**STATEMENT OF PROBLEM**

Develop a nodal Heat Transfer Code incorporating conduction, convection, radiation, variable mass heat transfer, effective space temperatures, and special start-up features.

**ABSTRACT:**

500-THGC is a generalized transient one, two, or three dimensional Heat Transfer Code, an outgrowth of 30-THGC<sup>1</sup>, with special options for handling SNAP circular orbit pre-start-up and start-up problems. Provision is made for mass transfer, dropping the heat shield and simulating environmental conditions by means of effective temperatures. Use of FAP coding and special treatment of matrix multiplication are used to minimize machine time.

**I. INTRODUCTION**

500-THGC is a generalized transient one, two, or three-dimensional Heat Transfer Code, an outgrowth of 30-THGC<sup>1</sup>, with special options for handling SNAP circular orbit pre-start-up start-up problems. Provision is made for mass transfer, dropping the heat shield and simulating environmental conditions by means of effective temperatures. Use of FAP coding and special treatment of matrix multiplication are used to minimize machine time.

This document is not meant to be a complete detailed discussion of the many types of problems this code will handle, it is rather a users manual for one who is familiar with such problems as discussed in references 2 and 3. The authors will be happy to discuss any features of this code and provide assistance in its use.

**II. THEORY**

Let us divide the region of interest into small volumes in which the temperature is defined at the center. We write the heat balance equation for node i,

$$(\rho C_p V)_i \frac{dT_i(\theta)}{d\theta} = \sum_j \left( \frac{KA}{\ell} \right)_{ij} [T_j(\theta) - T_i(\theta)] + \sum_j (\sigma FA)_{ij} [T_j^4(\theta) - T_i^4(\theta)] ; i=1, N \quad (1)$$

where

- $\theta$  = the time (hour, minute, second, etc.)
- $T_i$  = the temperature at node i at time  
(If there is radiation, T must be the absolute temperature in  $^{\circ}\text{K}$  or  $^{\circ}\text{R}$ ).
- $\sigma$  = the Stephan-Boltzman constant
- $\rho_i$  = the density of node i
- $C_{pi}$  = the specific heat of node i
- $K_{ij}$  = the conductivity between nodes i and j

**ATOMICS INTERNATIONAL**  
A Division of North American Aviation, Inc.

NO. NAA-SR-TDR-9664

DATE 3/27/64

PAGE 3 OF 49

$F_{ij}$	= form factor of node i as seen by node j
$l_{ij}$	= length between nodes i and j
$A_{ij}$	= area between nodes i and j
$V_i$	= volume of node i
$N$	= the number of nodes

and the sums are over all nodes j which can exchange heat with node i.

We make the following definitions:

$$C_{ij} = \frac{(KA/l)_{ij}}{(\rho C_p V)_i} , \quad \text{the conduction coefficient,}$$

$$R_{ij} = \frac{(\sigma FA)_{ij}}{(\rho C_p V)_i} , \quad \text{the radiation coefficient}$$

With the above definitions, equation (1) becomes

$$\frac{dT_i(\theta)}{d\theta} = \sum_j C_{ij} [T_j(\theta) - T_i(\theta)] + \sum_j R_{ij} [T_j^4(\theta) - T_i^4(\theta)] \quad ; \quad i=1, N \quad (2)$$

Note that if we also define

$$C_{ii} = - \sum_j C_{ij} ,$$

and

$$R_{ii} = - \sum_j R_{ij} ,$$

Equation (2) can be written in the form

$$\frac{dT_i(\theta)}{d\theta} = \sum_j C_{ij} T_j(\theta) + \sum_j R_{ij} T_j^4(\theta) ; \quad i=1, N \quad (3)$$

where the sums include the  $j = i$  term.

**ATOMICS INTERNATIONAL**  
A Division of North American Aviation, Inc.

NO. NAA-SR-TDR-9664

DATE 3/27/64

PAGE 4 OF 49

The time derivative is represented by the first forward differences:

$$\frac{dT_i(\theta)}{d\theta} \approx \frac{T_i(\theta+h) - T_i(\theta)}{h} \quad (4)$$

Substituting equation 4 in equation 3, multiplying through by  $h$ , and putting  $T_i(\theta)$  on the right hand side, we have

$$T_i(\theta+h) = T_i(\theta) + h \sum_j C_{ij} T_j(\theta) + h \sum_j R_{ij} T_j^4 \quad (5)$$

Thus given the temperature of all nodes which exchange heat with the  $i^{th}$ , at time  $\theta$ , we can predict the temperature of node  $i$  at time  $\theta+h$ .

Let us redefine the coefficients to simplify the equations.

Let

$$TN_i = T_i(\theta+h) \quad (6)$$

$$TO_i = T_i(\theta) \quad (7)$$

$$D_{ij} = \begin{cases} hC_{ij}, & i \neq j \\ 1+hC_{ii}, & i=j \end{cases} \quad (8)$$

$$S_{ij} = \begin{cases} hR_{ij}, & i \neq j \\ hR_{ii}, & i=j \end{cases} \quad (9)$$

With these new definitions, equation (5) becomes

$$TN_i = \sum_j D_{ij} TO_j + \sum_j S_{ij} TO_j^4 ; \quad i=1, N \quad (10)$$

Finally, the system of equations (10) can be written in matrix notation

$$\begin{bmatrix} TN \end{bmatrix} = \begin{bmatrix} D \end{bmatrix} \begin{bmatrix} TO \end{bmatrix} + \begin{bmatrix} S \end{bmatrix} \begin{bmatrix} TO^4 \end{bmatrix} \quad (11)$$

where  $TN$  and  $TO$  are  $N \times 1$  column vectors,  $D$  and  $S$  are  $N \times N$  square matrices which are in general sparse.

$D$  and  $S$  contain  $N^2$  elements, however in real physical problems a given node, in general, has no more than six adjacent nodes. Thus  $6N$  is a good

**ATOMICS INTERNATIONAL**  
A Division of North American Aviation, Inc.

NO. NAA-SR-TDR-9664

DATE 3/27/64

PAGE 5 OF 49

estimate of the number of non-zero elements in D and probably  $2N$  or  $3N$  non-zero elements in S. Assuming a typical problem of 300 nodes then, D and S contain 90,000 elements each, of which only some 1800 elements in D and 600-900 elements in S are non-zero.

Looking at equation 10, we see that if we could store the matrices D and S as square arrays that we would perform 600 multiplications and additions for each of the 300 nodes or a total of 180,000 multiplications and additions of which most operations are wasted.

The procedure actually used is to number the non-zero elements in D and S consecutively in an arbitrary order, so we have for each non-zero  $d_{ij}$  and  $s_{ij}$ ,  $d_\ell$ ,  $\ell=1, M$  and  $s_\ell$ ,  $\ell=1, MR$ . In addition we record the row and column indications  $i$  and  $j$  for each  $\ell$  as  $(i_d, j_d)$ ,  $\ell=1, M$  and  $(i_s, j_s)$ ,  $\ell=1, MR$  where the subscript d refers to the elements of D and s refers to the elements of S. Thus given an  $\ell$ , we know that  $d_\ell = d_{ij}$  where  $i = i_d$  and  $j = j_d$ .

This procedure represents a transformation (a mapping) of the two dimensional index set,  $(i, j)$  on to a one dimensional index set,  $\ell$ .

Mathematically we can reduce equation (11) to the form:

$$TN_i = \sum_{\ell=1}^M [d_\ell s_{i, i_d(\ell)}] T O_{j_D(\ell)} + \sum_{\ell=1}^{MR} [s_\ell s_{i, i_s(\ell)}] T O_{j_s(\ell)}^4 \quad (12)$$

Stated in words, for each  $\ell$  we form the products of  $d_\ell$  and  $T O_{j_D}$  where  $j$  is found from  $j_D(\ell)$  and add the product to  $TN_i$  where  $i$  is given by  $i_d(\ell)$  and similarly for the second series.

To clarify this still further let us see how this transformation simplifies the operation in the fortran language:

Letting  $\ell \rightarrow L$

$$\begin{aligned} i &= i_d(\ell) \rightarrow ID(L) \\ j &= j_d(\ell) \rightarrow JD(L) \\ d_{ij} &= d(\ell) \rightarrow D(L) \end{aligned}$$

$$L = 1, M$$

$$\begin{aligned} i &= i_s(\ell) = IS(L) \\ j &= j_s(\ell) = JS(L) \\ s_{ij} &= s(\ell) = S(L) \end{aligned}$$

$$L = 1, MR$$

Then we have

$$\begin{aligned} D\phi & \quad I \quad L = I, M \\ I & = ID(L) \\ J & = JD(L) \\ 1 \quad TN(I) & = TN(I) + D(L) * TO(J) \\ D\phi & \quad 2 \quad L = I, M, R \\ J & = JS(L) \\ 2 \quad TN(I) & = TN(I) + S(L) * TD(J) * * 4 \end{aligned}$$

Because of the importance of these manipulations, this portion of the code is optimized and coded in FAP (machine language). The reduction in running time was approximately a factor of ten.

The condition for the stability of (11) can be stated in the following way:

$$h \leq \left\{ \max_i \left[ -C_{ii} + \sum_j R_{ij} \left| \frac{T_j^4 - T_i^4}{T_j - T_i} \right| \right] \right\}^{-1} \quad (13)$$

where the maximum temperature difference expected is used.

### III. SPECIAL FEATURES

#### A. Effective Space Temperatures

These nodes are made to represent the variation of the outside temperature due to variation of the position of the vehicle with respect to the earth-sun relation.

1. A maximum of 200 nodes can be used as effective temperature nodes. Each of these has three regions of orbit dependence.

For the first,

$$\begin{aligned} T_{A_1}(\theta) &= A_2 \sin[A_3 \varphi(\theta) + A_4] + A_7, \quad 0 \leq \varphi(\theta) \leq A_{10} \\ \varphi(\theta) &= A_8 [T_3(N+A_9) - \theta] \\ N &= \text{integer part of } \theta/T_3 \end{aligned} \quad (14)$$

For the second,

$$T_{A_1}(\theta) = A_7, \quad A_{10} < \varphi(\theta) \leq A_{11} \quad (15)$$

For the third,

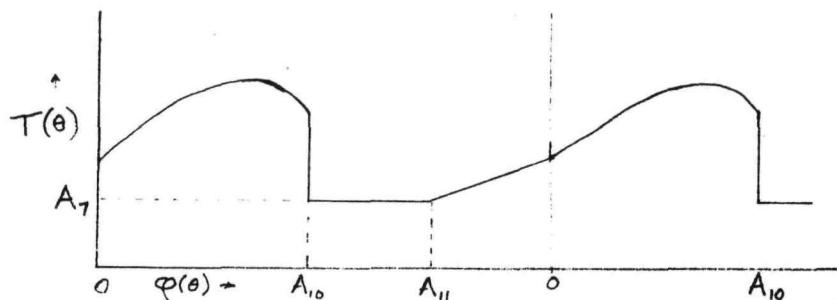

$$T_{A_1}(\theta) = A_5 \varphi(\theta) - A_6 + A_7, \quad \varphi(\theta) > A_{11} \quad (16)$$

**ATOMICS INTERNATIONAL**  
A Division of North American Aviation, Inc.

NO. NAA-SR-TDR-9664  
DATE 3/27/64  
PAGE 7 OF 49

Figure 1 is an example which should clarify the orbit dependence of the effective temperature nodes.

Figure 1

Since  $\varphi(\theta)$  is periodic with period  $T_3$ , the orbit time, the effective temperatures are similarly periodic in  $\theta$  with period  $T_3$ .

2. Node 296 (reactor node) has a special form with four regions of time dependence.

For the first,

$$T_{296}(\theta) = \left[ \frac{A_2 - T_{su}}{A_{10} - A_9} \right] (\theta - A_9) + T_{su} , \quad A_9 \leq \theta \leq A_{10} \quad (17)$$

where  $T_{su}$  = temperature of node 296 at  $\theta = A_9$

For the second,

$$T_{296}(\theta) = A_2 , \quad A_{10} < \theta \leq A_{11} \quad (18)$$

For the third,

$$T_{296}(\theta) = A_4 (\theta - A_{11}) + A_2 , \quad A_{11} < \theta \leq A_{12} \quad (19)$$

For the fourth,

$$T_{296}(\theta) = A_3 , \quad \theta > A_{12} \quad (20)$$

# ATOMICS INTERNATIONAL

A Division of North American Aviation, Inc.

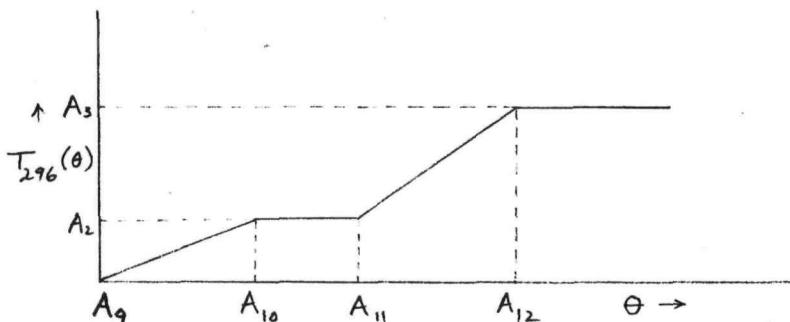

NO. NAA-SR-TDR-9664

DATE 3/27/64

PAGE 8 OF 49

Figure 2 gives an example which should clarify the time dependence of node 296.

Figure 2

3. Node 308 (space temperature as seen by reactor top) has a special form with three regions of orbit dependence.

For the first,

$$T_{308}(\theta) = A_2 \sqrt{1 - \left( \frac{FT(\theta)}{A_3} \right)^2}, \quad 0 \leq FT(\theta) \leq A_{10} \quad (21)$$

where  $FT(\theta) = \theta - T_3 \cdot N$

$N$  = integer part of  $\theta/T_3$

For the second,

$$T_{308}(\theta) = A_4, \quad A_{10} < FT(\theta) \leq A_{11} \quad (22)$$

For the third,

$$T_{308}(\theta) = A_2 \sqrt{1 - \left( \frac{FT(\theta) - A_5}{A_3} \right)^2}, \quad FT(\theta) > A_{11} \quad (23)$$

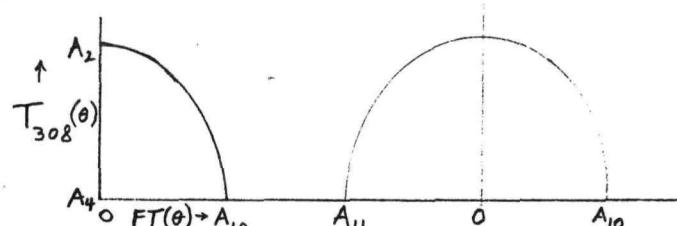

**ATOMICS INTERNATIONAL**

A Division of North American Aviation, Inc.

NO. NAA-SR-TDR-9664  
 DATE 3/27/64  
 PAGE 9 OF 49

Figure 3 gives an example which should clarify the orbit dependence of node 308

Figure 3

Since  $FT(\theta)$  is periodic with period  $T_3$  the orbit time,  $T_{308}$  is similarly periodic in  $\theta$  with period  $T_3$ .

B. Reactor Startup

1. When  $\theta > T_2$  (see input) a new calculation interval and a new print out interval are used. The  $D_{ij}$  and  $S_{ij}$  are changed accordingly. Variable mass transfer coefficients are read in and the coefficients are computed at each subsequent time step. When the condition  $T_{296} \geq T_{296\text{IN}}$  (see input) is satisfied the heat shield, which must consist of consecutive node numbers, is dropped. This is accomplished by deleting all transfer coefficients involving the heat shield and reading in new transfer coefficients between space and the radiator. As of the time of writing, this option has not been tested completely.

2. Variable Mass Transfer Coefficient Equations

Up to 6 variable mass transfer coefficient equations may be used with a maximum of 100  $C_{ij}$  being calculated by each one. Each of these equations has six regions of time dependence.

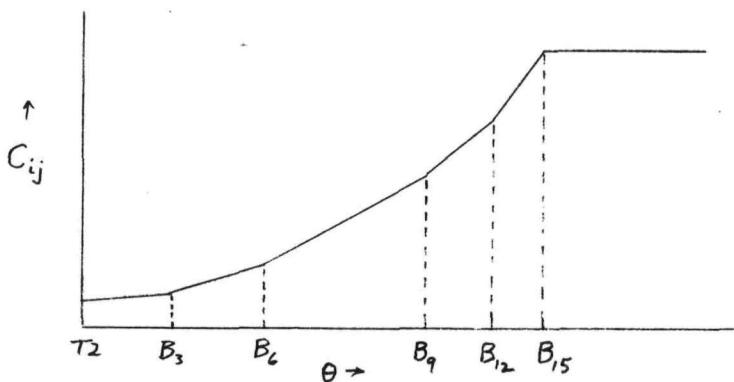

$$C_{ij} = B_{\ell k} \theta + B_{\ell k+1} \quad , \quad B_{\ell k-1} \leq \theta < B_{\ell k+2} \quad (24)$$

where  $\ell = 1, \dots, 6$  the equation number, and  $k = 1, \dots, 16$

$$B_{\ell 0} = T_2 \text{ and } B_{\ell 18} = \infty$$

Figure 4 gives an example which should clarify the time dependence.

Figure 4

#### C. Pre-Startup Only

Set  $T_2 > T_{MAX}$  and omit the cards that are special for startup.

#### IV. LIMITATIONS

500 nodes of which 200 may be effective temperatures.

2500 Radiation terms

2500 Conduction terms

6 variable mass transfer coefficient equations where each may be used with a maximum of 100  $C_{ij}$ 's being calculated by each one.

Multiple cases can not be run.

#### V. RUNNING TIME

The sample case took 2 minutes with an output of 700 lines of printing.

#### VI. USE OF CODE

500 - THGC is filed at Department 792 as Deck Number 3W543 .

Submit a short form and place data behind deck.

INPUT

DATA BLOCK 1 (12A6)

Title Card - all 72 columns may be used.

DATA BLOCK 2 (6I12)

NC	-	Number of conduction cards
N	-	Number of nodes $\leq 500$
L1O	1	All nodes have same initial temperature
	2	Some initial temps specified, all the rest have same temperature.
	3	All initial temperatures are specified.
IH	-	Heat shield initial node*
IHL	-	Heat shield final node number
NCT	-	Number of initial temperatures specified for L1O = 2 or 3.

DATA BLOCK 3 (6I12)

NETS	-	Number of effective temperatures
NC2	-	Number of radiation cards
NC3	-	Number of Variable Mass Transfer Coefficient Equations $\leq 6$
NC4	-	Number of radiation cards specified after the heat shield drops off.
IW	1	Normal printout.
	2	Special printout.

DATA BLOCK 4 (6F12.8)

TMAX	-	Maximum system time
THEAT	-	Not used at present
DELTA	-	Calculation interval
TØØ	-	Temperature of unspecified nodes for L1O = 1 or 2
TTØ	-	Print interval
EE	-	Not used at present

\* Note that heat shield nodes must be numbered consecutively.
