossproduct terms in b) not in a). Thus, this PQM model form contains 18 linear terms, 12 squared terms, and 56 crossproduct terms for a total of 86 model terms. The 86 model terms are listed in Table A.23.

Sets of 20 outer-layer glasses (Step 6 of Section A.4.7) and 15 inner-layer glasses (Step 8 of Section A.4.7) were also constructed in a similar fashion as described above for (1) a linear mixture model form and (2) a 54-term PQM model from having 36 quadratic terms, fewer than the 68 in the selected 86-term model form. It was found that designs (i.e., sets of outer- or inner-layer glasses) optimized for the 86-term and 54-term PQM model forms, but evaluated using the linear mixture model form, had design statistics that were only marginally worse than the statistics of designs optimized for the linear mixture model. On the other hand, designs optimized for the linear mixture model but evaluated for the 86-term and 54-term PQM model forms had much worse design statistics than the designs optimized for the PQM models. There were only small differences between the statistics for designs selected based on the 86-term and 54-term PQM model forms. Thus, the selected HLW07 matrix glasses were optimized for the 86-term PQM model to so that the data would include more information on nonlinear blending effects of components, with only marginal loss in estimation efficiency if linear mixture models are ultimately fitted to the data.

#### A.4.9 Graphical Assessment of Existing Glasses and HLW07 Test Matrix Glasses

The 165 glasses obtained by combining the 125 existing glasses and the 40 HLW Phase 2 glasses were graphically assessed to confirm that they adequately cover the least-restrictive HLW glass composition region defined by the constraints in Table 2.5. Henceforth, this region is referred to as the modeling composition region. Good coverage of this region without strong correlations among components is needed to support developing property-composition models from the data.<sup>6</sup> Recall that property-composition modeling will use all glasses having data for a

<sup>6</sup> Good coverage of the outer and inner portions of the EGCR defined by the constraints in Tables A.5 and A.12 is also desirable to verify the HLW07 test matrix. However, property-composition models will be developed and their validity determined over the least-restrictive modeling composition region.

given property. Thus, the modeling database for some properties may contain more than the 165 glasses assessed by the plots in this subsection. However, if the 165 glasses provides good support for developing property models, then more glasses for some properties will also provide good support.

Figure A.23 shows single-component distribution plots for the 18 components used to represent the compositions of the 125 existing and 40 HLW07 test matrix glasses. In these plots, the black circles denote the 125 glasses from past studies: 97 HLW02 and HLW03 glasses, 5 HLW06 glasses, and 23 algorithm support glasses (see Section 2) that have or were planned to have property data for all four HLW glass properties of interest. The blue box with a cross inside represents the new HLW07 center point, the four blue  $\times$ s represent the four new replicates selected for the HLW07 glasses, the green crosses represent the 20 new HLW07 outer-layer glasses, and the red triangles represent the 15 new HLW07 inner-layer glasses. In Figure A.23, the component mass fraction values are displayed along the x-axes, whereas the “index number” of each glass is displayed along the y-axes. Indices 1-125 correspond to the existing glasses, while indices 126-165 correspond to the 40 HLW glasses in the HLW07 test matrix. Most components show good distributions consistent with the component lower and upper limits used in the various HLW glass studies. Exceptions are (1) the Others1 component, which is constant for all of the HLW02 and HLW03 glasses, (2) the Constant component (as defined for the HLW07 study) comprised a relatively consistent fraction of the HLW02 and HLW03 glasses, varied for the Algorithm HLW glasses, and then is constant at one of two values for the HLW07 outer- and inner-layer glasses, and (3) the Remaining component generally varies up to about 0.015 mass fraction (1.5 wt%) for HLW02, HLW03, and the Algorithm HLW glasses and then is zero for the HLW07 outer- and inner-layer glasses. However, there are two HLW06 glasses with the Remaining component having mass fraction values near 0.03 (wt% values near 3.0).

Figure A.24 shows predicted property plots for spinel  $T_{1\%}$  ( $^{\circ}\text{C}$ ), PCT-B release (g/L), viscosity at 1150 $^{\circ}\text{C}$  (poise), and EC at 1150 $^{\circ}\text{C}$  (S/cm). The same plotting symbols and colors are used as in Figure A.23. Note that many of the 40 HLW07 glasses have predicted property values (for spinel  $T_{1\%}$ , viscosity at 1150 $^{\circ}\text{C}$ , and EC at 1150 $^{\circ}\text{C}$ ) at limiting values used in defining the outer and inner layers of the EGCR. This is expected because the glasses were selected from the sets of outer- and inner-layer vertices, which must satisfy at least 17 of the constraints defining the outer layer or the inner layer. However, in comparing the 60 subsets of 20 outer-layer glasses and subsequently the 60 subsets of 15 inner-layer glasses that were selected by optimal experimental design (see Section A.4.8), designs with fewer glasses “stacked up” at limiting values were preferred. The set of 20 outer-layer glasses selected gave a noticeably better distribution of property values than other options. The top few choices for subsets of 15 inner-layer glasses had trade-offs when considering the distribution of property values and the number of glasses stacked-up at limiting values. For example, one set of 15 inner-layer glasses considered had a slightly better distribution of PCT-B release values, but had a poorer distribution of spinel  $T_{1\%}$  values with more of them stacked-up at the limit. The 15 inner-layer glasses selected were judged to be the best compromise of property and composition distributions among the top several of the 60 subsets generated.

One additional aspect of Figure A.24 requires a brief discussion. One of the replicate glasses selected (HLW03-07) is seen in the figure to have a predicted spinel  $T_{1\%}$  value of

approximately 1150°C. The measured value originally was 1213°C. Values of spinel T<sub>1%</sub> this large raise questions about whether crystallinity in glass melts might be high enough to affect viscosity and EC measurements. This issue was considered in selecting replicate glasses. However, selecting at least one of the higher T<sub>1%</sub> glasses as a replicate was the only way to achieve the desired separation of glass compositions and properties. Also, when tested the first time HLW03-07 did not exhibit indications of crystallinity affecting viscosity and EC measurements, so it is considered a “safe” choice for a replicate.

Figure A.25 is a scatterplot matrix showing scatterplots for all pairs of the 14 main components plus Others1 and Others2. The Constant and Remaining components were not included in the scatterplot matrix for space reasons and because they do not show any more than can be seen in the single-component distribution plots in Figure A.24. The same plotting symbols and colors are used in Figure A.25 as described previously. Although the individual scatterplots in the scatterplot matrix are small, they are sufficient for judging how well the composition space is covered (in two-dimensional projections), whether there are outlying data, or whether there are strong pairwise correlations. The plots show good coverage of the composition space by the 125 existing plus 40 new HLW07 glasses. In some cases there are uncovered subregions in individual scatterplots. However, those generally correspond to edges of component ranges that are included in the least-restrictive component ranges (see Table 2.5) but were not included in the EGCR for the HLW07 study. Further, it should be kept in mind that all glasses with values of a given property will be used to develop models for that property. Hence, plots such as Figure A.25 with all glasses having values for each glass property would contain additional points that may improve the coverage of the HLW07 and least-restrictive composition regions.

In summary, Figures A.23 to A.25 show that the 125 existing plus 40 new HLW07 glasses provide good coverage of the HLW glass composition region defined by the least-restrictive constraints in Table 2.5. Hence, these glasses provide a good basis for developing property-composition models over the corresponding HLW glass composition region.

## **A.5 Quality Assurance**

The test matrices described in Sections A.3 and A.4 of this appendix were constructed to support the development of HLW property-composition models, as described in Section A.1 and the Test Plans (Gan and Pegg 2002, Piepel and Cooley 2003). The properties to be modeled included PCT releases. Because the data and PCT models will be waste glass quality-affecting, software control procedures that meet DOE/RW-0333P (QARD) requirements (U. S. DOE-RW 2004) were implemented at PNWD for the software used to generate the test matrices discussed in Sections A.3 and A.4. The test matrices were generated using commercially available software packages that have undergone appropriate verification and validation. This work did not involve software development; rather existing software packages were used as tools to develop the test matrices.

PNWD addressed internal verification and validation requirements by conducting an Independent Technical Review of this appendix (when it was a separate letter report in early 2006) in accordance with the PNWD procedure QA-RPP-WTP-604 applicable at the time. This

and Viscosity Model Development  
Final Report, VSL-07R1240-4, Rev. 0*

review verified that the reported results are traceable, that inferences and conclusions are soundly based, and the reported work satisfied the Test Plan objectives. This review procedure was part of PNWD's *WTPSP Quality Assurance Requirements and Description Manual*. See Section 12 of the report for a more general discussion of QA implementation.

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) The “Point Type” notation begins with an abbreviation of the HLW study phase (e.g., Ph1a denotes Phase 1a). After a separating dot, the notation continues (when appropriate) with “Center”, “OL”, or “IL”, denoting whether the glass was a center point, outer-layer point, or inner-layer point. The “Center”, “OL”, or “IL” designation is with respect to the given study phase. Next, “XX” denotes the number of each outer-layer, inner-layer, or other point with respect to the given study phase. Replicate points are denoted by “Rep.HLW02-xx” and “Rep.HLW03-xx”, where the “xx” represents a specific ID number for a replicated glass.
- (c) The wt% values in the table are rounded to three decimal places and may not sum to 100.000 exactly, but the sum is achieved in the data base.

**Table A.2. 18-Component Target Glass Compositions (wt%) for the 143 Existing Glasses Having Viscosity and Electrical Conductivity Data (continued).**

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) The “Point Type” notation begins with an abbreviation of the HLW study phase (e.g., Ph1a denotes Phase 1a). After a separating dot, the notation continues (when appropriate) with “Center”, “OL”, or “IL”, denoting whether the glass was a center point, outer-layer point, or inner-layer point. The “Center”, “OL”, or “IL” designation is with respect to the given study phase. Next, “XX” denotes the number of each outer-layer, inner-layer, or other point with respect to the given study phase. Replicate points are denoted by “Rep.HLW02-xx” and “Rep.HLW03-xx”, where the “xx” represents a specific ID number for a replicated glass.
- (c) The wt% values in the table are rounded to three decimal places and may not sum to 100.000 exactly, but the sum is achieved in the data base.

**Table A.2. 18-Component Target Glass Compositions (wt%) for the 143 Existing Glasses Having Viscosity and Electrical Conductivity Data (continued).**

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) The “Point Type” notation begins with an abbreviation of the HLW study phase (e.g., Ph1a denotes Phase 1a). After a separating dot, the notation continues (when appropriate) with “Center”, “OL”, or “IL”, denoting whether the glass was a center point, outer-layer point, or inner-layer point. The “Center”, “OL”, or “IL” designation is with respect to the given study phase. Next, “XX” denotes the number of each outer-layer, inner-layer, or other point with respect to the given study phase. Replicate points are denoted by “Rep.HLW02-xx” and “Rep.HLW03-xx”, where the “xx” represents a specific ID number for a replicated glass.
- (c) The wt% values in the table are rounded to three decimal places and may not sum to 100.000 exactly, but the sum is achieved in the data base.

**Table A.2. 18-Component Target Glass Compositions (wt%) for the 143 Existing Glasses Having Viscosity and Electrical Conductivity Data (continued).**

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) The “Point Type” notation begins with an abbreviation of the HLW study phase (e.g., Ph1a denotes Phase 1a). After a separating dot, the notation continues (when appropriate) with “Center”, “OL”, or “IL”, denoting whether the glass was a center point, outer-layer point, or inner-layer point. The “Center”, “OL”, or “IL” designation is with respect to the given study phase. Next, “XX” denotes the number of each outer-layer, inner-layer, or other point with respect to the given study phase. Replicate points are denoted by “Rep.HLW02-xx” and “Rep.HLW03-xx”, where the “xx” represents a specific ID number for a replicated glass.
- (c) The wt% values in the table are rounded to three decimal places and may not sum to 100.000 exactly, but the sum is achieved in the data base.

**Table A.2. 18-Component Target Glass Compositions (wt%) for the 143 Existing Glasses Having Viscosity and Electrical Conductivity Data (continued).**

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) The “Point Type” notation begins with an abbreviation of the HLW study phase (e.g., Ph1a denotes Phase 1a). After a separating dot, the notation continues (when appropriate) with “Center”, “OL”, or “IL”, denoting whether the glass was a center point, outer-layer point, or inner-layer point. The “Center”, “OL”, or “IL” designation is with respect to the given study phase. Next, “XX” denotes the number of each outer-layer, inner-layer, or other point with respect to the given study phase. Replicate points are denoted by “Rep.HLW02-xx” and “Rep.HLW03-xx”, where the “xx” represents a specific ID number for a replicated glass.
- (c) The wt% values in the table are rounded to three decimal places and may not sum to 100.000 exactly, but the sum is achieved in the data base.

**Table A.3. Composition Expansions of Others1, Others2, and Constant Components for the 143 Existing Glasses in Table A.2 Having Viscosity and Electrical Conductivity Data.**

| Glass ID <sup>(a)</sup> | Others1 Components (wt%) <sup>(b)</sup> |                               |                 | Others2 Components (wt%) <sup>(b)</sup> |       |       |       | Constant Components (wt%) <sup>(b)</sup> |                                |       |                   |       |                  |                                |                                |                   |                                |                  |                                |                  |                 |                               |       |

(a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.

(b) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.2, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

**Table A.3. Composition Expansions of Others1, Others2, and Constant Components for the 143 Existing Glasses in Table A.2 Having Viscosity and Electrical Conductivity Data (continued).**

| Glass ID <sup>(a)</sup> | Others1 Components (wt%) <sup>(b)</sup> |                               |                 | Others2 Components (wt%) <sup>(b)</sup> |       |       |       | Constant Components (wt%) <sup>(b)</sup> |                                |       |                   |       |                  |                                |                                |                   |                                |                  |                                |                  |                 |                               |       |

(a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.

(b) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.2, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

**Table A.3. Composition Expansions of Others1, Others2, and Constant Components for the 143 Existing Glasses in Table A.2 Having Viscosity and Electrical Conductivity Data (continued).**

| Glass ID <sup>(a)</sup> | Others1 Components (wt%) <sup>(b)</sup> |                               |                 | Others2 Components (wt%) <sup>(b)</sup> |       |       |       | Constant Components (wt%) <sup>(b)</sup> |                                |       |                   |       |                  |                                |                                |                   |                                |                  |                                |                  |                 |                               |       |

(a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.

(b) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.2, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

**Table A.3. Composition Expansions of Others1, Others2, and Constant Components for the 143 Existing Glasses in Table A.2 Having Viscosity and Electrical Conductivity Data (continued).**

| Glass ID <sup>(a)</sup> | Others1 Components (wt%) <sup>(b)</sup> |                               |                 | Others2 Components (wt%) <sup>(b)</sup> |       |       |       | Constant Components (wt%) <sup>(b)</sup> |                                |       |                   |       |                  |                                |                                |                   |                                |                  |                                |                  |                 |                               |

(a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.

(b) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.2, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

**Table A.3. Composition Expansions of Others1, Others2, and Constant Components for the 143 Existing Glasses in Table A.2 Having Viscosity and Electrical Conductivity Data (continued).**

| Glass ID <sup>(a)</sup> | Others1 Components (wt%) <sup>(b)</sup> |                               |                 | Others2 Components (wt%) <sup>(b)</sup> |       |       |       | Constant Components (wt%) <sup>(b)</sup> |                                |       |                   |       |                  |                                |                                |                   |                                |                  |                                |                  |                 |                               |

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.2, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

**Table A.4. Composition Expansions of Remaining Components for the 143 Existing Glasses in Table A.2 Having Viscosity and Electrical Conductivity Data.**

| Glass ID <sup>(a)</sup> | Remaining Components (wt%) <sup>(b)</sup> |                                |       |                                |       |                                |       |                  |                  |                  |                   |                               |

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) For each glass, the sum of the wt% values for the components comprising Remaining equals the wt% value listed in the Remaining column of Table A.2, except for any differences resulting from rounding wt% values to three decimal places.

**Table A.4. Composition Expansions of Remaining Components for the 143 Existing Glasses in Table A.2 Having Viscosity and Electrical Conductivity Data (continued).**

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) For each glass, the sum of the wt% values for the components comprising Remaining equals the wt% value listed in the Remaining column of Table A.2, except for any differences resulting from rounding wt% values to three decimal places.

**Table A.4. Composition Expansions of Remaining Components for the 143 Existing Glasses in Table A.2 Having Viscosity and Electrical Conductivity Data (continued).**

| Glass ID <sup>(a)</sup> | Remaining Components (wt%) <sup>(b)</sup> |                                |       |                                |       |                                |       |                  |                  |                  |                   |                               |

(a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.

(b) For each glass, the sum of the wt% values for the components comprising Remaining equals the wt% value listed in the Remaining column of Table A.2, except for any differences resulting from rounding wt% values to three decimal places.

**Table A.4. Composition Expansions of Remaining Components for the 143 Existing Glasses in Table A.2 Having Viscosity and Electrical Conductivity Data (continued).**

| Glass ID <sup>(a)</sup> | Remaining Components (wt%) <sup>(b)</sup> |                                |       |                                |       |                                |       |                  |                  |                  |                   |                               |

(a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.

(b) For each glass, the sum of the wt% values for the components comprising Remaining equals the wt% value listed in the Remaining column of Table A.2, except for any differences resulting from rounding wt% values to three decimal places.

**Table A.4. Composition Expansions of Remaining Components for the 143 Existing Glasses in Table A.2 Having Viscosity and Electrical Conductivity Data (continued).**

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) For each glass, the sum of the wt% values for the components comprising Remaining equals the wt% value listed in the Remaining column of Table A.2, except for any differences resulting from rounding wt% values to three decimal places.

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) The “Point Type” notation begins with an abbreviation of the HLW study phase (e.g., Ph1a denotes Phase 1a). After a separating dot, the notation continues (when appropriate) with “Center”, “OL”, or “IL”, denoting whether the glass was a center point, outer-layer point, or inner-layer point. The “Center”, “OL”, or “IL” designation is with respect to the given study phase. Next, “XX” denotes the number of each outer-layer, inner-layer, or other point with respect to the given study phase. Replicate points are denoted by “Rep.HLW02-xx” and “Rep.HLW03-xx”, where the “xx” represents a specific ID number for a replicated glass.
- (c) The wt% values in the table are rounded to three decimal places and may not sum to 100.000 exactly, but the sum is achieved in the data base.

**Table A.6. Composition Expansions of Others1, Others2, and Constant Components for the Ten HLW05 and HLW06 Glasses in Table A.5 Selected to Have Viscosity and Electrical Conductivity Data Collected.**

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.5, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) For each glass, the sum of the wt% values for the components comprising Remaining equals the wt% value listed in the Remaining column of Table A.5, except for any differences resulting from rounding wt% values to three decimal places.

**Table A.8. Observations on Distributions of Property Values for HLW Glasses in Studies HLW02, HLW03, HLW05, and HLW06.**

| <b>Property</b>                                           | <b>Distribution Peak, (Range)</b>             | <b>Data Deficient Location</b> | <b>Data Useful for Better Coverage of Property Values</b> |
|-----------------------------------------------------------|-----------------------------------------------|--------------------------------|-----------------------------------------------------------|
| $T_{1\%}$ of Spinel (HLW02, HLW03, HLW05, HLW06)          | ~950°C, (650-1300°C)                          | None apparent                  | Not specific                                              |
| $T_{1\%}$ of Zr-, Th-related (HLW02, HLW03, HLW05, HLW06) | Data scattered (750 – 1500°C)                 | Around 950°C                   | Additional data around 850, 950 and 1000°C                |
| Viscosity (HLW02, HLW03)                                  | ~10 to 20 most concentrated, (10 – 190 poise) | Around 50 to 80 poise          | Additional data around 50, 60, 70, 80 poise               |
| Electrical conductivity (HLW02, HLW03)                    | ~0.3, (0.1 to 0.8 S/cm)                       | Around 0.4 to 0.55 S/cm        | Additional data around 0.4 and 0.5 S/cm                   |
| PCT-B (g/L) (HLW02, HLW03, HLW06)                         | ~0.5, (0.02 – 4.5, two around 12)             | 5 to 16.7 g/L                  | Additional data around 5 to 11 g/L                        |

**Table A.9. Components and Their Lower and Upper Bounds Defining the Inner and Outer Layers of the EGCR for the HLW07 Study.**

| Component                      | Inner Layer       |                   | Outer Layer       |                   | Existing Glasses <sup>(a)</sup> |                     |
|--------------------------------|-------------------|-------------------|-------------------|-------------------|---------------------------------|---------------------|
|                                | Lower Limit (wt%) | Upper Limit (wt%) | Lower Limit (wt%) | Upper Limit (wt%) | Minimum (wt%)                   | Maximum (wt%)       |
| Al <sub>2</sub> O <sub>3</sub> | 5                 | 10                | 3                 | 11.5              | 1.88                            | 13                  |
| B <sub>2</sub> O <sub>3</sub>  | 8                 | 11                | 6                 | 13                | 4.3                             | 15                  |
| Cr <sub>2</sub> O <sub>3</sub> | 0.15              | 0.4               | 0.05              | 0.6               | 0                               | 0.6                 |
| Fe <sub>2</sub> O <sub>3</sub> | 6                 | 11                | 4                 | 14                | 1.4                             | 15                  |
| Li <sub>2</sub> O              | 1                 | 3.5               | 0                 | 4.5               | 0                               | 6.01                |

| Others1                        | 0                 | 1.36              | 0                 | 1.36              | 0.40 <sup>(b)</sup>             | 0.78 <sup>(b)</sup> |
| Others2                        | 0                 | 1.24              | 0                 | 2.48              | 0.00 <sup>(b)</sup>             | 2.56 <sup>(b)</sup> |
| Constant                       | 1.74              | 1.74              | 3.48              | 3.48              | 0.82 <sup>(b)</sup>             | 4.69 <sup>(b)</sup> |

- (a) The existing glasses in this case refer to all 167 glasses from the HLW02, HLW03, HLW05 and HLW06 studies.
- (b) The minimum and maximum values listed are for Others1, Others2, and Constant, which are defined for the existing glasses in the same way they are defined for the HLW07 glasses in Tables A.10, A.11, and A.12, respectively.

**Table A.10. Definition of “Others1” Component for the HLW07 Study.**

| Oxide                         | Composition (wt%) | Maximum in Glass (wt%) | Basis for Maximum in Glass       |
|-------------------------------|-------------------|------------------------|----------------------------------|
| MoO <sub>3</sub>              | 28.68             | 0.39                   | S8.1 <sup>(a)</sup>              |
| P <sub>2</sub> O <sub>5</sub> | 47.06             | 0.64                   | G2 & actual waste <sup>(b)</sup> |
| SO <sub>3</sub>               | 24.26             | 0.33                   | G2 & actual waste                |
| Sum                           | 100.00            | 1.36                   | (c)                              |

- (a) S8.1 refers to Specification 8.1 in Section C of the WTP Contract (DOE-ORP 2003).
- (b) “G2 and actual waste” refers to calculations made with the WTP dynamic simulation flowsheet (G2) for actual waste compositions.
- (c) Not applicable.

**Table A.11. Definition of “Others2” Component for the HLW07 Study.**

| Oxide | Composition (wt%) | Maximum in Glass (wt%) | Basis for Maximum in Glass               |
|-------|-------------------|------------------------|------------------------------------------|
| CdO   | 40.32             | 1                      | Max (1.39) hit previously <sup>(a)</sup> |
| CoO   | 9.27              | 0.23                   | S8.1 <sup>(b)</sup>                      |
| CuO   | 9.68              | 0.24                   | S8.1                                     |
| PbO   | 40.73             | 1.01                   | G2 & actual waste <sup>(c)</sup>         |
| Sum   | 100.00            | 2.48                   | (d)                                      |

- (a) The maximum value of interest was achieved in a previous WTP HLW study.
- (b) S8.1 refers to Specification 8.1 in Section C of the WTP Contract (DOE-ORP 2003).
- (c) “G2 and actual waste” refers to calculations made with the WTP dynamic simulation flowsheet (G2) for actual waste compositions.
- (d) Not applicable.

**Table A.12. Definition of “Constant” Component for the HLW07 Study.**

| Oxide                          | Intended Composition (wt%) | Intended Maximum in Glass on Outer Layer (wt%) | Actual <sup>(d)</sup> Composition (wt%) | Actual <sup>(d)</sup> Maximum in Glass on Outer Layer (wt%) | Basis for Maximum in Glass               |
|--------------------------------|----------------------------|------------------------------------------------|-----------------------------------------|-------------------------------------------------------------|------------------------------------------|
| CaO                            | 8.62                       | 0.3                                            | 8.65                                    | 0.3                                                         | max (0.8) hit previously <sup>(a)</sup>  |

- (a) The maximum value of interest was achieved in a previous WTP HLW study.
- (b) S8.1 refers to Specification 8.1 in Section C of the WTP Contract (DOE-ORP 2003).
- (c) “G2 and actual waste” refers to calculations made with the WTP dynamic simulation flowsheet (G2) for actual waste compositions.
- (d) Ta<sub>2</sub>O<sub>5</sub> was inadvertently omitted from the compositions of the test matrix glasses, and thus was not included when the glasses were batched and melted.
- (e) Not applicable.

**Table A.13. Glass Components Excluded from the HLW07 Study.**

| Oxide                          | Composition (wt %) | Basis for Exclusion <sup>(a)</sup>      |

| TiO <sub>2</sub>               | 0                  | max (0.15) hit previously               |
| Tl <sub>2</sub> O              | 0                  | max (0.19) hit previously               |
| V <sub>2</sub> O <sub>5</sub>  | 0                  | max (0.03) hit previously               |

(a) The maximum value of interest for each component was achieved or approached in a previous WTP HLW study.

**Table A.14. Property Constraints Used to Define Both the Outer and Inner Layers of the EGCR for the HLW07 Study.**

| Property                                                | Property-Composition Model               | Units | Lower Limit       | Upper Limit        |
|---------------------------------------------------------|------------------------------------------|-------|-------------------|--------------------|
| Spinel $T_{1\%}$ ( $T_{1\%}$ )                          | Model in Table 6.8 of Kot et al. (2005a) | °C    | None              | 1000°C             |
| Viscosity at 1150°C ( $\eta_{1150}$ )                   | Model 16 in Table 8 of Gan et al. (2004) | poise | 10 <sup>(a)</sup> | 100                |
| Electrical Conductivity at 1150°C ( $\epsilon_{1150}$ ) | Model 5 in Table 10 of Gan et al. (2004) | S/cm  | 0.2               | 0.7 <sup>(b)</sup> |

- (a) On the inner layer of the HLW07 EGCR, this lower limit on viscosity could not be achieved. The minimum model-predicted viscosity value over all vertices of the inner layer was 13.34 poise.
- (b) On the inner layer of the HLW07 EGCR, this upper limit on electrical conductivity could not be achieved. The maximum model-predicted electrical conductivity value over all vertices of the inner layer was 0.463 S/cm.

**Table A.15. Property-Composition Models Used to Implement the Property Constraints in Table A.12 for the HLW07 Study.**

| Property Modeled Property Units |                    |                                                |             |                                               |                    |

- (a) The spinel T<sub>1%</sub> model is a reduced linear mixture model in which the components are expressed in normalized mass fraction values. The normalized mass fractions of the components for a given glass are obtained by dividing the original mass fractions of the components by the sum of the mass fractions of components in the model. This model is from Table 6.8 in Kot et al. (2005a).
- (b) The ln( $\eta_{1150}$ ) model has a nonmixture-temperature form in which the components are expressed in original (unnormalized) wt% values. This model is from Gan et al. (2004)
- (c) The ln( $\epsilon_{1150}$ ) model has a mixture-temperature form in which the components are expressed in original (unnormalized) wt% values. This model is from Gan et al. (2004)
- (d) N/A = not applicable, because a mixture-temperature model form was used.

**Table A.16. Multi-Component Constraints Used in Defining the Outer and Inner Layers of the EGCR for the HLW07 Test Matrix.<sup>(a)</sup>**

| HLW07 Component         | Property           | Waste Loading    | $T_{1\%}$                | $\eta_{1150}$             | $\epsilon_{1150}$            |

- (a) The multi-component constraints listed in this table are expressed using mass fractions of the HLW glass components. In cases where these constraints were previously expressed using wt% values, the appropriate conversions were made.
- (b) Constraints implemented from the inputs in Tables A.14 and A.15 were re-expressed and normalized by dividing all constraint coefficients by the largest (in absolute value) constraint. This process resulted in equivalent constraints with the largest (in absolute value) coefficient being one. See Section A.4.6 for detailed discussion. Also, note that the large number of decimal places in coefficients of the constraints is to maintain the equivalency between the constraints before and after the re-expression and normalization.
- (c) A “–” indicates that the component was not involved in the constraint (i.e., the component’s coefficient in the constraint is zero).

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) The “Point Type” notation begins with an abbreviation of the HLW study phase (e.g., Ph1a denotes Phase 1a). After a separating dot, the notation continues (when appropriate) with “Center”, “OL”, or “IL”, denoting whether the glass was a center point, outer-layer point, or inner-layer point. The “Center”, “OL”, or “IL” designation is with respect to the given study phase. Next, “XX” denotes the number of each outer-layer, inner-layer, or other point with respect to the given study phase. Replicate points are denoted by “Rep.HLW02-xx” and “Rep.HLW03-xx”, where the “xx” represents a specific ID number for a replicated glass.
- (c) The wt% values in the table are rounded to three decimal places and may not sum to 100.000 exactly, but the sum is achieved in the data base.

**Table A.17. 18-Component Target Glass Compositions (wt%) for the 125 Existing HLW Glasses Augmented by the HLW07 Test Matrix (continued).**

| Glass ID <sup>(a)</sup> | Point Type <sup>(b)</sup> | Al <sub>2</sub> O <sub>3</sub> | B <sub>2</sub> O <sub>3</sub> | Cr <sub>2</sub> O <sub>3</sub> | Fe <sub>2</sub> O <sub>3</sub> | Li <sub>2</sub> O | MnO   | Na <sub>2</sub> O | NiO   | SiO <sub>2</sub> | SrO   | ThO <sub>2</sub> | UO <sub>3</sub> | ZnO   | ZrO <sub>2</sub> | Others1 | Others2 | Constant | Remain | Sum <sup>(c)</sup> |

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) The “Point Type” notation begins with an abbreviation of the HLW study phase (e.g., Ph1a denotes Phase 1a). After a separating dot, the notation continues (when appropriate) with “Center”, “OL”, or “IL”, denoting whether the glass was a center point, outer-layer point, or inner-layer point. The “Center”, “OL”, or “IL” designation is with respect to the given study phase. Next, “XX” denotes the number of each outer-layer, inner-layer, or other point with respect to the given study phase. Replicate points are denoted by “Rep.HLW02-xx” and “Rep.HLW03-xx”, where the “xx” represents a specific ID number for a replicated glass.
- (c) The wt% values in the table are rounded to three decimal places and may not sum to 100.000 exactly, but the sum is achieved in the data base.

**Table A.17. 18-Component Target Glass Compositions (wt%) for the 125 Existing HLW Glasses Augmented by the HLW07 Test Matrix (continued).**

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) The “Point Type” notation begins with an abbreviation of the HLW study phase (e.g., Ph1a denotes Phase 1a). After a separating dot, the notation continues (when appropriate) with “Center”, “OL”, or “IL”, denoting whether the glass was a center point, outer-layer point, or inner-layer point. The “Center”, “OL”, or “IL” designation is with respect to the given study phase. Next, “XX” denotes the number of each outer-layer, inner-layer, or other point with respect to the given study phase. Replicate points are denoted by “Rep.HLW02-xx” and “Rep.HLW03-xx”, where the “xx” represents a specific ID number for a replicated glass.
- (c) The wt% values in the table are rounded to three decimal places and may not sum to 100.000 exactly, but the sum is achieved in the data base.

**Table A.17. 18-Component Target Glass Compositions (wt%) for the 125 Existing HLW Glasses Augmented by the HLW07 Test Matrix (continued).**

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) The “Point Type” notation begins with an abbreviation of the HLW study phase (e.g., Ph1a denotes Phase 1a). After a separating dot, the notation continues (when appropriate) with “Center”, “OL”, or “IL”, denoting whether the glass was a center point, outer-layer point, or inner-layer point. The “Center”, “OL”, or “IL” designation is with respect to the given study phase. Next, “XX” denotes the number of each outer-layer, inner-layer, or other point with respect to the given study phase. Replicate points are denoted by “Rep.HLW02-xx” and “Rep.HLW03-xx”, where the “xx” represents a specific ID number for a replicated glass.
- (c) The wt% values in the table are rounded to three decimal places and may not sum to 100.000 exactly, but the sum is achieved in the data base.

**Table A.18. Composition Expansions of Others1, Others2, and Constant Components for the 125 Existing HLW Glasses in Table A.17.**

| Glass ID <sup>(a)</sup> | Others1 Components<br>(wt%) <sup>(b)</sup> |                               |                 | Others2 Components<br>(wt%) <sup>(b)</sup> |       |       |       | Constant Components<br>(wt%) <sup>(b)</sup> |                                |       |                   |       |                  |                                |                                |                   |                                |                  |                                |                  |                                |                 |                               |       |

(a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.

(b) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.17, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

**Table A.18. Composition Expansions of Others1, Others2, and Constant Components for the 125 Existing HLW Glasses in Table A.17 (continued).**

| Glass ID <sup>(a)</sup> | Others1 Components<br>(wt%) <sup>(b)</sup> |                               |                 | Others2 Components<br>(wt%) <sup>(b)</sup> |       |       |       | Constant Components<br>(wt%) <sup>(b)</sup> |                                |       |                   |       |                  |                                |                                |                   |                                |                  |                                |                  |                                |                 |                               |       |

(a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.

(b) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.17, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

**Table A.18. Composition Expansions of Others1, Others2, and Constant Components for the 125 Existing HLW Glasses in Table A.17 (continued).**

| Glass ID <sup>(a)</sup> | Others1 Components<br>(wt%) <sup>(b)</sup> |                               |                 | Others2 Components<br>(wt%) <sup>(b)</sup> |       |       |       | Constant Components<br>(wt%) <sup>(b)</sup> |                                |       |                   |       |                  |                                |                                |                   |                                |                  |                                |                  |                                |                 |                               |       |

(a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.

(b) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.17, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

**Table A.18. Composition Expansions of Others1, Others2, and Constant Components for the 125 Existing HLW Glasses in Table A.17 (continued).**

| Glass ID <sup>(a)</sup> | Others1 Components<br>(wt%) <sup>(b)</sup> |                               |                 | Others2 Components<br>(wt%) <sup>(b)</sup> |       |       |       | Constant Components<br>(wt%) <sup>(b)</sup> |                                |       |                   |       |                  |                                |                                |                   |                                |                  |                                |                  |                                |                 |                               |       |

(a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.

(b) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.17, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

**Table A.19. Composition Expansions of Remaining Components for the 125 Existing HLW Glasses in Table A.17.**

| Glass ID <sup>(a)</sup> | Remaining Components (wt%) <sup>(b)</sup> |                                |       |                                |       |                                |       |                  |                  |                  |                   |                               |

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) For each glass, the sum of the wt% values for the components comprising Remaining equals the wt% value listed in the Remaining column of Table A.17, except for any differences resulting from rounding wt% values to three decimal places.

**Table A.19. Composition Expansions of Remaining Components for the 125 Existing HLW Glasses in Table A.17 (continued).**

| Glass ID <sup>(a)</sup> | Remaining Components (wt%) <sup>(b)</sup> |                                |       |                                |       |                                |       |                  |                  |                  |                   |                               |

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) For each glass, the sum of the wt% values for the components comprising Remaining equals the wt% value listed in the Remaining column of Table A.17, except for any differences resulting from rounding wt% values to three decimal places.

**Table A.19. Composition Expansions of Remaining Components for the 125 Existing HLW Glasses in Table A.17 (continued).**

| Glass ID <sup>(a)</sup> | Remaining Components (wt%) <sup>(b)</sup> |                                |       |                                |       |                                |       |                  |                  |                  |                   |                               |

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) For each glass, the sum of the wt% values for the components comprising Remaining equals the wt% value listed in the Remaining column of Table A.17, except for any differences resulting from rounding wt% values to three decimal places.

**Table A.19. Composition Expansions of Remaining Components for the 125 Existing HLW Glasses in Table A.17 (continued).**

- (a) R1 after a Glass ID indicates the glass batching, melting, and testing was repeated.
- (b) For each glass, the sum of the wt% values for the components comprising Remaining equals the wt% value listed in the Remaining column of Table A.17, except for any differences resulting from rounding wt% values to three decimal places.

**Table A.20. 18-Component Target Glass Compositions (wt%) for the 40-Glass HLW07 Test Matrix.**

- (a) The “Point Type” notation begins with Ph2 to denote HLW Phase 2. After a separating dot, “Center”, “OL”, or “IL”, denotes whether the glass was a center point, outer-layer point, or inner-layer point. Next, “XX” denotes the number of each outer-layer, inner-layer, or other point with respect to the given study phase. Replicate points are denoted by “Rep.HLW02-xx” and “Rep.HLW03-xx”, where the “xx” represents a specific ID number for a replicated glass.
- (b) The wt% values in the table are rounded to three decimal places and may not sum to 100.000 exactly, but the sum is achieved in the data base.

**Table A.20. 18-Component Target Glass Compositions (wt%) for the 40-Glass HLW07 Test Matrix (continued).**

| Glass ID | Point Type <sup>(a)</sup> | Al <sub>2</sub> O <sub>3</sub> | B <sub>2</sub> O <sub>3</sub> | Cr <sub>2</sub> O <sub>3</sub> | Fe <sub>2</sub> O <sub>3</sub> | Li <sub>2</sub> O | MnO   | Na <sub>2</sub> O | NiO   | SiO <sub>2</sub> | SrO   | ThO <sub>2</sub> | UO <sub>3</sub> | ZnO   | ZrO <sub>2</sub> | Others1 | Others2 | Constant | Remain | Sum <sup>(b)</sup> |

(a) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.20, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

**Table A.21. Composition Expansions of Others1, Others2, and Constant Components for the HLW07 Test Matrix in Table A.20 (continued).**

(a) For each glass, the sum of the wt% values for the components comprising Others1, Others2, and Constant equal the wt% values listed in the Others1, Others2, and Constant columns of Table A.20, except for any differences resulting from rounding wt% values to three decimal places. The equalities are exact to the additional decimal places contained in the data base.

**Table A.22. Composition Expansions of Remaining Components for the HLW07 Test Matrix in Table A.20.**

(a) For each glass, the sum of the wt% values for the components comprising Remaining equals the wt% value listed in the Remaining column of Table A.20, except for any differences resulting from rounding wt% values to three decimal places.

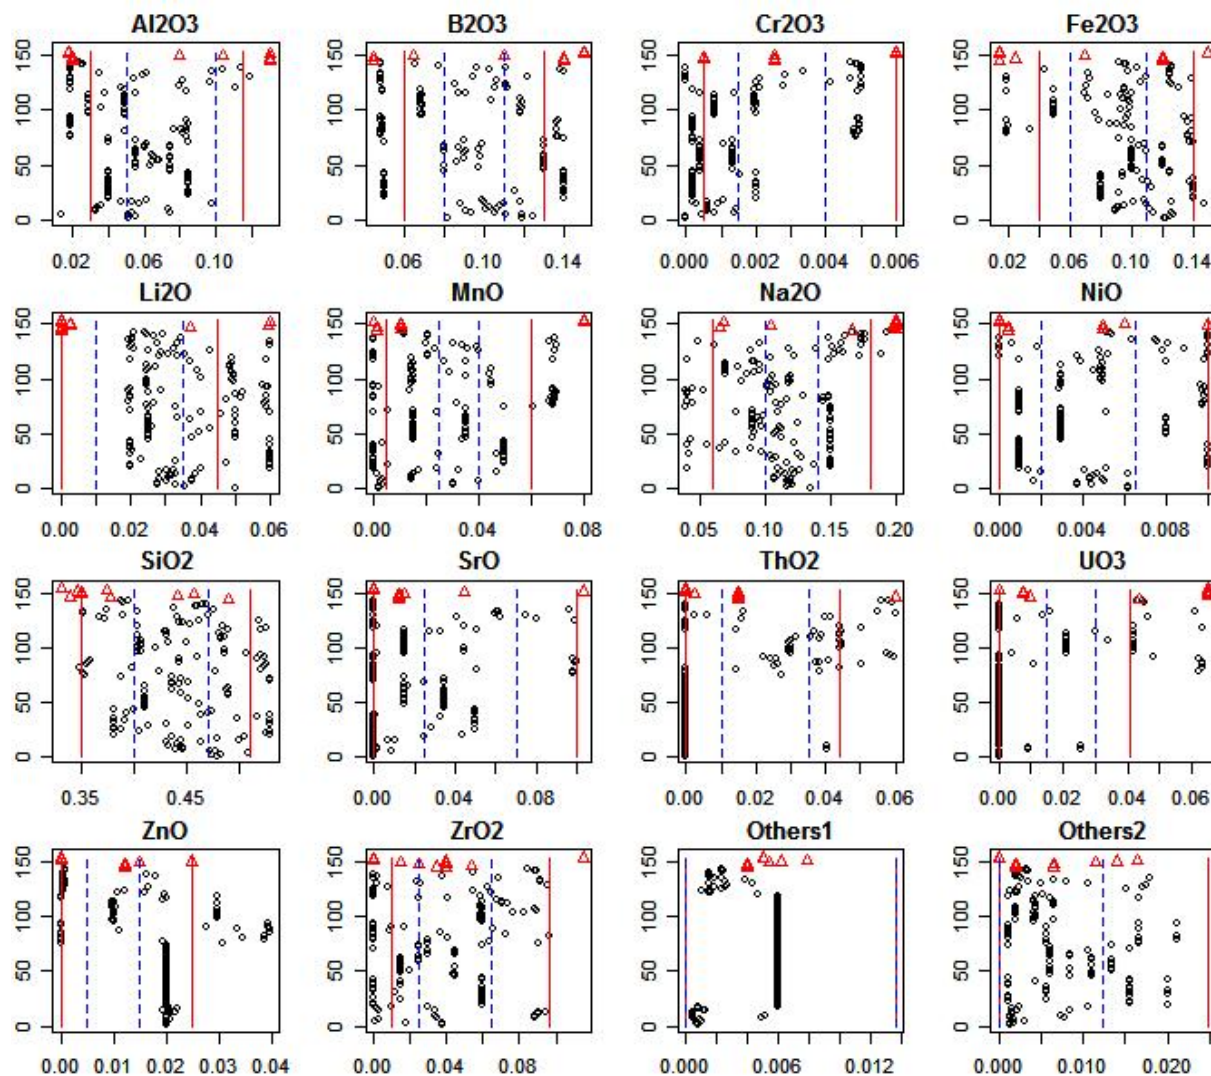

**Table A.22. Composition Expansions of Remaining Components for the HLW07 Test Matrix in Table A.20 (continued).**

## **APPENDIX B**

### **Compositions and PCT Release Data for HLW Glasses Used to Validate PCT Models**

## APPENDIX B

### Compositions and PCT Release Data for HLW Glasses Used to Validate PCT Models

This appendix contains the compositions and corresponding PCT release data for 554 glasses used to validate the Immobilized High Level Waste (IHLW) PCT property-composition models considered in this report. The 554 validation glasses are a subset of 574 glasses described and presented in the report (and appendix) by Vienna et al. (2002). That report actually contains data for 576 glasses. However, two of the glasses (WVDG-40 and WVDG-46) were listed twice in the summary tables. Hence, there are data for 574 unique glasses in the Vienna et al. (2002) report. Of the 574 glasses, 20 glasses (designated HLW98 glasses) were included in the PCT modeling dataset of 266 glasses (see Section 5.1.1). This left 554 of the 574 glasses available for validating the PCT models developed in this report. However, 75 of these glasses did not contain  $\text{Li}_2\text{O}$ , and thus did not have PCT-Lithium (PCT-Li) releases. Thus, out of 574 glasses in Vienna et al. (2002), there were 554 glasses that could be used to validate PCT-Boron (PCT-B) and PCT-Sodium (PCT-Na) models, and  $554 - 75 = 479$  glasses that could be used to validate PCT-Li models.

In addition, glasses initially included in the 266-glass PCT modeling dataset but eventually excluded as outliers based on initial modeling work (see Section 5.1.1) were also used as validation data. Specifically, two glasses (HLW03-13 and HLW-ALG-26) with very low PCT-B releases were excluded from the PCT-B modeling dataset, but were included in the PCT-B validation dataset. Thus, there were  $554 + 2 = 556$  glasses in the final PCT-B validation dataset. Also, one glass (HLW98-94) with very low PCT-Li release was excluded from the PCT-Li modeling dataset. Thus, there were  $479 + 1 = 480$  glasses in the final PCT-Li validation dataset. Initial modeling work for PCT-Na did not identify any outliers to exclude from the PCT-Na modeling dataset, so there were 554 glasses in the final PCT-Na validation dataset.

Compositions for the three glasses originally in the PCT model development dataset but moved to the model validation sets (HLW03-13, HLW-ALG-26, and HLW98-94) are given in Table 5.2. PCT release data for these three glasses are given in Table 5.3.

Table B.1 gives the compositions of the 554 validation glasses previously described. The compositions are given in mass fractions, normalized to sum to 1.0 over the 25 components identified in Section 5.1.1 as having sufficient data in the modeling dataset to support separate model terms. These components are  $\text{Al}_2\text{O}_3$ ,  $\text{B}_2\text{O}_3$ ,  $\text{CaO}$ ,  $\text{CdO}$ ,  $\text{Cr}_2\text{O}_3$ ,  $\text{Fe}_2\text{O}_3$ ,  $\text{K}_2\text{O}$ ,  $\text{La}_2\text{O}_3$ ,  $\text{Li}_2\text{O}$ ,  $\text{MgO}$ ,  $\text{MnO}$ ,  $\text{Na}_2\text{O}$ ,  $\text{NiO}$ ,  $\text{PbO}$ ,  $\text{Sb}_2\text{O}_3$ ,  $\text{SeO}_2$ ,  $\text{SiO}_2$ ,  $\text{SrO}$ ,  $\text{ThO}_2$ ,  $\text{TiO}_2$ ,  $\text{Tl}_2\text{O}$ ,  $\text{UO}_3$ ,  $\text{ZnO}$ ,  $\text{ZrO}_2$ , and Others (the sum of the remaining components). The compositions for these glasses presented in the report by Vienna et al. (2002) were given in terms of 66 components. In cases where Vienna et al. (2002) listed glass compositions in original (old) oxide forms, the compositions were converted to the revised (new) oxide forms (see Table 2.10 in this report). In cases where the sum of the wt% values of the 25 components was not exactly 100 wt%, the compositions were normalized to sum to 100 wt%. Because the property models for HLW glasses were developed using mass fractions of components, the validation compositions were converted to mass fractions that sum to 1 for each glass.

Table B.2 contains PCT data on the elemental releases of boron (PCT-B), lithium (PCT-Li), and sodium (PCT-Na) for the 554 validation glasses. PCT releases are given in unnormalized units of ppm and in normalized units of g/L. The normalized releases are based on HLW glass compositions expressed in the revised (new) oxides given in Table 2.10. Thus, the normalized releases may differ slightly from those listed in older reports that had been normalized based on glass compositions expressed in the original (old) oxides. Table B.2 contains columns that identify which of the 554 separate validation glasses were ultimately used for validation of PCT-B, PCT-Li, and PCT-Na models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation.**

| Glass ID  | Al <sub>2</sub> O <sub>3</sub> | B <sub>2</sub> O <sub>3</sub> | CaO     | CdO     | Cr <sub>2</sub> O <sub>3</sub> | Fe <sub>2</sub> O <sub>3</sub> | K <sub>2</sub> O | La <sub>2</sub> O <sub>3</sub> | Li <sub>2</sub> O | MgO     | MnO     | Na <sub>2</sub> O | NiO     | PbO     | Sb <sub>2</sub> O <sub>3</sub> |
|-----------|--------------------------------|-------------------------------|---------|---------|--------------------------------|--------------------------------|------------------|--------------------------------|-------------------|---------|---------|-------------------|---------|---------|--------------------------------|

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.1. Normalized 25-Component Compositions (mass fractions) of 554 HLW Glasses Used for PCT Model Validation (continued).**

(a) The component mass fractions are normalized to sum to one over the 25 components listed in this table. The normalized component mass fractions listed in this table were rounded to five decimals, and may not sum exactly to 1.00000 as listed. However, complete compositions listed to more decimal places and summing to 1.0000 were used for validating PCT-composition models.

**Table B.2. PCT Release Data for 554 Validation Glasses.**

| Glass      | PCT-B (ppm) | PCT-Li (ppm)     | PCT-Na (ppm) | PCT-B (g/L) | PCT-Li (g/L) | PCT-Na (g/L) | In Validation Set for Which PCT Releases |

(a) NA indicates the data are not available. The dash “-” indicates the glass did not contain Li<sub>2</sub>O and thus no PCT-Li release was recorded.

**Table B.2. PCT Release Data for 554 Validation Glasses (continued).**

| Glass ID           | PCT-B (ppm)       | PCT-Li (ppm) | PCT-Na (ppm) | PCT-B (g/L) | PCT-Li (g/L) | PCT-Na (g/L) | In Validation Set for Which PCT Releases |

(a) NA indicates the data are not available. The dash “-” indicates the glass did not contain Li<sub>2</sub>O and thus no PCT-Li release was recorded.

**Table B.2. PCT Release Data for 554 Validation Glasses (continued).**

| Glass ID            | PCT-B (ppm)       | PCT-Li (ppm) | PCT-Na (ppm) | PCT-B (g/L) | PCT-Li (g/L) | PCT-Na (g/L) | In Validation Set for Which PCT Releases |

(a) NA indicates the data are not available. The dash “–” indicates the glass did not contain Li<sub>2</sub>O and thus no PCT-Li release was recorded.

**Table B.2. PCT Release Data for 554 Validation Glasses (continued).**

| Glass ID | PCT-B (ppm)       | PCT-Li (ppm) | PCT-Na (ppm) | PCT-B (g/L) | PCT-Li (g/L) | PCT-Na (g/L) | In Validation Set for Which PCT Releases |
|----------|-------------------|--------------|--------------|-------------|--------------|--------------|------------------------------------------|

(a) NA indicates the data are not available. The dash “–” indicates the glass did not contain Li<sub>2</sub>O and thus no PCT-Li release was recorded..

## **Appendix C**

### **Statistical Methods Used to Develop, Evaluate, and Validate Property-Composition Models**

## Appendix C

### Statistical Methods Used to Develop, Evaluate, and Validate Property-Composition Models

This appendix presents various statistical methods used for developing, evaluating, and validating waste glass property-composition models. Section C.1 discusses mixture experiments, introduces two general forms of mixture experiment models, and two variants of one of the model forms appropriate for assessing the presence of “block effects”. Section C.2 discusses mixture-temperature model forms appropriate for glass properties such as viscosity and electrical conductivity (EC) that depend on temperature as well as composition. Section C.3 discusses the least squares regression methods used to fit models to data and corresponding assumptions. Section C.4 discusses the statistical methods and summary statistics used for model evaluation based on the data used to fit a model. Section C.5 discusses statistical methods for model augmentation (i.e., adding terms to a model) and model reduction (i.e., removing unneeded terms from a model). Section C.6 discusses the statistical methods and summary statistics used for model validation based on data not used to fit a model. Section C.7 discusses several statistical intervals used to quantify uncertainties in model predictions.

#### C.1 Mixture Experiments, Model Forms, and Assessing Block Effects

A *mixture experiment* involves mixing two or more components in various proportions, and then measuring one or more response variables for the resulting end-product mixtures. If the proportions of  $q$  mixture components are denoted  $x_i$ ,  $i = 1, 2, \dots, q$ , then these proportions are subject to the basic mixture constraints

$$0 \leq x_i \leq 1 \quad \text{and} \quad \sum_{i=1}^q x_i = 1. \quad (\text{C.1})$$

Often in practice, the component proportions will be subject to additional single-component constraints

$$0 \leq L_i \leq x_i \leq U_i \leq 1 \quad (\text{C.2})$$

and/or multiple-component constraints that can be written in the general form

$$\sum_{i=1}^q A_{ki} x_i + A_{k0} \geq 0, \quad k = 1, 2, \dots, K. \quad (\text{C.3})$$

In Equation (C.2)  $L_i$  and  $U_i$  denote, respectively, the lower and upper constraints on the  $i^{\text{th}}$  component ( $i = 1, 2, \dots, q$ ). In Equation (C.3), the  $A_{ki}$  ( $i = 1, 2, \dots, q$ ) and  $A_{k0}$  denote the coefficients of the  $k^{\text{th}}$  multiple-component constraint. Cornell (2002) provides a comprehensive

discussion of statistical methods for the design, modeling, and data analysis of mixture experiments.

Section C.1.1 introduces the linear mixture (LM) model, partial quadratic mixture (PQM) model, and partial cubic mixture (PCM) model forms for mixture experiment data. Section C.1.2 discusses two variations of the LM model that can be used to assess modeling data collected in two or more blocks (e.g., at different times or under different conditions) for “block effects”.

### C.1.1 Linear, Partial Quadratic, and Partial Cubic Mixture Model Forms

The LM model form is given by

$$f(y) = \sum_{i=1}^q b_i x_i + E, \tag{C.4}$$

the PQM model form is given by

$$f(y) = \sum_{i=1}^q b_i x_i + \text{Selected} \left\{ \sum_{i=1}^q b_{ii} x_i^2 + \sum_{i < j}^{q-1} b_{ij} x_i x_j \right\} + E, \tag{C.5}$$

and the PCM model form is given by

$$f(y) = \sum_{i=1}^q b_i x_i + \text{Selected} \left\{ \begin{aligned} & \sum_{i=1}^q b_{ii} x_i^2 + \sum_{i=1}^{q-1} \sum_{j=i+1}^q b_{ij} x_i x_j + \sum_{i=1}^q b_{iii} x_i^3 \\ & + \sum_{i=1}^{q-1} \sum_{j=i+1}^q b_{ijj} x_i^2 x_j + \sum_{i=1}^{q-2} \sum_{j=i+1}^{q-1} \sum_{k=j+1}^q b_{ijk} x_i x_j x_k \end{aligned} \right\} + E \tag{C.6}$$

In Equations (C.4) to (C.6),  $y$  is a property or response variable that can be measured for each end-product mixture;  $f(y)$  is some mathematical transformation of  $y$  (which could be the identity transformation); the  $x_i$  ( $i = 1, 2, \dots, q$ ) are proportions of  $q$  components subject to the constraints in Equation (C.1) and possibly constraints of the forms in Equations (C.2) and/or (C.3); the  $b_i$  ( $i = 1, 2, \dots, q$ ) and the  $b_{ii}$ ,  $b_{ij}$ ,  $b_{iii}$ ,  $b_{ijj}$ , and  $b_{iik}$  (selected) are coefficients to be estimated from data; and  $E$  is a random experimental and property measurement error for each data point. Many statistical methods exist for the case where the  $E$  are independent (i.e., not correlated) and normally distributed with mean 0 and standard deviation  $\sigma$ . In Equations (C.5) and (C.6), “Selected” means that only some of the terms in curly brackets are included in the model. The subset is selected using standard stepwise regression or related methods (Draper and Smith 1998; Montgomery et al. 2001). LM models and PQM models are discussed in more detail and illustrated, respectively, by Cornell (2002) and Piepel et al. (2002).

Cornell (2002) discusses many other empirical mixture model forms that can be more appropriate than models of the forms in Equations (C.4) to (C.6) in certain specialized conditions. However, models of the form in Equations (C.4) and (C.5) are widely used in many

application areas (including waste glass property modeling) and have been shown to perform very well. Equation (C.6) is a natural extension of Equation (C.5) to allow the inclusion of cubic terms as well as quadratic terms.

### C.1.2 Variants of the Linear Mixture Model for Assessing Block Effects

Two variants of the LM model, useful in assessing the presence or absence of “block effects” in a modeling dataset comprised of two subsets of data collected at different times and/or locations (i.e., “blocks”), are presented in this section. These LM model variants can easily be extended for use with modeling datasets comprised of three or more subsets of data.

The following model form is applicable if: (1) the LM model accounts for the majority of the compositional dependence of  $f(y)$  and (2) there is a constant difference in  $f(y)$  values for one subset of data (i.e., block) compared to the other:

$$f(y) = b_0 B + \sum_{i=1}^q b_i x_i + E, \tag{C.7}$$

where  $B = 0$  for one of the two subsets of modeling data and  $B = 1$  for the other subset. The remaining notation is as described previously. If there is a reason to believe one subset is unbiased and the other biased, then  $B = 0$  should be used for the subset believed to be unbiased. In Equation (C.7),  $b_0$  is a coefficient estimated from the modeling data that gives the estimated magnitude of the constant difference in  $f(y)$  values between the two subsets. If the  $b_0$  coefficient is statistically different from zero, then that is an indication there is a significant constant difference between the  $f(y)$  values for one subset of the modeling data compared to the other.

The following model form is applicable if: (1) the LM model accounts for the majority of the compositional dependence of  $f(y)$  and (2) the difference in  $f(y)$  values for one subset of data compared to the other depends on the composition of the mixture:

$$f(y) = \sum_{i=1}^q b_i^0 x_i + \sum_{i=1}^q b_i^1 x_i B + E, \tag{C.8}$$

where the choice of  $B = 0$  or  $B = 1$  and the remaining notation is the same as previously discussed. In Equation (C.8), the  $b_i^0$  coefficient represents the linear blending effect of the  $i^{\text{th}}$  component for the subset of modeling data represented by  $B = 0$ . The  $b_i^1$  coefficient represents the change or bias in the linear blending effect of the  $i^{\text{th}}$  component for the subset of modeling data represented by  $B = 1$ . If any of the  $b_i^1$  coefficients ( $i = 1, 2, \dots, q$ ) are statistically different from zero, that is an indication that there are compositionally-dependent differences in the  $f(y)$  values for one subset of the modeling data compared to the other.

The model forms in Equations (C.7) and (C.8) are intended for use in assessing whether data collected at different times, locations, or conditions are subject to effects (biases) related to

the change in time, location, or conditions of data collection. If significant bias is indicated by such models, it should ideally be confirmed by other means (e.g., results on a standard collected at different times, locations, and conditions). It is beyond the scope of this discussion to address what to do when biased data are detected and confirmed. The appropriate steps will depend on the specific situation, the intended use of the data, and any requirements or limitations regarding the use of biased (or bias-corrected) data.

Equations (C.7) and (C.8) are for cases where a LM model accounts for the majority of the compositional dependence of  $f(y)$ . This will usually be the case for most waste glass property models. It is possible to include block effect terms similar to those in Equations (C.7) and (C.8) in cases where there is substantial non-linear compositional dependence. However, doing this can have added complications for some waste glass property-composition databases, and so is not discussed further.

Ultimately, investigation of block effects was not performed in conjunction with property-composition modeling work discussed in this report. The use of Equations (C.7) and (C.8) to assess block effects is complicated if different glass components vary, or vary over different ranges for groups of data in the property-composition modeling dataset. These factors can cause block effects to appear significant even though there is no systematic bias in property values across groups. Hence, investigation of block effects is often not performed in such cases. Further, because (i) procedures for batching, melting, and testing of waste glasses are well established, (ii) no block effects have been identified in previous phases of the WTP property-composition modeling work, and (iii) assessment of replicate data over groups showed no sign of block effects, investigation of block effects was deemed unnecessary for the property-composition modeling work discussed in this report.

## C.2 Mixture-Temperature Models for Viscosity and Electrical Conductivity

Viscosity and EC of glass melts depend on the melt temperatures as well as the compositions of the glasses. Equations for representing the temperature dependence of viscosity or EC for a given glass composition are discussed in Section C.2.1. Then, Section C.2.2 discusses using the temperature-dependence equations as a basis for developing property-composition-temperature model forms for viscosity and EC.

### C.2.1 Equations for Temperature Dependence of Viscosity and Electrical Conductivity

The temperature dependence for a given glass can be represented by the *Arrhenius equation*

$$\ln(y) = A + \frac{B}{T} + E \quad (\text{C.9})$$

where  $y$  = viscosity or EC for a given glass,  $\ln(y)$  denotes the natural logarithm of  $y$ ,  $A$  and  $B$  are coefficients specific to a given glass, and  $T$  is temperature in Kelvin. Sometimes there is curvature in the relationship between  $\ln(y)$  and  $1/T$ , which can be represented by the *T2 equation*

$$\ln(y) = A + \frac{B}{T} + \frac{C}{T^2} + E \quad (\text{C.10})$$

or the *truncated-T2 equation*

$$\ln(y) = A + \frac{C}{T^2} + E \quad (\text{C.11})$$

In these two equations,  $B$  and  $C$  represent coefficients specific to a given glass. The T2 equation is a second-order Taylor series expansion of the Vogel-Fulcher equation

$$\ln(y) = A + \frac{B}{T - T_0} + E \quad (\text{C.12})$$

with coefficients  $A$ ,  $B$ , and  $T_0$ . However, the Vogel-Fulcher equation is non-linear in its coefficients (specifically  $T_0$ ). Hence, iterative nonlinear least squares methods are required to fit the Vogel-Fulcher equation to data rather than the single-step solution of linear least squares methods. Feng et al. (2004) showed that the T2 and truncated-T2 equations can provide adequate approximations of the Vogel-Fulcher equation, while requiring only linear least squares fitting methods.

In each of Equations (C.9) to (C.12), the  $E$  denotes a random error for each data point. When these errors are independent (i.e., not correlated) and have equal variance across the data set, ULS regression can be used to fit the equation.

### C.2.2 Models for Temperature and Compositions Dependence of Viscosity and Electrical Conductivity

The equations for temperature dependence in Section C.2.1 are applicable to specific glasses, with the equation coefficients differing from glass to glass. Hence, the temperature dependence equations can be converted to models representing the effects of both temperature and glass composition on viscosity or EC by writing the coefficients as functions of glass composition. For viscosity and EC, linear functions of glass composition (specifically, linear mixture models) may be sufficient. Thus, expanding the coefficients of the Arrhenius equation using LM models yields

$$\ln(y) = \sum_{i=1}^q a_i x_i + E_G + \sum_{i=1}^q b_i \frac{x_i}{T} + E_T, \quad (\text{C.13})$$

where  $a_i$  and  $b_i$  are coefficients for the  $i^{\text{th}}$  glass component estimated from data,  $x_i$  is the mass fraction of the  $i^{\text{th}}$  glass component such that  $\sum x_i = 1$ ,  $E_G$  is a random error associated with determining  $y$  for each glass, and  $E_T$  is a random error associated with determining  $y$  at the temperature values for a given glass. The random errors  $E_G$  and  $E_T$  are assumed to be normally distributed with zero means and standard deviations  $\sigma_G$  and  $\sigma_T$ . Further, the  $E_G$  and  $E_T$  are assumed to be statistically independent (i.e., not correlated).

In a similar manner, expanding the coefficients of the T2 equation using LM models yields

$$\ln(y) = \sum_{i=1}^q a_i x_i + E_G + \sum_{i=1}^q b_i \frac{x_i}{T} + \sum_{i=1}^q c_i \frac{x_i}{T^2} + E_T, \quad (\text{C.14})$$

while expanding the coefficients of the truncated-T2 equation yields

$$\ln(y) = \sum_{i=1}^q a_i x_i + E_G + \sum_{i=1}^q c_i \frac{x_i}{T^2} + E_T, \quad (\text{C.15})$$

where  $c_i$  is the coefficient of the corresponding component-temperature model term for the  $i^{\text{th}}$  glass component, and all other notations have been defined previously. In some cases it may be required to expand one or more coefficients in a temperature-dependence equation using a PQM model. Such models for viscosity or EC are discussed in the main body of the report where appropriate.

The two error terms,  $E_G$  and  $E_T$ , in Equations (C.12) to (C.15) are a result of a “restriction on randomization” in measuring  $y$  (viscosity or EC). Specifically, the property  $y$  is measured at multiple temperatures on each glass before moving on to the next glass. This is a natural way to measure viscosity or EC, because glass is a “hard-to-change” factor while temperature is an “easy-to-change” factor. Thus, it is infeasible to completely randomize all combinations of glass composition and temperature in measuring viscosity or EC. Hence, the way in which viscosity or EC is measured is a “restriction on randomization” that requires a proper analysis of the data. Experiments with this sort of restriction are referred to as *split-plot experiments* in the statistical literature, because of their early use in agricultural experiments. However, this type of restricted-randomization data collection is common in engineering and other experiments where there is at least one hard-to-change factor and at least one easy-to-change factor. The main consequence of the split-plot nature of the data is that there are two uncertainty standard deviations, one related to whole plots (WPs) and one related to sub-plots (SPs). For viscosity and EC, glasses are the WP “treatments” and the associated uncertainty standard deviation is denoted  $\sigma_G$ . Temperature values are the SP “treatments” and the associated uncertainty standard deviation is denoted  $\sigma_T$ . The observations within a WP (e.g.,  $y$  values at four temperatures) are correlated. Thus, it is improper to use ordinary least squares (OLS) regression, which has only one uncertainty standard deviation and assumes observations are uncorrelated. Generalized least squares (GLS) regression modeling is needed for the split-plot data structure present with viscosity and EC data.

GLS regression modeling simultaneously estimates the model coefficients as well as  $\sigma_G$  and  $\sigma_T$ . See Section C.3.3 for further discussion and references on these topics.

Investigation of block effects by adding block effect terms to the models in Equations (C.13) to (C.15) is an added complication on top of the split-plot structure of the data for such models. Assessing block effects is further complicated if different glass components vary, or vary over different ranges for groups of data in the property-composition-temperature modeling dataset. These factors can cause block effects to appear significant even though there is no systematic bias in property values across groups. Hence, investigation of block effects is often not performed in such cases. Further, because (i) procedures for batching, melting, and testing of waste glasses are well established, (ii) no block effects have been identified in previous phases of the WTP property-composition modeling work, and (iii) assessment of replicate data over groups showed no sign of block effects, investigation of block effects was deemed unnecessary for the property-composition-temperature modeling work discussed in this report.

### C.3 Least Squares Regression Methods and Assumptions for Fitting Models

Empirical or semi-empirical property-composition models are typically fitted to data sets using unweighted least squares (ULS) or weighted least squares (WLS) regression. However, in some cases generalized least squares (GLS) regression is required. Section C.3.1 discusses ULS and WLS regression, while Section C.3.2 discusses GLS regression. Section C.3.3 discusses the case of GLS regression for data with a split-plot structure such as occurs when measuring viscosity and EC of glasses at various temperatures. Draper and Smith (1998) and Montgomery et al. (2001) provide additional discussion of the ULS, WLS, and GLS topics.

#### C.3.1 Unweighted and Weighted Least Squares Regression

The underlying assumptions of ULS and WLS regression are:

- (i) The predictor variable values (e.g., mass fractions of glass components) are known or measured without uncertainty, or at least that the uncertainty is small relative to the uncertainty in response variable (glass property) values
- (ii) The testing and/or measurement errors in a response variable (glass property) over a model development data set are independently distributed (i.e., the errors are not correlated). For ULS regression, the additional assumption is made that the errors are identically distributed (i.e., with zero mean and the same variance). For WLS regression, the errors are also assumed to have zero mean, but the variance can be different for different data points.
- (iii) The errors from (ii) are normally (Gaussian) distributed.

Regarding assumption (i), the true composition of glasses in a model development data set are generally not known, and so any representation of glass composition selected (e.g., target compositions, analyzed compositions, or adjusted and normalized versions of analyzed compositions) will be subject to uncertainty. Weier and Piepel (2003) discuss a procedure for performing adjustments and weighted normalization of analyzed glass compositions that corrects for biases and reduces uncertainties in analyzed glass compositions. As long as representations of glass composition do not have significant biases (or those biases are appropriately corrected), it is generally expected that uncertainties will be small compared to uncertainties in glass property values. Further, uncertainties in glass compositions are expected to be small compared to errors in using empirical or semi-empirical model forms to approximate the true (but unknown) property-composition relationships. Hence, assumption (i) is sufficiently satisfied for most waste glass property-composition modeling situations.

The portion of assumption (ii) having to do with the independence of errors in testing and measuring properties may not be completely satisfied when model development data sets are comprised of subsets of data generated at different times or locations (e.g., different laboratories). There is the potential for errors in testing and measuring properties to vary for different subsets of data, and be more alike within the same subset of data. However, this issue has generally not been a problem in many past property-composition modeling efforts. If needed, GLS methods that account for correlations among data points could be applied.

The “identically distributed” portion of assumption (ii) for ULS regression is not valid for some properties, because the variance of errors in testing and measurement of properties depends on the value of the property. For example, the variances of viscosity and durability results for waste glasses tend to increase as the values of these properties increase. In cases where the identically distributed (equal variance) assumption is violated, it can often be remedied by applying an appropriate mathematical transformation to the property values (e.g., a logarithmic transformation). The Box-Cox family of transformations contains transformations (including the logarithmic transformation) appropriate for many models (see Draper and Smith 1998). Such transformations also often yield better fitting empirical or semi-empirical property-composition models. In some cases, a property transformation used in a particular model form may be preferred for some reason (e.g., provides a better fit), but does not satisfy the constant variance assumption of (ii). Or, it may be that the difference in variances across response values in the modeling data set cannot be rectified by a response transformation. In such cases, other regression methods such as WLS regression or generalized linear models (Myers et al. 2002) could be applied.

The assumption of normally distributed measurement and testing errors in the measured response variable values allows the use of normal theory regression tests and uncertainty equations associated with the fitted regression model. For example, normal theory confidence intervals and prediction intervals can be used (see Section C.7).

As discussed in preceding text, ULS regression requires that all response values for the modeling data have constant variance (i.e., uncertainty). WLS regression accounts for response values having different variations by using a weight for each data point ( $w_i$ ). Often,  $w_i$  is chosen

to be proportional to the reciprocal of the variance (squared standard deviation) of the response for the  $i^{\text{th}}$  data point ( $y_i$ ).

$$w_i = \frac{\lambda}{\text{Var}(y_i)} = \frac{\lambda}{[\text{SD}(y_i)]^2} \quad (\text{C.16})$$

where  $\lambda$  is a proportionality constant (which could be 1). Thus, in such a WLS regression the weighted response values  $\sqrt{w_i} y_i$  then have equal variance. However, other methods for selecting weights can be applicable for various situations.

In summary, assumptions of ULS regression may not be completely satisfied for typical property-composition data sets and models. Violations of the constant variance assumption for property values over a modeling data set can sometimes be addressed by appropriate property transformations so that ULS regression may be used. Other violations may be small enough that ULS regression methods can still be used without significant consequence. However, if there are large enough differences in variances of property values across a modeling data set that cannot be addressed by a property transformation, then WLS regression methods should be used. If there are correlations among data points in a regression set, GLS methods are needed as discussed in the following subsection.

### C.3.2 Generalized Least Squares Regression

The underlying assumptions of GLS regression are:

- (i) The predictor variable values (e.g., mass fractions of glass components) are known or measured without uncertainty, or at least that the uncertainty is small relative to the uncertainty in response variable (glass property) values
- (ii) The testing and/or measurement errors in a response variable (glass property) over a model development data set are normally distributed with a mean vector of zeros and a variance-covariance matrix  $V$ .

Under these assumptions, the data to be modeled by GLS regression can be written in the general form

$$\mathbf{y} \sim N(\boldsymbol{\mu}(\mathbf{x}, \boldsymbol{\beta}), \mathbf{V}), \tag{C.17}$$

which denotes that the vector of property values  $\mathbf{y}$  is normally distributed with mean vector  $\boldsymbol{\mu}(\mathbf{x}, \boldsymbol{\beta})$  and variance-covariance matrix  $\mathbf{V}$ . The mean vector is a function of the vector of predictor variables  $\mathbf{x}$  and the unknown model parameter vector  $\boldsymbol{\beta}$ . Most commonly, functions linear in the parameters  $\boldsymbol{\mu}(\mathbf{x}, \boldsymbol{\beta}) = \boldsymbol{\beta}' \mathbf{a}$  are used, where  $\mathbf{a}$  is an expansion of  $\mathbf{x}$  in the form of the model. Note that such functions can still be linear as well as nonlinear in the predictor variables. If the variance-covariance matrix  $\mathbf{V}$  is known, the estimate of the parameter vector obtained by GLS can be written as

$$\hat{\boldsymbol{\beta}} = (\mathbf{A}'\mathbf{V}^{-1}\mathbf{A})^{-1} \mathbf{A}'\mathbf{V}^{-1}\mathbf{y} \tag{C.18}$$

with the variance of the parameter estimates denoted by

$$\text{Var}(\hat{\boldsymbol{\beta}}) = (\mathbf{A}'\mathbf{V}^{-1}\mathbf{A})^{-1} \tag{C.19}$$

(see Montgomery et al. 2001, Section 5.5.1). In both of these equations,  $\mathbf{A}$  is the matrix of data used to fit the model, expanded in the form of the model. If the variance-covariance matrix  $\mathbf{V}$  is not known in advance, for some problems it can be estimated at the same time as the model parameters are estimated (see Section C.3.3 for further discussion). In such a case, Equation (C.19) is only approximate.

Note that ULS and WLS regression are special cases of GLS regression. ULS applies when the diagonal elements of  $\mathbf{V}$  (the variances of the data points) are all the same, and the off-diagonal elements (covariances) are all zero. WLS applies when the diagonal elements of  $\mathbf{V}$  differ and the off-diagonal elements are all zero.

### C.3.3 Generalized Least Squares Regression for Split-Plot Data Structures

Viscosity and EC are examples of glass properties for which GLS regression is required when data are collected using the approach typical for those properties. Specifically, viscosity (or EC) is measured at each of several temperatures for one glass, then another glass, etc. This is referred to in the statistical literature as a “restriction on randomization” because the property is not measured on composition-temperature combinations in a completely random order. The glass composition is referred to as a hard-to-change factor, and temperature is referred to as an easy-to-change factor. It is easier to make viscosity or EC measurements at various temperatures for one glass, then the next glass, etc., but it results in a restriction on randomization. Experimental data collected in this way are referred to as having a split-plot structure. The terminology originally came from agricultural experiments with restrictions on randomization, where fields

were split into “whole plots” and “sub plots”. However, this terminology is also used for experiments in various non-agricultural application areas.

Every viscosity (or EC)-at-temperature data point is subject to one uncertainty related to batching and melting a glass, as well as the uncertainty associated with the set-up and property measurement of a given glass. The associated standard deviation is denoted  $\sigma_G$ . The data points for a given glass are also subject to a second uncertainty related to measuring the property at various temperatures. The associated standard deviation is denoted  $\sigma_T$ . The property-at-temperature values for each given glass are correlated. The variance-covariance matrix for the split-plot structure typical for viscosity or electrical conductivity data on several glasses is given by

$$V = \begin{bmatrix} T_1 & 0 & \dots & \dots & 0 \\ 0 & T_2 & 0 & \dots & 0 \\ 0 & 0 & \ddots & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & T_g \end{bmatrix}, \tag{C.20}$$

where  $g$  denotes the number of glasses in a modeling dataset and a  $T_i$  matrix is given by

$$T_i = \begin{bmatrix} \sigma_G^2 + \sigma_T^2 & \sigma_G^2 & \sigma_G^2 & \sigma_G^2 \\ \sigma_G^2 & \sigma_G^2 + \sigma_T^2 & \sigma_G^2 & \sigma_G^2 \\ \sigma_G^2 & \sigma_G^2 & \sigma_G^2 + \sigma_T^2 & \sigma_G^2 \\ \sigma_G^2 & \sigma_G^2 & \sigma_G^2 & \sigma_G^2 + \sigma_T^2 \end{bmatrix}. \tag{C.21}$$

These equations are based on ones given by Myers and Montgomery (1995, Section 9.6.3). This form of  $T_i$  assumes viscosity or EC is measured at four temperatures for each glass. The  $T_i$  matrix would expand or contract accordingly if the number of temperatures at which a property is measured for a given glass would increase or decrease.

If  $\sigma_G$  and  $\sigma_T$  were known, then  $V$  in (C.20) could be used in Equations (C.18) and (C.19) to estimate viscosity or EC model coefficients and their uncertainties. However,  $\sigma_G$  and  $\sigma_T$  generally are not known and must be estimated from data. Statistical software is available for fitting so-called *mixed models*, that is, models that require simultaneous estimation of data uncertainties (e.g.,  $\sigma_G$  and  $\sigma_T$ ) and model coefficients. The PROC MIXED routine in SAS (2005) was used to fit the viscosity and EC models presented in this report.

#### C.4 Statistical Methods for Model Evaluation

There are many statistical methods (both numerical and graphical) for assessing models. *Evaluation methods* assess a model with the data used to develop the model. Such data are

referred to as *model development data*. The goals of model evaluation are to assess: (1) how well a model fits the data used to develop it, (2) how well the least squares or other regression method assumptions are satisfied (see Section C.3), and (3) whether there are any outlying or influential data points that significantly affect the fitted model. Problems detected by model evaluation such as violation of assumptions, detection of outlying data points, or detection of model inadequacy require implementing various remedies in the model development process until the problem(s) are corrected. When the model being evaluated acceptably fits the data used to develop the model, *model validation* methods should be applied using data not used to develop the model. Such data are referred to as *model validation data*. If model validation data are not available, *crossvalidation methods* can be applied using the model development data. Crossvalidation methods leave out one or more data points at a time, so that some of the data are used for model development and some for model validation. Such methods are also referred to as data-splitting validation methods, where part of the data is used for model development and evaluation, while the other part is used for validation. Draper and Smith (1998) and Montgomery et al. (2001) discuss statistical methods for evaluating and validating models.

Model evaluation techniques include predicted versus measured (PvM) property plots, standardized residual plots, outlier diagnostics, three  $R^2$  statistics, root mean squared error (*RMSE*), and statistical lack-of-fit (LOF) tests. Each of these is explained briefly below. The following notation is used in the subsequent descriptions and definitions:

- $n$  = the number of data points used to fit a model,
- $p$  = the number of parameters (coefficients) in a model form estimated via regression on the data,
- $y_i$  = the measured property value (mathematically transformed, if appropriate for the model form used) for the  $i^{\text{th}}$  data point,
- $\hat{y}_i$  = the predicted property value (mathematically transformed, if appropriate for the model form used) for the  $i^{\text{th}}$  data point made using the model fitted to all  $n$  data points,
- $r_i$  = the residual for the  $i^{\text{th}}$  data point =  $y_i - \hat{y}_i$ ,
- $\hat{y}_{(i)}$  = the predicted property value (mathematically transformed, if appropriate for the model form used) for the  $i^{\text{th}}$  data point made using a model fitted to all  $n$  data points except the  $i^{\text{th}}$ ,
- $w_i$  = the weight applied to the  $i^{\text{th}}$  data point in cases where WLS regression is used. Typically,  $w_i$  is proportional to the reciprocal of the variance of the response variable for the  $i^{\text{th}}$  data point,

$\bar{y}$  = the unweighted average (mean) of the  $n$  measured property values  
 (mathematically transformed, if appropriate for the model form used),

$\bar{y}_w$  = the weighted average (mean) of the  $n$  measured property values  
 (mathematically transformed, if appropriate for the model form used)

$$\bar{y}_w = \frac{\sum_{i=1}^n w_i y_i}{\sum_{i=1}^n w_i} \tag{C.22}$$

The model evaluation methods are now briefly described.

- Predicted versus measured (PvM) property plots show how well model predicted values  $\hat{y}_i$  compare to the measured values  $y_i$  for the glasses in the model development data set. Predicted property values  $\hat{y}_i$  are plotted on the  $y$ -axis and measured property values  $y_i$  are plotted on the  $x$ -axis. A line with slope one is included in the plot for reference purposes, and represents the ideal of predicted values equaling measured values. Plotted points falling above this line correspond to glasses for which the model over-predicts the property, while plotted points falling below this line represent glasses for which the model under-predicts the property. A preponderance of plotted points in a portion of the plot falling above or below the line indicates that the model tends to yield biased predictions for that range of property values. Plotted points far from the line are outlying or potentially influential data points.

For WLS regression, an *ordinary (unweighted) PvM plot* of  $\hat{y}_i$  versus  $y_i$  could be viewed as is done for ULS regression. Or, a *weighted PvM plot* of  $\sqrt{w_i} \hat{y}_i$  versus  $\sqrt{w_i} y_i$  could be viewed. The ordinary (unweighted) PvM plot has the advantage of retaining the units of the response (or its transformation), but the disadvantage that points with smaller weights (i.e., higher uncertainties) may appear farther from the line with slope one. However, rather than considering this a disadvantage, it may be better thought of as showing the penalty paid in obtaining predictions having more uncertainty for modeling data points with smaller weights (i.e., higher uncertainty). The weighted PvM plot would show the model predictive performance for the modeling data points after accounting for (i.e., removing the scatter due to) the differing weights (i.e., uncertainties).

For GLS regression, an ordinary PvM plot could be viewed as is done for ULS regression. Or, a modified version could be viewed that accounts for the variance-covariance structure of the data. Because such modified PvM plots are more complicated, they are not discussed or used in this report. In this report, ordinary PvM plots are viewed regardless of whether ULS, WLS, or GLS regression is employed to fit models.

- RMSE is given by

$$RMSE_U = \sqrt{\frac{\sum_{i=1}^n (\hat{y}_i - y_i)^2}{n - p}} \quad (C.23a)$$

for ULS regression, and by

$$RMSE_W = \sqrt{\frac{\sum_{i=1}^n w_i (\hat{y}_i - y_i)^2}{n - p}} \quad (C.23b)$$

for WLS regression. If the fitted model is adequate and does not have a statistically significant lack-of-fit, this statistic provides an estimate of the experimental and measurement uncertainty standard deviation associated with melting glasses and measuring the associated property. The statistic  $RMSE$  is included as standard output in most regression software, and has units the same as the property values  $y_i$  (including any mathematical transformation of the property in the model form) for ULS regression and the units of  $\sqrt{w_i} y_i$  for WLS regression.

RMSE values are not traditionally calculated and reported by software implementing GLS regression because of the more complicated uncertainty structure of the data. In this report we have opted for using  $RMSE_U$  to provide an overall summary measure of GLS fitted models. Note that  $RMSE_U$  will not directly give proper estimates of  $\sigma_G$ ,  $\sigma_T$ , or  $\sqrt{\sigma_G^2 + \sigma_T^2}$  and should not be interpreted as such.

- *Standardized residual plots* display standardized residuals ( $s_i$ , differences in predicted and measured property values divided by their standard deviations) versus various quantities, such as: glass component mass fractions ( $x_i$ ), predicted property values ( $\hat{y}_i$ ), or an index associated with each data point. The formula for a standardized residual is given by

$$s_i = \frac{r_i}{RMSE_U \left[ 1 - \mathbf{a}_i^T (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{a}_i \right]^{0.5}} \quad (C.24a)$$

for ULS regression, by

$$s_i = \frac{\sqrt{w_i} r_i}{RMSE_W \left[ 1 - w_i \mathbf{a}_i^T (\mathbf{A}^T \mathbf{W} \mathbf{A})^{-1} \mathbf{a}_i \right]^{0.5}} \quad (C.24b)$$

for WLS regression, and by

$$s_i = \frac{r_i}{\left[1 - \mathbf{a}_i^T (\mathbf{A}^T \mathbf{V}^{-1} \mathbf{A})^{-1} \mathbf{a}_i\right]^{0.5}} \quad (\text{C.24c})$$

for GLS regression. In Equations (C.24a), (C.24b), and (C.24c):  $s_i$ ,  $w_i$ , and  $r_i$  are as previously described;  $RMSE_U$  and  $RMSE_W$  are respectively given by Equations (C.23a) and (C.23b);  $\mathbf{a}_i$  is the composition (column) vector for the  $i^{th}$  modeling data point expanded in the form of the model;  $\mathbf{A}$  is an  $n \times p$  matrix of the compositions (and temperatures in the case of viscosity or EC) in the modeling data set expanded in the form of the model;  $\mathbf{W}$  is an  $n \times n$  matrix with the weights  $w_i$  along the main diagonal, and zeros elsewhere; and  $\mathbf{V}$  is an  $n \times n$  matrix representing the variance-covariance structure of the modeling dataset.

Patterns in the  $s_i$  versus  $\hat{y}_i$  plot can indicate a violation of the least squares regression assumptions and suggest a property transformation to remedy the situation. Patterns in the  $s_i$  versus  $x_i$  plots can indicate inadequacies of the model or least squares assumptions. Patterns in  $s_i$  versus data indices can indicate subsets of the data for which a model may be inadequate. Standardized residuals are typically used in residual plots because the majority should fall within the range of  $\pm 2.0$  and almost all should fall within  $\pm 3.0$ . Comparing standardized residuals to such a range provides an easy criterion for judging whether a data point is outlying.

- Normality plots display normal scores versus the ordered (from smallest to largest) standardized residuals (from Equations (C.24a), (C.24b), or (C.24c) for ULS, WLS, and GLS regression, respectively) for the  $n$  data points used to fit the model being assessed. Normal scores are the expected values of a sample of size  $n$  from standard normal distribution (with mean 0 and standard deviation 1). The plotted points are compared to the ideal of a straight line corresponding to a normal distribution. A straight middle portion of the plot with curved “tails” on each end of the plot indicate the presence of outlying data points, which cause a heavier-tailed distribution than the normal distribution.
- Outlier diagnostics and plots indicate data points that are outlying or influential with respect to property value or composition. There are too many of these diagnostics and plots to discuss here, but several produced by the R software (Ihaka and Gentleman 1996, R Core Development Team 2006) and the SAS software (2005) were considered in this work. Draper and Smith (1998) and Montgomery et al. (2001) discuss outlier diagnostics and plots for ULS regression, but software such as R and SAS produce the appropriate versions of diagnostics and plots for WLS and GLS as well as ULS regression.
- $R^2$  statistics quantify the proportion of variation in the property values  $y_i$  (for ULS regression) or weighted property values  $\sqrt{w_i} y_i$  (for WLS regression) accounted for by the fitted model. Three  $R^2$  statistics are used, as discussed later in this section. Typically  $R^2$  type statistics are not calculated and reported by software that performs GLS regression. This is because of the more complicated uncertainty structure of the data. It may be possible to develop such statistics for GLS regression, but the interpretations would be modified.

- A statistical lack-of-fit (LOF) test checks whether the differences (for ULS regression) or weighted differences (for WLS regression) between measured and predicted property values from a fitted model are larger than expected based on the experimental and measurement uncertainty in the data. If the predicted versus measured differences are larger than data uncertainty at a high enough statistical confidence (e.g., greater than 90%), the model is said to have a statistically significant LOF. Replicate data points containing all applicable sources of experimental and measurement uncertainty<sup>1</sup> are required to perform statistical LOF tests. This process is conducted using a LOF F-test given by

$$F = \frac{(SSE - SSPE)/(n - p - f)}{SSPE/f} = \frac{\left[ \left( \sum_{i=1}^n (\hat{y}_i - y_i)^2 - \sum_{k=1}^K \sum_{j=1}^{m_k} (y_{kj} - \bar{y}_k)^2 \right) / (n - p - f) \right]}{\sum_{k=1}^K \sum_{j=1}^{m_k} (y_{kj} - \bar{y}_k)^2 / f} \quad (C.25a)$$

for ULS regression, and by

$$F = \frac{(SSE - SSPE)/(n - p - f)}{SSPE/f} = \frac{\left[ \left( \sum_{i=1}^n w_i (\hat{y}_i - y_i)^2 - \sum_{k=1}^K \sum_{j=1}^{m_k} w_j (y_{kj} - \bar{y}_k)^2 \right) / (n - p - f) \right]}{\sum_{k=1}^K \sum_{j=1}^{m_k} w_j (y_{kj} - \bar{y}_k)^2 / f} \quad (C.25b)$$

for WLS regression. In Equations (C.25a) and C.25b): SSE = sum of squares error; SSPE = sum of squared pure error (i.e., from replicates);  $n$  and  $p$  are as described previously such that  $n-p$  is the degrees of freedom for SSE; and the degrees of freedom for pure error is given by  $f = \sum_{k=1}^K (m_k - 1)$ , where  $m_k$  is the number of replicate data points in the  $k^{th}$  replicate set,  $k = 1, 2, \dots, K$ . In practice, if the F-test is statistically significant at a significance level (often referred to as a  $p$ -value) of 0.05 or smaller (i.e., 95% confidence or higher), then it would be concluded that the fitted model has a statistically significant LOF for the modeling dataset. See Draper and Smith (1998) or Montgomery et al. (2001) for additional discussion of the statistical test for model LOF.

---

<sup>1</sup> To be appropriate replicate data points, two or more glass samples of the same composition must be batched and melted at different times, and have their properties measured at different times. It is insufficient, for example, to batch and melt a glass once, and measure its properties several times (because the batching and melting sources of uncertainty are not included in the data). Similarly, replicate samples should not be measured at the same time (or close in time) because all sources of measurement uncertainty will not be included in the data.

Statistical tests of LOF for GLS-fitted models have not been provided in the statistics literature. An ad hoc assessment of LOF for GLS-fitted viscosity and EC models (see Section C.3.3) is provided by considering

$$\frac{\hat{\sigma}_G^2 + \hat{\sigma}_T^2}{\text{Pure Error Estimate of } \sigma_G^2 + \sigma_T^2} \tag{C.25c}$$

where  $\hat{\sigma}_G^2$  and  $\hat{\sigma}_T^2$  are estimates of the whole-plot (glasses) and sub-plot (temperatures) variance components that are outputs of the GLS software used to fit viscosity and EC models. The denominator of Equation (C.25c) is a “pure error” estimate of  $\sigma_G^2 + \sigma_T^2$  based on viscosity or EC data on replicate glasses. Developing the theory for the ratio in Equation (C.25c) was beyond the scope of the work in this report. However, a ratio as large as 1.5 to 2.0 provides evidence of a possible model LOF.

Even when a fitted model has a statistically significant LOF, the LOF may not be “practically significant”. An example of such a situation is when a fitted model yields biased predictions for higher and/or lower values of a property or in a particular subregion of compositions, but the model will not be applied to such areas in practice. Another example is when the model fits the data very well (e.g.,  $R^2 > 0.95$ ) without bias over the model’s region of validity, but the LOF is statistically significant because the experimental and measurement uncertainty is very small (e.g., because glasses can be batched, melted, and properties measured with excellent repeatability). Finally, a statistically significant LOF may not be practically significant if the uncertainty in model predictions is considerably smaller than uncertainty that can be tolerated and still meet requirements.

The model evaluation techniques discussed in the preceding bullets are included in, or can be obtained from, the output of the R software (Ihaka and Gentleman 1996, R Core Development Team) and SAS software (2005). See Draper and Smith (1998) or Montgomery et al. (2001) for further discussion of the concepts.

Three different  $R^2$  statistics are useful in evaluating models fitted to glass property-composition data. These are denoted as  $R^2$ ,  $R_A^2$ , and  $R_P^2$ , which are discussed subsequently. Formulas for these statistics are given when models are fitted by ULS or WLS. It may be possible to develop formulas for these statistics in the case of GLS regression, but doing so was beyond the scope of work in this report. Hence, only  $R^2$  values as calculated by the ULS formula are given in this report for models fitted by GLS.

The (ordinary)  $R^2$  statistic is given by

$$R^2 = 1 - \frac{\sum_{i=1}^n (\hat{y}_i - y_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2} \quad (\text{C.26a})$$

for ULS regression, and by

$$R^2 = 1 - \frac{\sum_{i=1}^n w_i (\hat{y}_i - y_i)^2}{\sum_{i=1}^n w_i (y_i - \bar{y}_w)^2} \quad (\text{C.26b})$$

for WLS regression, where  $\bar{y}_w$  in Equation (C.26b) is the weighted mean whose formula is given in Equation (C.22).  $R^2$  is interpreted as the fraction of variability in the unweighted (for ULS regression) or weighted (for WLS regression) property data (transformed if appropriate) accounted for by the fitted model. The *adjusted  $R^2$  statistic* is given by

$$R_A^2 = 1 - \frac{\sum_{i=1}^n (\hat{y}_i - y_i)^2 / (n - p)}{\sum_{i=1}^n (y_i - \bar{y})^2 / (n - 1)} \quad (\text{C.27a})$$

for ULS regression, and by

$$R_A^2 = 1 - \frac{\sum_{i=1}^n w_i (\hat{y}_i - y_i)^2 / (n - p)}{\sum_{i=1}^n w_i (y_i - \bar{y}_w)^2 / (n - 1)} \quad (\text{C.27b})$$

for WLS regression.  $R_A^2$  is interpreted as the adjusted fraction of variability in the unweighted or weighted property data (transformed if appropriate) accounted for by the fitted model. The adjustment is for the number of parameters ( $p$ ) and number of data points ( $n$ ) used in fitting the model. A version of  $R_A^2$  for GLS regression has not been proposed in the literature, and so this statistic is not calculated and reported for models fitted by GLS regression.

The *predicted  $R^2$  statistic* is given by

$$R_P^2 = 1 - \frac{\sum_{i=1}^n (\hat{y}_{(i)} - y_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2}, \quad (\text{C.28a})$$

for ULS regression, and by

$$R_p^2 = 1 - \frac{\sum_{i=1}^n w_i (\hat{y}_{(i)} - y_i)^2}{\sum_{i=1}^n w_i (y_i - \bar{y}_w)^2}, \quad (\text{C.28b})$$

for WLS regression.  $R_p^2$  is interpreted as the leave-one-out crossvalidation fraction of variability in the unweighted or weighted property data (transformed if appropriate) accounted for by the fitted model. This statistic is calculated by a method equivalent to leaving each data point out of the model fit, and then evaluating how well the model predicts the property for that data point.  $R_p^2$  estimates the fraction of variability that would be explained in predicting new observations drawn from the same composition space. However, computational simplifications for ULS and WLS regression do not require re-fitting a model with each data point removed. Unfortunately, no such simplification exists for GLS regression. Thus,  $R_p^2$  is not calculated in this report for models fitted by GLS.

Generally  $R^2$  statistics take values between 0 and 1. However,  $R_A^2$  and  $R_p^2$  can take negative values for a poor fitting model, a model that contains many more terms than needed to fit the data, or a model fitted to data with one or more very influential data points. Among the three  $R^2$  statistics, typically  $R^2 > R_A^2 > R_p^2$ . More than a minor difference between  $R^2$  and  $R_A^2$  indicates that the model may contain more terms than needed to achieve the same goodness of fit. A substantial difference between  $R^2$  and  $R_p^2$  is indicative of one or more data points being very influential in determining the fit of the model. Some reduction from  $R^2$  to  $R_p^2$  is expected because  $R^2$  corresponds to using all data to fit the model, whereas  $R_p^2$  corresponds to leaving each data point out of the fit when evaluating the performance of the model for that point. In general, a model will tend to predict better for data used to fit it than for data not used to fit it.  $R_p^2$  is a crossvalidation evaluation method.

## C.5 Statistical Methods for Model Reduction and Augmentation

Section C.5.1 discusses methods for identifying and removing unnecessary terms from mixture experiment models. Section C.5.2 discusses methods for augmenting linear mixture models with quadratic terms or other nonlinear blending terms.

### C.5.1 Statistical Methods for Reducing Mixture Experiment Models

In evaluating a fitted regression model, it may often be determined that there are unnecessary terms in the model. Such terms may not improve, and can even degrade, the predictive performance of the model in applications to data not used to develop the model.

The most basic statistical method to identify unnecessary terms in a model is a *t-test* to perform a hypothesis test of whether the coefficient of a model term is statistically different from zero. The *t-test* computes a *t-statistic* equal to a model coefficient divided by the standard deviation of the coefficient. The *t-statistic* is then compared to the Student-*t* probability distribution to determine the probability of getting a *t-statistic* at least that large. The resulting probability is referred to as a *p-value*, and represents the probability of incorrectly deciding a coefficient is significantly different than zero. Most regression software outputs estimated model coefficients, coefficient standard deviations, *t-statistics*, and *p-values*. Typically, practitioners require a *p-value* to be smaller than 0.05 or 0.01 as strong evidence that the coefficient is significantly different than zero, and thus that the corresponding model term is needed. If there are not too many potentially unnecessary terms in a model, a practitioner can assess the *t-statistics* and *p-values* for the coefficients in a “full” model, and remove the model term whose coefficient is least statistically significant. Then, the model would be refitted without that term, and the *t-statistics* and *p-values* again considered, deleting the model term with the least statistically significant coefficient. This process continues until all terms in the model have *p-values* lower than 0.05, say. *Backward elimination* (Draper and Smith 1998, Montgomery et al. 2001) is a widely used statistical method for removing unneeded terms from a model. This method basically automates the process just described, where the practitioner sets a stopping criterion.

Unfortunately, there are some model forms for which the model reduction methods just described are inappropriate. In general, these are model forms where a model coefficient being small (e.g., near zero) does not imply the corresponding model term is unneeded. That is, some model forms may have terms with significant effects even though the coefficients of those terms are small. One class of models in this category relevant to this work is the class of *mixture experiment models* (Cornell 2002), of which LM, PQM, and PCM models are given in Section C.1.1. The LM model (or the linear blending portion of a PQM model or a PCM model) is of the form  $\sum_{i=1}^q b_i x_i$ , where the  $b_i$  are coefficients and the  $x_i$  are proportions of the mixture components (e.g., mass fractions of waste glass components) that must sum to one (i.e.,  $\sum_{i=1}^q x_i = 1$ ). When each  $x_i$  can vary from zero to one, the coefficient  $b_i$  represents the estimated response variable value for pure component  $i$  [i.e., when  $x_i = 1$  and  $x_j = 0$  ( $j \neq i$ )]. When the ranges of the mixture component proportions  $x_i$  are constrained, each  $b_i$  represents extrapolated response values for pure component  $i$ . Because hypotheses concerning LM model coefficients (or the coefficients of linear terms in PQM or PCM models) equaling zero are not related to the importance or non-importance of a given component, it is inappropriate to use *t-tests* or the standard backward elimination method to reduce the linear portion of a mixture experiment model. However, mixture models can contain nonlinear terms in the components (such as in the PQM and PCM model forms discussed in Section C.1.1), and it is appropriate to use *t-tests* or the standard stepwise, forward, or backward elimination *variable selection methods* (see Draper and Smith 1998 or Montgomery et al. 2001) on such terms.

### Component Response Trace Plots

*Component response trace plots* (Cornell 2002) provide for graphically assessing the effects of mixture components on a response variable of interest. These plots are generally produced using a fitted mixture model. The model is used to predict, for each component, the response for a series of compositions lying along an *effect direction* for that component. The most commonly used effect direction corresponds to subtracting or adding a component to a reference (or baseline) mixture. Along such a direction, the component of interest is varied within the allowable composition region of interest. The changes in the component of interest are offset by changes in the remaining components, such that they remain in the same relative proportions as in the reference mixture. The predicted response values along the effect direction for a given component form a *component response trace*. The response traces for the components varied in a mixture experiment plotted together form the *component response trace plot*. The predicted response values are plotted on the y-axis and changes in each component from its reference mixture value are plotted on the x-axis. Components with steeper response traces have stronger effects on the response. A response trace that is nearly horizontal indicates the corresponding component has little or no effect on the response. Components whose response traces are very close may have similar effects on the response. Thus, component response trace plots can be used to guide the reduction of components appearing in a mixture experiment model (e.g., see Piepel and Redgate 1997).

### Component Slope Linear Mixture Model

Piepel (2006b, 2007) discusses a re-parameterization of the linear mixture model in Equation (C.4) referred to as the *component slope linear mixture (CSLM) model*. The details of the model form are not given here, but it suffices to say that the coefficients of the CSLM model are slopes of the component response traces produced using a fitted linear mixture model. It is appropriate to perform t-tests that determine whether the slopes are significantly different from zero. Hence, this approach can be used to identify components that do not significantly affect the response variable.

### Backward Elimination Algorithm for Reducing Linear Mixture Models

A special backward elimination method for mixture experiments has been developed to reduce linear mixture models and linear portions of mixture models (Piepel and Cooley 2006). The reduction method is performed in stages. In general at the end of each stage, either (i) a mixture component is dropped and the remaining components are renormalized, or (ii) two components are combined. As an option, model reductions of the form (i) can be skipped and only reductions of the form (ii) considered. For each stage, the process occurs as follows.

- If reductions of the form (i) are allowed, each mixture component still in the model is in turn dropped from the model, the remaining mixture component proportions are renormalized to sum to one. Then a linear mixture model without the dropped component is fitted to the data. The dropped mixture component that causes the smallest increase in the error sums of squares (the quantity being minimized in ULS regression) is then the component permanently dropped from the model at the current stage. After each

component is dropped, the remaining components are renormalized according to the mixture experiment definition that a response variable depends only on the relative proportions of the mixture components that affect the response variable (Cornell 2002).

- For reductions of the form (ii), each allowable pair of components is combined and the corresponding reduced linear mixture model is fitted. The pair of components causing the smallest increase in the error sum of squares is then permanently combined at the current stage.

Similar stages continue, with either one component dropped [option (i)] or one pair of components combined [option (ii)], until the stage in which a model reduction causes the full-reduced model F-test (Draper and Smith 1998, Montgomery et al. 2001) to declare a statistically significant increase in the error sum of squares. This then signals the stopping point for the backward elimination algorithm. Note that the algorithm allows for the user specifying the components (if any) that can be dropped, and components that can be combined. These options provide for incorporating glass science knowledge into the model reduction process.

### C.5.2 Statistical Methods for Adding Terms to Models

It is often of interest to add additional terms onto a starting model in the hopes of improving the predictive performance of the starting model. For example, a linear mixture model may be considered as a starting model. However, if it has a significant LOF, adding nonlinear composition terms may be considered in hopes of improving the predictive performance of the model. *Stepwise regression* is the most commonly used method to add terms to an existing starting model. In stepwise regression, certain terms can be forced into the model, and a candidate list of possible terms to add is identified. The procedure identifies the term from the candidate list that, if added to the model, would yield the greatest reduction in the error sum of squares (i.e., the sum of squared differences in measured and model-predicted values across the modeling data set). If the reduction is statistically significant, that term is added to the model. Stepwise regression proceeds in stages, with one additional term being added at each stage unless the user-selected stopping criterion is reached. After adding a term, stepwise regression checks all other terms in the model to assess if they are still statistically significant. If not, a term can be removed during a stage.

The stepwise regression algorithm requires that a significance level be specified for terms to enter the model, and that a significance level be specified for terms to remain in the model. In each iteration of a stepwise regression application, t-tests are conducted for each term already in the model and for terms being considered for inclusion in the model. To describe the results of these t-tests, a p-value is calculated for each of the terms. Loosely speaking, the p-values represent the probability that the respective model terms do not make a significant contribution to the predictive ability of the model. Terms whose corresponding p-values are small (often  $<0.05$  is considered sufficiently small) are considered important in the model. The significance levels specified for the stepwise regression algorithm indicate how small p-values must be for the corresponding terms to be included in the model. The statistical literature generally indicates that the stepwise algorithm is somewhat liberal in allowing terms into models. Yet, models

containing unnecessary terms are undesirable because they tend to have inflated prediction variance. Thus, it is typically advisable to use tight significance levels such as 0.05 or 0.01 when applying the stepwise regression algorithm.

One particular variation of stepwise regression that can be used to select terms for model building is what the SAS statistical software package (SAS 2005) refers to as the Maximum R-squared Improvement (MAXR) selection method. For the MAXR criterion (as with other criteria for stepwise regression), terms can enter and leave (being replaced by another term) the model. Sequential changes to the model are based on maximal increases to the model's  $R^2$  value, and MAXR tries to find the "best" model having a specified numbers of terms. However, MAXR is not the same as the "best subsets" algorithm because it does not consider all possible models with a given number of terms. Therefore, MAXR is not guaranteed to find the model with the highest  $R^2$  value among all models having a given number of terms. This method tends to have a better chance of finding more nearly optimal models than does the stepwise selection method using other criteria (Freund and Littell 1995). The MAXR method does not require significance levels to control term selection, but does require the user to identify any terms to force into the model and to specify the number of terms to include in models being considered.

The standard stepwise regression procedure (regardless of the criterion used for model term selection) is not appropriate for linear mixture models or linear portions of other mixture experiment models for similar reasons as described previously with regard to the standard backward elimination method. However, it is appropriate for adding nonlinear mixture terms or non-mixture terms to mixture models.

## C.6 Statistical Methods for Model Validation

Model validation methods assess how well a fitted model predicts property values for glasses not used in fitting the model. A validation dataset could be separate from the modeling dataset, or it could be a subset obtained by splitting or partitioning the modeling dataset into modeling and validation subsets.

The glasses used for validation ideally should be in the same composition region as the data used to fit the property-composition models, because (in general) fitted empirical and semi-empirical models should not be used to extrapolate much beyond the region covered by the modeling data. Also, ideally the validation data should be evenly distributed over the region of model validity<sup>2</sup> to properly assess predictive ability over the region. These ideals can generally be achieved when splitting or partitioning the modeling dataset into modeling and validation subsets. However, they can difficult to achieve in practice for a separate validation dataset because such data are typically not designed, but often consists of whatever extra data are available.

---

<sup>2</sup> A model validity region is a composition region for models that are functions of composition, whereas it is a composition-temperature region for models that are functions of composition and temperature.

Validation generally consists of using a fitted model to predict property values for a set of validation data, and then comparing the predicted property values to the measured values from the validation database. The following subsections describe several methods for comparing predicted and measured values of properties.

### C.6.1 Validation $R^2$

Statistical summary comparisons of predicted and measured property values are also useful to see if differences are larger than their expected uncertainties. One such comparison is the *validation*  $R^2$  ( $R_V^2$ ) statistic, which in general is given by

$$R_V^2 = 1 - \frac{\sum_{i=1}^n (\hat{y}_i - y_i)^2}{\sum_{i=1}^n (y_i - \bar{y})^2}. \quad (C.29a)$$

However, in cases where WLS regression is used to fit the model and corresponding weights are available for the validation dataset, a weighted version of the *validation*  $R^2$  statistics is given by

$$R_V^2 = 1 - \frac{\sum_{i=1}^n w_i (\hat{y}_i - y_i)^2}{\sum_{i=1}^n w_i (y_i - \bar{y}_w)^2}. \quad (C.29b)$$

If weights are not available for the validation dataset in the WLS case, then weights  $w_i = 1$  can be used, which is equivalent to using Equation (C.29a) instead of Equation (C.29b).  $R_V^2$  is interpreted as the fraction of variability in the unweighted or weighted property values (transformed if appropriate) in the validation data accounted for by the fitted model. Note that  $R_V^2$  is defined exactly the same as the ordinary  $R^2$  defined in Equations (C.26a) and (C.26b), except that model validation data are used to assess model predictive performance instead of the model development data. Hence, the  $y_i$ ,  $\hat{y}_i$ ,  $\bar{y}$ ,  $w_i$ , and  $\bar{y}_w$  values in Equations (C.29a) and (C.29b) correspond to the model validation data. Because it was beyond the scope of the work in this report to develop formulas for validation statistics on models fitted by GLS regression, the ULS formulas are used for such models in this report.

Generally  $R_V^2 \leq R_p^2 \leq R_A^2 \leq R^2 \leq 1$ . However,  $R_V^2$  can take negative values (when a model predicts a validation set very poorly) and can take values larger than  $R_p^2$ ,  $R_A^2$ , or  $R^2$  (when a model predicts a particular validation dataset better than estimated by these statistics based on the modeling data).

### C.6.2 Validation RMSE

Another useful summary statistic for model validation is *validation RMSE* ( $RMSE_V$ ). This statistic is calculated by

$$RMSE_V = \sqrt{\frac{\sum_{i=1}^n (\hat{y}_i - y_i)^2}{n_V}} \tag{C.30a}$$

for ULS-fitted models and by

$$RMSE_V = \sqrt{\frac{\sum_{i=1}^n w_i (\hat{y}_i - y_i)^2}{n_V}} \tag{C.30b}$$

for WLS-fitted models. For the WLS case, if weights are not available for the validation dataset, then weights  $w_i = 1$  are used. This is equivalent to using Equation (C.30a) instead of Equation (C.30b). For GLS-fitted models, the ULS formula is used in this report.

In Equations (C.30a) and (C.30b), the denominator  $n_V$  is the number of observations in the validation dataset. The denominator is different than the  $n - p$  denominator for the modeling RMSE given in Equations (C.23a) and (C.23b), where  $n$  is the number of observations in the modeling dataset and  $p$  is the number of model coefficients estimated using the modeling dataset. In Equations (C.23a) and (C.23b), the  $n - p$  denominator accounts for estimating the  $p$  model coefficients using the  $n$  observations in the modeling dataset. However, because no model coefficients are estimated from a validation dataset, the denominator in Equations (C.30a) and (C.30b) is  $n_V$  rather than  $n - p$ .

In general,  $RMSE_V$  calculated by Equations (C.30a) and (C.30b) is expected to be larger than RMSE calculated by Equations (C.23a) and (C.23b) because of not using the validation subset to fit the model. The difference can be larger when the validation dataset is small relative to the modeling dataset, so that  $n_V$  is much smaller than  $n - p$ . The difference between RMSE and  $RMSE_V$  depends not only on how well a model predicts for the validation dataset, but also on the distribution of points in the validation dataset relative to the distribution in the modeling dataset. The non-representativeness of a smaller validation dataset can thus cause a larger difference between RMSE and  $RMSE_V$ .

### C.6.3 Predicted Versus Measured Plots

Predicted and measured values for a model validation data set can be compared by plotting the predicted versus the measured property values for each data point. Such *predicted versus measured plots* are the same as described in Section C.4, except model validation data are used instead of model development data. Also, similarly as described in Section C.4, *unweighted*

*PvM plots* or *weighted PvM plots* may be produced and viewed to validate models fitted by WLS regression.

Optionally, error bars consisting of 95% two-sided prediction intervals (95% PIs) on the predicted values can be included in the predicted versus measured plot for validation. Then, if the error bar for a given validation data point overlaps a line with slope one superimposed on the PvM plot, the model is validated for that data point. Draper and Smith (1998) and Montgomery et al. (2001) provide additional discussion of 95% PIs for regression models. The formulas for a 95% two-sided PI in the ULS, WLS, and GLS cases are given in Section C.7.3 following.

### C.7 Statistical Intervals for Describing Uncertainties in Model Predictions

Several types of statistical intervals are available to describe the uncertainty associated with model predictions. Each type of statistical interval has a particular interpretation. A common assumption for all statistical intervals based on regression models is that the model represents the true underlying response surface (property-composition or property-composition-temperature relationship for waste glasses) without a statistically significant lack-of-fit.

The following subsections present the formulas for one-sided upper (or lower) confidence intervals (Section C.7.1), two-sided confidence intervals (Section C.7.2), and two-sided prediction intervals (Section C.7.3). These types of statistical intervals are used to describe the uncertainty associated with model predictions at a single specific composition, or at single specific composition and temperature for properties such as viscosity and EC that depend on temperature as well as composition. Section C.7.4 presents the formulas for simultaneous upper confidence intervals, which are used to describe the uncertainty associated with model predictions at many glass compositions, or at many composition-temperature combinations for properties such as viscosity and EC. The formulas for these types of statistical intervals are given in each subsection for the ULS, WLS, and GLS cases. Section C.7.5 presents equations for the various statistical intervals for bias-corrected PCT models. Section C.7.6 discusses aspects of using the statistical intervals.

#### C.7.1 One-Sided Confidence Interval

A  $100(1-\alpha)\%$  *upper confidence interval (UCI)* for the true mean response value for a given glass composition  $\mathbf{x} = (x_1, x_2, \dots, x_q)$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}) + t_{1-\alpha}(n-p)\sqrt{\mathbf{a}^T \mathbf{C}_U \mathbf{a}} &= \hat{y}(\mathbf{x}) + t_{1-\alpha}(n-p)\sqrt{\mathbf{a}^T [(\mathbf{A}^T \mathbf{A})^{-1} \text{MSE}_U] \mathbf{a}} \\ &= \hat{y}(\mathbf{x}) + t_{1-\alpha}(n-p) \text{RMSE}_U \sqrt{\mathbf{a}^T (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (\text{C.31a})$$

for ULS regression, and by

$$\begin{aligned} \hat{y}(\mathbf{x}) + t_{1-\alpha}(n-p)\sqrt{\mathbf{a}^T \mathbf{C}_W \mathbf{a}} &= \hat{y}(\mathbf{x}) + t_{1-\alpha}(n-p)\sqrt{\mathbf{a}^T [(\mathbf{A}^T \mathbf{W} \mathbf{A})^{-1} \text{MSE}_W] \mathbf{a}} \\ &= \hat{y}(\mathbf{x}) + t_{1-\alpha}(n-p) \text{RMSE}_W \sqrt{\mathbf{a}^T (\mathbf{A}^T \mathbf{W} \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (\text{C.31b})$$

for WLS regression. The formula is similar for properties such as viscosity and EC that depend on glass composition and melt temperature and have models fitted by GLS regression. A  $100(1-\alpha)\%$  UCI for the true mean response value for a given glass composition  $\mathbf{x} = (x_1, x_2, \dots, x_q)$  and temperature  $T$  (in Kelvin) is given by

$$\begin{aligned} \hat{y}(\mathbf{x}, T) + t_{1-\alpha}(n_g - p_g)\sqrt{\mathbf{a}^T \mathbf{C}_G \mathbf{a}} &= \hat{y}(\mathbf{x}, T) + t_{1-\alpha}(n_g - p_g)\sqrt{\mathbf{a}^T [(\mathbf{A}^T \hat{\mathbf{V}}^{-1} \mathbf{A})^{-1}] \mathbf{a}} \\ &= \hat{y}(\mathbf{x}, T) + t_{1-\alpha}(n_g - p_g)\sqrt{\mathbf{a}^T (\mathbf{A}^T \hat{\mathbf{V}}^{-1} \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (\text{C.31c})$$

In Equations (C.31a), (C.31b), and (C.31c), the superscript  $T$  notation indicates a vector or matrix transpose, not temperature. Only the  $T$  appearing in  $\hat{y}(\mathbf{x}, T)$  denotes temperature. Otherwise, the vector  $\mathbf{a}$  is a function of both composition and temperature as explained following. The other notations in Equations (C.31a), (C.31b), and (C.31c) are defined as follows.

- $\hat{y}(\mathbf{x})$  = model predicted value at composition  $\mathbf{x}$ ,
- $\hat{y}(\mathbf{x}, T)$  = model predicted value at composition  $\mathbf{x}$  and temperature  $T$ ,
- $100(1-\alpha)$  = desired confidence (e.g., 90%) for the confidence interval, where  $\alpha$  denotes the significance level (e.g.,  $\alpha = 0.10$  for 90% confidence),
- $t_{1-\alpha}(n-p)$  =  $100(1-\alpha)$ -percentile of the Student's  $t$ -distribution with  $n-p$  degrees of freedom,
- $t_{1-\alpha}(n_g - p_g)$  =  $100(1-\alpha)$ -percentile of the Student's  $t$ -distribution with  $n_g - p_g$  degrees of freedom,
- $n$  = number of data points used to fit the model,
- $p$  = number of parameters estimated in the model,
- $n_g$  = number of glasses used to fit a viscosity or EC model,
- $p_g$  = number of parameters estimated in the composition-only portion of the model (as differentiated from the composition-temperature portion of the model).
- $\mathbf{C}_U$  = estimated variance-covariance matrix for the estimated coefficients of a model fitted by ULS regression =  $(\mathbf{A}^T \mathbf{A})^{-1} \text{MSE}_U$ ,
- $\mathbf{C}_W$  = estimated variance-covariance matrix for the estimated coefficients of a model fitted by WLS regression =  $(\mathbf{A}^T \mathbf{W} \mathbf{A})^{-1} \text{MSE}_W$ ,

- $C_G$  = estimated variance-covariance matrix for the estimated coefficients of a model fitted by GLS regression, which is approximated by  $(A^T \hat{V}^{-1} A)^{-1}$ ,
- $a^T$  = the vector transpose of the glass composition vector  $\mathbf{x}$  and temperature (if involved in the model) expanded in the form of the model,
- $A^T$  = the matrix transpose of the data matrix (consisting of glass compositions and temperatures, if involved in the model) expanded in the form of the model,
- $W$  = an  $n \times n$  diagonal weight matrix with entries  $w_i, i = 1, 2, \dots, n$  (i.e., the weights associated with the model development set of  $n$  data points),
- $MSE$  = mean squared error, which is obtained from the ULS ( $MSE_U$ ) or WLS ( $MSE_W$ ) regression fit of the model,
- $RMSE$  = the root mean squared error =  $\sqrt{MSE}$ , with  $RMSE_U$  and  $RMSE_W$  resulting from ULS and WLS regression fits of a model, respectively.

A  $100(1-\alpha)\%$  UCI, as given by Equations (C.31a), (C.31b), and (C.31c) is appropriate when an uncertainty statement is desired about the true mean response for a given composition  $\mathbf{x}$  and temperature  $T$  (for properties that also depend on temperature).

Equation (C.31c) is approximate because of using an estimate  $\hat{V}$  of  $V$  (the variance-covariance matrix for the vector of viscosity- or EC-at-temperature data used to fit the model—see Sections C.3.2 and C.3.3). Further, the number of degrees of freedom ( $n_g - p_g$ ) associated with the t-distribution multiplier is approximate. However, there is no practical consequence to using this approximate number of degrees of freedom because of the large number of glasses used to develop viscosity and EC models. In such cases, the t-distribution multiplier will essentially be a z-distribution (standard normal) multiplier, and thus there is no practical consequence.

The formulas for a one-sided lower confidence interval are the same as in Equations (C.31a), (C.31b), and (C.31c) except the plus signs following  $\hat{y}(\mathbf{x})$  and  $\hat{y}(\mathbf{x}, T)$  are changed to minus signs. Thus, a  $100(1-\alpha)\%$  lower confidence interval (LCI) for the true mean response value for a given glass composition  $\mathbf{x} = (x_1, x_2, \dots, x_q)$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}) - t_{1-\alpha}(n-p)\sqrt{\mathbf{a}^T \mathbf{C}_U \mathbf{a}} &= \hat{y}(\mathbf{x}) - t_{1-\alpha}(n-p)\sqrt{\mathbf{a}^T [(\mathbf{A}^T \mathbf{A})^{-1} MSE_U] \mathbf{a}} \\ &= \hat{y}(\mathbf{x}) - t_{1-\alpha}(n-p)RMSE_U \sqrt{\mathbf{a}^T (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (C.32a)$$

for ULS regression, and by

$$\begin{aligned} \hat{y}(\mathbf{x}) - t_{1-\alpha}(n-p)\sqrt{\mathbf{a}^T \mathbf{C}_W \mathbf{a}} &= \hat{y}(\mathbf{x}) - t_{1-\alpha}(n-p)\sqrt{\mathbf{a}^T [(\mathbf{A}^T \mathbf{W} \mathbf{A})^{-1} \text{MSE}_W] \mathbf{a}} \\ &= \hat{y}(\mathbf{x}) - t_{1-\alpha}(n-p) \text{RMSE}_W \sqrt{\mathbf{a}^T (\mathbf{A}^T \mathbf{W} \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (\text{C.32b})$$

for WLS regression. The formula is similar for properties such as viscosity and EC that depend on glass composition and melt temperature and have models fitted by GLS regression. A  $100(1-\alpha)\%$  LCI for the true mean response value for a given glass composition  $\mathbf{x} = (x_1, x_2, \dots, x_q)$  and temperature  $T$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}, T) - t_{1-\alpha}(n_g - p_g)\sqrt{\mathbf{a}^T \mathbf{C}_G \mathbf{a}} &= \hat{y}(\mathbf{x}, T) - t_{1-\alpha}(n_g - p_g)\sqrt{\mathbf{a}^T [(\mathbf{A}^T \hat{\mathbf{V}}^{-1} \mathbf{A})^{-1}] \mathbf{a}} \\ &= \hat{y}(\mathbf{x}, T) - t_{1-\alpha}(n_g - p_g)\sqrt{\mathbf{a}^T (\mathbf{A}^T \hat{\mathbf{V}}^{-1} \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (\text{C.32c})$$

where the notation is as previously defined. Equation (C.32c) is approximate for the same reasons given following Equation (C.31c).

### C.7.2 Two-Sided Confidence Interval

A  $100(1-\alpha)\%$  two-sided confidence interval (CI) for the true mean response value for a given glass composition  $\mathbf{x} = (x_1, x_2, \dots, x_q)$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}) \mp t_{1-\alpha/2}(n-p)\sqrt{\mathbf{a}^T \mathbf{C}_U \mathbf{a}} &= \hat{y}(\mathbf{x}) \mp t_{1-\alpha/2}(n-p)\sqrt{\mathbf{a}^T [(\mathbf{A}^T \mathbf{A})^{-1} \text{MSE}_U] \mathbf{a}} \\ &= \hat{y}(\mathbf{x}) \mp t_{1-\alpha/2}(n-p) \text{RMSE}_U \sqrt{\mathbf{a}^T (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (\text{C.33a})$$

for ULS regression, and by

$$\begin{aligned} \hat{y}(\mathbf{x}) \mp t_{1-\alpha/2}(n-p)\sqrt{\mathbf{a}^T \mathbf{C}_W \mathbf{a}} &= \hat{y}(\mathbf{x}) \mp t_{1-\alpha/2}(n-p)\sqrt{\mathbf{a}^T [(\mathbf{A}^T \mathbf{W} \mathbf{A})^{-1} \text{MSE}_W] \mathbf{a}} \\ &= \hat{y}(\mathbf{x}) \mp t_{1-\alpha/2}(n-p) \text{RMSE}_W \sqrt{\mathbf{a}^T (\mathbf{A}^T \mathbf{W} \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (\text{C.33b})$$

for WLS regression. The formula is similar for properties such as viscosity and EC that depend on glass composition and melt temperature and have models fitted by GLS regression. A  $100(1-\alpha)\%$  CI for the true mean response value for a given glass composition  $\mathbf{x} = (x_1, x_2, \dots, x_q)$  and temperature  $T$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}, T) \mp t_{1-\alpha/2}(n_g - p_g)\sqrt{\mathbf{a}^T \mathbf{C}_G \mathbf{a}} &= \hat{y}(\mathbf{x}, T) \mp t_{1-\alpha/2}(n_g - p_g)\sqrt{\mathbf{a}^T [(\mathbf{A}^T \hat{\mathbf{V}}^{-1} \mathbf{A})^{-1}] \mathbf{a}} \\ &= \hat{y}(\mathbf{x}, T) \mp t_{1-\alpha/2}(n_g - p_g)\sqrt{\mathbf{a}^T (\mathbf{A}^T \hat{\mathbf{V}}^{-1} \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (\text{C.33c})$$

In Equations (C.33a), (C.33b), and (C.33c), the notation is all the same as described in Section C.7.1, except that  $t_{1-\alpha/2}(n-p)$  denotes the  $100(1-\alpha/2)$ -percentile of the Student's  $t$ -distribution

with  $n - p$  degrees of freedom. Similarly,  $t_{1-\alpha/2}(n_g - p_g)$  denotes the  $100(1-\alpha/2)$ -percentile of the Student's  $t$ -distribution with  $n_g - p_g$  degrees of freedom. Equation (C.33c) is approximate for the same reasons given following Equation (C.31c).

### C.7.3 Two-Sided Prediction Interval

A  $100(1-\alpha)\%$  two-sided prediction interval (PI) for an individual response value for a given composition  $\mathbf{x}$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}) \mp t_{1-\alpha/2}(n-p) \sqrt{MSE_U + \mathbf{a}^T \mathbf{C}_U \mathbf{a}} \\ = \hat{y}(\mathbf{x}) \mp t_{1-\alpha/2}(n-p) RMSE_U \sqrt{1 + \mathbf{a}^T (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (C.34a)$$

for ULS regression, and by

$$\begin{aligned} \hat{y}(\mathbf{x}) \mp t_{1-\alpha/2}(n-p) \sqrt{\frac{MSE_W}{w_i} + \mathbf{a}^T \mathbf{C}_W \mathbf{a}} \\ = \hat{y}(\mathbf{x}) \mp t_{1-\alpha/2}(n-p) RMSE_W \sqrt{\frac{1}{w_i} + \mathbf{a}^T (\mathbf{A}^T \mathbf{W} \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (C.34b)$$

for WLS regression. The formula is similar for properties such as viscosity and EC that depend on glass composition and melt temperature and have models fitted by GLS regression. A  $100(1-\alpha)\%$  two-sided PI for an individual response value for a given composition  $\mathbf{x}$  and temperature  $T$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}, T) \mp t_{1-\alpha/2}(n_g - p_g) \sqrt{\hat{\sigma}_y^2 + \mathbf{a}^T \mathbf{C}_G \mathbf{a}} \\ = \hat{y}(\mathbf{x}, T) \mp t_{1-\alpha/2}(n_g - p_g) \sqrt{(\hat{\sigma}_G^2 + \hat{\sigma}_T^2) + \mathbf{a}^T (\mathbf{A}^T \hat{\mathbf{V}}^{-1} \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \quad (C.34c)$$

where

$\hat{\sigma}_y^2$  = estimate of the variance of a response variable observation  $y$ . For the split-plot structure associated with viscosity and EC data, as discussed in Sections C.2.2 and C.3.3,  $\hat{\sigma}_y^2 = \hat{\sigma}_G^2 + \hat{\sigma}_T^2$ .

The remaining notations in Equations (C.34a), (C.34b), and (C.34c) are defined as given following the UCI formulas in Section C.7.1. Equation (C.34c) is approximate for the same reasons given following Equation (C.31c).

The preceding equations for  $100(1-\alpha)\%$  two-sided PIs are easily converted to  $100(1-\alpha)\%$  one-sided PIs by replacing “ $\mp$ ” with “ $-$ ” or “ $+$ ”, replacing  $t_{1-\alpha/2}(n-p)$  with  $t_{1-\alpha}(n-p)$ , and replacing  $t_{1-\alpha/2}(n_g - p_g)$  with  $t_{1-\alpha}(n_g - p_g)$ .

Note in Equation (C.34b) that the  $w_i$  under the square root applies when PIs are calculated for modeling data, validation data, or application data (i.e., data used in applying the models and PIs) with weights. In situations where validation or application data do not have weights,  $w_i$  should be set to 1.

A  $100(1-\alpha)\%$  PI is appropriately used when comparing a model predicted response value for a given composition to an individual measurement of the response for that composition. This type of application arises in validating the predictive performance of a model for one or more glass compositions not used to fit the model. Specifically, Equations (C.34a), (C.34b), and (C.34c) can be used to produce 95% PIs displayed as error bars in PvM plots for validation data, as described at the end of Section C.6.

#### C.7.4 Simultaneous Upper Confidence Intervals

At times it is desirable to describe the uncertainty associated with predictions obtained for a specified group of compositions. For example, a statement may be desired that indicates with high confidence that the predicted response value for every composition  $\mathbf{x}$  in a specified group of compositions (or composition region) is below a particular regulatory limit. Such a confidence statement requires a statistical interval called a simultaneous upper confidence interval. The formula for a  $100(1-\alpha)\%$  simultaneous upper confidence interval (SUCI) associated with predictions on an unlimited number of compositions  $\mathbf{x}$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}) + \sqrt{pF_{1-2\alpha}(p, n-p)}\sqrt{\mathbf{a}^T \mathbf{C}_U \mathbf{a}} \\ = \hat{y}(\mathbf{x}) + RMSE_U \sqrt{pF_{1-2\alpha}(p, n-p)}\sqrt{\mathbf{a}^T (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \tag{C.35a}$$

for ULS regression, and by

$$\begin{aligned} \hat{y}(\mathbf{x}) + \sqrt{pF_{1-2\alpha}(p, n-p)}\sqrt{\mathbf{a}^T \mathbf{C}_W \mathbf{a}} \\ = \hat{y}(\mathbf{x}) + RMSE_W \sqrt{pF_{1-2\alpha}(p, n-p)}\sqrt{\mathbf{a}^T (\mathbf{A}^T \mathbf{W} \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \tag{C.35b}$$

for WLS regression. The formula is similar for properties such as viscosity and EC that depend on glass composition and melt temperature and have models fitted by GLS regression. The formula for a  $100(1-\alpha)\%$  SUCI associated with predictions on an unlimited number of combinations of composition  $\mathbf{x}$  and temperature  $T$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}, T) + \sqrt{pF_{1-2\alpha}(p, n_g - p_g)} \sqrt{\mathbf{a}^T \mathbf{C}_G \mathbf{a}} \\ = \hat{y}(\mathbf{x}, T) + \sqrt{pF_{1-2\alpha}(p, n_g - p_g)} \sqrt{\mathbf{a}^T (\mathbf{A}^T \hat{\mathbf{V}}^{-1} \mathbf{A})^{-1} \mathbf{a}} \end{aligned} \tag{C.35c}$$

In Equations (C.35a) and (C.35b)

$$F_{1-2\alpha}(p, n - p) = 100(1-2\alpha)\text{-percentile of the } F\text{-distribution with } p \text{ and } n - p \text{ degrees of freedom}$$

while in Equation (C.35c)

$$\sqrt{pF_{1-2\alpha}(p, n_g - p_g)} = 100(1-2\alpha)\text{-percentile of the } F\text{-distribution with } p_g \text{ and } n_g - p_g \text{ degrees of freedom.}$$

The remaining notations are the same as defined previously. Equation (C.35c) is approximate because of using an estimate  $\hat{\mathbf{V}}$  of  $\mathbf{V}$  (the variance-covariance matrix for the vector of viscosity or EC-at-temperature data used to fit the model—see Sections C.3.2 and C.3.3). Further, the numbers of degrees of freedom for the numerator ( $p_g$ ) and denominator ( $n_g - p_g$ ) of the F-distribution multiplier are approximate.

### C.7.5 Statistical Intervals for Bias-Corrected PCT Models

Section 5.7 discusses bias-corrected versions of the recommended and second-choice PCT-B, PCT-Li, and PCT-Na models, where a constant bias-correction is applied if the predicted release from a given model is above the cutoff value specified in Equation (5.7). Equation (5.9) gives the form of the bias-corrected PCT models, which consists of the base-portion (PQM model terms) plus a bias-correction constant ( $a_0$ ) applied when needed.

The statistical literature does not provide equations for statistical intervals when bias-corrections of the nature applied to the PCT models are used. While the statistical theory may provide for developing such equations, the work would be non-trivial. Hence, doing that work was not possible given that the decision to bias-correct the PCT models came late in the preparation of this report. Instead, the following adaptations of statistical interval equations presented in previous subsections are given. These adaptations account for the uncertainty in the base-portion of a PCT model as well as the uncertainty in the bias-correction constant. The statistical confidence values for the following equations may only be approximate because of the adaptations made to the multipliers for the statistical intervals. Finally, note that only equations for models fit by ULS are provided, because that is how the base-portions of PCT models were developed.

The formula for a 100(1- $\alpha$ )% UCI for the true mean PCT release value for a given glass composition  $\mathbf{x} = (x_1, x_2, \dots, x_q)$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}) + t_{1-\alpha}(n-p)\sqrt{\mathbf{a}^T \mathbf{C}_U \mathbf{a}} & \quad \text{if } \hat{y}(\mathbf{x}) \leq \text{cutoff} \\ \hat{y}(\mathbf{x}) + a_0 + t_{1-\alpha}(n-p-1)\sqrt{\mathbf{a}^T \mathbf{C}_U \mathbf{a} + \hat{\sigma}_{a_0}^2} & \quad \text{if } \hat{y}(\mathbf{x}) > \text{cutoff} \end{aligned}, \quad (\text{C.36})$$

where  $\hat{y}(\mathbf{x})$  denotes the PCT-B, PCT-Li, or PCT-Na prediction in ln(g/L) units before the bias-correction is applied, “cutoff” denotes the value from Equation (5.7) that determines whether a PCT-B, PCT-Li, or PCT-Na bias-correction is applied, and  $\hat{\sigma}_{a_0}^2$  denotes the estimated standard deviation of the bias-correction constant  $a_0$ . Tables containing the  $a_0$  and  $\hat{\sigma}_{a_0}$  (note this is the standard deviation) values for the PCT models are referenced in Section 5.7. All other notation is as defined in Section C.7.1. Note that this equation is an adaptation of Equation (C.31a). For PCT, 100(1- $\alpha$ )% LCIs and 100(1- $\alpha$ )% CIs are not needed, so adaptations of Equations (C.32a) and (C.33a) are not provided.

The formula for a 100(1- $\alpha$ )% PI for an individual PCT release value for a given composition  $\mathbf{x}$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}) + t_{1-\alpha/2}(n-p)\sqrt{MSE_U + \mathbf{a}^T \mathbf{C}_U \mathbf{a}} & \quad \text{if } \hat{y}(\mathbf{x}) \leq \text{cutoff} \\ \hat{y}(\mathbf{x}) + a_0 + t_{1-\alpha/2}(n-p-1)\sqrt{MSE_U + \mathbf{a}^T \mathbf{C}_U \mathbf{a} + \hat{\sigma}_{a_0}^2} & \quad \text{if } \hat{y}(\mathbf{x}) > \text{cutoff} \end{aligned}, \quad (\text{C.37})$$

where all notation is as previously defined in this section and in Section C.7.3. Note that this equation is an adaptation of Equation (C.34a). Adaptations for one-sided lower or upper prediction intervals could be made to Equation (C.37) similar to the discussion at the end of Section C.7.3.

The formula for a 100(1- $\alpha$ )% SUCI associated with PCT release predictions on an unlimited number of compositions  $\mathbf{x}$  is given by

$$\begin{aligned} \hat{y}(\mathbf{x}) + \sqrt{pF_{1-2\alpha}(p, n-p)}\sqrt{\mathbf{a}^T \mathbf{C}_U \mathbf{a}} & \quad \text{if } \hat{y}(\mathbf{x}) \leq \text{cutoff} \\ \hat{y}(\mathbf{x}) + a_0 + \sqrt{(p+1)F_{1-2\alpha}(p+1, n-p-1)}\sqrt{\mathbf{a}^T \mathbf{C}_U \mathbf{a} + \hat{\sigma}_{a_0}^2} & \quad \text{if } \hat{y}(\mathbf{x}) > \text{cutoff} \end{aligned} \quad (\text{C.38})$$

where all notation is as previously defined in this section and in Section C.7.4. Note that this equation is an adaptation of Equation (C.35a).

### C.7.6 Statistical Intervals in Transformed and Untransformed Units

Equations (C.31) to (C.38) yield statistical intervals in transformed units when a transformed property is modeled. For example, a natural logarithm transformation of a response  $y$  [i.e.,  $\ln(y)$ ] is often used for property-composition models. Hence, the statistical intervals calculated using the preceding equations would be in  $\ln(y)$  units. The statistical intervals can be transformed back to the original units of  $y$  by exponentiating the endpoint(s) of the statistical interval. However, the process of back-transforming (exponentiating) a statistical interval can change its interpretation. For example, if a 90% UCI in  $\ln(y)$  units has the value “ $v$ ”, the back-transformed 90% UCI in the original units of  $y$  is given by  $e^v$ . The 90% UCI in units of  $\ln(y)$  is a statement about the true mean response in  $\ln(y)$  units for a given glass composition  $x$  (at a given temperature for properties that also depend on temperature). However, the resulting back-transformed interval is a 90% UCI on the true median response value for the given composition  $x$  (and temperature, if applicable), under the assumption that experimental errors in the data used to develop the model are lognormally distributed. This assumption corresponds to the assumption of the natural-log-transformed response data being normally distributed. This change in interpretation occurs because the mean and median of a normal distribution are the same, but the mean of a lognormal distribution is larger than the median of a lognormal distribution.

Hence, back-transforming a 100(1- $\alpha$ )% UCI on a mean response for a given composition  $x$  and temperature (if applicable) in  $\ln$ -units (see Sections C.7.1 and C.7.5) yields a 100(1- $\alpha$ )% UCI on the median response for a given composition  $x$  in original units. This then underestimates a 100(1- $\alpha$ )% UCI on the mean response for a given composition  $x$  and temperature (if applicable) in original units. Similar interpretations hold for 100(1- $\alpha$ )% LCIs (see Section C.7.1) and CIs (see Section C.7.2). Back-transforming 100(1- $\alpha$ )% SUCIs (see Sections C.7.4 and C.7.5) given in log-transformed units has a similar change in interpretation. Whereas the original 100(1- $\alpha$ )% SUCIs are statements about the true mean values of responses in log-transformed response units for multiple compositions  $x$  and temperatures (if applicable), the back-transformed 100(1- $\alpha$ )% SUCIs are statements about the true median values of responses in original response units for multiple compositions  $x$  and temperatures (if applicable). However, a 100(1- $\alpha$ )% PI (see Sections C.7.3 and C.7.5) in log-transformed units does not have a change in interpretation when back-transforming, because the original statement (in log-transformed units) and the back-transformed statement (in original units) are both about a true individual response value.

Alternatives exist to using normal-theory-based Equations (C.31) to (C.38) and back-transforming them when a transformed response variable is modeled. One alternative is to modify the statistical interval equations so that the statistical statement is about the true mean response value in the original units for a given composition  $x$  and temperature (where applicable) [e.g., Equation C.31) for an UCI] or a set of compositions  $x$  and temperature combinations (where applicable) [e.g., Equation (C.35) for a SUCI]. Although this type of alternative is discussed in the literature for non-regression problems (e.g., Gilbert 1987), no references were found for the regression context. Another alternative, the *generalized linear model* regression approach (Myers et al. 2002), avoids directly transforming the response variable and instead uses

the transformation indirectly. These alternative approaches were not pursued in this work. However, the interested reader may refer to the references given.

Note that Equations (C.31) to (C.38) require knowledge of the variance-covariance matrix  $C_U = MSE_U(A^T A)^{-1}$  for ULS regression,  $C_W = MSE_W(A^T W A)^{-1}$  for WLS regression, and  $C_G = (A^T \hat{V}^{-1} A)^{-1}$  for GLS regression. The  $MSE_U$  and  $MSE_W$  are mean squared errors equal to the squares of  $RMSE_U$  and  $RMSE_W$  given by Equations (C.23a) and (C.23b). This information is included in the ULS, WLS, or GLS regression software output that comes with the estimates of the  $p$  model coefficients. A variance-covariance matrix is a  $p \times p$  matrix with coefficient variances along the diagonal, and covariances between coefficient pairs in the off-diagonal entries.

## **APPENDIX D**

### **Variance-Covariance Matrices Associated with the Coefficients of PCT, Spinel $T_{1\%}$ , Electrical Conductivity, and Viscosity Models for HLW Glasses**

## APPENDIX D

### Variance-Covariance Matrices Associated with the Coefficients of PCT, Spinel $T_{1\%}$ , Electrical Conductivity, and Viscosity Models for HLW Glasses

This appendix contains the variance-covariance matrices of selected property models for HLW glasses discussed in this report. Included are variance-covariance matrices for PCT and spinel  $T_{1\%}$  models, which are functions of HLW glass composition. Also included are variance-covariance matrices for electrical conductivity (EC) and viscosity models, which are functions of HLW glass composition and glass melt temperature.

Tables D.1, D.2, and D.3, respectively, contain the variance-covariance matrices for three  $\ln(\text{PCT-B, g/L})$  models for HLW glasses: (1) the 13-component reduced linear mixture (LM) model given in Table 5.6, (2) the 18-term partial quadratic mixture (PQM) model given in Table 5.7, and (3) the 15-term PQM model given in Table 5.8. The variance-covariance matrix in Table D.2 also applies to the coefficients of the 18 PQM terms in the 19-term recommended PCT-B model with bias-correction given in Table 5.19. The standard deviation associated with the bias-correction term is also given in Table 5.19. The variance-covariance matrix in Table D.3 also applies to the coefficients of the 15 PQM terms in the 16-term second-choice PCT-B model with bias-correction given in Table 5.20. The standard deviation associated with the bias-correction term is also given in Table 5.20. The 13-component reduced LM model for PCT-B was judged inferior to the two PQM models and was not bias-corrected, but it provides a baseline for comparison.

Tables D.4, D.5, and D.6, respectively, contain the variance-covariance matrices for three  $\ln(\text{PCT-Li, g/L})$  models for HLW glasses: (1) the 13-component reduced LM model given in Table 5.10, (2) the 18-term PQM model given in Table 5.11, and (3) the 15-term PQM model given in Table 5.12. The variance-covariance matrix in Table D.5 also applies to the coefficients of the 18 PQM terms in the 19-term recommended PCT-Li model with bias-correction given in Table 5.21. The standard deviation associated with the bias-correction term is also given in Table 5.21. The variance-covariance matrix in Table D.6 also applies to the coefficients of the 15 PQM terms in the 16-term second-choice PCT-Li model with bias-correction given in Table 5.22. The standard deviation associated with the bias-correction term is also given in Table 5.22. The 13-component reduced LM model for PCT-Li was judged inferior to the two PQM models and was not bias-corrected, but provides a baseline for comparison.

Tables D.7, D.8, and D.9, respectively, contain the variance-covariance matrices for three  $\ln(\text{PCT-Na, g/L})$  models for HLW glasses: (1) the 13-component reduced LM model given in Table 5.14, (2) the 18-term PQM model given in Table 5.15, and (3) the 15-term PQM model given in Table 5.16. The variance-covariance matrix in Table D.8 also applies to the coefficients of the 18 PQM terms in the 19-term recommended PCT-Na model with bias-correction given in Table 5.23. The standard deviation associated with the bias-correction term is also given in Table 5.23. The variance-covariance matrix in Table D.9 also applies to the coefficients of the 15 PQM terms in the 16-term second-choice PCT-Na model with bias-correction given in Table 5.24. The standard deviation associated with the bias-correction term is also given in Table 5.24. The 13-

component reduced LM model for PCT-Na was judged inferior to the two PQM models and was not bias-corrected, but provides a baseline for comparison.

Tables D.10, D.11 and D.12, respectively, contain the variance-covariance matrices for three spinel  $T_{1\%}$  ( $^{\circ}\text{C}$ ) models for HLW glasses: (1) the 15-component reduced LM model given in Table 6.9, (2) the recommended 20-term PQM model given in Table 6.10, and (3) the second-choice 20-term PQM model given in Table 6.11. The 15-component reduced LM was judged as inadequate for predicting spinel  $T_{1\%}$ , but provides a baseline for comparison to the other two models.

Tables D.13 and D.14, respectively, contain the variance-covariance matrices for two  $\ln(\text{EC}, \text{S/cm})$  models: (1) the 27-term truncated T2-LM model given in Table 7.7, and (2) the 22-term truncated T2-LM model with one quadratic composition term given in Table 7.9. The 22-term model is the one recommended for use, while the 27-term model is a second-choice model without the quadratic composition term and with fewer of the composition-temperature terms removed.

Tables D.15 and D.16, respectively, contain the variance-covariance matrices for two  $\ln(\text{Viscosity}, \text{poise})$  models: (1) the 24-term truncated T2-LM model given in Table 8.8 and (2) the 29-term truncated T2-LM model with five quadratic crossproduct terms given in Table 8.9. The 29-term model is the one recommended for use, while the 24-term model serves as a second-choice model without quadratic composition terms.

**Table D.1. Variance-Covariance Matrix Associated With the Estimated Coefficients of the 13-Component Reduced Linear Mixture Model for ln(PCT-B, g/L) of HLW Glasses.**

## **Appendix E**

### **Calculating Estimated $T_{1\%}$ Values and Corresponding Standard Deviations**

## Appendix E

### Calculating Estimated $T_{1\%}$ Values and Corresponding Standard Deviations

The high-level waste (HLW) glasses considered in this report were heat-treated at various temperatures and then samples of the heat-treated glass were analyzed to determine the volume percent (vol%) crystallinity as well as the primary and any secondary crystalline phases. Section E.1 describes how the (temperature, vol% crystallinity) data for each HLW glass was used to calculate the temperature at which the equilibrium crystal fraction is one volume percent of the molten glass ( $T_{1\%}$ ). Section E.2 illustrates using the equations to calculate  $T_{1\%}$  and its uncertainty.

#### E.1 Equations for Calculating Estimated $T_{1\%}$ and It's Standard Deviation

For each HLW glass, the temperature and volume %-crystallinity data were used to fit a separate regression equation of the form

$$T = a_0 + a_1v, \quad (\text{E.1})$$

where  $v$  is the volume % crystallinity at a given temperature  $T$  ( $^{\circ}\text{C}$ ), and  $a_0$  and  $a_1$  are the fitted intercept and slope of the  $T$  vs.  $X$  model for that glass. Equations of the form (E.1) were fit for each HLW glass having sufficient (temperature, vol%) data using unweighted least squares (ULS) regression. Substituting  $v = 1$  vol% into the fitted equation for a given glass yields an estimate of  $T_{1\%}$  for that glass. Using statistical regression theory and equations, the standard deviation of the  $T_{1\%}$  value, denoted  $\text{SD}(T_{1\%})$ , can also be calculated.

In Equation (E.1), temperature ( $T$ ) was used as the response variable, and vol% crystals ( $v$ ) was used as the explanatory variable. This assignment of variables is considered an *inverse regression* approach. In the *classical regression* approach, the explanatory variable should have no uncertainty, or uncertainty that is small relative to the uncertainty in the response variable. Hence, with the classical approach,  $T$  would be the explanatory variable and  $v$  would be the response variable. However, the classical approach presents problems for calculating the uncertainty of  $T_{1\%}$  values. Also, statistical research (Shukla 1972) has shown that if the number of data points is small, it is better to use the inverse regression approach.

Equations involving matrix algebra can be used to calculate the  $\text{SD}(T_{1\%})$  values mentioned above. However, because simple linear regression is used to relate temperature to

volume %-crystallinity in Equation (E.1), a simpler equation can be used to calculate the  $SD(T_{1\%})$  values. This equation is

$$SD(T_{1\%}) = \sqrt{MSE \times \left( \frac{1}{n} + \frac{(v_0 - \bar{v})^2}{\sum_{i=1}^n (v_i - \bar{v})^2} \right)}, \quad (E.2)$$

where  $n$  is the number of temperature versus volume %-crystallinity data points used in the simple linear regression to calculate the slope, intercept, estimated  $T_{1\%}$  value, and  $SD(T_{1\%})$  for a particular glass;  $v_0$  is 1 volume %-crystallinity;  $v_i$  is the  $i^{\text{th}}$  volume %-crystallinity value among the  $n$  data points;  $\bar{v}$  is the mean volume %-crystallinity value for the  $n$  data points; and MSE is the mean squared error for the simple linear regression involving the  $n$  data points. The MSE is calculated using

$$MSE = \frac{SSE}{n-2} = \frac{\sum_{i=1}^n (T_i - \hat{T}_i)^2}{n-2}, \quad (E.3)$$

where  $T_i$  (°C) is the measured temperature for the  $i^{\text{th}}$  data point among the  $n$  data points used in the simple linear regression, and  $\hat{T}_i$  (°C) is the predicted temperature corresponding to the  $i^{\text{th}}$  volume %-crystallinity value among the  $n$  data points. Section E.2 contains an example that illustrates the use of Equations (E.1) through (E.3) to calculate estimated  $T_{1\%}$  values and their corresponding standard deviations.

## E.2 Example Illustrating the Use of $T_{1\%}$ Equations

This section illustrates the use of Equations (E.1) to (E.3) for calculating the estimated  $T_{1\%}$  value and corresponding standard deviation for one HLW glass, namely HLW02-52. The temperature versus volume %-crystallinity data for HLW02-52 are given in Table 4.3 and Table 6.2, but are listed again here for convenience.

|                        |     |     |     |     |      |
|------------------------|-----|-----|-----|-----|------|
| Temperature (°C)       | 750 | 850 | 900 | 950 | 1050 |
| Volume %-Crystallinity | 2.5 | 1.3 | 2.1 | 1.2 | 0.4  |

Simple linear regression using the above data with temperature as the response results in the regression line

$$\hat{T} = 1077.78 - 118.52v, \quad (E.4)$$

where  $v$  is the volume %-crystallinity and  $\hat{T}$  is the corresponding temperature estimate. As explained in Section E.1, this regression equation form can be considered an inverse regression because temperature would typically be the more suitable predictor variable. For a volume %-crystallinity value of 1, the above regression line in Equation (E.4) produces an estimated  $T_{1\%}$  value of

$$\hat{T} = 1077.78 - 118.52(1) = 1077.78 - 118.52 = 959.3^\circ\text{C}$$

Note that the intercept (1077.78), slope (-118.52), and estimated  $T_{1\%}$  value (959.3) for HLW02-52 are given in Table 6.3.

A graphical depiction of the temperature versus volume %-crystallinity data for HLW02-52, together with the calculated regression line in Equation (E.4) is shown in Figure E.1. The black diagonal line in Figure E.1 is the regression line used to obtain the estimated  $T_{1\%}$  value for HLW02-52. The dashed line in Figure E.1 represents using the regression line to calculate the estimated  $T_{1\%}$  value for HLW02-52. As depicted in Figure E.1, the dashed red line corresponds to a volume %-crystallinity value of 1.0, and results in an estimated temperature of 959.3°C.

**Figure E.1. Temperature versus Volume %-Crystallinity Data, Regression Line, and Estimated  $T_{1\%}$  Value for HLW02-52.**

The standard deviation associated with the estimated  $T_{1\%}$  value for HLW02-52 is calculated using Equations (E.2) and (E.3). Equation (E.3) is used first to calculate the mean squared error ( $MSE$ )<sup>1</sup>, which is then substituted into Equation (E.2) to calculate  $SD(T_{1\%})$  value for HLW02-52. As indicated in Equation (E.3), estimated  $T_i$  (i.e.,  $\hat{T}_i$ ) values are needed for each of the five temperature versus volume %-crystallinity data points available for HLW02-52. These estimated  $\hat{T}_i$  values are obtained by applying the regression Equation (E.4) to each of the five volume %-crystallinity values for HLW02-52. The estimated temperature calculations are shown below.

| Volume %-Crystallinity | Estimated Temperature ( $\hat{T}_i$ ) <sup>(a)</sup> |
|------------------------|------------------------------------------------------|
| 2.5                    | $1077.7778 - 118.5185(2.5) = 781.482$                |
| 1.3                    | $1077.7778 - 118.5185(1.3) = 923.704$                |
| 2.1                    | $1077.7778 - 118.5185(2.1) = 828.889$                |
| 1.2                    | $1077.7778 - 118.5185(1.2) = 935.556$                |
| 0.4                    | $1077.7778 - 118.5185(0.4) = 1030.370$               |

(a) Intercepts, slopes, and estimated  $T_{1\%}$  values are given in greater decimal accuracy here than were used in Table 6.3 in order to ensure two decimal accuracy in the calculated standard deviation below.

Thus, using Equation (E.3) yields

$$\begin{aligned}
 MSE &= \frac{\sum_{i=1}^n (T_i - \hat{T}_i)^2}{n - 2} \\
 &= \frac{(750 - 781.482)^2 + (850 - 923.704)^2 + (900 - 828.889)^2 + (950 - 935.556)^2 + (1050 - 1030.370)^2}{5 - 2} \\
 &= \frac{991.116 + 5432.280 + 5056.774 + 208.629 + 385.337}{3} \\
 &= \frac{12074.136}{3} = 4024.712
 \end{aligned}$$

Prior to using Equation (E.2) to calculate  $SD(T_{1\%})$  value for HLW02-52, the mean volume %-crystallinity value is needed. This is calculated as

$$\bar{v} = \frac{\sum_{i=1}^n v_i}{n} = \frac{2.5 + 1.3 + 2.1 + 1.2 + 0.4}{5} = 1.5$$

<sup>1</sup> Although Equation (E.3) can be used to calculate the  $MSE$ , it (or its square root, known as  $RMSE$ ) is typically included in the output of many regression software routines.

Substituting  $MSE$  and  $\bar{v}$  into Equation (E.2), and using  $v_0 = 1$ , the standard deviation associated with the estimated  $T_{1\%}$  value for HLW02-52 is calculated as follows

$$\begin{aligned}
 SD(T_{1\%}) &= \sqrt{MSE \left( \frac{1}{n} + \frac{(v_0 - \bar{v})^2}{\sum_{i=1}^n (v_i - \bar{v})^2} \right)} \\
 &= \sqrt{4024.712 \left( \frac{1}{5} + \frac{(1 - 1.5)^2}{(2.5 - 1.5)^2 + (1.3 - 1.5)^2 + (2.1 - 1.5)^2 + (1.2 - 1.5)^2 + (0.4 - 1.5)^2} \right)} \\
 &= \sqrt{4024.712 \left( 0.2 + \frac{0.25}{2.7} \right)} \\
 &= 34.32
 \end{aligned}$$

This calculated standard deviation is as given in Table 6.3.

The process described in Section E.1 and illustrated in Section E.2 was used, where possible, to calculate estimated  $T_{1\%}$  values and their corresponding standard deviations for both modeling and validation glasses. See Section 4.2 for additional discussion.

## **Appendix F**

## **Appendix G**

### **Glass Melt Electrical Conductivity and Viscosity Values at a Temperature of 1150°C Calculated Using Vogel-Fulcher Equation Fits**

## **Appendix G**

### **Glass Melt Electrical Conductivity and Viscosity Values at a Temperature of 1150°C Calculated Using Vogel-Fulcher Equation Fits**

This appendix lists electrical conductivity (EC) and viscosity values of high-level waste (HLW) simulated glasses calculated at a temperature of 1150°C using Vogel-Fulcher fits to the property-temperature data for each HLW glass. Specifically, the Vogel-Fulcher equation (Equation 4.1 in Section 4.3.1) was fitted to the EC-at-temperature and viscosity-at-temperature data collected for each of 214 simulated HLW glasses having data for EC and/or viscosity. The fitted Vogel-Fulcher equation for each HLW glass was then used to calculate the EC or viscosity at 1150°C for that HLW glass. Out of the 214 glasses, 210 have EC data while a different subset of 210 have viscosity data.

**Table G.1. Glass Melt Electrical Conductivity (S/cm) and Viscosity (P) at a Temperature of 1150°C Calculated Using Vogel-Fulcher Equation Fits.**

| Glass ID | Electrical Conductivity at 1150°C | Viscosity at 1150°C | Glass ID | Electrical Conductivity at 1150°C | Viscosity at 1150°C       |

(a) Measurements of electrical conductivity were not performed.  
(b) Non-Newtonian behavior observed at all measurement temperatures.
